Then this paper will raise the following questions and try to give an answer through analysis: What is the relationship between the demographic structure of the Venice main island and the stock of housing in the past 50 years? How does the relation between housing supply and demand change affected by the development of tourism industry? How does the tourism industry affect on the quality and function of the traditional housing on the island? Has the government taken any appropriate intervening measures to improve the living conditions of local residents and how is the impact?

2 THE IMBALANCE STRUCTURE OF SUPPLY AND DEMAND OF RESIDENTIAL HISTORIC BUILDINGS IN VENICE

2.1 THE IMBALANCE OF SUPPLY AND DEMAND

Since the 1950s, the population of Venice has been declining. In 1951, the average number of people living in per room is 1.34(Citta di Venezia,2012b), which means that generally speaking, Venice was in a state of housing tension: the total number of housing units and the number of rooms per set are both insufficient. After the 1970s, due to the out-migration, the total number of housing on the main island of Venice began to exceed the number of households, which means it began to have a housing stock of vacant houses. In accordance with the normal market disciplines, when housing supply increases, the falling price will stimulate demand, to ease the situation of local residents' moving outside and even to attract more Mestre mainland residents. However, the fact was that the number of local residents still continued moving out, so it can be concluded that phenomenon of living crowded is not the proper reason to explain the reduction of population.

Between 1951 and 2010, the number of households and the population of Venice main island is still decreasing: the number of registered households decreased by 40%; the population decreased by 65%__the decreasing rate of households is far less than the rate of population reduction. Compared with 4.9 people per household on average in 1951, the current average is only 2 people per household (Citta di Venezia,2012b). By calculating the data above all, we can know that the proportion of the reduction rate of households with more people has been decreasing the most, at around 95%. The reason is that considering the house area and the number of rooms, current housing stocks on the island are more

suitable for small family units, which led directly to the imbalance structure between different housing supplies and demands.

2.2 THE EXPLANATION OF THE IMBALANCE STRUCTURE OF SUPPLY AND DEMAND

Since the 1980s, people have tried to explain the declining of effective housing supply through two aspects: on the one hand, large number of historic residential buildings are used as rental estate instead of being provided to local residents; on the other hand, the house owner's failing to afford its maintenance costs also leads to the phenomenon of vacant residential buildings. In 2000 or so, by comparing the relevant data of gas, water, electricity payers and residents, it is possible to distinguish which buildings are vacant, which are still used and of which the residential functions have already been transformed, and then to show the analysis of the population loss and current condition of residential building use (Table 1).

Function			Number of units	Proportion	
Residential	Dwellings	Living function	23390	61.7%	
Non-residential	Hotels	Tourism	4810	8.4%	29.2%
	Private-owned	B&Bs	3800	9.4%	
		Other services	4610	11.4%	
Vacant	Vacant		3640	9.1%	

Table 1 -Statistics on the function of historical buildings on the main island of Venice (Sources: Comune di Venezia,2010)

By putting the number of residents, the total number of housing units, the number of available housing needs no repair and the number of housing under functional transformation into the same coordinate system (Figure 3), it can be known that area A shows the demanding is far beyond the supply before the 1980s when the population in Venice is too much. After 1980s, B+C area says the total amount of housing supply exceed residents' demand. While area B means residential buildings that are vacant due to poor housing conditions or the owner's relocation, area C shows the residential buildings that can be put to the market without repair. However, there exist a large number of residential buildings offered to non-residents, including tourists, students, immigrant workers and so on. In 2000, this part of the housing occupancy ratio reached 29.3%. So if we consider excluding the above part from the available housing supplies, the real total housing supply for local residents cannot meet their demand actually. The overall area D indicates a housing shortage for local residents. To sum up, although the total number of available residential housing is increasing, the situation of supply shortage for locals has deteriorated to a severe structural imbalance.

Figure 3 -The changing of supply and demand structure of residential housing on Venice mainland (Sources: Citta di Venezia,2012)

3 THE LIMITATIONS OF GOVERNMENT INTERVENTIONS

3.1 THE INTRODUCTION OF GOVERNMENT INTERVENTIONS

As mentioned above, the depopulation in the main island of Venice is directly related to the lack of housing supply for local residents. The urgency of repairing houses and the over-conversion from resident houses to non-residential houses have created great pressure on the residential market. Italian law No.798/1984 has specially provided a separate allocation of protection funds for the main residential area of Venice, trying to use government intervention to soften the impact by tourism industry on the market of resident housing. The object of this intervention is the public housing owned by the government and the ground floor space of private houses.

For the public housing, the government has taken measures to repair them and provide them as low-cost temporary housing for low-incomes. With the collaboration with the non-profit organizations of Venice and the UNESCO UK Council, the government has finished the repair of the 17th-century houses located at Calle Delle Beccarie. Take one of the buildings as an example: it consisted a number of single rooms before the repair and afterwards it turned to four sets of apartments (Figure 4). After the implementation of the project, the vacant space of public housings can be fully used with an affordable rent to low-income residents, while the government can also receive some rental income to cover the corresponding part of repairing spending.

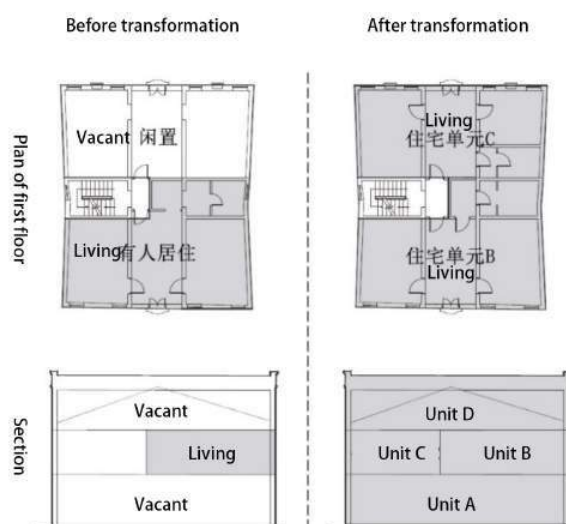

Figure 4 -The comparison between before the functional transformation and after (Sources: Good,2005)

The ground floor of historic buildings are not comfortable for living because of high humidity and difficulties on lighting and ventilation usually used for catering, job or retail function. On the main island of Venice, the housing units on the ground floor were the by-products at a population explosion period; there were 4,000 units, accounting for about 11.5% of the total Venice housing units, but of which more than 90% have been converted to non-residential use such as catering, retailing or workshop since decades ago. So what the government can do is only the transformation of the left 10% part, which has not been converted into non-residential use, to contribute them to the local housing supply market.

From 1993 to 1998, the intervention programs on the public housing and the ground floor of historic buildings have succeeded to provide 749 sets of apartments and dormitories for the elderly and students, with a total of 52,000 square meters (Pickard, 2001).

3.2 THE LIMITATION OF GOVERNMENT INTERVENTIONS

In terms of heritage protection and improvement of living conditions for residents, the renovation of public housing has achieved great success. However, from the point of view of housing supply, the limitation of

the project is that the proportion of housing owned by government (public housing) is too small, only 4% of the entire dwelling market, so even if it was possible to refurbish and provide them with a low price to low-income local people, the number would be also very limited. On the other hand, cyclical floods heavily affect the housing base, every 20 years the canal is divided into sections to evacuate the water for repairing the building base, which creates greater financial pressure on social welfare funds.

As of 1998, of the £699 billion that the government subsidizes to the residential renovation projects, only 84% are released and 60% have been used, and only 43% of the projects are completed (Pickard, 2001). In addition, the more serious problem is that even if the buildings finish all the repairing procedures, they will be put into the open market facing to students, tourists and other participants who can provide high prices, so the local residents are still difficult to get effective housing supply.

4 TOURISM INDUSTRIES CONTINUE TO HAVE STRONG IMPACT ON THE HOUSING MARKET

4.1 HIGH DEMANDS OF SHORT-TERM ACCOMMODATION DRIVEN BY BLOOMING TOURISM INDUSTRIES

According to official statistics_Citta di Venezia,2012a_, residential buildings under functional transformation account for 8.4% of the total residential volume, with an even greater number of tourism-oriented conversions. According to the work report of Municipality of Venice called "Osservatorio Quarto Rapporto", the average selling price per square meter of the short-term housing available for tourism is 13.6 times(Table 2) the price per square meter of normal residential housing for locals, and the same situation happens in the rental market, visitors and other non-residents can pay the price 13 times than the residents can pay for a rental house. Due to the influence of tourism, the cost of materials, transportation, labor and others are all increasing, adding more financial burden on historical building maintenance, which is bound to increase the pressure of long-term residents. Driven by the blooming of tourism industries, the house owners are more willing to rent their houses, and instead, some owners will even choose to move themselves to the Mestre mainland for more economic benefits. To sum up, large amount of the temporary housing needs of tourists, students and related workers in the historical center of Venice, especially the short-term accommodation demand of tourists, are the biggest incentive for the transformation of residential functions on the island.

SELL	Non-residential		13.6	RENT	Non-residential	Short term rent	13
	Non-residential	After repair	1.7		Residential	Mestre mainland	2.5
		No repair	1.3			Other	1.5
		Need repair	/			surrounding area	

Table 2 – The selling and rental prices for the housing on Venice main Island
(take the average affordability of local residents as 1)(Sources: Good,2005)

4.2 FUNCTIONAL TRANSFORMATION OF RESIDENTIAL BUILDINGS BY MARKET FORCE

The benefits of converting normal houses into hotels or B&Bs are such significant that a large number of owners ignore the protection requirements of residential buildings and change the structure of the building to make it more suitable for short-term living. After transformation, such short-term housings usually become hot resources with relatively lower price than the same level hotels on the website like Airbnb, Booking and others, which is a great attraction for tourists with limited economic budget. Although this transformation mode has been quite common on the island, still, the original function and layout of the house is more beneficial to the protection of historical buildings. The reason is that compared to short time rent space, there will be more functional spaces like kitchen, toilet, living room and study room which can maintain the original structure of the building, instead of changing the structures as well as the whole interiors to make one building separate to several simple units for tourist.

Taking a residential building in Dorsoduro community as an example (Figure 5), the original layout of three bedrooms and two bathrooms was reconstructed into two small apartments, including separate kitchens and living spaces, and rent to the short-term tenants at a price of 45 euros per square meter per month. This kind of space subdivision on the one hand provides more choices of flexibility for tourists, on the other hand, also gives house owners more benefits __smaller space means more profitable. In fact, the most favorable area in short-term rental market is of 50 square meters; on the contrary, the house of 120 square meters can only earn the lowest profit. (Good, 2005)

From the perspective of government management, it is difficult to supervise this informal housing division behavior which also does harm to the housing structure, and the government can only hold the attitude of acquiescence of such function transformations, which can explain why the number of residential units are increasing without additional constructions on the main island of Venice (see Figure 3). The decline in average living area significantly affected the quality of life of residents; the small size units cannot meet the needs of families with children. A study by the Municipality of Venice for the finance funding families can get for their first suite of house shows that this kind of funding is only valid when the demands and willingness of the residents can agreed with the market supplies. That is to say, if the residents demand 75-100 square meters of residential, but the market only offers 50-70 square meters options, the government cannot provide financial support because residents will complain the space is too small and turn to the Mestre mainland to seek a more spacious house with the same price. All these are resulting in the population loss of the main island of Venice.

Figure 5 -The division methods in functional transformation of traditional housing (Sources: Good,2005)

5 THE VICIOUS CIRCLE OF THE FUNCTIONAL TRANSFORMATION OF RESIDENTIAL BUILDING ON THE MAIN ISLAND OF VENICE

The development of the tourism industries has great impacts on every aspect of Venice Main Island that, not only does the urban space slowly turn to tourism-oriented; also, the housing supply shows more preference towards tourist's choice. On the one hand, the number of public housing units owned by the government is limited, and the subsidy for refurbishment is not sufficient as well; On the other hand, the illegal conversion of private housing into tourism services happens continuously. Although the total number of tourists in Venice is increasing every year, the tourism taxes collected by government are still unable to balance the subsidy invested in solving the housing problem of the local population. The increasing cost of housing refurbishment due to excessive tourism has been a great burden for local government all the time. At the national level, the financial support for residential buildings has been reduced year by year, so at the local level, government lacks funds to invest in residential maintenance. With the strong pressure by tourism market, speculations appear in residential buildings and even public housing. By converting them into short-term accommodations or other hotels, restaurants, retail stores and commercial buildings, the original fair-price supermarkets, schools, hospitals, pet shops, barber shops which serve for local residents are of a sharp reduction, exacerbated the difficulties for locals to continue living here. Instead, they turn to the mainland suburbs to seek for a favorable inhabiting environment that can provide education, medical and other necessary services. It can be forecasted that with the prosperity of the tourism industries in Venice, the market forces will further catalyze the formal and informal functional transformation of

residential buildings towards tourism services, finally into a vicious circle as Figure 6(Russo,2000;Bernadette,2007), in which sense making Venice gradually lost its authenticity in living and original spirits of places.

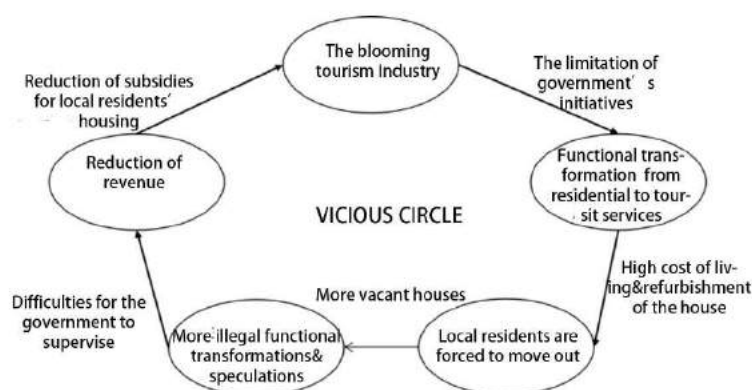

Figure 6 -The vicious circle of functional transformation of local residential housing on Venice main island (Sources: Author)

6 PROSPECTS: THE STRATEGIES TO DEAL WITH THE DEPOPULATION AND IMPROPRIATE RESIDENTIAL FUNCTIONAL TRANSFORMATION

Under the influence of market economy, the social problems related to the decline of Venice main island could be understood as the incompatibility between the housing demand and the supply structure. The continuous reduction of local residents is because the inflated cost of the housing market is not affordable for them anymore. Besides, government's shortage of funds for building refurbishment has undoubtedly given opportunities to those who do the illegal transformation just to attract tourists, resulting in serious consequences like exclusion of aborigines and loss of authenticity. Therefore, the core strategy for the government is to strengthen the guidance and supervision of the transformation mechanism of historic dwellings, providing affordable residential units in the market and enhance the long-term living conditions for low-income residents as much as possible (Massiani and Santoro,2012).

The primary principle is to realize the significance of preserving the original resident's life on the main island of Venice. The traditional lifestyle of natives itself composes the most crucial part of the world-famous historic city. While stabilizing the residents of Venice to maintain social, economic and political stability, the awareness of building protection should also be considered carefully especially towards those buildings after or under functional transformation. Recognizing the informal conversion and illegal split into smaller units according to the gas, water and other bills, and try to acquire the housing property through public-private partnership, finally manage to recover the refurbish the building to meet the needs of local residents, at an affordable rental price.

Secondly, under the circumstances where the historic buildings are divided into different residential units and rent to different tenants, the government need to formulate detailed rewards and penalties through correspondent policies in the process of acquiring and rearrange the building, in order to avoid the possibility that multiple stakeholders' interests conflict with each other. Above all, the government has the right to make a legal penalty for people who subdivide the building against the preservation requirements for historic buildings of Venice.

Finally, to provide residents willing to live in Venice for a long time with subsidies to buy their first suite of housing, so that residents can compete with foreign tourists since they have a relatively fair competitive environment. These policies need to be strengthened, and a rigorous review and evaluation is also needed when it comes to any project including the content of functional transformation from residential to tourism services, in order to ensure the effective supply of local residential housing market(Musu,2011).

ID 1330 | MAKING THE MOST OF THE EUROPEAN CAPITAL OF CULTURE. CULTURAL EVENTS AND SPATIAL STRATEGIES IN EUROPEAN PORT CITIES

Enrico Tommarchi¹
e.tommarchi@2016.hull.ac.uk

1 INTRODUCTION

Since the experience of Glasgow, European City of Culture in 1990, and Barcelona, which hosted the Olympic Games in 1992, European port cities have displayed a growing interest in hosting cultural mega-events – i.e. "large scale cultural (including commercial and sporting) events which have a dramatic character, mass popular appeal and international significance" (Roche, 2000, p. 1) – as a strategy to trigger or boost urban regeneration and local development (Qu and Spaans, 2009). Mega-events have increasingly been interpreted as chances to accelerate existing urban projects, to encourage discussions about future development scenarios and strategies, to improve local institutional capacities and to raise local communities' ambition. In other words, cultural mega-events are understood as potential drivers of urban development and as unique occasions for producing positive intangible legacies in the long term.

In this context, the European City/Capital of Culture (ECoC) programme has played a crucial role in the last decades. Major European port cities such as Rotterdam and Genoa attempted to capitalise their year as ECoC in order to deliver a renewed image and reposition themselves within global urban networks. Aarhus in Denmark and Paphos in Cyprus are the ECoC 2017, while Valletta and Rijeka have been awarded the title respectively for 2018 and 2020. Liverpool, ECoC in 2008, inspired the UK City of Culture initiative with the aim of extending the positive benefits of event-led and culture-led regeneration to other British cities (DCMS, 2009; ICC, 2012): so far, two port cities have been designated as UK City of Culture, namely Derry-Londonderry in 2013 and Hull in 2017. This interest appears to some extent fostered by a recognition of the potential contribution of cultural mega-events – such as the ECoC – to urban regeneration and development in port cities. In this context, legacy has become a key concept in the rhetoric of the ECoC, while the embeddedness of cultural strategies into long-term planning agenda is increasingly considered a precondition for achieving a positive legacy from the event (Smith, 2012), as well as for cultural mega-events more generally (Bramwell, 1997). Surprisingly, there is little understanding of

the extent to which the socio-economic and spatial strategies entailed by ECoC programmes are integrated – or ought to be integrated – to broader planning frameworks. This connection appears particularly relevant in port cities, where the rationale for the ECoC is associated with the need of responding to the profound structural socio-economic consequences of deindustrialisation and loss of maritime functions.

This paper discusses the rationale, the key questions and methodological approaches of an early-stage PhD research on event-led regeneration in European port cities. In particular, it aims to propose a research agenda and methodology to examine how event-led regeneration – driven by the ECoC – is embedded into broader frameworks and strategies of urban planning in European port cities and how it may introduce new planning concepts and procedures. Section 2 summarises the common structural changes and challenges that have been characterising the transition to a post-industrial economy in most European port cities, which set the rationale for event-led regeneration. Section 3 briefly reviews the literature on culture-led and event-led regeneration, as well as on urban regeneration in port cities, and on the ECoC programme. Section 4, presents the rationale for studying the ECoC in the context of port cities, identifying a few key research questions, on the basis of the issues and gaps arising from the literature review. Section 5, proposes a methodology to approach these issues, while section 6, gives account of the expected results of this study.

2 PORT CITIES IN TRANSITION

European port cities have historically been a key driving force in the spatial organisation of economies and societies (Hoyle and Pinder, 1992). Harbour areas and quays have contributed to the development of European urban culture itself, as public spaces and places of encounter. However, since the 1960s, major structural changes have contributed to reshaping this traditional port-city relationship. Technological developments such as containerisation, the increase of ships size and the reorganisation of maritime transport raised the need of deeper water, more space and greater accessibility (Hayuth and Hilling, 1992) which fostered the migration of ports to new locations outside the city and the consequent separation between port and urban functions (Hoyle, 1988). The abandonment of traditional harbour areas produced derelict urban environments in central urban locations and on waterfronts that set the rationale at the basis of the worldwide phenomena of waterfront redevelopment (Schubert, 2011; Brownhill, 2013; see section 2.1). Since the 1990s ports have been more and more interconnected to transnational networks (Meyer, 1999) and their fortunes increasingly depend on external phenomena on which they have no control (Hayuth and Hilling, 1992; Ducruet and Lee, 2006). In this context, the interdependency between ports and cities is weakening: ports are less dependent from urban labour markets, while cities may explore other thriving economic functions (Ducruet et al., 2010, in Hall and Jacobs, 2012). European port cities have had different fortunes in coping with these structural changes. For instance, Rotterdam and Hamburg managed to retain their role as maritime hubs and to diversify their economies (Hein, 2014; Savitch and Kantor, 2002). However, many of them – such as Hull in the UK – were unable to respond to these challenges and have experienced rising unemployment, urban decay and socio-economic decline.

2.1 WATERFRONT REDEVELOPMENT

Since the 1960s, derelict quays and traditional inner harbours have increasingly been perceived as strategic areas for pursuing extensive urban regeneration. Waterfront redevelopment projects began to be deployed in many port cities throughout the world with the aim of recovering the key role played by their centres (Meyer, 1999) and of re-launching these cities through the development of a single area (Bruttomesso, 2001). Schubert (2011) suggests that four generations of projects have characterised this worldwide phenomenon from the 1960s to the 2000s. First, a number US cities – in particular Baltimore – displayed project-led approaches to waterfront redevelopment in the 1960s. Second, many port cities across the world undertook larger-scale projects in the 1980s, for instance the redevelopment of London Docklands. Third, waterfront projects in the 1990s were characterised by a more participatory approach. Finally, waterfront redevelopment in the 2000s has been generally based on public-private partnerships in context of scarce public resources.

Despite being such a widespread phenomenon, many authors question that it has also been a worldwide story of success (Hoyle, 2000). Waterfront redevelopment projects have been criticised for having failed to meet their socio-economic and political goals (Hoyle, 1988) and for being renewed expressions of forces of capital (Malone, 1996). They have also been considered an effective means to affirm post-modern socio-cultural values (Nordcliffe et al., 1996) and city-making paradigms (Marshall, 2001) under the dominant discourse on neoliberal urbanism. However, the research on waterfront redevelopment, whether advocative or harshly critical, has focused on spatial and economic aspects, adopting quite a narrow approach to these complex urban transformation. More recent studies (Desfor et al., 2011) have attempted to widen the analytical approach to these phenomena, deploying innovative theoretical and methodological tools – such as assemblages (Brownhill, 2013) – to explore broader social and cultural dimensions of waterfront redevelopment.

2.2 CONTEMPORARY PORT-CITY RELATIONSHIPS

Today, ports and cities display an even more complex relationship (Daamen and Louw, 2016), which is only in part explained by technological developments and structural changes in maritime transportation systems and is becoming context specific (Daamen, 2007). Despite the abovementioned migration processes of port activities, major maritime ports are still urban (Hall and Jacobs, 2012) and, where there is a physical separation between ports and cities, their development trajectories are still closely interconnected (Daamen and

van Gils, 2006). However, while ports have shaped cities' development paths for centuries, the main spatial driving force is now the city (Wiegman and Louw, 2011). Thus, the search for redevelopment of port areas and waterfronts is fuelling spatial, socio-economic and political tensions (Daamen and Vries, 2013) at the port-city interface (the liminal space between port areas and the city, see Hayuth, 1982; Hoyle, 2000), for instance between new urban uses and still thriving port functions or between new residents and professionals attracted by regenerated urban areas and former working class residents.

The literature on the port-city relationship, in particular from an urban perspective, displays extensive gaps and a clear separation between port and urban studies (Ducruet and Lee, 2006). Even though the classic spatial focus – too narrow to explain recent developments (Daamen, 2007) – has progressively been enriched by behavioural and governance approaches (Oliver and Slack, 2006), further work is needed to understand the social, cultural and political components of contemporary port-city relationships and their regional specificity throughout the world. In this context, event-led and culture-led regeneration at the port-city interface introduce a further perspective that is currently underexplored and suggest the need to investigate the impacts of such interventions on the port-city relationship and the broader trajectories of urban planning in port cities.

3 EUROPEAN (PORT) CITIES OF CULTURE

The literature on waterfront redevelopment recognised the growing relevance of the cultural dimension in waterfront projects. For instance, Meyer (1999, 48) suggested that waterfronts are privileged spaces for promoting a “culturalised urbanism”, since they offer attractive locations to companies and institutions, in some way anticipating Florida's discourse of creative urban environments (Florida, 2002).

Culture-led regeneration is indeed closely associated with the redevelopment of former harbour areas and quays, as happened since the 1980s in many port cities such as Bilbao and Barcelona (García 2004), Newcastle (Bailey et al., 2004), Marseilles (Llorente, 2002) and Genoa (Porrello and Tommarchi, 2009).

3.1 CULTURE-LED REGENERATION

A growing body of literature has explored the contribution of culture to urban regeneration and the connection between cultural activity and local development goals (Bianchini et al. 1988; Bianchini and Parkinson 1993; Evans and Shaw 2004; García 2004). The contribution of culture to urban development has been recognised since the nineteenth century (Bassett, 1993), while cultural policies gained political

relevance in the 1970s (Bianchini, 1993b), for instance in the UK, approaching goals of community development (Lees and Melhuish, 2015). The 1980s represented a dramatic point of cultural turn for urban planning (Freestone and Gibson, 2006), characterised by a widespread dominance of economic development and urban regeneration (Bianchini, 1993b).

Classic critiques to culture-led regeneration projects in the 1980s interpret these interventions as a “carnival mask” (Harvey, 1989, 21) to cover social problems or as strategies fostered by a worst-case scenario when no other options are available (Zukin, 1995). Bianchini (1993a) identified three sets of dilemmas raised by such projects, involving spatial tensions between city centres and periphery, economic contrapositions between production- and consumption-oriented strategies, conflicts in funding between permanent and ephemeral events. On more recent projects, similar criticisms suggest that the delivery of cultural projects is easier than any investigation on structural social issues and that gentrification is the most likely output of culture-led regeneration (Miles, 2005), in which economic goals are dominant (García, 2004). For instance, public expenditure for culture-led regeneration has generated disappointment among local communities in port cities suffering high levels of unemployment, such as Bilbao and Marseilles (Llorente, 2002). The focus on flagship projects has been criticised for creating white elephants (García, 2004), disconnected from the context – including the waterfront – they are supposed to regenerate, eventually producing unused or unsafe environments (Evans, 2005). Standardisation represents a major risk, whereas the replication of successful strategies applied elsewhere erodes local identities and specificities. This is particularly evident in many culture-led waterfront redevelopments labelled as ‘MacWaterfronts’ (Daamen and Gils, 2006), which fuelled disappointment in local communities – sometimes expressed through activism and protests, such as in Hamburg (Desfor and Laidley, 2011) – about redevelopments that are perceived as alien and threatening, as happened in Liverpool (Llorente, 2002).

Past research on culture-led regeneration has been criticised of considering few successful cases as evidence that culture may contribute to solving urban problems (Miles, 2005) and being uncritically positive (Shaw 1999, in Evans and Shaw, 2004). Evans provides an interesting perspective when he observes that such research offers either uncritical case studies or unsupported harsh criticisms, fuelling a “culture of pessimism” (Evans, 2005, p. 7). Other critiques concern the focus on short-term impacts (Evans and Shaw, 2004), the reliance on fuzzy theories and the lack of rigorous evaluation criteria (Markusen and Gadwa, 2010). Despite the growing number of studies on culture-led regeneration, the research on this field appears to be still affected by the same theoretical and methodological issues observed in the last decades (Campbell et al., 2017), as well as by an evident economic focus in evaluation criteria. Future research should take into account tangible and intangible impacts on other urban domains, such as community wellbeing or governance landscapes.

3.2 THE EUROPEAN CAPITAL OF CULTURE

Since the 1990s, policy makers and urban commentators have increasingly been concerned with the potential of cultural mega-events in terms of urban regeneration and local development. In this context, the European Capital of Culture (European City of Culture before 2001) represents a particularly interesting case. Envisioned in 1983 with the aim of celebrating European diversity and promoting cohesion, it has progressively become a unique chance for cities to promote a new image and profile and to pursue urban regeneration and development. The first awarded cities since the launch of the initiative in 1985 – Athens, Florence, Amsterdam, West Berlin and Paris – were recognised cultural capitals and celebrated their year as ECoC through cultural festivals focused on fine arts. Glasgow, ECoC in 1990, represented a watershed in the history of the programme, as it was the first city to organise a year-round event and to embed its cultural programme into a broader strategy of urban regeneration (Bianchini et al., 2013). Many other port cities have then attempted to capitalise the potential of the ECoC in this sense, such as Rotterdam in 2001, Genoa in 2004 and Liverpool in 2008, while the connection between cultural activity and regeneration has become a common element of the ECoC itself.

In the last 15 years, these experiences have fuelled a growing body of research on the rationale and the impacts of the ECoC. For instance, Richards and Wilson (2004) analysed the impacts of the ECoC 2001 on different components of the image of Rotterdam, highlighting a positive impact in the short term. García (2005) evaluates the long-term impacts of Glasgow 1990 analysing media discourses and personal narratives. Griffiths (2006) uses discourse analysis to unpack the bids of three contenders for the 2008

title, Liverpool, Bristol and Cardiff, emphasising common discourses on identity as port cities, integration, connection between culture and social cohesion and of potential economic benefits of culture. Boland (2010) and Cox and O'Brien (2012) provide a critique of the 'Liverpool model', outlined in the Impact 08 study on the effects of the ECoC 2008 (García et al. 2010). Bianchini et al. (2013) explore the possible strategies of awarded cities for pursuing the symbolic, physical, economic and social dimensions of regeneration and suggest that, despite the difficulty of assessing the regenerative impacts of the ECoC, policy makers are increasingly interested in the initiative. Finally, Gomes and Librero-Cano (2016) compare economic performances of cities awarded the ECoC title with those of unsuccessful bidders, showing that awarded cities experience some extent of economic growth after the event. They also suggest that sociocultural, political and environmental effects are less investigated than economic impacts and that grounded evidence of benefits on the long term is still missing. The literature on event-led regeneration, as well as on culture-led regeneration more in general, is indeed dominated by an economic focus – which reflects the priority of economic goals complained by many critics – and displays little attention to other dimensions and potential impacts. Although the most investigated and cited case studies are indeed port cities, and presumably many others will follow, virtually no studies address event-led regeneration in this specific context and in relation to the interactions between urban and port functions. Furthermore, virtually no studies attempt to contextualise urban regeneration exercises within broader framework of urban planning, confirming a general disconnection – both in research and practices – of these phenomena from the development perspective of the city as a whole.

4 A RESEARCH AGENDA

This disconnection suggests the need to investigate the relationship between the ECoC and urban planning agendas, with a specific focus on port cities. Two key questions arise: firstly, how does the ECoC impact the port-city interface? Secondly, how does the ECoC relate to urban planning in European port cities?

4.1 THE ECOC AT THE PORT-CITY INTERFACE

Firstly, it is important to ask what is the effective role of culture in such processes of event-led regeneration. If the ECoC contributes to encouraging or accelerating processes of urban transformation at the port-city interface, forms of culture-led regeneration may indeed be incidental, with limited connection to broader processes of regeneration. Secondly, event-led regeneration that takes place in this complex geographical space affects a broader set of spatial, socio-economic and cultural phenomena that are seldom investigated or addressed in flagship projects or other redevelopments. New cultural infrastructures and regenerated spaces generate new socio-spatial relationships and conflicts, since they come to be adjacent to working class districts or still active port areas. This raises the question of whether new cultural activities, as well as their users, are welcome in such liminal environments and indicates potential conflicts between new 'sanitised' spaces and existing 'unsanitised' ones, suggesting a further dimension of the spatial dilemmas observed by Bianchini (1993a). This spatial juxtaposition and competition among port, (existing) urban and (new) cultural/leisure uses is perhaps the visible dimension of a more complex set of social, economic and political conflicts among actors with rather different – and sometimes conflicting – stakes (e.g. port authorities, transnational shipping companies, urban governments, local businesses, trade unions, and so forth). This 'urban takeover' on port functions and spaces appears to characterise the most recent phase of port-city relationships in many contexts (Daamen and Vries, 2013). Thirdly, a major issue concerns the kind of culture that is promoted by the ECoC in European port cities. If it is true, as emerged for instance from the analysis provided by Griffiths (2006), that the city's identity as a port is generally emphasised in ECoC discourses, we should ask whether the resulting event-led regeneration succeeds to promote a maritime culture founded on local specificities. The risk is indeed that European port cities import strategies from (supposed) successful ECoCs, pursuing standardised models of culture and regeneration that may generate a loss of specificity and may exacerbate socio-spatial tensions. Culture-led and event-led regeneration, through cultural initiative such as the ECoC, are chances for local governments and communities to frame their cities' profile and development trajectories. In this context, a key issue is the extent to which such processes produce local responses, arising from local specificities and maritime identity, against globalising pressures exacerbated by the evolution of world maritime trade.

4.2 ECO PROGRAMMES AND URBAN PLANNING

The relationship between event-led regeneration and urban planning raises concerns of process, content of strategies and, finally, planning theory. In general, recent ECoCs adopt a governance model based on a separate delivery vehicle – usually a public company – responsible for the organisation and delivery of the event, which operates in collaboration with the local council (DG for Internal Policies, 2013). In addition, given the extraordinary and usually urgent character of event-related infrastructures, event-led regeneration strategies and actions may be programmed and pursued through ad-hoc plans. From the process perspective, this raises

the question of whether event-led regeneration is part of ordinary planning processes or it takes place outside planning procedures and arenas. In either context, cooperation between event and urban governance structures is a major concern. Considering the content of strategies, a key question is whether event-led regeneration contributes to shaping new development trajectories for European port cities and how these are embedded into urban planning practices. Finally, this call for integration between the ECoC and urban planning suggests a potential theoretical and methodological contribution to the latter. Since the ECoC, even in the case of an unsuccessful bid (ICC, 2012), encourages local communities to discuss the future of their cities, we should ask whether this produces new concepts and discourses that are developed even after the unsuccessful bid. Even though classic critiques of mega-events suggest that their exceptionality and urgent character may produce controversial practices (Hall, 2006; Smith, 2012), it may also be argued that they provide occasions of institutional learning and of experimentation.

5 TOWARDS A METHODOLOGY TO ADDRESS EVENT-LED REGENERATION AT THE PORT-CITY INTERFACE

The two key research questions and the related issues mentioned in the previous section offer a different perspective on the ECoC and on event-led regeneration. This investigation requires further reflection on a suitable methodology that allows to go beyond the assessment of the economic impacts of the ECoC and to explore more intangible socio-cultural and political impacts in the complex space of the port-city interface.

5.1 APPROACHING A CASE STUDY ANALYSIS

A comparative case study analysis of the ECoC in a set of European port cities might not portray the whole complexity of this phenomenon. However, a deep analysis of a few case studies, approached using an individualising strategy (Robinson, 2011) and reported through an extensive narrative that gives account of the historical, geographical and political context of each locality, might help to explore the issues mentioned above. Such strategy lets context-specific issues to emerge, providing crucial background information to develop a more grounded understanding of the studied phenomena, and helps to identify those conditions that must be taken into account in order to compare such different contexts. The framework for the selection of case studies is a crucial element and it is based on four geographical and socio-economic criteria. Firstly, the 'port' character of cities: port cities could be understood as coastal or riverside cities that are closely connected – functionally and culturally, not necessarily in terms of physical proximity – to a maritime port, where port functions are, or have been, a crucial element of their economic base. Secondly, acknowledged that neither ports nor cities are static entities, trajectories of change are more interesting for the purpose of this study whereas they reflect processes of restructuring or repositioning: selected cities are either struggling to recover from the loss of traditional maritime functions or managing to introduce new strategic elements into their economic base. Thirdly, selected cities should have been awarded the ECoC title in the last twenty years and managed the event as a component of their strategy of urban regeneration and development. This ensures that longer-term legacy could be addressed and that the event has not been hosted as a mere special occasion with no impacts on local development. Finally, a comparable size is a prerequisite for the comparison. Considering these criteria, potential case studies are: Rotterdam, ECoC in 2001; Genoa, where the event took place in 2004 after the 1990 FIFA World Cup and the Expo in 1992; Liverpool, ECoC in 2008.

5.2 A MIXED QUALITATIVE APPROACH

In order to approach the case study analysis, I propose to adopt a mixed qualitative research methodology. A classic ex-post, qualitative and descriptive policy analysis examines local politico-institutional contexts and policy processes and contents. In terms of context, a background narrative encompasses key historical, geographical and political features, giving account of the decades prior to the successful bid for the event. The analysis of policy processes and contents involves the review of policy documents about the ECoC, as well as urban plans and other documents or statements related to urban planning and event-led regeneration, with a focus on the last twenty years. Further information is gathered through semi-structured interviews to key informants: ten to fifteen informants per locality are selected among port officials, policy makers, planners, culture experts and developers. This classic policy analysis, undertaken through content and process analysis, is then coupled by a discourse analysis, from an institutional perspective (Healey, 1997; 1999), which examines spatial concepts, narratives and vocabularies. Discourse analysis may be helpful in unpacking the rhetoric of the ECoC and of event-led regeneration, as shown by Griffiths (2006) and García (2005), as well as identifying the features that local communities and policy communities perceived as key local specificities. Mapping and other spatial representation techniques help to give account of the complex spatial, socio-economic and political tensions that event-led regeneration contributes to generating at the port-city interface.

6 DISCUSSING EVENT-LED REGENERATION AT THE PORT CITY-INTERFACE

This case study analysis may help to address comparisons between the different experiences, in order to highlight the differences displayed in local approaches to the ECoC and its regenerative impacts. This could help to fill one of the most evident gaps in the literature, which lacks any substantial reflection on how different approaches affect outcomes (as suggested with regards to cultural planning by Markusen & Gadwa, 2010). Despite the remarkable differences arising from context specificities and the uniqueness of places, as cities sharing the same specialisation and part of transnational networks of maritime trade, European port cities may also share common structural issues, such as the competition between urban and port uses and the conflict between different stakes, the tensions between global pressures – encouraging standardisation – and local forces that ‘resist’ through local responses and specificities, the attitude – in the case of Rotterdam – or the need – as happened in Glasgow – of developing the cultural dimension of the city’s image alongside the profile of industrial port.

The three potential case studies also present context-specific problematics and unique approaches. For instance, Rotterdam explored the connection between modern architectures and water, which has become a major component of its image, as observed by Richards and Wilson (2004). Genoa addressed event-led regeneration building on its maritime identity, as suggested by the realisation of the Aquarium in occasion of the Expo in 1992 or the Galata maritime museum and the recovery of the lighthouse for the ECoC 2004. Liverpool adopted an opposite approach with regards to maritime heritage, prioritising issues of economic benefits over conservation. This provides relevant recommendations and suggestions for European port cities aiming to host the ECoC, as well as other cultural events. For instance, event-led regeneration in Hull fostered by the UK City of Culture (UKCoC) 2017 raises similar concerns.

The perspective of event-led regeneration in port cities helps to explore from a different point of view the complex port-city relationship, and to fill the traditional gap regarding broader socio-cultural impacts of cultural mega-events displayed by the literature, as well as to overcome the traditional spatial and static view of port-city relationships. It also explores political aspects of planning at the port-city interface, which have only recently been investigated by governance approaches to port studies (e.g. Daamen and Vries, 2013). For instance, the fluctuating port-city interface in Rotterdam offers an interesting perspective on the relationship between culture-led regeneration and strategic decisions on port development and competing urban-port uses.

A crucial feature of this study and the proposed approach is the connection between event-led regeneration and planning, which has seldom been explored in the literature. As mentioned in the previous sections, if there is a recognition that culture- and event-led regeneration are more effective when embedded into broader visions of future development, little knowledge has been produced about how this happens or how this connection ought to take place, both in terms of contents of strategies and of governance processes. In turn, governance episodes emerging from extraordinary practices and

approaches displayed by port cities involved in event-led regeneration might provide interesting insights for planning theory, as well. Such experiences may encourage innovative approaches and creative solutions to recurrent problems and may introduce new discourses and spatial concepts. For instance, in Genoa, the ECoC programme and the strategic plan explored issues of sustainability and legacy of event-led regeneration, introducing the concept of 'durability'. Governance episodes justified by the extraordinary character of a bid for the ECoC or of the event itself may then become part of ordinary governance and planning practices. New planning processes, discourses and strategies are as an interesting legacy of the ECoC as its economic impacts, albeit much less investigated. They may also fuel and enrich general debates on planning theory and practices.

7 CONCLUSION

In this paper, I presented the rationale at the basis of a PhD research – at its early stage – on event-led regeneration in European port-cities. The paper focused on the European Capital of Culture, formulating key research questions and proposing a methodology to address them. The starting point is the lack of any focus on port cities in the literature on event-led regeneration, albeit many port cities have been and will be awarded the ECoC title, as well as its extensive gaps concerning the complex dynamics at the port-city interface, the cultural, socio-economic and political aspects of event-led regeneration and its relationships with other domains of urban policy. Two key research questions emerge, regarding the impact of the ECoC on the port-city interface and its integration to broader urban planning frameworks. The proposed methodology involves a comparative case study analysis of the ECoC in a few European port cities, approached through policy analysis, interviews to key informants, discourse analysis and mapping. Such an approach to event-led regeneration provides recommendations for European port cities that will host either the ECoC or similar cultural mega-events. It also provides an innovative contribution to the debate on the future development trajectories of European port cities, on the evolution of the port-city relationship, on culture- and event-led regeneration and on its connection and integration to urban planning. In a context of growing interest on the cultural dimension of planning, it highlights potential contributions of event-led regeneration to planning theory and practices, arising from the discussion of governance episodes.

zachary.jones@polimi.it

1 MEGA-EVENTS AS A PLANNING STRATEGY

For the last 150 years, mega-events have been used as instruments to define cities and distinguish them from one another. They have been praised as opportunities for innovation and cursed as overly bloated expenditures, both a blessing or a scourge for the modern and modernizing city. As cities have sought to compete not just nationally, but globally, the hosting of a mega-event has become a sort of qualifier or standard to be achieved. Ongoing discussions debate the professed benefits they bring to host cities and the reality of their legacy. The legacy of the event deals not just with a physical memory, but also a new image or brand for a city that has been projected through the event. Therefore, mega-events have been used as part of cultural and creative strategies to secure much desired global recognition and attract future economic investment (Horne and Manzenreiter 2006; Roche 1994, 2002; Short 2008; Young and Wamsley 2005). The first key aspect of events is the large public spending that accompanies them, introducing a range of physical and social effects on the city, such as new infrastructure projects or facilities (Ponzini and Jones 2015). Secondly, they can also serve as a focusing-event that introduces strict deadlines accompanied by huge expectations, the conditions that can induce actors to put aside differences in order to collaborate (McGillivray and McPherson 2012). These two qualities in particular, mass investments restricted to a hard timetable presents a potential for synergy or friction with the urban heritage of a city.

Generally, urban heritage is one of the more particularly sensitive areas of the city. The introduction of mass tourism, often one of the intended consequences of a mega-event can greatly impact both the physical and the social qualities of these spaces. The decisions made as part of these events can lead also to altering the physical appearance and substance of a place through either conservation or demolition of heritage. These changes can significantly alter or potentially destroy these valued areas of cities. The historic nature of a place can also inversely impact the planning of the event or potentially become a key part of the The direct and indirect impacts of mega-events on European Urban Heritage attraction. While physical changes may be the most immediately visible, the changes to the governance of heritage areas, as well as their definitions, can have the most lasting impact. Whether a city chooses to highlight and promote its built heritage as an integral asset can continue to determine how the city values and protects its heritage even long after the event has ended. The combination of heritage cities and mega-events is therefore one that contains great potential as well as risk and deserves further consideration and study. In the last several years, a number of high profile cities including Boston, Rome and Budapest have cancelled their bids to host the Olympic Games, citing extreme costs and low public support. To broaden the appeal of the Olympics and promote more sustainable practice, Agenda 2020 has established new guidelines.

Specifically, recommendation 2.2 aims to promote the re-use of existing infrastructures (Gold and Gold 2016). This shift could result in the Olympics being more integrated into the existing city fabric. The

previous bid by Budapest for the 2024 Olympics served as a good example as they specifically recognized the use of important historic locations throughout the city to serve as the venues for various events, integrating the games into the city itself more than has been the norm in recent years. With this changing paradigm of megaevents, the European context can provide beneficial examples of how to properly integrate large events within existing city fabric. Over the last thirty years, lesser known cultural mega-events have played an important role in the development of cities and have become a common strategy for cities to turn to. While large Chinese cities such as Beijing and Shanghai have hosted events including the 2008 Olympics and 2010 Expo respectively, if trends continue, smaller scale cities in China and elsewhere may also pursue cultural and sporting events to promote themselves at an international scale. As the Agenda 2020 recommendations become more common and mega-events are more integrated into the city itself, it will be important for cities to recognize and plan how to utilize these events for their greatest benefit. The cases presented herein provide three examples to consider and learn from how the urban heritage of a city can benefit or be put at risk by the significant investments and protracted deadlines of a mega-event.

2 THE EUROPEAN CAPITAL OF CULTURE A MODEL OF AN INTEGRATED MEGA-EVENT

The European Capital of Culture (ECoC) is a yearlong cultural program consisting of a series of events typically situated within the city. This event is one of the longest running continuous EU policies and the flagship cultural program for the European Commission. Beginning in 1985, the event has operated for 30 years with over 50 cities throughout Europe holding the much-coveted title of European Capital of Culture (García and Cox 2013). A key component of the program is the promotion of a distinctively “European culture” (European Commission 2014). The 50+ cities have interpreted European culture in many different ways, sometimes with traditional built heritage taking a leading role, while other cities have chosen to not include it within their programs at all. Typically, the activities of the ECoC are embedded directly within the city itself, with the potential to reference and actively include built heritage more than is typically possible with the Olympics, which have often resided outside of the city and relied more heavily on newly built infrastructure.

While the ECoC program may not be as renowned as other mega-events, it has become the inspiration for a number of similar programs. There has been a UK City of Culture program since 2013 with many British cities desiring to participate following the success of the 2008 Liverpool ECoC. Since 1996 there has also been an Arab Capital of Culture initiative organized through the Arab League and since 2015 there has also been the Capitale italiana della cultura in Italy. With the ECoC program slated to continue until 2033, it is a mega-event worthy of continued study. Due to the content of the program and its direct relationship to the city itself, the European Capital of Culture is a relevant mega-event for which to examine how a megaevent adds value to the city itself, particularly its urban heritage.

The three selected case studies of Genoa 2004, Liverpool 2008 and Istanbul 2010 represent three very diverse cities in terms of the contents of their events, their planning systems and approaches to heritage.

In addition to hosting the ECoC, each city has also been recognized as a UNESCO World Heritage site (WHS) for being of outstanding universal value (OUV). While many of the other ECoC host cities also contain important urban heritage, the quality of being a WHS created another point of comparison between the three cases. The application process for WHS is an intensive process that guarantees these cities have valued their heritage enough to ensure its global recognition. The cases will be used to illustrate the great potential and risk they can pose to built heritage through a range of approaches.

Genoa 2004 was selected as the quintessential example of using a mega-event to regenerate the image of the city through a heritage-led approach. The WHS site of Genoa was actually recognized in 2006, two years following the event due to many of the restorations included within as part of a larger long-term strategy of the city that also included the 2001 G8. Liverpool 2008 was seen as an ideal counter point to Genoa for the study. Though the city received WHS status as “Liverpool – Maritime Mercantile City” in 2004, the heritage of the city was largely absent from the 2008 events. Eventually the site was added to the List of World Heritage in Danger in 2012 and presents an interesting opportunity to examine the long term effects of a city choosing to ignore its heritage within a mega-event. Finally, Istanbul 2010 was

chosen both for its focus on heritage, but also for taking the mega-event strategy and expanding it to the extremes within a global city. The planning of the event also different from the strategies of Genoa and Liverpool, revealing the diversity of approaches.

2.1 GENOA EUROPEAN CAPITAL OF CULTURE 2004

Genoa and its revival has generally been declared a success of a post-industrial regeneration (Gastaldi 2016; Bonfantini 2015). While Genoa clearly utilized the transnational mega-event strategy propagated by many cities, it is distinct for its usage of heritage as the key component. The story of Genoa's revival traces its origins to some early renewal projects in the late 1980s, followed by the Expo 1992 and considered finalized with the 2001 G8 and 2004 European Capital of Culture. Through all of these efforts, the historic city centre has played an essential role. The city's 'Golden Age of Reuben' occurred during the The direct and indirect impacts of mega-events on European Urban Heritage 16th and 17th centuries, when as an independent wealthy maritime republic the city was very wealthy and established itself as a centre of banking (Bobbio 2008, 2005a). While the city then enjoyed a period of continuous growth up until the 1970s, it entered a period of several decades of decline and shrinkage. This new scenario resulted from changing national and international trends (Bobbio 2008). By the 1990s, the city centre was in a serious state of degradation, disconnected from the waterfront and, despite containing a Medieval historic core and series of impressive Palaces, it was not known or recognized as a city of culture or tourism.

A key aspect of Genoa's approach was embedding the event within the wider plans for the city. Genoa presents a case where the plans for the city were molded around the event, specifically with the 1999 Strategic Conference and 2000 Operation Plan for the Historic Center. The city brought together the key institutions and actors to establish the goals of these plans to address the issues of tourism, education, development, livability and infrastructure (Comune di Genova 1999). Despite a complex web of projects and funding sources, the city used the strategic conference and the subsequent operation plan to succinctly guide the mass physical transformation of the city. The series of 16th and 17th century Rolli Palaces were selected to be restored in particular with the explicit intention of applying for UNESCO WHS status. This recognition was considered key in establishing the city as a cultural destination and became one of the main goals. The massive shift to focus so heavily on the heritage of the city was a significant change for a city that had not been considered a 'cultural' city during the previous century. These plans and the event reveal a new way of thinking about the city.

It was hoped that this investment in heritage would perform multiple tasks for the city. First, it formed the main theme and attraction for 2004. The idea was that the city itself would draw local residents and visitors back to the city center, both during the ECoC year itself and beyond. While a year of exhibits and concerts might prove exciting for a year, it was not believed to guarantee a long-term return on that investment (Da Molo, personal interview, 2016). Heritage was therefore tasked with creating both a previously non-existent tourism sector as well as an anchor to attract a new creative sector to the city to initiate the regeneration of the city. These expectations were quite high, particularly in a place where there was no strong presence of a tourism industry in a country already competitive in world-renown heritage offerings in cities such as Rome, Florence and Venice.

Figure 1) The Rolli Palaces. (a) Palazzo Bianco (b) Palazzo Rosso (source: author, 2016).

2.1.1 THE OUTPUTS OF GENOA 2004

Over 160 individual restorations and urban improvement projects were completed between the two coordinated mega events. A key to the proper completion of works was the pre-existing academic studies and research that allowed conservationists to make the best decisions for each individual structure restored (Carbonara 2001). In Genoa particularly, with its vast array of painted facades, it would have been nearly impossible to complete the work without seriously damaging their authenticity without such preparation. The works included the grandest palaces of the city: Rosso, Bianco, Tursi and Reale, the same first made famous by Reuben. The facades of a number of smaller palaces within the medieval core were also restored. Several other important projects were the pedestrianisation of several of the key streets throughout the city. These works both improved the urban quality of these spaces to make them more accessible and enjoyable as well as guarantee the long term protection of the city's heritage by significantly reducing harmful pollution. Without the advanced preparation and integration of the event into larger strategic city plans, it was possible to properly complete the restoration works despite the restricted schedule.

Figure 2) Newly restored and pedestrianised public spaces (a) Piazza Ferrari and fountain (b) Via San Lorenzo (source: author, 2016).

The incredible volume of works completed in Genoa through the event cannot be denied. The facade restorations revealed a previously unseen and unknown Genoa. At the time of the events, there were two key issues identified for the continued long-term success of the event. First and foremost, the continued regular maintenance of this newly restored heritage. Otherwise, the city risks eventually losing these structures or they will become even more expensive to restore when major future interventions are required (Alcozer 2005; Pittarello 2001; Storti 2005). Second, key developments were identified in order to continue the forward motion of the city, in particular the Ponte Parodi project, a large cultural and entertainment center on the waterfront (Alcozer 2005), and the Erzelli Citadel by Renzo Piano, a new research and technology district. The direct and indirect impacts of mega-events on European Urban Heritage (Bobbio 2005b). The ability to implement these strategies without the extraordinary funding the city provided by mega-events is identified as a key challenge to overcome (ibid.).

Figure 3) Map of the building projects and public spaces renovated for 2001 and 2004 (source: author, based on Osservatorio Civis).

2.1.2 THE LEGACY OF GENOA 2004

Of the nearly €650 million that Genoa invested in its heritage from 1993 to 2005, nearly a third was allocated for the 2004 event (Gastaldi 2009). To put this figure in perspective, the €200 million of the ECoC nearly equals the annual budget of the Ministry of Culture for restoration works for all of Italy (MiBACT 2017). 2004 represents a key point of change for Genoa in terms of tourism. Compared to the number of visitors 5 years prior to the event, there was a 20% increase during 2004 alone (García and Cox 2013). In 2005, the city received a total of 586,633 overnight visitors, which has since expanded to 801,833 in 2014, a 65% increase (Comune di Genova 2015). The heritage of the city has become a main attractor to draw visitors. Within a national context, the region that Genoa is located in, Liguria, is now the 4th most visited region in Italy. It seems quite clear, based on the available data, that the 2004 European Capital of Culture and the mass restoration works completed through the event have significantly and successfully contributed to establishing Genoa as a cultural destination. The other clearly stated goal for the city was the attainment of UNESCO World Heritage Site status, considered a seal of approval of the transformation of the city and its reputation. This achievement would confirm Genoa's place not only as an important facet of history, but also as an established cultural destination. In 2006, "Genoa: Le Strade Nuove and the system of the Palazzi dei Rolli", was recognized with WHS status. A majority of the listed palaces were restored during the works for the events.

Despite the significant number of improvements, the city yet continues to face a number of social and economic issues with the population continuing to decrease slightly. In large part due to the global economic crisis, the development projects of Ponte Parodi and the Erzelli Citadel have been significantly delayed and remain in the planning stages. The years following 2004 also witnessed a massive decrease in funding for preservation projects nationally (Bodo and Bodo 2016), thus the continued maintenance program has not been implemented as hoped. While the mega-event can therefore be a great force to organize and motivate actors, it often leaves a void that is difficult to replace. Therefore, the heritage-led approach can be effective in terms of rescuing the city's urban heritage and establishing a tourism industry, but, on its own, may not be enough of an attractor to revitalize all social and economic elements of a city. Therefore, while the significant investments in heritage throughout the city were well planned and implemented, this approach may have yet further benefited from greater integration with other innovative social and economic policies and strategies for the city to fully address the many needs of the city.

2.2 LIVERPOOL EUROPEAN CAPITAL OF CULTURE 2008

At the outset, many similarities can be drawn between the cases of Genoa and Liverpool. The trajectories of both cities nearly parallel one another since WWII. They have long functioned as important ports within their national contexts, but were heavily bombed and never quite recovered their former position following periods of deindustrialization. The populations of both cities have been cut in half from the start of the 20th century and they have focused on reestablishing new economic footholds. Perhaps unsurprisingly, Liverpool also intended to use the ECoC to replicate the success of other cities. In particular, Liverpool chose to emulate Glasgow (The Liverpool Culture Company Limited 2002), which hosted the 1990 European Capital of Culture. However, heritage did not play a significant role within the preparations or execution of the event. Therefore, the relationship between the event and the urban heritage of the city is drastically different from what was observed in Genoa and makes for a valid comparison. Liverpool is often cited by academics and other bidding cities as one of the most successful ECoCs ever (García, Melville, and Cox 2010). The event has been noted as playing a key role in revitalizing the image and economy of the city. The main question then is whether there can still be any benefit for heritage when ignored by an event, or, is there a significant risk to the long term viability and value of these areas?

Liverpool has over 2,700 listed buildings and 36 conservation areas (CA) with a total of 9% of the city has been designated as a CA (Liverpool City Council 2017). The city was also recognized as "Liverpool - The Maritime Mercantile City" by UNESCO in 2004 with the site consisting of the waterfront areas and a section of the city centre, so the city has a significant volume of built heritage. By the late 1990's, a coalescing of political, institutional and individual efforts occurred, culminating in a unified vision for the regeneration of the city (Cocks 2013). This conglomeration of actors included the North-West Development Agency, English Partnerships, Liverpool City Council and the newly created Liverpool Vision (ibid.). It is during this period that the city bids for and wins the ECoC, aiming to move beyond the previous

decades of decline and negative stereotypes to establish a Liverpool poised to become the 'Shanghai of Europe' (Paker 2008).

Leading up to the 2008 ECoC then, the heritage of Liverpool found itself at an interesting point. After decades of decline and abandonment, it had come to play a key role in the rebirth of the city starting in the 1980s and culminating in the awarding of WHS. While much of the heritage of the city can be found concentrated within the center, many important historic areas can be found spread throughout greater city. The direct and indirect impacts of mega-events on European Urban Heritage region. As the population of the city has halved over the last 70 years, many important structures and neighborhoods now find themselves isolated and lacking their original context due to sprawl and slum clearance during the 60s and 70s. In fact, by 2009, there were still 440 listed buildings considered at risk, so the city's heritage did require further attention.

2.2.1 THE PLANS FOR THE CITY AND LIVERPOOL 2008

Like Genoa, the city also used a series of plans to create an overarching vision for the city, starting with the 20-year Regional Economic Strategy (RES). This strategic plan would provide the basis from which plans produced by Liverpool Vision and the city council would fit within with the 2008 ECoC coming to feature as a key deadline for the city to aim for and central to its regeneration. While plans like the City Centre Movement Strategy, Public Realm Implementation Framework, Townscape Heritage Initiative and other improvement schemes were created to guide public works, the program for Liverpool 2008 did not incorporate any restoration works. Therefore, while the city's original bid recognizes the importance of the city's heritage as a key asset that creates a 'rich environment' (The Liverpool Culture Company Limited 2002), it never comes to serve as a crucial component of the event itself. The intention of the city was that by reshaping Liverpool as an exciting and forward looking destination, the unused historic structures of the city would eventually benefit indirectly. Therefore, the protection of heritage areas was left to conservation focused institutions or the private sector, with the local government serving more as a coordinator or go between actor. While the city and event itself did not oversee the restoration of historic structures or areas, there were 10 restoration projects coordinated to re-open with the ECoC celebrations in 2007 (the city's 800th birthday) and 2008.

The most important of structure restored was St. George's Hall, a Grade I listed neoclassical building from 1854 that provided the city with law courts along with a town hall and concert room that came to serve as the site for many large public events during 2008. Liverpool University also created The Victoria Gallery and Museum in the original university building that has sat unused for the last several decades. There had been previous attempts to find a new function for the historic building, but the funding and motivation were never sufficient. With the announcement of 2008, the university felt an obligation to contribute and give something back to the city (Clough, personal interview, 2016). Therefore, the university agreed to restore the building and establish the gallery and museum, which unified pre-existing collections of the university in one location. Additionally, several historic buildings were restored as hotels in anticipation of the many visitors to the city during the year. While these physical works were nowhere as comprehensive as those in Genoa, the city did in many ways transform through the broader public rehabilitation plans and the opening of a new £ 1-billion private retail center, Liverpool One, which also aligned its grand opening with 2008.

Figure 5) The Victoria Gallery and Museum (right, source: Author, 2016)

2.2.2 THE LEGACY OF LIVERPOOL 2008

Unlike Genoa, built heritage was largely absent from considerations of the event, yet that does not mean it has not been impacted as a result. With a rejuvenated interest in the city, the number of individual listed buildings considered at risk have been drastically reduced in recent years, despite the lack of restoration within the event itself. In 2009, there were 440 listed buildings at risk compared to only 66 in 2016. Many structures have been converted to hotels as well as residences, particularly student housing. Though the pure numbers are impressive, not all instances of buildings removed from this list would be considered conservation success stories. A series of renovations have led to the destruction and loss of historic buildings in the years since the ECoC such as the demolition of the Dale Street Georgian shops in 2015 and the Futurist Cinema in 2016.

The biggest development since 2008 for the heritage of Liverpool is UNESCO placing the city's WHS on the List of World Heritage in Danger in 2012. The main factor in UNESCO's decision has been the proposed, but not yet implemented, development scheme for Liverpool Waters by The Peel Group. Liverpool Waters is a £5.5 billion proposed scheme covering 60 ha located in and around Liverpool's northern docks, with portions situated within the WHS itself as well as in the buffer zone. Specifically, plans for several skyscrapers within the site have caused the most concern. Despite several design changes, UNESCO continues to deem the height of the towers a threat to the OUV of the site (UNESCO 2012). While the city has enjoyed WHS status since 2004, it has struggled to properly promote this international recognition. There are no clear markings throughout the city or maps to allow locals or visitors to understand when they are within the site. While reminders of the Beatles are an inescapable part of the city, one could easily be excused for not knowing Liverpool is in fact a WHS city. In addition to the physical condition of the city's heritage, the last 15 years have witnessed a clear shift in official policy towards preservation. While the 2004 Heritage Investment Framework placed the city's heritage as a crucial component for future development, the 2010 update framework does not highlight heritage in the future of the city other than The direct and indirect impacts of mega-events on European Urban Heritage through further cooperation with private developers (Liverpool City Council 2010). No replacement plan has been produced since its expiration in 2015. There has also been an ongoing reduction in the number of conservation officers devoted to the protection of heritage within the city council as faced with budget cuts.

Figure 6) The proposed Liverpool Waters Scheme (source: Chapman Taylor)

Liverpool maintains a tenuous relationship with its heritage. While it has a successful history of regeneration through heritage, that tradition has not been carried through the event or city plans. By 2008 there were still hundreds of listed buildings in need of repair that could have benefited from a mass program of restoration such as Genoa. Instead, the city chose to let the private sector take the lead in re-using and restoring its heritage through regeneration schemes. While this approach has at times resulted in projects that are well restored to a high quality, in others it has led to the demolition of sites. The main impact of the event can be observed through the secondary effects that have bolstered independent groups to align their actions with the event. This reliance on the intentions of external entities is a potential gamble that does not guarantee heritage protection or promotion. This case also suggests that the positioning of the event does come to impact long term thinking and policy of the city. Heritage has continued to take a backseat to the continued festivalization and new development of the city. The success of one mega-event may inevitably prescribe their future repetition as Liverpool now hopes to host future large cultural and sporting events. If this strategy comes at the expense of a long-term valuing of the city's heritage, instead of a coordinated effort, the results could be truly catastrophic. The current strategy in

Liverpool, as stated by the Mayor (Belger 2016), is that buildings are saved when viable. Therefore, regeneration seems to have become the ultimate motto/goal of the city. When heritage can benefit those processes it will be valued and included, but otherwise is viewed as a nuisance or something merely standing in the way of development.

2.3 ISTANBUL EUROPEAN CAPITAL OF CULTURE 2010

Istanbul is a case of extremes. It is a city with an 8,000-year history and the sheer scale of the city tests the limits of a mega-event and its ability to meaningfully impact such a large city. A cornerstone of the 2010 Istanbul ECoC was the heritage of the city. However, the approach of Istanbul relied far more heavily on public participation in determining projects with the event not integrated into a set of city coordinated plans guiding the works, as seen in both Genoa and Liverpool. This case therefore additionally explores the benefits and risks of a public participatory model for planning large events, a particularly unique feature of this case. The framework of institutions responsible for the protection of heritage sites is a fractured and complicated network. In Istanbul, these layers range from the involvement of local municipalities, central ministries, and international organizations. Once again, the responsibilities and jurisdiction of these actors are often unclear to outside observers as well as to the actors themselves leading to frequent disputes. As noted by Marquart (2014), the management of heritage in Turkey is in a constant state of change and evolution.

Though new powers were given to local level authorities in 2004, most of the power remains with central ministries. Under the Ministry of Culture and Tourism (MoCT) exists the General Directorate of Cultural Heritage and Museums and the General Directorate of Religious Foundations that separately manages Ancient/Byzantine and Islamic/Ottoman heritage sites respectively (Bonini Baraldi and Shoup 2014; Bonini Baraldi, Shoup, and Zan 2013). Therefore, the newly created 2010 Agency, the body responsible for managing the event, became an additional institution responsible for heritage within this already complicated web.

The most noted heritage sites in Istanbul are included in the Historic Areas of Istanbul, the four WHS properties located on the Historic Peninsula recognized in 1985. While the buffer zone comprises the entire peninsula, the four main areas are the Archaeological Park, which includes Topkapi Palace, Hagia Sophia and the Sultanahmet Mosque (Blue Mosque); the Suleymaniye quarter and Mosque complex; the Zeyrek area surrounding the Zeyrek Mosque (former Pantocrator church); along with the massive Theodosian land walls. Parts of these historic areas have suffered severely from decades of decay and neglect. This current situation has resulted from a variety of factors, including lack of resources and funding, both publically and privately (Çelik 2010). Laws promoting urban renewal, tourism incentive and prevention of earthquake damage have also significantly impacted historic through either their 'touristification' or demolition and reconstruction (Bezmez 2008; Candan and Kolluoğlu 2008; Çorakbaş, Aksoy, and Ricci 2014; Dokmeci, Altunbas, and Yazgi 2007; Günay 2010; Günay and Dokmeci 2012; Keyder 2010; Kocabaş 2006; Marquart 2014; Somuncu et al. 2005). In 2003, UNESCO announced that Istanbul's four WHS would be considered for inclusion on the World Heritage in Danger List. Of particular concern was the lack of a proper site management plan for the 4 WHS areas as well as the whole of the historic peninsula. In fact, the mission reports by UNESCO suggest utilizing the 2010 ECoC as a tool to restore threatened sites, recognizing the additional funding and urgency of the event as potential heritage resources (UNESCO 2006, 2008).

2.3.1 THE ISTANBUL 2010 PROGRAM

The direct and indirect impacts of mega-events on European Urban Heritage While the bid for 2010 started life as an entirely bottom-up proposal by several NGOs, the 2010 Agency was ultimately comprised of many central government actors with civil society groups losing much of their influence. As a result, there were varying intentions for the ECoC. For some involved, it was primarily seen as an opportunity to advertise the city on a global stage, with its heritage as the main attractor. However, other representatives of the 2010 Agency, proposed an alternative vision where arts, culture and heritage were localized to make them more accessible to local citizens in areas where they normally do not exist. In the end, both of these intentions are represented in some ways. The report by Ernst-Young (2011) notes that 49% (€ 137 million) of the total budget of the ECoC was devoted to the city's heritage. While a significant investment

for the city's heritage, Karaca (2013) argues that a mega-event should not have been necessary to ensure the financing of these restoration projects in the first place, but rather already regularly maintained and promoted.

Figure 7) The spread of restoration projects for Istanbul 2010 (source: author)

In total, the event was responsible for over 50 separate restoration projects, several of which were in a severe state of degradation. The works range from religious, civil, military and even industrial sites spanning the Republican, Ottoman and Byzantine eras and ranged from some of the city's grandest and most well-known built heritage to rather small and virtually unknown sites along with several urban pedestrianisation schemes. The most notable monuments of the city that were worked on include Hagia Sofia, Sultanahmet Square and Topkapi Palace, the former home of the Ottoman sultans and the most visited museum in the country. The 2010 event also served as an opportunity to revitalize structures like the Vortvots Vordomon Church, which had been abandoned for over a century. This important Armenian heritage property likely would have otherwise remained left to decay as prior attempts to raise funding for the project over the previous decade had been unsuccessful. Notably, this project was the first ever Armenian cultural property to be funded by the Turkish Government, representing a significant step in the recognition of the country's diverse past and heritage. The Historic Wooden Home Repair Program implemented in the Zeyrek and Süleymaniye areas was another important project that brought together several existing institutions to not only restore some of the iconic wooden homes of Istanbul, but also to develop training programs to provide the skill sets and knowledge of traditional construction methods (Istanbul 2010 European Capital of Culture Agency 2011).

Figure 8) The Vortvots Vordoman Cultural Center (a) before and (b) following the restoration in 2010 (source: (a) Kevork Özkargoz, (b) author, 2015)

In addition to the physical works completed, two important heritage plans were produced as part of the 2010 event: The Historic Peninsula Site Management plan (SMP) and the Sur-i Sultani Strategic Vision. These plans were both important attempts to secure the city's heritage for the future and generate a longterm vision that had been lacking. Unfortunately, neither plan has been implemented to the degree hoped for. The SMP seems to have lost the ability to cast a forward thinking vision for the future that could be effectively implemented. However, with the document's completion in 2011, UNESCO decided to

remove the Istanbul sites from consideration for the warning list. Additionally, the 2010 Agency was also able to bring together heritage actors from throughout the city that had previously not worked together. New networks were created between local actors with weekly meetings including academics, practitioners and elected officials to engage in conversations about the pressing issues facing the city and its urban heritage.

While the 2010 Agency was not exclusively a heritage body, it was in many ways able to ‘fill the gaps’ within the complex heritage network for a period of time.

2.3.2 LONG-TERM OUTCOMES OF ISTANBUL 2010

Overall, the 2010 ECoC contributed greatly to the city in terms of physical regeneration, management structures and promoting a culture of preservation of built heritage. However, while the event was used to impact a broad range of heritage, the hard deadline of the event and significant investments may not have been enough. First, over half of the projects were not finished in time for the event itself with many still left incomplete. In other instances, some completed structures have been left susceptible to future damage or excluded from public access. In 2012 the Istanbul Metropolitan Municipality promoted its level support of restoration efforts with a report entitled “Istanbul: Reborn in the Historical City” (IMM 2012). It cites an 860€ million investment between the years 2004-2012 in culture and tourism. However, of that total figure, only 113€ million were spent on actual restoration works, with the rest going mostly to advertising. However, a 2014 report calls into question the state of preservation of Istanbul’s monuments and requests UNESCO to reconsider the properties for the World Heritage in Danger list. Specifically, the report sites ongoing practices at construction sites that have directly damaged the Theodosian Land Walls, one of the four WHS (Çorakbaş, Aksoy, and Ricci 2014). The urban regeneration schemes have continued to be implemented in historic areas, leading to their continued loss (Marquart 2014; Yetiskul, Kayasü, and Ozdemir 2016; Yildirim 2015).

Figure 9) Construction site at the Theodosian Land Walls (source: author, 2015)

The works completed as part of the 2010 ECoC represent an important turning point for Istanbul and the protection of its heritage, as recognized by UNESCO rescinding its possible inclusion on the Heritage in Danger List. In this case, the ECoC was responding to an emergency scenario in terms of the city’s heritage. Without a doubt, many of the heritage assets of the city would yet be decaying and abandoned if it were not for the event. In this sense, the event has been invaluable in ensuring the continuation of these heritage sites for future generations. The efforts made for inclusivity and a participatory approach should be applauded, particularly in a context like Turkey where such practices are not common. However, this structure, which lacked a single cohesive plan for the event and was divorced from other strategies for the city resulted in reduced efficiency. While the event can be an effective engine to address short term and immediate problems, like the restoration of a decaying structure, it was not as successful in addressing the embedded systematic shortcomings in the existing complex governance structure of the city’s heritage. Also, while the investment was significant, it was perhaps not adequate to meet the need of a city like Istanbul with such a vast heritage offering. Ultimately, in a city as large as Istanbul, it would be difficult for an event of any magnitude to dramatically impact in a cohesive and consistent way.

3 CONCLUSIONS: HERITAGE UTILIZING MEGA-EVENTS AS A TOOL

There are several key conclusions to be drawn from these cases that can be applied to historic cities hosting mega-events. As opportunities of great funding that allow for the promotion of the city and an occasion to unify actors within an accelerated timeline, they are capable of introducing a new heritage-centric focus to the city where one may not have previously exist. Genoa successfully used the event to first complete the necessary restoration of the urban core and then subsequently establish itself as a new destination, now known for its heritage and waterfront. While the city may yet have other issues it must continue to address, its heritage has been recognized by UNESCO and its tourism continues to grow. Therefore, for cities wanting to protect and develop their heritage sector, the event can be one tool to use. It can serve as a mechanism with which to protect heritage and address emergency situations of physical decay that otherwise might be lost. However, cities must be careful to properly manage and integrate such efforts into comprehensive and strategic city plans. While an event may be successful to initiate short term goals, a city cannot rely solely on the event, it must plan long-term to maintain and protect its heritage. Therefore, while increased funding and expedited delivery can benefit heritage, their focus and implementation are crucial.

While many physical restorations can be implemented, the event also can improve heritage management and policy. Istanbul included public participation, which could potentially broaden the scope and definition of heritage. However, when not connected to an overall plan, the outcomes can be diffused and not result in a cohesive outcome. Having the event embedded within larger plans also provides greater assurance that desired projects will be completed. Both a potential benefit and drawback of the mega-event is its restricted and steadfast deadline. While this aspect may motivate actors to work together and accomplish tasks on time, it can also result in rushed works that harm instead of protect heritage. Even if the physical restoration is properly carried out, but the long-term care, maintenance or use is not planned for, the site can quickly return to being at risk of degradation or abuse. Therefore, it's crucial to be well planned in advance and recognize the entirety of the task involved and adequately prepare with the appropriate research and planning for both the event and afterward.

Liverpool illustrates the potential for positive secondary effects for heritage from an event, but also the risk of sacrificing historic areas to development interests. Especially when an event is considered successful, but has not emphasized its heritage, it may lead to the city perceiving its heritage as being not as valuable an asset. Regardless of the inclusion of heritage as a focus of the event or not, each of the cases have faced their own struggles in the transition following the event, either in their ability to complete projects that were unfinished or in maintaining the overall initiative and drive following the event's close. While legacy planning is often mentioned as an important part of the process, it is typically far more difficult to implement, even when programmed in advance.

A clear issue in Istanbul, and a potential factor for many Chinese cities, is the greater the scale of the city, the more difficult to evenly distribute the impacts throughout the city while still creating a worthwhile outcome. While, the Shanghai Expo 2010 established a precedent for reusing industrial heritage The direct and indirect impacts of mega-events on European Urban Heritage (Sha et al. 2014), it was restricted to a single area. Therefore, the potential does exist for mega-events to serve as the impetus for innovative heritage renewal in vastly varying contexts, but these efforts can be greatly expanded upon. Ultimately, planning and preparation are a crucial element to best take advantage of the increased budget and time scale that mega-events provide. They can therefore indeed be a potential tool for conservationists and planners to use for the benefit of urban heritage while developing mega-events that are more sustainable and integrated into existing cities.

ID 1421 | TOURISM AS ECONOMIC RESOURCE FOR PROTECTING THE LANDSCAPE: INTRODUCING TOURISTIC INITIATIVES IN PROTECTED AREAS OF ALBANIA

Enrico Porfido¹

¹IDAUP - Researcher and Lecturer, Observatory of Mediterranean Basin, POLIS University Tirana
enrico_porfido@universitetipolis.edu.al

ABSTRACT: The paper aims to investigate the relation between landscape and tourism, with a special focus on coastal protected areas of Albania. The relationship between tourism and landscape is mutually reliant: there is no tourism without landscape attractive features and, on the other hand, landscape needs economic resources to be conserved and protected. The survival of each component is strictly related to the other. Today, the Albanian protected areas appear as isolated islands, too far away from each other to build an efficient network and to avoid waste in terms of energy, economy and work force. This study wants to stress the importance of cooperation in terms of common strategies and the necessity of introducing a touristic sustainable model in Albania. Comparing the protection system of neighbor countries of the Adriatic-Ionian region and through a desk review on the best practices of protected areas that benefit from touristic activities, the study proposes the creation of the Albanian Riviera Landscape Park. This action will impact positively the whole southern Albania territory, introducing a sustainable tourism network aimed at valorizing the local heritage and stopping the coastal exploitation processes. The main output is the definition of future development scenarios in Albania with the establishment of new protected areas and the introduction of touristic initiatives.

KEYWORDS: Albanian Riviera, ecotourism, protected areas, tourism for landscape.

1 INTRODUCTION

“There is no tourist development without a landscape; it also seems that landscapes, especially those called cultural landscapes, need tourism as an economic activity to be sustained” (Goula et al, 2012).

How can tourism and landscape coexist? Referring to the above quotation, those two elements are strictly interrelated. The absence of natural or cultural landscapes in a specific area means not only an absence of interest in visiting it, but, more generally, a lack of interest in developing and investing in it. On the other hand, when in an area there are one or more iconic (Dudley and Stolton, 2009) elements, the risk is to overdevelop it and affect irreparably its heritage components.

So, which are the tools for the pacific coexistence of tourism and landscape? One possible answer to the question is the institution of protected area systems. The role of protected areas is to gather valuable elements and protect them from market pressure, but also to valorize and make them accessible to everybody. In the specific context of a touristic developing region, the designation of a protected area aims to switch from a mass tourism destination to an educated and responsible one.

In this general framework, what is the potential of Albania? Due to its accelerated development process, the risk of exploitation is high. The strategic use of the protection system can offer the possibility to slow down this development process and better plan future steps that ought to be taken.

2 PROTECTED AREAS AND TOURISM: FOCUS ON BALKANS

Tourism “in protected areas produces benefits and costs [and] these effects interact often in a complex way” (Eagles et al, 2009). Although the environmental risks are high, touristic activities should not be avoided, but constantly monitored and well managed. Luckily there are a lot of best practices that subvert the negative opinion about touristic development. The new trends of sustainable, responsible, eco tourism started to be discussed in 90s, but there are many different points of view. Ecotourism, for example, is

defined as “sustainable tourism with a natural area focus, which benefits the environment and communities visited, and fosters environmental and cultural understanding, appreciation, and awareness” (IPS, 2010). In the last few years, ecotourism is becoming nothing more than a kind of environmental show business (Hintze, 2008). So how to avoid this risk?

Touristic activities are often presented and sold as “eco”, but then in reality they strongly impact the environment. But it is also clear that “tourism planning and development aims to take advantage of the interest shown by tourists to as to: (i) enhance economic opportunities, (ii) protect the natural and cultural heritage, and (iii) advance the quality of life of all concerned” (Eagles et al, 2009). In order to develop the correct touristic strategy to include in the park management plan, the natural and cultural features of the area should be clearly identified and categorized according to the IUCN protected area management categories. The following figure (Figure 1) defines the priority of “tourism and recreation activities” according to the IUCN Protected Area classification.

IUCN category	tourism priority
Ia - Strict natural reserve	-
Ib - Wilderness Area	2
II - National Park	1
III - Natural Monument	1
IV - Habitat/Species Management Area	3
V - Landscape Park	1
VI - Protected Area with sustainable use of natural resources	3

Key: 1 - Primary Objective; 2 - Secondary Objective;
3 - Potentially applicable objective; - - not applicable

Figure 1 -Tourism and recreation activity priority in protected areas according to the IUCN categories (source Eagles et al, 2009).

The combination of touristic activities and protected areas is possible if allowed by relevant legislation and IUCN reference category. In the areas belonging to IUCN cat I (Ia -Strict Natural Reserve and Ib -Wilderness Area) and II (National Park), the human visitation is reduced to minimum excepted for indigenous communities who have the right to continue their activities on the territory. Categories III and IV are similar in objectives and different in subjects. IUCN cat 3 – Natural Monuments – includes small sites which are important mainly for their cultural heritage associated to significant biodiversity that needs to be protected, while the IV category (Habitat/Species Management Areas) has a more biological objective. In the last categories – V (Landscape Parks) ad VI (Protected Areas with sustainable use of natural resources) – the human and natural interaction is significant, favoring the development of ecotourism programs.

Balkans countries are rich in natural and cultural heritage -which represents a main potential economic resource, although every single country has a completely different approach to this theme. The following figure (Figure 2) shows the differences in protected areas’ extension in the Western Balkan countries, that are facing or close to the Adriatic and/or Ionian Sea.

Figure 2 -Terrestrial protected areas coverage expressed in percentage (sources: protectedplanet.net and Mustafa (2011), further elaborated by the author).

Slovenia clearly represents a unique case not only for the Balkan region, but worldwide. With its 2407 Protected Areas, the Republic of Slovenia has more than half of its territory protected by law. Those PA mainly belong to the IUCN category III -Natural Monuments (1159), Natural Reserve (59) and Landscape Park (43). Croatia and Greece follow both with a high percentage, but with different features. Croatia has 82 Significant Landscapes (IUCN cat V) and 81 Natural Monument (IUCN cat III), while Greece counts around 600 Wildlife Refugees (generally allocated in the IUCN cat IV). Albania ranks forth with a total of 60 areas that belong mainly to IUCN cat IV (23) and II (15) (Albanian Ministry Of Environment, 2014). In Bosnia Herzegovina, Montenegro, Serbia, Macedonia and Kosovo there is a prevalence of Protected Areas in IUCN cat III.

IUCN category	hard ecotourism	soft ecotourism	other forms
Ia	no	no	no
Ib	yes	no	no
II	yes	yes	no
III	yes	yes	no
IV	yes	yes	no
V	no	yes	yes
VI	no	yes	no

Figure 3 -Compatibility/suitability of forms of tourism with IUCN's Protected Area Management Categories (source Eagles et al, 2009).

As previously mentioned, the IUCN categories depend on the natural and cultural features of the site and they influence the possible activities to develop. According to Figure 3, there are three possible typologies of tourism to develop in protected areas: hard ecotourism, soft ecotourism and other forms. Hard activities are considered the adventurous and wilderness outdoors experiences with few comforts, while soft ones are more causal and with some comfort (Eagles et al, 2009). For other forms it is intended all other typologies that do not fit perfectly the "ecotourism" definition. The most rigid category is obviously the Ia, which does not allowed any of them. All the others allow only hard and soft tourism. IUCN cat V – Protected Landscape is the only one to allow other forms of tourism in its territory. This category is considered the most flexible one, due to the fact that it often includes wide territories.

3 SLOVENIA AS BEST PRACTICE: SEČ

Slovenia is considered a best practice in the field of sustainable tourism in protected areas, not only for the percentage of area coverage, but also for the effectiveness of its management plans. The case study of Sečovlje Salina Nature Park is presented here for better explaining the positive relation between touristic activities and landscape protection. The data reported is the results of an interview done by the authors to the director of the Park Klavdij Godnic (K. Godnic, personal communication, March 16, 2017). The Sečovlje saltpans are fascinating wetlands (Figure 4) that present an interesting combination of amazing natural heritage and anthropic cultural landscapes with over one hundred of saltpan houses.

Figure 4 -Sečovlje Salina Nature Park (source: Peter Malovrh, available on flickr.com).

The Seč--which is “an area with ovlje Salina Nature Park in Slovenia is a Landscape Park IUCN cat V intrinsic natural value where the influence of people in shaping, maintaining and caring the environment is evident” (Nature Conservation Act, 1999). In the objectives of this category we can find “the creation of opportunities for enjoyment, well-being and socio-economic activity through recreation and tourism” (Stolton et al, 2013). The Sečovlje Salina Nature Park is a good experience in terms of management. The fact that this protected area belongs to a category that allows to organize activities and events is the starting point for any touristic development process, supported by a Management Plans that clarifies duties, responsibilities and limitations. In this specific case, touristic activities are related to sport and environment.

In the last two years, the number of tourists increased by 24% -from 32'000 visitors in 2014 to 42'000 in 2016. This phenomena is mostly related to the great number of activities organized in the park, such as guided tours, creative workshops and educational programs, sporting activities (e.g. biking, rowing, parachuting, surfing, sailing, etc.). It is noteworthy the fact that, according to the MP, all people that decide to take part in sportive or educational activities are considered “paying costumers”, although they do not enjoy all the park traditional touristic services.

Those activities generate an income of 200'000€/year that, summed to the 250'000€/year received from the government, are used for the 15 employees' salaries and the park maintenance machines. The main difficulty in the economic management is the financial split of private and public activities, due to the fact that park is officially one body with one financial account. From an environmental point of view, the main risk is related to the possible pollution of the Adriatic water sea in the coastal area of the park.

4 ALBANIAN TOURISTIC POTENTIAL

Albania has an extremely interesting touristic potential. This potential is expressed in terms of natural heritage, as well as historical and cultural. Natural influencing factors are the favorable geographic and geo-touristic position, the variety of natural landscape, an appropriate climate, a rich water assets and rich flora and fauna system. From a historical point of view, the Albanian territory is widely characterized by cultural hotspots (Doka and Humolli, 2005).

In the last ten years, tourism in Albania has changed drastically. Since 90s, the Balkans were considered one of the best backpackers' travel destination. In 2011, Lonely Planet -world famous travel guide editor – ranked it as the first country in the top ten of must-visit world sites. The score was given according to topicality, excitement, value of money and attractiveness. This surely influenced the touristic trend and, in the following years, travel reports doubled and nicknamed Albania as the Europe Hidden Jewel. In addition to the above-mentioned data, tourism became a priority also due to EU strategies and a number of donor investments, because of the high economic development potential of this field.

In the EUSAIR – European Strategy for Adriatic and Ionian Region, Albania plays a fundamental role as coordinator of the forth pillar with Croatia: sustainable tourism. In a more specific way, the strategy aims to diversify the touristic offer and increase sustainability and responsibility in tourism management. In addition, EU adopts tourism as one of the priority measures in all cross-border-cooperation programs, focusing on preservation, renovation and capacity development. An example is the recently launched Interreg IPA CBC Italy-Albania-Montenegro program, which has its Priority Axis 2 titled “Smart management of natural and cultural heritage for the exploitation of cross border sustainable tourism and territorial attractiveness” (Interreg IPA-CBC program, 2016).

In 2015, the Albanian Government drafted the National Touristic Plan (Niented et al, 2017), emphasizing the importance of tourism as national economic resource and providing the first guidelines for future development. The Manifesto Albania 2030 (Aliaj et al., 2015) strongly stresses the importance of sustainable tourism development, basing its considerations on real touristic data provided by WTTC – World Travel and Tourism Council – and local administrations. Aliaj also lists some of the country's attractive spots – such as three main lakes (Shkoder, Oher and Prespa) and a network of small lakes both natural and artificial, a rich archaeological heritage (Butrinti, Apollonia, Durres, etc), numerous UNESCO sites as Gjirokastra and Berat.

According to the number of projects in progress (cfr Porfido et al., 2016), tourism has become a priority for a number of donors in Albania. The USAID, the World Bank, the AADF, Italian Cooperation, and the Albanian Development Fund all have a clear linkage to tourism, as a generator of local economic development and job creation. In territorial terms, the AADF through its Tourism Improvement District and Business Improvement Districts, is more focused on targeting specific areas in Albania, including key traditional historical towns such as Shkoder, Berat, Kruje, Vlore, Tirane, Gjirokaster and Korç

e. While the WB through its newly approved Integrated Urban and Tourism Development Project will be focusing on the southern qarks, mainly investing in improvement of infrastructure.

In the specific field of protected areas, the project NaturAL ("Strengthening capacity in national nature protection – preparation for Natura2000 network"), coordinated by Italian Development Cooperation (IDC) in synergy with Albanian authorities, aims to inform, communicate and educate young people, visitors, local communities, natural resource managers and all those interested in the importance of nature conservation in Albania and the role of its protected areas. One of the goals is to develop eco-tourism programs in protected areas, focusing on initiative typology, target visitors and management requirements and infrastructures.

5 PROTECTED AREAS AND TOURISM IN ALBANIA

Today Albania counts 59 Protected Areas, 4 of them under RAMSAR protection. In the past 10 years, the protected areas' total surface has tripled, passing from 5% to the 17.2% (www.natura.al).

Albanian Protection Categories	IUCN	PA	tourism
a) Strictly natural reserve / scientific reservation	I	2	no
b) National Park	II	15	yes
c) National Monument	III	6	yes*
d) Natural managed reservation	IV	23	yes*
e) Protected Landscape	V	5	yes
f) Protected area of managed resources / with multi-purpose utilization	VI	4	no
-) Emerald Areas	-	25	-

**only with previous authorisation issued by the responsible body*

Figure 5 -Albanian Protection Categories and Areas, in correlation with IUCN categories
(sources: Albania Ministry of Environment and Law on PA, elaborated by the author).

Focusing on ecotourism potential, the protected areas' law listed 59 protected areas divided in six protection categories (see Figure 5: Strict Nature Reserve, National Park, Nature Monuments, Managed Natural Reserve, Protected Landscape, Protected Area of Managed Resources) and 25 ecological Emerald Areas. The National Park category allows to perform seasonal touristic activities, as well as sailing boats and canoes, flying non-military helicopters, aerostatic balloons and delta-planes, mountain climbing and other outdoor activities. For Natural Monuments and Managed Natural Reserve, a special ministerial permission needs to be issued. Protected Landscapes are territories larger than 1000ha with specific landscape features, in which activities are allowed. While in the Protected Area of Managed Resources, access and interventions are strictly monitored due to the high environmental risk.

Touristic activities are recognized and allowed by law in four Albanian protected areas' categories, although two of those require previous authorizations issued by the responsible body. It is worthy to underline that 53 of 59 Protected Areas belong to those categories. In the entire country, only 6 areas are restricting access to authorized personnel. This evidences an important opportunity for transforming natural resources in fundamental economic ones.

6 FUTURE SCENARIOS: ALBANIAN RIVIERA PROTECTED LANDSCAPE

The famous Albanian Riviera (Figure 6), the south coast that starts from the Llogara National Park and ends in Saranda, is a promising touristic destination due to its unique natural landscapes, natural and cultural heritage. The whole area belongs to the District of Vlore (Qarku i Vlores) and counts 7 Protected Areas (Albanian Ministry of Environment, 2014) that cover 15% of the district surface and more than 200 Monuments of Culture, one of which is the UNESCO site of Butrinti. In spite of the importance of its heritage, only in the last years the Riviera started its “touristification” process. This delay is probably caused by the low-quality of the infrastructural system, which slowed down the “invasion”, but unluckily the Riviera started to be affected by illegal constructions. One of these cases is the Club Med Resort in Kakome Bay, few kilometers away from Saranda and exactly in front of Corfu Island. The famous French touristic company planned a resort with 350 luxury villas on the base of authorization issued erroneously by the responsible bodies (www.independent.co.uk), fortunately the process was arrested after the protests organized by the local community in 2005.

Figure 6 -Albanian Riviera (source: Angelo Pedrotti, available at panorama-photo.net).

This paragraph analyses the possibility of transforming the whole Riviera in a protected area, in order to add a layer of security to the already existing legal restrictions. The main goal of the unified park is to connect the heritage to its territory in order to operate strategically on it.

From a technical point of view, the IUCN category V -Protected Landscape perfectly meets the Riviera features and needs, joining the necessity of protecting both the natural and the cultural heritage and introducing economic activities as tourism to boost the local development. It is also in line with the Albanian Law for protected areas (Republic of Albania, 2002). A Protected Landscape is protected area where the interaction of people and nature over time has produced an area with a distinct character, significant ecological, biological, cultural and scenic value, and where safeguarding the integrity of this interaction is vital to the protection and support of the area and its associated values. As in the case of Sečovlje Salina Nature Park in Slovenia, this category allows to create “opportunities for enjoyment, well-being and socio-economic activity through recreation and tourism” (Stolton et al., 2013).

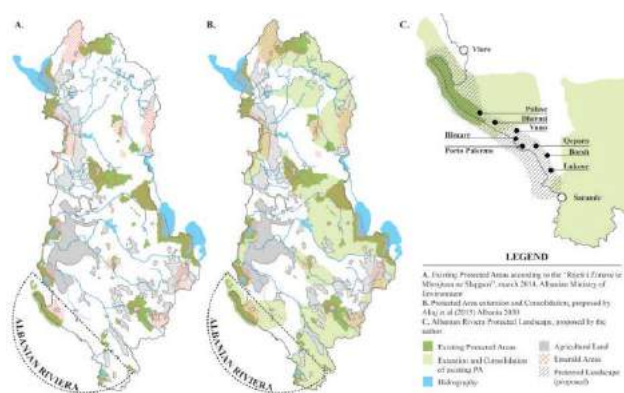

Figure 7 – Albanian Riviera Protected Landscape (source: Aliaj et al (2015), further modified by the author).

The touristic park product can be classified in two main categories: natural/landscape and anthropic/cultural. The first category includes all the natural resources that need to be protected, conserved and monitored through specific processes related to their biological features (e.g. biodiversity). The second one includes physical human interventions – such as ancient settlements both inhabited and abandoned (cfr. Figure 7C) – and activities from gastronomy,, production processes, immaterial cultural heritage, etc.

1. This strategy is based on four main pillars, developed according to the IUCN category assigned:
2. natural/landscape resources protection;
3. anthropic/cultural heritage valorization and re-use;
4. organization and connection of the resources;
5. information and coordination.

The fundamental strategic actions that should be adopted are:

- a. to stop building new structures for accommodation and services purposes and to invest in the existing ones, boosting a process of recovering and valorization of settlement heritage. This action is in line with the idea of starting long-term processes aligned with sustainability requirements, whose effects will not be immediately visible;
- b. to organize a slow mobility network, avoiding the construction of new infrastructures and reducing its impact on the environment through the adoption of alternative, soft, transportation means (bicycles, electric buses, kayak, etc);
- c. to organize the touristic product under a single brand, to coordinate the information and activities, in order to avoid investments' overlapping and waste.

The creation of a protected area with a special focus on touristic activities will also positively affects the labor market, where local communities are encouraged to protect and sell their products. The management role of local communities is an important aspect, but it is not discussed in this paper.

In conclusion, the use of protected area designation aimed at slowing down exploitation processes is not considered a substitute for traditional urban standards, but rather an additional tool that reinforces such standards.

ID 1431 | TOURISM, GLOCALIZATION AND URBAN REHABILITATION - TRANSFORMATIONS OF THE TOURISTIC ENVIRONMENT OF BAIXA IN LISBON

Carlos Henriques Ferreira¹

¹FAUL-CIAUD

cferr@fa.ulisboa.pt

1 INTRODUCTION

The tourism dynamics nowadays are the reflection of global and local interactions, verifying, with frequency, the confrontation between the preservation of the local values and their transformation according to the generalized tendency of the cultural patterns of consumption. This transformations, which are recognized for converting many of the trend tourism spots, involve diverse agents that end up arranging efforts to promote tourism locations. The most visible effects pass by a requalification of emblematic public spaces, or neighborhoods with a picturesque value and also areas with high commercial potential.

The urban rehabilitation strategies, with real estate valorization in mind, are also the central vectors for the touristification process. These transformations however raise some issues and possible problems. Some can be emphasized as the effects of gentrification, the heritage authenticity loss and the effects of urban cosmetic that overlap the preservation of the exceptional. On the other hand other positions claim that there should be an investment coordination as a way to avoid the degradation of historical centers or old city areas, which don't correspond with the current needs.

In this sense, this investigation contemplates a critical thinking on the tourism dynamics of actuality, through research on recent theories related with the theme. We try to focus on the relation between tourism and urban rehabilitation strategies, mainly on the oldest city areas. The case study is Baixa Pombalina in the Center of Lisbon. The choice was made due to the controversial application of this area to humanity heritage, as well as the strategies and safeguard plans content. We currently watch as big transformations unroll on Baixa under a bold urban rehabilitation, very visible on the rapid uses transformation and real estate dynamics. On this context we aim to investigate the value of Baixa and its narrow relation with the tourism strategies in the global and local interactions.

2 TOURISM AND URBAN REHABILITATION ON GLOCAL DYNAMICS

Tourism was initially more centered on demand has extended its incidences, pointing to a more complex tourism system, involving, tourist destination, transportation and the various industries associated. The perspective on the offer side highlights the importance of the economical activities, i.e., a business set that provides assets and services to travellers outside of their local residence, for leisure or business (Smith, 2007).

In this context, the cultural nature services are also included, where the cultural itineraries are emphasized and where it's also considered that cultural tourism covers more than the physical nature of monuments and notable buildings, contemplating intangible products (Gratton, 1996). The diversity and complexity of the tourism system points to other dimensions which extend the possibilities for a critical reading on the relation between tourism and territory.

We witness a growing importance of the thematic logics which are revealed on the touristic spaces, with emphasis on the urban tourism (Page and Hall, 2003). On this note, it's important to recognise the generating and inducing forces weight on the tourist imaginary (Ferreira, 2014).

Between the touristic election spots, we highlight the historical centers (Ashworth and Tunbridge, 2004), promoters of the territory in fragmented narratives, which are many times maladjusted of any sense of authenticity (Lew, 1989).

These forms of territory promotion are frequently served in a massified and distant way from the everyday places representing an alternative reality, with a certain ephemeral character, associated to the reasons and alternation of touristic flows.

The construction of public spaces, is frequently the reflexion of exterior forces, that when articulated they incorporate many of the local actors, exerting rapid transformations on the territory. These have effects, not only on the image or cosmetic of the spaces or buildings, but mainly on the economical and social component.

This composes a seeming factor of attractiveness for the touristic view and for the most competitive business opportunities which is many times accompanied by repulse and eviction of local population, by real estate pressure or even speculation associated with assets and services. This trend, which is expressed by the term of gentrification, also reflects the emphasize of specialized services, oriented for the touristic consumption, in detriment of a diversity of assets and services that support the daily life of neighborhoods.

Neighborhood attractiveness is many times associated with the deviation of its effective reality, where the social complexity is reduced to the typical and picturesque of its rehabilitated old houses, or the routes of winding streets expedited and qualified to captivate the pedestrians. This change in orientation is

supported by attractive pavement and illumination, which recreates itineraries of confort and contemplation of the commercial spaces for the tourist.

The places authenticity is transformed in a tourist authenticity constructed for the visitors, where the playful nature of the traveler overlaps the daily life of the residents.

Besides the traditional touristic destinations, which reference the urban touristic microcentralities, it's also demonstrated the particularity of events that reinforce its attractiveness or that sometimes deflects it to new ephemeral routes (Getz, 2001). The shows, fairs or themed parties are the motto

of transformation for the landscape, the creation of new fluxes, although many times they have little expression without the events. They also reference the ephemeral imaginary which are constituted more in function of the event theme and less on the place where it happens, in this way they are spaces of opportunity available for the alternative city and the occasion.

The construction of touristic spaces is the reflection of a vast factor network, where the infrastructures and transports assume a central role. The rapid transition between origin and destination, due to modern transportation system, with highlight on the aerial, gives privilege to the instability and rapid superficial consumption of places. This phenomenon, in connection with the development of the information and communication technologies, contributes for a certain compression of the relation "space-time" – where the far approaches the context of the established networks, enhanced by the vast shared experiences in real time and online. The itineraries and the shared experiences interact contributing to new touristic space perceptions and also to the construction of new touristic places.

The alteration of the relation between space and place and of the own touristic social space construction contributes to new types of commitments between visitor and local, where the meaning of place changes among the global and local interactions – GLOCAL (Robertson, 1992). The touristic system dynamics reveal themselves more and more as integral parts of the planning system and also as strategical urban-touristic visions (Ferreira, 2011). Although the unpredictability and fragility of the touristic activity within the globalization effects on the trending touristic territories, this constitutes an appealing financial resource which deserves a critical deepening under the efforts associated to the competitiveness of touristic destinations.

3 TOURISM STRATEGIES IN LISBON FOR THE 21ST CENTURY

The tourism of the 21st century in Portugal, with highlight in Lisbon, reflects the development of globalization and urban marketing trends launched in the nineties. Between the principal emergence factors of the new touristic fluxes, the accessibility and transportation improvement is one of them. The modernization of these vital systems improves the flux of people and assets which reference the quality of the touristic demand.

These factors, associated with the increment of the planning instruments and the establishment of strategical visions, seek to narrow the relation between tourism and territory, revealing themselves as an essential contribute for the urban tourism positioning. It's in this new context, that tourism places are promoted and asserted on its various agents, from associations, companies, institutions and individuals, contributing to new views and strategical opportunities.

Between the various initiatives and changes connected to tourism in the national and local context, we highlight the creation of INFTUR in 2001, the extinction of the Direção Geral de Turismo - DGT in 2006 and the creation of the public institute Turismo de Portugal (Tourism of Portugal) in 2007. A new national strategic positioning of tourism achieves expression in the preparation of a document which culminated in the presentation of the Plano Estratégico Nacional de Turismo – PENT 2008 (National Tourism Strategic Plan) defining the orientations for this sector. This document has been reviewed, with emphasis on 2011 version (PENT 2011), revealing the importance of new orientations on tourism due to the changes that occur, mainly after de 2008 crisis.

These document reflect many of the tourism system problems, such as product logics and tourism thematic and also a deeper knowledge on several segments of touristic demand. The approximations to

the definition of tourism strategies in the context of the great contemporary changes, on one hand, incorporates more open concepts and on the other, points to more precise actions on a short and medium deadline.

It's in this sense that the more recent proposals are developed, on the contents of the Strategic Tourism documents ET 2020 and ET 27, which demonstrate the necessity of a larger strategy convergence with the financial system, specifically on the community support boards.

On the wider tourism strategies expectations and their regional and local territory incidence, it's featured the dynamics associated with Lisbon tourism. The knowledge of Lisbon touristic space, taking in consideration the studies done in the 90's (Brito-Henriques, 1999), wins particular spotlight on the 21st century, through either national strategical references or by the various regional and municipal orientations. Although it's only through a series of three strategical tourism documents for Lisbon (TLx) that we can appreciate the increasing complexity of the tourism system: TLx 10 - 2007/2010, TLx 14 - 2010/2014, and the most recent TLx19 - 2015-2019.

These documents reflect an increasing complexity of the touristic system of Lisbon. The institutional changes and the production of tourism strategic orientations which reference Lisbon, allows us to identify a set of principles and actions with a substantial expression on the territory. Besides the statistical information that supports a better knowledge on the touristic dynamics, they also point to Lisbon's competitive perspective in a global context, when compared with other touristic destinations. In its contents we highlight a set of touristic micro centralities (already pointed out on TLx10), which indicate three main focus: the historical center of Lisbon, Belém in the occidental part of Lisbon and Parque das Nações, in the oriental part connected by the riverside axis.

These centralities, don't exclude other attractive focal points, which are the target for touristic promotion, representing however areas where there is a higher element concentration or recognized values in the touristic system.

In the three focus, it's identified the occidental area as a privileged memory of Manuelino and the discoveries period - the cultural and museum district. The central area represents the historical city, of the layers overlap, where the hills reveal themselves through the attractiveness of the picturesque, of the older neighborhoods confronted with the illuminist innovation in the post-earthquake planning of Baixa. The oriental area represents the progress - tribute to the occasional city, with the conquest of the city of events over the industrial heritage - the triumph of an alleged post-industrial city - the place of services, communication and new creative industries. From this new oriental city, the conqueror of public space, emerges a new urban and touristic centrality.

To each of these touristic centralities corresponds particular historical-urbanistic contexts, where beyond their relation with the touristic attractiveness, it's also shown their own dynamics associated with economical, technological and cultural factors, which interfere on the value of the social practices of leisure - "Lisbon is a trending spot", but it can stop being one!

The ability to receive hundreds of visitors has impacts on various levels and one of them is the quality of life and services to the people who live there. The touristic pressure is also accompanied by dilemmas on conservation and development, demanding commitments and placements between the public and private actors, in a way to give answer to development models intended for the tourism and territory connection. The relation between local residents and visitors is one-to-one, due to them having a high interaction, which shows a more or less friendly behavior from the locals towards the visitors, but also transmits a series of diverse external synergy to the visitors, influencing cities daily life.

There have been issued a series of warnings on the effects in Lisbon due to intense touristification, featuring the dangers of marketing addiction in Barcelona or even the adjectives for a "Disney-Sardinificada" (Disney-Sardinified). Even after these warnings it's inevitable recognizing the effects of touristic expectations on urban requalification, even though it is done under a certain cosmetic - but the apparent beauty has also the function of attracting view to the essence domains.

Of course we can't close our eyes to superficial rehabilitations or to an alleged disfigurement of Lisbon's identity, but also it is necessary some opening to understand the identity transformations in a world in rapid transformation, where Lisbon appears to be emerging in a new culture of urban corporation.

In an effervescent urban tourism culture it's important to identify some of the main factors of change and their costs and benefits. In this process, it is essential to consider strategies of urban resilience, this means, the resistance capacity to the touristic flux breaks. Some more emblematic areas of the city are too exposed to touristic demand, they are initially considered as exceptional on a global context, but can quickly fall into triviality, losing its differentiator factor. In Lisbon, Baixa constitutes one of the main references of this context and should take on as a central observatory of the relations between tourism and urban rehabilitation.

4 THE PLACE OF BAIXA: HERITAGE, PRODUCT E CONSUMPTION

Lisbon is a city with unique characteristics, with highlight on its scenic value of its hills and silver background and blue estuary. It's a secular city, birthplace of globalization in the discoveries period, it wins particular highlight on the 18th century, when it's devastated by a huge earthquake in 1755, followed by tsunami and various fires, destroying great part of the central area. Heir to an unusual multicultural heritage and capital to one of the world major empires, the city faces a tragic scenery of destruction and ruins.

Reborn from the ashes and from the strong will of renovation of the minister José Sebastião Carvalho e Melo, future Marques de Pombal, the lower area of the city is the target of a great urban renovation. Although this operation was, during centuries, badly appreciated. Besides the unity value of the facades in Praça do Comércio, the operation was considered monotonous, of bad taste and of atrocious rigidity.

Between various tries to value the reconstructed area, it's pointed out the exception accomplished on some Art deco buildings performed on the transition to the 20th century. Apart from the diversity in some constructions, the functional dynamic that emerged contributed to the improvement of the urban life conditions, with new stores, shops and diverse activities which characterize the commercial bourgeois position at Baixa.

The value of this compared with the attractiveness of the old picturesque neighborhoods of Alfama, Castelo and Bairro Alto was diminutive. The first references with acknowledged value in Baixa illuminism and a type of pre-modernism on the operations emerges with modernist architects in the thirties and forties, like Pardal Monteiro, Keil do Amaral, among others (Tostões; Rosa, 2008). However, it's in the sixties with the investigation of José Augusto França that the Baixa reconstruction process wins a new protagonism and a focus spot on international illuminist architecture and urbanism (França, 1987).

Despite the attempts to recognize Baixa as a national and international heritage, it only achieves spotlight after the fire in Chiado in 1988 and the reconstruction process of this area, which was concluded at the end of the 90's, close to the transition to the 21st century. In the last decades we assisted to specific operations on the requalification of public space, mainly with turning Augusta Street pedestrian, the interventions in Rossio (Praça D. Pedro IV), Praça da Figueira and more recently in Terreiro do Paço (Praça do Comércio) contributing for the touristic attraction improvement in the central area of the city. These operations, together with the transportation improvement, mainly on the metro-train and boat interfaces, besides various projects that involve the requalification of waterfront areas, have contributed for the enhancement of the urban environment on the central area.

The attractiveness of Baixa is placed between the values of the illuminist innovation of the post-earthquake Pombalino planning and the noltagic "iconography" of the city's memories before the earthquake. From the old city, little is recognisable, seen only through fragments, supported by a difficult narrative which allow us to understand it as a whole. The city of illuminist reconstruction maintains a strong presence, surviving the alterations of their rigorous authors, the military architects and engineers from the illuminist urbanism school – Casa do Risco.

Nowadays Baixa is a product of many achievements, which surpass the initial vision of their authors, either by the functional dynamic achieved or by the requalification of its public spaces, especially distant from the initial vision. However, the vision of an area supported on the most modern infrastructures is still a present reality, which was able to adjust to the circulation and hygiene challenges over the ages (Figure 1). This premature sense of modernity is a testimony clearly visible and distinguishable compared to other contemporary processes.

Figure 1 – View of Baixa in nowadays. Source: author

The urban-touristic appeal of Baixa is however an open value and in discovery process. The essential guide lines to recognize the value of this area are based on the discipline and hierarchy of its street layout and the unity on the facades. But, this illuminist utopia, in a certain way achieved, was also overcome by other values rather difficult to identify and quantify, namely, the appropriation that each owner and leaseholders made of the interior beyond the facades – the interior of the building and its programs. We refer to the achievements of the Baixa architectures over time. Without a pre-defined building that gave support to the drawings of the facades, Baixa was built as a testimony to the necessities and wishes of a society that evolved through the next centuries. It's heritage has an extended set of factors, in a certain way unknown, and that are suffering constant confrontation due to the tourism's pressure and the new concepts of an either light or heavy urban rehabilitation, associated to the levels of damage of the building (Figure 2).

Figure 2 – Baixa and some of rehabilitation processes. Source: author

We distinguish therefore various levels of compromise between the tourism dynamics and rehabilitation ones, among others. On one hand, a strong incidence in public space requalification, with focus on turning commercial streets pedestrian; on the other hand the rehabilitation of innumerable buildings, which are effectively in a significant run-down state. This rehabilitation, however, consists on maintenance or rehabilitation of the facades, with a complete renewal on their structure, system and function. It's possible to verify an improvement on the environment of Baixa and an important urban hygiene operation, but it is also important to deepen its effects on the diversity of the social contents and functions.

In this sphere the tourist value and attractiveness of Baixa deserves a critical reflection, where we identify some aspects to considerate. The importance, not only on the illuminist geometric guide lines, but also of some architectural contents that surpass it and that compose a distinctive and irreversible factor. The new functions oriented for a new mass consumption society are competing with historical activities, heirs to specific production sectors, which are quite difficult to reproduce after their destruction. These heirs have revealed low capacity to resist towards the first impacts of real estate pressure. Thus is essential to have a deeper thinking on the effects associated with the appealing surge of trending touristic spots, which is happening with Lisbon, providing a sustainable competitiveness and learning from experience (good and bad) from other touristic destinations that are exposed to the same effects.

5 CONCLUSION

The relation between the tourism dynamics and urbanistic development aren't always easy to determine. Yet we identify a processes change, mainly on the most emblematic areas of the city, in which it's recognizable an increase on touristic fluxes and a modification on the image of the urban space and buildings.

The plea to urban rehabilitation, mainly, on the older buildings is a key factor in the attractiveness of touristic places, where the image of older constructions in decay is substituted by the superficial cosmetic and by the regeneration or renovation of contents, adjusted to the new tourism demand segments. It is also verified a change in the older activities like traditional commerce, where some of the stores, already with decades or even a century of history, are substituted by new establishments. The big fashion brands overlap local commerce, which is overcome or reinterpreted by the global exchange networks, not only on the level of the final image, but also on the production and distribution processes.

The living spaces also suffer the pressure of new offers in housing and hotel business, where the living is substituted by the overnight stay. The old neighborhood life is influenced by new commercial activities with an ephemeral and intense nature, overcoming the daily life bonds and its own rhythms, which start disappearing or diluting in another cosmopolitan reality. The traditional neighborhood is transformed in the picturesque touristified neighborhood. The access to these neighborhoods and to the resident houses are conditioned on behalf of the urban requalification strategies, which are guided by the increase of pedestrian only areas.

The daily city life and its functional diversity starts being fictional and transforms into the historical touristified city, where touristic imaginaries emerge, fragments of reality recreated by diverse authors under the most diverse itineraries. In this transformation process of the tourism places, we witness the reinforcement of post-modern geographies, where each one constructs their touristic fantasies, through interconnections that feed a collective tourist memory based on the evasion of daily life and on the multiple growths forms of places communication. These are some of the factors that confront the (re)definition of the tourism places like Lisbon, between old patterns of exception, which gave them recognition and the new sharing patterns that connect a new global network of urban-touristic competitiveness.

ID 1507 | TOURISM IDENTITY IN SOCIAL MEDIA: THE CASE OF A CHINESE HISTORIC CITY, SUZHOU

Joon Sik Kim¹; Yi-Wen Wang¹
¹Xi'an Jiaotong-Liverpool University
joon.kim@xjtlu.edu.cn ; yiwen.wang@xjtlu.edu.cn

1 INTRODUCTION

The city's tourism identity has been emphasized in a contemporary tourism planning practice. Many studies on tourism planning and promotion have addressed that the investigation on local identities and tourism potentials in the development of the city's tourism strategy must go beyond the aspects of geographical space. With emerging social media communication and increasing crowd-sourced data, there is a great potential for engaging social media studies with tourism planning practice in order to reflect visitor's perceptions and subjective views onto the city's tourism strategies. This research seeks for a new approach of relating sense of 'spatial' place with 'digitally-presented' sense of place.

1.1 RESEARCH BACKGROUND

Tourism ecosystem has become increasingly globalized and extremely competitive. The development of global tourism identity and international reputation has been noticeable in the current tourism agenda in many cities across the world. The recent studies show that tourism in small and medium cities is in fact

often driven by standardized solutions for mass tourism with a greater emphasis on the city's major tourism attractions. In the context of tourism planning and promotion, the city's local tourism identity has been studied primarily based on geographical space and tangible tourism designations. Meanwhile, there is a wider acknowledgement that conceptualizations of tourism identity cannot be grounded in physical place anymore – for example, interpersonal relations, tourist activities, social networking. It is evident that uniformed tourist information and standardised tourism strategy can no longer closely connect to diverse interests of tourists and lead to an improvement in the quality of tourism environments. There are opportunities in late modern society, at least for people who are accessible to relevant communication technologies, for relating the identity of the city's tourism with digitally-presented tourists' perceptions and activities.

Many tourism designations across the world have employed the concept of 'smart tourism' and developed smart tourism solutions in various ways in order to facilitate the promotion of their tourism identity and provide an innovative information platform for tourists. In 2008, the State Council in China announced the importance of tourism industry in the strategic development of national economy. The words of professional tourism, digital tourism and smart tourism have been widely used in Chinese tourism industries (Huang, 2014). Prior study situated in China suggests that governments have played a primary role in building and regulating smart tourism instruments in the Chinese context. Many smart tourism projects in China provide similar functions and information, such as tourist information on scenic spots, ticketing, accommodations, public transport, and tourism facilities. However, key failures of smart tourism apps are due to listing fragments of tourist information without concerning diverse needs and interests of users. It is evident that uniformed tourist information and standardized tourism strategy can no longer connect well with diverse interests of tourists and lead to an improvement in the quality of tourism environments. However, there are opportunities in late modern society, at least for people who can access relevant technologies of electronically mediated communication, for relating the identity of the city's tourism with digitally-presented tourists' perceptions and activities.

1.2 RESEARCH AIM AND OBJECTIVES

The main aim of this research is to investigate the digital identity of the city's tourist designations as presented in online user-generated contents, and to explore possible uses of social media research in the tourism planning practice. It investigates the interplay between the city's digital tourism identity and the current tourism development strategy of the government. Key research questions include: where do the visitors of the city go to; what contents do they post in social media in relation to experiences and activities within the places they visited; how can we analyse the images and meanings of the city's tourism identity posted in social media; and, in what aspects of the captured digital tourism identity can be better informed to the tourism planning practice? The overall aims of the research are twofold:

1. To develop a possible evaluation framework to measure the digital tourism identity represented in social media ; and,
2. To outline possible recommendations to link a unique tourism identity perceived from social media data analysis to the tourism planning practice.

This research will employ a case study methodology. This is because the research is to investigate a 'contemporary phenomenon' in a 'real-life context' that can be only be satisfied by a case study methodology (Yin, 2013). To answer the above research questions, the city's tourism identity has been evaluated in four aspects: spatial analysis, temporal analysis, popularity analysis, and corpus analysis. The research framework is illustrated in Figure 1.

Figure 1 – Research Framework

2 CASE STUDY: CHINESE HISTORIC CITY, SUZHOU

2.1 SUZHOU TOURISM CHARACTERISTICS

The research follows a case study approach and conducts an empirical study on Suzhou, a historic city in China. Suzhou is located in Jiangsu Province in China (Figure 2), and has over 2,500 years of history. As one of important commercial centres of China since the 10th-century Song Dynasty, Suzhou has rich heritage resources and one of most famous historic water towns in China with the city's canals, stone bridges, and traditional gardens that were listed as the UNESCO World Heritage Sites in 1997 and 2000. There are 492 protected heritages in Suzhou, including 12 national heritages. Due to its water town image created by inner city canal networks, Suzhou is often titled as the 'Venice of the East' or 'Venice of China' (Pereira, 2004). Suzhou government also see the tourism potentials in association with the city's socio-economic development, as it stated in the 13th Plenary Session of the Eight Communist Party of the City. Suzhou's tourism strategies can be summarised in six headings:

1. International Strategy: promoting Suzhou's tourism globally to make Suzhou as an 'international first-class travel destination';
2. Branding Strategy: encouraging the revisit to Suzhou and improving the city's tourism reputations by enhancing the three brand image of the city, 'cultural tourism in an ancient town', 'romantic trip to a new town', and 'ecological leisure in Tai Lake'.
3. Integration Strategy: integrating tourism development with urban regeneration to improve the quality of life and revitalise the city's economy;
4. Information Strategy: facilitating tourism using ICT technologies, and promoting 'Smart Tourism' to develop a comprehensive tourism information platform;
5. Low-carbon Strategy: promoting the concept of green GDP with the development of low-carbon tourism and eco-tourism; and,
6. Marketing Strategy: structuring the market development mechanism with collaboration between government and enterprises.

Figure 2 – Location of Suzhou, China

Generally accepted criticisms on Suzhou's tourism practice are the monotonous tourism attractions and limited activities for tourists. Suzhou is well-known for its classical gardens. Although this dominant image of Suzhou brings a significant number of tourists to the city, this also restricts tourists to explore Suzhou beyond the gardens and experience diverse localities and culture. Suzhou has faced a challenge to rethink its tourism development approaches and strategies to diversify the tourism attractions and promote cultural tourism.

2.2 RESEARCH METHODS

This research analyses the city's digital tourism identity from crowd-sourced social media database. The research relates the analysis outcomes to enhance the city's tourism performance by employing innovative bottom-up forms of data collection and mapping of existing tourist's activities. This method supports the

involvement of international and domestic tourists in: mapping their own interests and resources; raising the visibility on existing place-based tourist activities; and, identifying potential local, cultural and symbolic resources, which normally are excluded from mainstream tourism routes. To support the case study, the research can be divided into four distinct parts: (1) conceptualisation; (2) social media survey; (3) data analysis; and (4) evaluation.

The first part of this research is to conceptualize the digital tourism identity based on theories of place identity and tourism planning through literature reviews. As there has been little analysis or evaluation on the use of social media study in tourism planning, the research has developed a possible evaluation framework to categorise diverse tourism identities represented in social media. Secondly, social media survey has been conducted based on evaluation framework developed. In this stage, the research employs a series of interviews to identify widely used social media sites in China, and a novel form of bottom-up data collection methods by using crowd-sourced social media database. The 20 most popular local tourism designations in Suzhou are selected as case studies, and much of survey data has been collected from representative social media sites in China. In total, 640 social media postings, which contain 3960 samples of text comments and images, have been analysed in order to understand the tourism identity spatially and temporally. Thirdly, with social media data collected, tourism identity has been analysed in four aspects: (1) spatial analysis to investigate the spatial relations between tourism designations; (2) temporal analysis to examine the temporal change of digital tourism identities; (3) popularity analysis to review digital tourism identities in 20 tourism designations, and, (4) corpus analysis to explore linguistic landscape of the user's comments posted in social media. Finally, the research findings have been analysed and articulated to investigate how social media research can be applied to the practice of tourism planning and management. To evaluate the Suzhou's tourism practice and activities, the research also uses the participant observation research methods to reflect the insights from the authors' own experiences of living in Suzhou and visiting the city's tourism designations.

3 CONCEPTUALISING DIGITAL TOURISM IDENTITY

The greatest concern over the disadvantages of social media study is perhaps the lack of theoretical framework that may provide little basis for systematic evaluation. This section explores how the tourism development has been engaged with social media research, and how the digital tourism identities can be evaluated in the basis of the place identity measurement framework.

3.1 TOURISM DEVELOPMENT AND SOCIAL MEDIA

In modern society, people can access to more information and use the information in their everyday life, and this is often described as 'Smart' (Du and Yang, 2013). New patterns of interaction between tourism and technology shift the tourism trend towards a sharing of information and experiences through digital communications. Smart tourism is now firmly on the agenda of tourism development across the world. This enables self-organised tourism more feasible and manageable, as individual tourists are able to collect comprehensive tourism information, services, and experiences from diverse online resources (Fu and Zheng, 2013). According to the Chinese government report, Advice on Accelerating Development of Tourism Industry (State Council), emerging smart tourism has greatly promoted the socio-economic and cultural development. In recent years, the development of the tourism-related mobile apps is vast. Many cities in China including Jinan, Wuhan, Chun'an, Tianjin and Nanjing have also launched 'smart tourism' projects in order to provide integrated tourism resources to tourists.

Another significant influence of smart technology into tourism is social media. Social media can provide direct services instantly to individual tourists with latest tourism information. Social media, as a new type of online media, creates interactive relations between users, and forms personal or business networks.

Once this relationship is formed, users tend to maintain the online relations and communications for a longer period of time (Zhang and Zhang, 2013). Social media communication in tourism includes not only information on tourism designations and its surrounding environments, but also their personal experiences and satisfactions. Online user-generated content has transformed the tourism markets and industries to be more interactive. This new media has also provided an opportunity for tourism industries to understand and respond to the needs and demands of tourists more quickly and systematically. Analysing user-

generated data can help understanding how the real-world works and finding patterns in human behaviours (Krumm et al, 2008). As social media is one of popular user-generated contents, data collected from social media could be a valuable asset to evaluate the place identity and overall image of places perceived from tourists (Zhu and Liu, 2011). There is a widely held view that social media study can contribute to investigating tourism identity of particular tourism designation from the tourist's experiences and understanding their behaviour.

3.2 COMPONENTS OF PLACE IDENTITY

In many previous studies, the concept of place identity has been defined as the contribution of place attributes to one's self-identity (Proshansky, 1978; Sabine, 1983; Proshansky et al., 1983; Rivlin, 1987; Korpela, 1989). Place identity is a sense of dependence and belonging of individuals to a certain place psychologically. Individuals experiencing a particular place can generate a certain symbolic meaning or emotional attachment. Place identity is not permanent. When place identity of the self becomes stronger, it will affect to the self-cognition on a place and behaviour of individuals (Zhao and Wu, 2013). A definition of place goes beyond a simple geographic location, and is attached to human activities happening in a place. Human activities include people's perception, lifestyle, diet, transport, events, and habits, to list a few. This human-centric approach of place identity is also closely associated with historical and cultural dimensions of a place. Different geographies, climates and environments influence inhabitants' life, habits, traditions and customs. The unique climate, historic stories and the legacy of the past enrich the cultural attribute of a place (Bernardo and Palma-Oliveira, 1977). While cultural and social aspects of place identity are emphasised in many literatures, there is no doubt that the physical asset of a place is the fundamental element of the place identity. Notably, the geomorphic features, landscapes, architecture styles, and materials are the primary foundation of the place identity. In a systematic approach to explaining the concept of place identity, Montgomery (1998) has applied the notions of physical setting, activities and meaning to the conceptual framework to define sense of place (Figure 3). With an attempt to combine physical and psychological elements of place, the three components of place identity can be summarised as follows:

- Physical Setting: scales, intensity, permeability, landmarks, built form, architecture, and public realm;
- Activity: diversity, vitality, street life, people watching, café culture, events, pedestrian flow, and attractors; and,
- Meaning/Image: legibility, symbolism, memory, sensory experience, knowledgeability, receptivity, psychological access, and fear.

Figure 3 – Three Components of Place Identity (modified from Montgomery, 1998)

3.3 EVALUATION FRAMEWORK OF PLACE IDENTITY

Place identity is becoming prominent in the city's tourism development. Tourism development cannot be isolated from the city's locality, such as culture, lifestyle, festivals, local specialties, customs and other tangible and intangible features. Although it is critical reflect place identity in the development of the city's tourism strategies, there are operational difficulties in examining place identities. This is because the

description of place identity, which can be seen as phenomenological perspectives of the self, is almost impossible to communicate with others fully (Proshansky et al, 1983). While few human geographers (Sack, 1997; Duan, 1998) argued that place, as 'space', can be presented accurately in the aspects of geographic location and physical form, Relph (1976) addressed that psychological meaning is more important than physical environment or human activities.

It is clear that a concept of place identity is consistent with that of physical setting, activities and meaning. However, there is difficulty in applying the notion of physical setting, activities and meaning as an analytical framework for evaluating or quantifying place identity. This is mainly because there is considerable duplication between the three. There are also other challenges in terms of geographical scales of place. Place identity can be formed on micro (e.g. indoor environment, architecture, and landmark), meso (e.g. community, and city), and macro (e.g. region, state, and continental) levels of geospatial aggregation. These three components are useful to explain the concept of place identity, but it is difficult to separate each quality as a dependent variable. Therefore, there is the need to simplify the concept of physical setting, activity and meaning in developing an evaluation framework of place identity. In this context, the research has developed a possible evaluation framework of place identity that can be applied to social media research (Table 1).

Main Category	Sub-category	Descriptions
Physical Setting	Scenery	natural landscape, panoramic view, building skyline
	Topography	canal, streams, hills,
	Landscape	artificial landscape (i.e. gardens)
	Landmark	recognizable natural or artificial feature
	Architecture	one or two building(s), but not landmarks
	Public Space	public realm (street, square, park, etc.)
	Object	detailed elements of physical features
	Public Arts	arts objects in public space (graffiti, cultural items, etc.)
Activity	Transport	transportation and route finding
	Water Transport	water transport, boat riding
	Shopping	shopping and commercial activities
	People	local culture, social activities, street life
	Food	food and drinks (food and café culture)
	Event	specific events organised
	Paid Activity	paid tourist/leisure activities
	Attractor	items attracting attentions (animals, unusual items, etc.)
Meaning	Memory	memory of place, evidence of visit, selfie, self-portrait photo
	Emotion	feelings and psychological meaning
	Knowledge	knowledgeable explanations, craftsmanship
	Sensorial	sight, hearing, taste, smell, touch
	Seasonal	seasonal changes, city lightings (night view)

Table 1 – Evaluation Framework of Place Identity

The framework has three main categories: physical setting, activity and meaning. In order to collect and analyse social media data in the three main categories, 21 sub-categories have also been constructed. Sub-categories are to not only reflect the concept of place identity discussed in existing literatures, but also apply the framework to a concrete example of the historic city, Suzhou. For example, considering the Suzhou's tourism characteristics as a historic water town coming from the city's extensive canal network, the sub-categories of the activity criteria have the two separate categories of 'transport' and 'water transport'.

4 SOCIAL MEDIA DATA COLLECTION

4.1 SELECTING THE CASE STUDIES

As there are a vast number of social media sites available online, it is necessary to select a manageable number of social media sites for a sampling purpose. Drawn from a number of interviews with social media users in China, the research has initially identified 24 candidates of social media platforms including Weibo, Dianping, Ctrip, Qunar, Tongcheng, Tuniu, Lvmama, 58 City, and Mafengwo. Among 24 candidates, the research has chosen three social media platforms for the case studies: Weibo (similar to Facebook, most popular social media in China); Ctrip (similar to TripAdvisor, well-established enterprise-led online tourism platform); and, Dianping (restaurant/place review site, one of largest user-generated

review sites in China). The selection was based on the number of users, reputation, popularity, the quantity of user-generated contents, and at least 5 years of the operation period. It is also expected that the three different types of social media platforms may enable to collect diverse opinions and experiences of tourists in various data formats (photo-oriented and text-oriented postings).

In terms of defining the geographical scope of the research, 20 tourism designations in Suzhou are selected by paying systematic attention to the rankings of tourism designations presented in Weibo, Ctrip and Dianping. Moreover, as the Baidu online map service (similar to Google Map) provides the real-time density data of their service users (density heat map), this spatially presented density data has been taken into account in the selection process (Baidu density heat map from 6th June to 12th June 2016). The selected 20 tourism designations of Suzhou in this research can be categorised as follows:

- Classical Gardens (5): Humble Administrator's Garden, Master of the Nets Garden, Lingering Garden, Lion Grove Garden, Pavilion of Surging Waves
- Old Towns (4): Feng Bridge, Mudu Ancient Town, Tongli Ancient Town, Zhouzhuang Ancient Town
- Streets (3): Guanqian Street, Pingjiang Road, Shantang Street
- Historic Heritages (3): Hanshan Temple, Panmen Gate, Tiger Hill
- Natural Landscapes (2): Qionglong Mountain, Tianping Mountain
- Artificial Landscapes (3): Suzhou Amusement Land, Jinji Lake, Suzhou Museum

4.2 COLLECTING SOCIAL MEDIA DATA

The analysis results in this research are based on 640 social media postings from the three online platforms, Ctrip, Dianping and Weibo. As a single social media posting contains multiple images and/or text comments, this dataset contains 3,960 valid samples in text and/or image formats. Due to constraints of resources, the research is focused on the social media data posted from 1st of January to 30th of June 2016 (for six calendar months). Considering there are many casual postings in social media that are not closely related to the topic of this research, the data was collected through a selection process, rather than randomly, in order to obtain meaningful data effectively and efficiently. As the research deals with different types of social media platforms, the data collection methods have been adjusted for the particular social media platform. As the research evaluates the temporal change of social media data, the social media data is collected evenly throughout the six months of the data collection period. The collected social media posting data was classified using 21 sub-categories of place identity (Table 1). In this process, maximum 5 sub-categories could be tagged for a single social media posting, because there could be multiple interpretations from a single posted image or comment. In order to conduct a quality measurement for the text-format comments, trained surveyors had evaluated each comment using 10 likelihood classifications from -5 to +5 (-5 means strongly negative comments, 0 means neutral, +5 means strongly positive comments). For corpus linguistic analysis, 45 words were selected as most frequently used words in the collected text-format data, and used for further analysis.

4.3 DATA VERIFICATION

While the research uses 640 postings, the sample size for each tourism designation per a calendar month is relatively small. As there might be a concern on the sample size, the research conducted a pilot test to compare the data analysis results with one from a larger sample group. For this purpose, Humble Administrator's Garden, the most well-known tourism designation in Suzhou, was selected for the comparison. The data collected for 21 sub-categories of tourism identity was compared in two different sample groups, one with 142 samples and one with 603 samples (Figure 4). The results showed that there was no significant difference (less than 3%) between the two sample groups. Considering the survey resource efficiency, the analysis results show that the research outcomes from a smaller sample size may also be able to illustrate a snapshot of the city's tourism identity.

Figure 4 – Comparison of Survey Data from Different Sample Sizes

5 ANALYSING PLACE IDENTITY FOR TOURISM PLANNING

In the process of place identity classification, 640 social media postings had been tagged with 1,775 place identity categories. Among three main categories of place identity, the social media data shows that the postings related to physical setting is noticeable mostly (Figure 5), especially, the architecture element. One possible explanation on this is that the unique architectural style of Suzhou (black roofs and white walls) attracts visitors' attentions and is considered as 'something different' from other cities in China. Another interesting result from the physical setting category is that people publish many postings on scenery landscape and detail objects, however, are less interested in posting contents on the city's landmarks. In the activity category, food and people watching is most common posting, and attractors such as animals and unusual items are also one of popular postings. In the meaning category, not surprisingly, the memory category that includes selfie and evidence of visits is recognised as a popular posting. Additionally, seasonal change is another item posted commonly.

Figure 5 – Social Media Postings and Place Identity

5.1 SPATIAL ANALYSIS

In order to explore the spatial pattern of Suzhou's tourism activities, the research has identified the top 100 tourism designations, which were ranked in the three social media platforms used in this research. The heat map analysis is conducted with the weight of the ranked popularities in social media, and the result is shown in Figure 6.

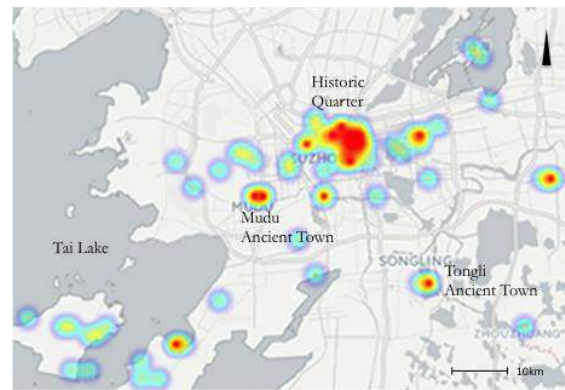

Figure 6 – Spatial Distribution of Suzhou's Top 100 Tourism Designations

There is little doubt that Suzhou has a tremendous potential for tourism throughout the whole area of the city. However, the spatial analysis result recognises the importance of the existing attractions and tourist hotspots. Most popular tourism attractions of Suzhou are located at the historic quarter, and others are clustered in the different parts of the city. Suzhou Tourism Master Plan (2009-2020) has also addressed this issue, and summarised as the tourism strategy of 'One Core, One Belt, Three Districts'. It is notably desirable that links between all the tourist venues are established with "cross marketing" ventures so that tourists can see the wide spectrum of activities available within the area. To make the city's tourism strategy mirroring what visitors perceive in the tourism designations, it is necessary to investigate popularities and marketing potentials in each tourism designations that will be explored further in the following sections.

5.2 TEMPORAL ANALYSIS

From 1,775 place identity tagged in 640 social media postings, the results of temporal analysis are shown in Figure 7. Although a number of postings are different in each calendar month, there is no significant difference in terms of the proportion of the three categories: physical setting, activity and meaning. There was an hypothetical expectation that visitors may post more seasonally related contents in the change of seasons, for example postings on flower blossom in spring, it seems that the seasonal significance is not visible in the analysis result. While visitors post many seasonal contents in their social media accounts (Figure 5), there is no particular proportional change of seasonally related contents throughout the survey period.

Figure 7 – Temporal Analysis Results (January to June 2016)

5.3 POPULARITY ANALYSIS

Popularity analysis is in twofold. Firstly, all 1,775 tagged categories were analysed based on 20 tourism designations (Table 2). An interesting result is shown in the 'shopping' category. Humble Administrator's Garden, which is the most well-know classical garden in Suzhou, is recognised as the most popular place for shopping activities presented in social media. However, Guanqian Street scored lower in 'shopping' activity, although it has been the city's town centre shopping district. This result can be explained by the decline of Guanqian Street in recent years, due to newly developed large-scale shopping malls in Suzhou. In the case of Pingjiang Road, the 'food' and 'sensorial' categories are highly ranked, although this is one

of main tourism development areas with rich architectural heritages and a concentration of art craftsmanship shops. Suzhou Museum is also worthy of paying attention, as the 'knowledge' category is scored lower considering it is a museum, and the 'architecture' category is also not recognised while this museum building is designed by one of representative Chinese architects. Those analysis results have great potentials in rethinking the tourism marketing and promotion strategies of individual tourism designations.

Popularity Analysis		Physical Setting										Activity										Meaning					Review Score (Avg. 3.9)
		Society	Topography	Landscapes	Landmarks	Architecture	Public Space	Chores	Public Arts	Transport	Water	Shopping	People	Food	Events	Paid Activity	Amusement	Memory	Education	Knowledge	Sentiment	Seasonal					
Classical Garden	Humble Administrator's Garden	7	10	10	6	8	2	7	3	13	11	33	12	6	0	8	6	4	12	2	0	10	6.8				
	Master of the Nets Garden	0	0	5	0	4	6	2	3	0	6	0	5	2	0	0	6	3	4	2	0	3	1.2				
	Lingering Garden	1	0	12	6	6	2	11	12	0	6	0	5	6	0	0	5	4	3	6	0	3	4.5				
	Lion Grove Garden	3	1	7	3	5	2	7	12	0	0	0	6	0	22	15	8	4	0	2	0	1	5.9				
	Pavilion of Surging Waves	6	4	9	6	5	4	9	0	0	0	0	2	0	0	0	3	4	3	12	0	9	3.1				
Old Towns	Feng Bridge	4	3	3	1	3	8	3	6	19	9	11	2	3	0	4	6	4	9	6	0	1	1.9				
	Mudu Ancient Town	5	7	7	4	6	11	4	3	0	0	0	5	9	22	8	8	4	3	4	0	3	2.2				
	Tongli Ancient Town	7	17	3	4	6	11	3	3	19	11	22	3	16	11	4	0	8	12	8	0	4	5.9				
	Zhouzhuang Ancient Town	5	6	4	0	3	0	3	0	0	6	11	6	3	22	8	0	3	4	4	0	3	1.6				
	Streets	Guanyin Street	2	1	0	4	2	13	1	3	6	6	6	3	0	0	0	6	8	1	10	0	6	2.4			
	Pingjiang Road	1	6	1	3	4	4	3	9	6	6	0	6	20	0	4	3	10	13	4	22	6	7.2				
	Shantang Street	7	17	4	4	5	6	5	0	0	0	0	11	3	0	8	10	4	6	12	22	9	4.2				
Historic Heritage	Hanshan Temple	3	5	5	12	8	6	7	18	13	0	0	8	0	0	4	3	3	7	4	0	8	3.3				
	Patmen Gate	7	2	5	1	6	4	3	3	0	6	6	5	6	11	0	3	3	9	6	33	2	1.9				
	Tiger Hill	4	8	6	7	7	0	6	3	0	0	0	3	2	0	0	3	3	3	2	0	7	5.3				
Natural Landscapes	Qiongzong Mountain	10	1	6	13	6	4	11	5	0	20	6	5	5	11	0	8	10	0	4	22	9	4.2				
	Taihu Mountain	9	0	7	4	3	2	3	3	13	0	0	6	3	0	8	8	4	3	6	0	6	5.6				
Artificial Landscapes	Suzhou Amusement Land	7	3	2	3	3	6	6	6	6	3	0	6	6	0	12	5	9	1	0	0	5	1.1				
	Jinji Lake	12	8	0	12	3	9	2	9	0	9	6	2	8	0	0	6	6	3	4	0	4	5.0				
	Suzhou Museum	0	0	7	3	5	2	3	3	6	3	0	0	2	2	0	29	2	5	1	2	0	4	4.1			

Table 2 – Popularity Analysis Results (unit: %, except Review Score)

Secondly, 10 likelihood classifications on positive and negative comments posted on social media are also calculated in popularity analysis (Table 2, Review Score). The weights from +5 to -5 are added in the review score calculation and standardised by the numbers of comments posted in each tourism designation. The average review score is 3.9, and Pingjiang Road and Humble Administrator's Garden show higher visitor satisfaction, while Suzhou Amusement Land (theme park) is awarded the lowest score for the visitor satisfaction.

5.4 CORPUS ANALYSIS

The research analysed the frequency of word appearance in the text-format comments in all 640 postings using a word counting software. Considering the similarity of the meanings, 45 words are selected for further corpus analysis in 20 tourism designations. In general, the abstract words like 'wonderful', 'beautiful' and 'eating' are mostly used in collected social media postings (Figure 8). However, there are also differences in corpus analysis results based on the tourism designations (Table 3). For example, Humble Administrator's Garden, the largest and most popular classical garden, is tagged with the words describing feelings, such as 'wonderful', 'beautiful' and 'knowledgeable', while other smaller gardens are described with the words related to the particular activity and physical appetences, such as 'evening activity', 'Suzhou Pingtan (a local musical performance)', 'stroll', 'flower' and 'rockery'.

Figure 8 – Word Cloud Results from Corpus Analysis

	Frequently Used Words	1st	2nd	3rd
Classical Gardens	Humble Administrator's Garden	wonderful	beautiful	knowledgeable
	Master of the Nets Garden	wonderful	Suzhou Pingtan	evening activity
	Lingering Garden	stroll	knowledgeable	rockery
	Lion Grove Garden	rockery	amusement	enjoyable
	Pavilion of Surging Waves	flower	beautiful	culture
Old Towns	Feng Bridge	poem	canal	bell tone
	Mudu Ancient Town	Yans Garden	beautiful	architecture
	Tough Ancient Town	ticket	eating	walk
	Zhouzhang Ancient Town	beautiful	eating	Wansan's pig feet
Streets	Guangjian Street	snack	stroll	unique feature
	Pingjiang Road	eating	stroll	chicken feet
	Shantang Street	eating	wonderful	unique feature
Historic Heritages	Hanshan Temple	poem	ticket	temple
	Panmen Gate	city gate	good	boating
	Tiger Hill	tower	jian pool	history
Natural Landscapes	Qionglong Mountain	high	amusement	air
	Tiangping Mountain	red maple	stone	high
Artificial Landscapes	Suzhou Amusement Land	exciting	quene	installation
	Jinji Lake	ferry wheel	existing pier	nightscap
	Suzhou Museum	Bei Yuning	design	modern

Table 3 – Corpus Analysis Results

6 CONCLUSION

The research found that this new method has a major advantage of mapping existing place-based tourist activities, and plotting visitors' personal interests and perceived resources that can be closely associated with future strategic tourism development of the city. The analysis results show that the social media study is potentially useful to identify the key characteristics of particular tourist designations of the city from the visitor's perspective. The social media research can also be applied to the quality evaluation of tourism experiences and the practice of tourism planning and management. In terms of survey methods, the traditional tourism planning practice usually employs the data collection methods using questionnaires and interviews that are resource-incentive survey methods. As discussed, considering place identity is subjective feelings of individuals, the main weakness with questionnaire and interview survey methods is that the poorly designed questionnaires and the untrained interviewers can mislead the survey results. However, the social media data collection method may be beneficial for place identity survey as it may be influenced less by the survey environments, because social media is user-generated contents.

ID 1614 | THE SPECTACULARIZATION OF THE URBAN SPACE FOR TOURISM IN BRAZIL AND ITS CONTRADICTIONS

Renata Maia de Paula¹; Randal Martins Pompeu¹

¹UNIFOR

renatampds@gmail.com ; andal@unifor.br

1 INTRODUCTION

The third industrial revolution based on the interaction of microelectronics with computers and the consequent collapse of the Fordism model of mass production led the major western economies to rethink their models of accumulation.

As a consequence, the capitalist system, unable to continue the process of accumulation in the actual productive base, has been seeking other mechanisms of recovery. Among these is the tertiary sector, where tourism is an important activity for growth resumption. This has implied an increasing capital investment in physical infrastructure to support the production, circulation and consumption of goods and services.

In this sense, starting in the 1970s, many cities in the world started to invest in reinventing their urban spaces. Under the logic of commodities (MARX, 1983), spaces are reinvented and facilities are built to give life and to promote the development of tourism.

In Brazil, the State and its partners have been investing in the revitalization of architectural structures and in the reinvention of the urban landscape in favor of tourism, in the last three decades. In Fortaleza, state of Ceará, shortly after the announcement that Brazil would host the 2014 World Cup, the authorities announced a package of initiatives: the reform of the Maritime Terminal of passengers in the Port of Fortaleza and Castelão Stadium, the revamping and expansion of Pinto Martins International Airport and the works of urban mobility, mainly the Light Vehicle on Rails (VLT), which is the focus of this paper.

This article aims to investigate the contradictions of the recent projects of embellishment (DEBORD, 1997) of urban spaces in the city of Fortaleza, specifically those called "World Cup Works" and their purported promise to revitalize the tourism infrastructure in the city through the Growth Acceleration Program (PAC).

Throughout the research we sought to give some visibility to the relationships maintained by the process of reorganization of the urban space and the logic of capital and the current crisis in their mode of production, as well as identify the negative impacts that such works have incurred on the lives of residents, particularly those families living in the areas surrounding the construction of VLT, and the damage incurred on the city's coffers and on the urban environment.

As for the methodology, we opted in favor of the dialectic method, due to an understanding that only a critical approach may reveal the multiple relationships that the process of reinvention of the urban space maintains with the prevalent social, economic and cultural system. As for the approach, the research

has a qualitative and exploratory nature. We used the techniques of survey of the literature, documentary research, empirical observation and interviews with persons and institutions who had (or have) experiences with the object searched. Finally, the data collected were analyzed with the use of content analysis technique (Bardin, 2004) and with the support of Atlas \ ti software version 7.5.

2 THE CRISIS OF THE FORDIST MODEL OF MASS PRODUCTION AND THE APPEAL TO THE TERTIARY SECTOR

The last three decades of the 20th century, especially in the period from 1980 to 1990 were marked by a crisis in the Fordist model of mass production. Human labor, until then adapted "to the rhythm of the machine, can now be fully replaced by technical commands and by robotics" (Kurz, 1997, p. 370). Thus, unemployment, high rates of inflation in the context of the economy and the consequent sharp decline in purchasing power in the western countries showed signs at that time that the Fordism cycle of accumulation was exhausted. It is a crisis that has been deteriorating considerably, until today (2016), "by means of the revolution in information technology" (JAPPE, 2006, p. 147).

According to Jappe (2006, p. 147) "the computer definitively cuts the link between productivity and the performance of abstract work embodied in value". This is shaking the structure of society, leading to the belief that an entire production mode, based on the unbridled industrial exploitation of human labor force is in a "terminal stage" (Kurz, 1997, p. 372).

In another of his writings, Kurz (2005) points out the self-contradiction of the capitalist mode of production based on the exploitation of the labor force and the mass production of goods. He says:

In the three industrial revolutions, the standard of productivity was raised higher and higher through competition. However, the higher productivity implies a lower amount of work, represented by each of the goods and, therefore, the lower the value of the

commodity. That is when we see the self-contradicting logic of capitalism: on the one hand, it seeks the endless accumulation of value and, on the other hand, it is capitalism itself that progressively removes the substance of the value of the goods. Historically, this contradiction was compensated by the capitalist expansion: the lower the value of a commodity, the larger quantity of that commodity had to be produced and sold. [...] In the third industrial revolution the equation no longer works: the overall mass unemployment matches the internal devaluation of goods. (Kurz, 2005, p.01).

With the drop in profitability in the productive sectors and an industry based increasingly on microelectronics, capitalism needs, more than ever, the wide support of the tertiary sector - services, trade, the financial sector.

In this sense it is the tertiary sector of the economy that allows for the movement and distribution of numerous goods, such as: transport services, telephony, telecommunications, health, education, trade, energy, water supply, tourism and leisure activities and their facilities (hotels, lodges, restaurants, snack bars, dance clubs, parks, zoos, libraries, bookstores, among many others).

Thus, services emerge as mechanisms of indirect capital appreciation (JAPPE, 1999), covering the territories of the market in search of formulas for overcoming the crisis endured by Capital. Given those conditions, starting in the 1980s, the tourism activity was recognized and valued as an important factor for the sustained growth of the world economy.

3 TOURISM AS A SURVIVAL STRATEGY OF CAPITAL

Tourism, as an output of the productive machinery of the capitalist system, and a social and spatial phenomenon which is translated into a strategy of capital accumulation (BEDIN, 2008), departing from the metropolises of the rich industrialized countries, rapidly sets foot in the countries that are already adapted to urban living. This is the case of Brazil, a country that has been putting large efforts to implement this activity since the 1970s, in order to become a coveted destination within the wide network of global tourism.

It is worth pointing out the role of urban planning as a tool for preparing the places to meet the interests of capital in the form of tourism. In this case, the State acts as an organizing and unifying agent that manifests its power by commanding the spectacle in a defined area. In his book "The Society of the Spectacle", Guy Debord makes it clear about the link between politics and spectacle. For him "the oldest social specialization, the exercise of power, lies at the root of the spectacle" (Debord, 1997, p. 20).

According to David Harvey, in his book "Spaces of Capital: Towards a critical geography" (2005), the capitalist state not only regulates competition, for the accumulation of capital, but offers infrastructure for capitalist production and exchange. According to him, there are currently very few aspects of production and consumption that are not deeply affected, directly or indirectly, by the policies of the state" (HARVEY, 2005, p. 79).

Under such conditions, tourism as a particular form of spectacle, must necessarily, with the protection of the state, seize the spaces, since in modern societies these spaces have to be continuously refurbished to meet the needs of the new economic practices. Says Debord:

By shaping everything around it, society has devised a special technique to act on what gives support to those tasks: the very territory. Urbanism means that capitalism takes possession of the natural and human environment and, to develop the logic of absolute domination, can and will now remodel the entire space as if it was its own spectacular set (Debord, 1997, p. 112).

Thus, seeking to boost an economy in crisis, the enormous transformations of urban areas aim to support tourism and attract a clientele with purchasing power for the consumption of shows (commodities).

4 SPECTACULARIZATION OF THE URBAN SPACE FOR TOURISM IN BRAZIL: THE WORKS OF THE 2014 WORLD CUP

In 2007, when Brazil was officially selected as the host of the 2014 World Cup and the 2016 Olympic Games, twelve cities in Brazil - Rio de Janeiro, São Paulo, Porto Alegre, Salvador, Belo Horizonte, Brasília, Curitiba, Manaus, Cuiabá, Natal, Recife and Fortaleza - became co-hosts of those mega events.

To carry out the World Cup and the Olympic Games, the selected cities were "contemplated" with investment packages for the revitalization of their urban spaces. The initiative comprised several interventions, such as urban mobility (avenues, tunnels, overpasses, among others), tourism infrastructure (revamping and expansion of passenger terminals and airports) and especially renewal and construction of new stadiums, in order to attract and encourage private capital with interests in the big business involved in the games.

The organizers of the World Cup and the Olympic Games boasted that these mega events would create opportunities to attract the investment necessary to improve infrastructure in the selected cities, and the impacts would certainly bring economic benefits to the country and improve the living conditions of the population (CUP PORTAL, 2016). According to Curi (2013):

The organizers, comprising representatives of sports federations and members of federal and state governments, were quite euphoric with the whole situation. They considered the mega events as being automatically beneficial to the country and its people. The sporting mega-events were depicted as a means to enhance and accelerate development in the host country.

However, despite the optimism of their promoters, the infrastructure built in the host cities, in order to support the mega-events, not only had negative economic impacts, but were also responsible for social and environmental problems. Moreover, many works never even started and others were not completed and today (2017), there is no way to predict when they will be handed out to society.

In December 2010, when the evictions, on account of these Mega Events, were already in place, the United Nations (UN) special rapporteur on the Right to Adequate Housing, Raquel Rolnik, sent a letter of allegation (formal instrument used by UN rapporteurs when they receive complaints) to the Brazilian government, denouncing forced evictions generated by works of the World Cup and the Olympics. Among the allegations listed in the document one points out the works approved without a bidding process, forced evictions without prior consultation with the residents, urban interventions that breach the environmental legislation, lack of dialogue and transparency, lack of participation in discussions by the populations living in the communities involved. At the time she received no reply from the government (Raquel Rolnik, 2011).

Nevertheless, Brazil is a signatory of the International Covenant on Economic, Social and Cultural Rights – ICESCR (UNITED NATIONS, 1992), which presents, in its Article 11, adequate housing as a right of every person. It is also worth pointing out the General Comment No. 4 of the Committee on Economic, Social and Cultural Rights that interprets Article 11.1 of the ICESCR and lists the components of the right to adequate housing and identifies what must be done in the case of evictions (Brazil, Secretary of Human Rights of the Presidency of the Republic - Right to adequate housing, 2013, p. 34)

National Coordination of World Cup Committees (ANCOP) confirms that among the various violations of human rights, during the preparations for the World Cup and the Olympics in Brazil, they can list: the exclusion of communities in the discussion and definition on evictions or the existing alternatives; the lack of information from the authorities to the residents of the affected communities; the payment of compensation was considered insufficient and transfers of residents to distant areas within 50 miles (ANCOP, 2014).

As if such violence against the residents, reported by the popular committees of the World Cup and by the media was not enough, many of the construction companies in charge of carrying out the reforms of the urban space as required by FIFA, started working without delivering the Environmental Impact Study/Environmental Impact Report (EIA/RIMA) and a good part of the legislation for the protection of the natural and architectural environment was modified or ignored.

In Fortaleza the economic losses derived from the interruption of VLT works, for more than two years, have not yet been figured out, but the waste of public funds and the negative environmental impacts are visible throughout the entire line.

According to the piece (Fantástico, 2016), R\$ 103 million had already been spent on the construction works and on the purchase of train wagons that were never used," notes reporter Alessandro Torres. The reporter is horrified to find wagons, purchased for the VLT, abandoned in a secluded area" of Companhia Cearense de Transportes Metropolitanos (METROFOR), "alongside subway compositions in maintenance". Equipment that have cost dear to the public treasury and which should be transporting people are in decay. The report also showed that the envisioned stations became garbage dumps. He showed the sad conditions of the area still holding the houses that have not yet been demolished by the progress of the VLT works. According to him, the families who did not accept the severance payments, or the rent proposed by the government, live "in the midst of rubble" from the demolitions.

The report showed the position of the then executive secretary of the Federal Comptroller Office (CGU), Carlos Higino Alencar, on the VLT unfinished works. According to the secretary, referring to the audit report, "the big problem was the lack of planning". For Alencar, "lack of planning causes not only paralyzed works, but sometimes waste of et renders equipment that may be damaged by non-use" (Fantastico, 2016).

The evictions, presented as a mandatory measure, without any other available alternatives, and the low value of the indemnities and social rents offered to those who had their homes demolished, have been and are being some of the other problems faced by the residents of the communities affected by the VLT. In an interview, the former federal prosecutor Alessandro Sales, said that it would only be correct if the State gave 'adequate shelter to the families that will be evicted, but for this, he says, there has to be a for resettlement plan. Sales says (2016)

Adequate Housing means, first, a decent housing unit. But it is not only a decent dwelling: you have to reestablish all the labor, affective, and other bonds, that that person had in the original community. So what is the best way to do this, i.e., how can such disruption, such loss of housing be less traumatic? The answer is to provide another house, with an adequate size, with adequate sanitary conditions and as close as possible to the previous dwelling unit. Why is that? Because the previous dwelling had already established all these ties, labor ties, community bonds. To transfer people to faraway places means disrupting a community. [...]. Thus we have been struggling for the state to prepare a resettlement plan. And according to the norm, such a resettlement plan must provide for the transfer of people to a site as close as possible.

Regarding the value of the social rent, many displaced families are content with a State aid - which, according to the residents, after much struggle, went up from R\$ 200.00 to R\$ 400.00. Some families complain that they have to take money out of your pocket to pay the difference in rents. For Sales (2016), "the social rent price is absolutely outdated, people are unable to rent a property nearby. So it has to be readjusted." The representative of the Public Prosecutor argues: "one thing that cannot happen is an urban intervention to make the lives of people worse" (SALES, 2016).

In March of 2016, specifically on the 5th, as described in the table below, two people considered leaders in two communities, among those mentioned above, were: Trilha do Senhor and Aldacy Barbosa. The choice was due to the location of the communities along the stretch where the works of the VLT are located, the greater availability of the community leaders in the dates defined in the work schedule and, above all, the history of struggle that these two communities carry.

Interviewed	Community	Role that represents in the community	Date / time
A	Trilha do Senhor	Community Leader	5/3/2016 at 9h
B	Aldacy Barbosa	Community Leader	5/3/2016 at 14h

Table 1 – Information about interviews
Font: by the author, 2016.

From the incursions to the selected communities, it was revealed more than the one reported in the Fantástico report, namely: the neglect of public power by these populations, devoid of basic services structure, permeated by the daily violence of drug trafficking, fighting of gangs between traffickers, among other problems.

The residents live in modest, low-quality homes built without planning. The houses are piled up in narrow alleys, alleys and alleys without paving and basic sanitation. The scenario is embarrassing and expresses the state of inequality in which low-income residents live in the city of Fortaleza. Some middle-class buildings contrast with the lack of power in the areas studied.

The problems already existing in the communities are accentuated when the implantation of the VLT implies several annoyances and harms the dynamics of the daily life and of the daily activities of the residents. In the following pages of this work, we intend to show how the communities consulted, in the person of their leaders, are experiencing the process of resistance / negotiation on expropriations, removals and resettlements due to the installation of the VLT in the city of Fortaleza.

Figure 1: Community Trilha do Senhor

The Trilha do Senhor community, one of the 22 communities affected by the VLT project and is located in an area of great concentration of people. The landscape of the community in every direction that gazes at the eye shows wreckage and residues resulting from the demolition of real estate formerly occupied by families who had to leave their old place of residence because of the works of the VLT.

On March 5, 2016, an interview was conducted with the community leader of the referred community (here called A) containing questions associated with the Light Rail Vehicle (VLT). The first inquiry was to know how the resident evaluates the fact that the community will have to be removed to make way for the VLT facilities. The respondent replied that it was "very bad, bewildering".

Too bad, right? It is a very worrying thing to know that we will be forced to leave here. We're kind of bewildered. You do not know where you're going; What are you going to do with us? Where are we going, will people be helpful? Will they want to help you when you need them? And for us to leave here to live in another place, it's like ... our head ... look ... it's never going to be like here. Here everyone is known; When we need it, everybody comes together (A, Trilha do Senhor).

It was evident in the answer to the question raised the rejection of the obligation to remove residents from their current housing, without alternative, since this may end up destroying the social bonds of friendship and loss of the current space of coexistence of the residents. According to the resident, those who suffer the most from the removal process are the elderly.

Look, the elderly have suffered the most and have been suffering from this news that we have to get out of here. That moved and moved their heads a lot, there are elderly people here who are depressed. Here is a lady who is very skinny, worried, because she's going to leave here, and she does not even know where she's going (A, Trilha do Senhor).

Regarding the level of satisfaction of the families that already received the indemnities, the interviewee reported that many residents were dissatisfied with the indemnities and much more with the value of the rents. According to A, even among those who have received a new property, some are repentant.

Look, here is very good, everything is close. The hospital, the health center, everything is very close. Many people who have been removed work here. Now you imagine, most were moved to the Garden City at Zé Valter. Look, we count on the fingers the people who left here who are 100% satisfied with the new address. Others say they are fine, but at the same time they are not. That's a long way off. Place that neither here does not exist (A, Trilha do Senhor).

Concerning the disturbances that the work was causing to the community, the interviewee pointed out as main annoyances: excess of dust in the residences, noise pollution, rubble resulting from the demolitions of the residences of the families that have already gone through expropriation, but above all the forced removal of its current places of housing. Community leader A says: "No one was happy with this idea, not even those who got on well with the damages."

When asked about which government decision would make the residents more satisfied, the community representative replied that the best alternative would be to revitalize the community by building new homes, recreational spaces, basic sanitation, schools, kindergartens and other equipment.

Figure 2: Community Aldaci Barbosa

The Aldaci Barbosa community is located in the neighborhood of Fátima near the Central Bus Station. Its occupation dates back to 1950 and was consolidated in the 1970s, with the struggle of the residents involved with the resettlement resulting from the removal of families in favor of the works of the new central bus station, which later resulted in the promoted housing partnership by the state government in 1985/1986. With a history of struggle, the community was one of the first to resist forced removals by the VLT.

On March 5, 2016, with an appointed date and time, an interview was held with the community leader of the community (here called B). The interview contained open questions associated with the VLT project. The result showed the residents' involvement in combating the removals and impacts of this project on the lives of residents. Despite the resistance movement and negotiations with the government and the gains from the struggle of the organized movement, with the help of other actors, the community scene is still chaotic. The few living and leisure spaces, facilities of the place (court and community center) are poorly maintained and almost the entire extension of the community is surrounded by rubble from the demolition of residences of families that have already been indemnified.

The community leader informed, shortly before the interview, about the situation that the community is facing with the negative legacy of the work.

We live with a mouse, a cockroach, a scorpion, a termite, ants, an insect, all that's bad we have inside our houses, so nothing has been done here, dirt continues. Those responsible for all this are called SEINFRA, the Secretariat of Cities and Metrofor. It was they who were responsible to have all this cleaning done and so far not had the humility to have it cleaned. Those who live in the dirt are us, they are not they, they do not feel in

the skin what we feel. Are you understanding? It's like health, they have private plan, even taking longer they are taken care of, and the poor if you want to look for SUS. Girl, it's a neglect. This makes me very angry (B, community leader Aldaci Barbosa).

The first issue raised in the interview was about the process of negotiating removals. The interviewee revealed that everything started very violently.

The government here, when it comes to tinkering within our communities, it does not arrive with two years, three years before to prepare the heart of the families, not he arrives already attacking at the hour, making psychological pressure, if not leave has to leave with Police, cavalry, that's how it started, you understand? It started here when Cid Gomes came here at about seven o'clock in the evening, then joined the staff of the association and put Cid Gomes to run, the governor. From then on, those same people who did this ended up coming to the government and negotiating on the doors of our house. I put them to run because I know how to fight for my things, I've been a community leader for more than thirty-two years (B, community leader, Aldaci Barbosa).

The second question was about the annoyances caused by the impacts of the work. Similar to what was revealed on the Trilha do Senhor, the community leader pointed to the following problems: excessive dust in homes, noise pollution, increased respiratory diseases and loss of living space due to demolition.

Asked for a break in the interview, the community leader draws attention to the environment: "open sewers within the community, much debris. This neglect is the inheritance of past management, along with that now "(B, community leader Aldaci Barbosa).

When asked if he would be given the right to choose on the removal question what would be the position of the community? She replied: "I would not say all, but probably the majority would not leave the community" (B, community leader Aldaci Barbosa).

Regarding the level of satisfaction of the families, the community representative said that many of the residents are dissatisfied with the compensation. "This is a position of almost all the residents. Girl, everybody likes it here, love this place. Some people have lived here for over fifty years. There are people who were born here, were raised here "(B, community leader Aldaci Barbosa).

Finally, when asked about which government decision would make the residents more satisfied, the interviewee replied that "the best alternative would be a housing project in the community itself or in the immediate vicinity, with basic sanitation, recreational spaces, schools and day care centers for children." According to the interview, this proposal has already been negotiated with the government and the local association, but does not know when it will leave.

It is interesting to note that the community leaders interviewed came to converge in some points of the answers to the questions formulated to them. This is proof that the judgment of the two leaders is deeply involved with the interests they represent. It is a sign that the communities of Trilha do Senhor and Aldaci Barbosa live similar situations and share the same struggle.

6 CONCLUSION

The arguments presented above, as well as the empirical observation, the research applied in some segments connected to the problem studied and the field research conducted directly in the communities affected by VLT works, gave evidence that the right to the city is still being governed under the logic of the commodity (the Spectacle), in the conceptual meaning of Marx and Debord. Since the results of the research showed that the actions involved in the creation and revitalization of urban space in order to generate tourism flows through the exploitation of capital surpluses are not concerned with the losses in the city's coffers, or with the environmental issues and the needs of those who suffer the loss of their places of residence.

In fact, while for the companies involved directly and indirectly with the mega events, as well as for the businesses connected to them these works are economically favorable, the opposite is true for those residents who are being evicted on account of the works linked to FIFA and the 2016 Olympic Games. The

embellishment of urban spaces, for tourism, means not only the loss of shelter, caused by the evictions, but the extinction of entire communities. With another aggravating factor: those responsible for projects of urban reinvention, besides not complying with national and international standards of the right to shelter, in what concerns the issue as of involuntary evictions, have breached the environmental legislation. These results only demonstrate that the projects of city revitalization are governed by spectacularization for spectacularization, in the same sense as Debord (1997) affirms, in saying that the spectacle does not want to reach anything other than itself. What it means to say, under the light of his theory, that in capitalism the sole purpose of production is the production of money.

For the apologists of spectacular urbanism the spectacularization of the urban space is capable of bringing economic and social growth, in this work it has been critically shown that these perspectives are mutually exclusive, when it is found that the places inhabited by poor populations are destroyed by same contradictory logic that makes these activities (tourist) a call for financial investments.

This work was based on radical criticism of the way of thinking and reinventing the city and the elaboration of projects of urban restructuring, that come to the encounter of a new way of life based on sustainable principles. What is essential is necessarily the discussion of the need for urban planning beyond the exclusive interests of capital, therefore, another development paradigm, whose primary goals are the sustainability of local and global space and the improvement of people's quality of life.

To conclude, it suggest some possible questions to be addressed in later works that seek to investigate the urban transformations undergone by the great Brazilian metropolises (the increase of socio-environmental inequalities, the spread of poverty throughout the urban fabric, the emergence of new forms of segregation of the middle strata of the population in others). The contrasts between situations of extreme poverty and extreme wealth in the Brazilian metropolises: what has led to such conditions to perpetuate themselves in the city of Fortaleza? Who is interested in the processes of structuring and restructuring the urban space in the city of Fortaleza? What is the importance of a Resettlement Plan for urban revitalization projects involving removals? Finally, it is expected that this work can contribute to the search of innovative strategies in the management of cities, inserting social and environmental components in the reinvention projects of urban space.

ABSTRACT: The article discusses importance issues of medical tourism and resort medicine for the case of Southern Georgian resorts, especially resorts in Samtskhe-Javakheti Region Akhaltsikhe, Borjomi and Abastumani. Cluster analysis principle is applied and the central role of health-care tourism and resort medicine in Tourism and Recreation Cluster of Samtskhe-Javakheti is defined. Historical experience of Georgia in health-care tourism and resort medicine is highlighted. Renewed development of health-care tourism and resort medicine should be related to the Sustainable Urban Development of these settlements, therefore, future policy should be determined. In this regard, complex activities in following issues were offered: education improvement in the field of resort medicine, considering appropriate resort treatment in insurance packages, urban planning solutions and Smart city management, environmental and protective planting issues, rehabilitation of resort infrastructure. We offer to create health-care tourism cluster for Georgia considering contemporary trends, and for this were defined successful examples of developed countries, in particular, German and Hungarian cases. The direct contribution of Travel and Tourism to GDP was 6.5% in 2015 in Hungary. The raising part of tourism is medical tourism in Hungary and the most popular area situated near to the Austrian border. All over the country there are many type of baths and the therapeutic use of them is common. The good examples of them could be helpful to create a brand new touristic destination in Georgia. Also a good example for Georgian healthcare Tourism Cluster development is a managed system of German resorts named Deutscher Heilbäderverband. Resorts of Germany have united functional system, with interactive map and comprehensive information, resorts profile and category classification, affordable health-care activities, etc. In tourism and recreation cluster of Samtskhe-Javakheti are considered Akhaltsikhe, Borjomi and Abastumani, like resorts, determining main profile of the region. Also potential thermal resorts of South Georgia should be considered for future development. In this regard climatic and geographic characteristics, also balneology resources potential of above mentioned resort cities were shown. Sustainable urban development recommendations for the rehabilitation and further development of the health-care tourism and resort medicine field were worked out.

KEYWORDS: Medical tourism, Resort medicine, Sustainable urban development, Regional Development

1 INTRODUCTION

Georgia in 20th century was well known as health-care center of former Soviet Union. Huge resort industry have been the major sector of the country economy. According to the data of 1981, 2 million guests, between them for the health-care purposes, came to Georgia annually (Encyclopedic Dictionary, 1983). Many mountain and sea resorts are presented on the whole territory of Georgia. In this paper we focus our attention on the South Georgian tourism and recreation geographic cluster of Samtskhe-Javakheti region, where are concentrated the most outstanding climatic and balneology resorts.

Objectives: main objective of this research is to prove that the development of the health-care direction of the tourism is most important for the sustainable development of South Georgian resorts Borjomi, Akhaltsikhe and Abastumani, which are most remarkable cities in Samtskhe-Javakheti Region; major tasks are: to define ways, to develop concepts for the activation and revitalization of these resorts. Based on great experience in near past, to find and suggest appropriate foreign examples for significant results whenever possible.

METHODS

Comparative research of foreign examples, cluster analysis, SWOT-Analysis, review of regional development strategies and contemporary sources were used in this paper.

2 RESULTS AND DISCUSSION

2.1 GEORGIA

Historical preconditions: history of medical tourism in Georgia begins in ancient times. “At the beginning of 20th century on the territory of Borjomi mineral springs, during captive works, at the depth of seven meters the remains of stone built baths were discovered, which were considered by archeologists as buildings of 1st century. (Amiredjibi et al., General Plan of Land Use of Borjomi, Development Vision, 2007 p 6.)

Figure 1. Georgia. Map of Resorts in 18th century (Koniashvili, Ushveridze e.al. Atlas of Resorts and Resort Ressources, 1989).

In 18th Century Prince Vakhushiti Bagrationi declares about the usage of thermal water springs in medieval Georgia: “On the mountain slope there is a spring, huge, hot and boiling, named Otskhe. Above is the bath, and many are bathing there, because it has a healing power of diseases”. (Bagrationi, Geography of Georgia, Samtskhe, 1892, redaction of 1999). During medieval wars the territory of Samtskhe-Javakheti, named to that times Samtskhe, Tori and Javakheti have been abandoned and population migrated to safe places. New development begun in 30th of 19th century, with attempts of Russian Kingdom. There was almost good health-care infrastructure for that time. Several resort places and towns performed to popular resorts.

Figure 2. Composition of Historic Photos. 1. Borjomi water source. 2. Romanov's Palace. Photos of Sergei Prokudin-Gorskii, appr. 1912. (Prokudin Gorskii Collection)

Balneology potential of Borjomi, Akhaltsikhe and Abastumani were investigated at the same time. Romanov's time was the time of rapid development, and resort development was one of the successful commercial projects of Russian Empire. (Borjomi, 2015). Although, many important steps and activities were performed to develop this area: Mineral water bottling and glass production factories were founded; 300 MW power plant was built; several hotels and summer houses of beautiful architecture mostly for nobles were arranged.

Figure 3. Composition of Historic Photos. 1. Borjomi water processing. 2. Borjomi water source. Photos of Sergei Prokudin-Gorskii, appr. 1912. (Prokudin Gorskii Collection)

Borjomi and Abastumani became most beloved places for Georgian and Russian intelligence and also for guests from other countries. For example, Persian prince built adorable small palace at the entrance of Mineral water Park, named "Firuse" because of its turquoise blue color. Akhaltsikhe played another role – communication hub and bordering city was not significantly comfortable for the rest, although in its surroundings a lot of thermal springs were located.

After Revolution of 1917 conditions changed, but resort development continued soon. In soviet times, until 90's of 20th century, in Borjomi 12 sanatoriums, and in Abastumani 10 sanatoriums with strong health-care facilities functioned. They were almost fully loaded. Up to 4000 guests at the same time could have rest in that facilities in small resort city Borjomi, with appr. 15000 inhabitants. For example, Likani sanatorium have hosted 1070 guests, Hotel "Borjomi" – 750, Sanatorium "Kechkhobi" – 700, "Mtis kheoba" – 500, "Plato" – 300, "Poly-clinical union" – 200, "Firuse" – 180, "Bakhtrioni" – 120, etc. (According to the interview with former employee of Resort management department of Borjomi).

In 90's of 20th century due to social and political crisis, resort facilities have stopped functioning. Most of them were ruined and degraded. As a result, unemployment led to environmental problems like illegal logging of forests. Different negative influences could cause unchangeable processes and dangerous threats to the main climatic conditions of resorts.

Figure 3. Samtskhe-Javakheti, Map of Resorts in 20th century. (Koniashvili, Ushveridze e.al. Atlas of Resorts and Resort Ressources, 1989) Importance of resorts according to red circle size.

Nowadays the condition of resort development becomes better. Tourism, especially health-care tourism, wellness and spa are the most prospective branches. It is not possible to develop any other industry for recreation regions. Medical tourism becomes one of the major directions in tourism diversification. Although, tourism development strategy 2025 doesn't consider the great importance of medical tourism development for the degraded regions of Georgia (World Bank 2015, Tourism Strategy 2025).

Climatic conditions of above mentioned resort cities are the following:

Borjomi is a famous resort, located between the slopes of Meskheta and Trialeti ranges, in the valley of river Mtkvari and its tributaries, Borjomula and Gujareti water. Inhabitants: 10,5 thousand (Census 2014). Height above sea level- 800-1000 m. Peculiarities of Borjomi climate are conditioned by the location of the resort in moderate climate, low mountain forested zone. The average January temperature is $-2,8^{\circ}\text{C}$. The average temperature in July, is the same as in August, 19°C . The average annual temperature is $8,3^{\circ}\text{C}$. Relative humidity is 77%. The average annual rainfall 658,6 mm. The amount of precipitation is more in the warm period (April-September (356,6 mm)), and less - in cold period of the year (October-March (302 mm)). The sunshine duration is 1350-1400 hours per year. (N. Saakashvili, I. Tarkhan-Mouravi e. al., Resort Borjomi). In the city there are several mineral water springs, between them thermal, which are located mainly in the historical Mineral water park of Borjomi.

Akhalsikhe is an administrative center of the Samtskhe-Javakheti region. Inhabitants – 17,9 thousand (census 2014), The city has status of resort, but resort infrastructure is less developed, probably due to its border position and less forest coverage. "Geographic location – southern slope of Meskheta (Adjara-imereti) mountains, gorge of river Potskhovi Tskali. Height above sea level - 980 m. The terrain - hilly, climate - moderately dry, low mountain. Winter cold, with little snow. Average temperature in January - $3,8^{\circ}\text{C}$. Summer is warm, moderately dry. August's average temperature is $20,4^{\circ}\text{C}$. The yearly rainfall - 400-600 mm. The average annual relative humidity - 69%. Duration of sunshine a year - 2000-2100 hours. Natural healing factors: the low mountain climate and thermal (38°C), carbonate, hydrocarbonate, magnesium-sodium waters with the total mineralization of 9 g/dm³. Types of treatment: mineral water intake (to drink), mineral water baths, passive climate therapy" (N. Saakashvili, I. Tarkhan-Mouravi e. al., Curortography and Resort Therapy of Georgia). City is a communication and tourism hub; recently old fortress named "Rabati" became popular touristic attraction. Akhalsikhe and its surroundings are rich on thermal springs, but totally without any infrastructure or facilities.

Abastumani is a small resort town in Adigeni municipality with excellent climatic and balneology healing features. Inhabitants – 750, during touristic season – 2000 (Census 2014). Abastumani characteristics: "The climate - the middle mountains lower zone, winter - cold, snowy. Average temperature of January: -6°C . Summer - moderately warm, 16°C average temperature in August. Relative annual humidity is 77%,

average annual rainfall number - 688 mm. Duration of sunshine per year - 1967 hours.” (N. Saakashvili, I. Tarkhan-Mouravi e. al., Curortography and Resort Therapy of Georgia). Abastumani shows unique results in the treatment of lung diseases. Also here are thermal hot water springs with different healing features. Abastumani is outstanding also with its cultural heritage buildings – up to 122 houses of 19th and 20th centuries were recognized as cultural heritage buildings. Also astrophysical observatory (built in 1936) gives interesting prospects to the resort development.

Borjomi, Akhaltsikhe and Abastumani could be considered as key points for the regional planning and development of the tourism and recreation cluster of Samtskhe-Javakheti region. Therefore we developed SWOT-Analysis for these three resorts.

2.2 TABLES

SWOT ANALYSE - STRENGTHS, WEAKNESSES, OPPORTUNITIES AND THREATS

BORJOMI, AKHALTSIKHE, ABASTUMANI

Strengths	Weaknesses	Opportunities	Threats
established and well known brand	Weakness of the logistical connections and of the long-distance as well city transport network, lack of decision-making skills locally	Increase of the role of Borjomi as international recreational resort, improvement of resort infrastructure, arrangement of exhibition- and concert halls	Loss of connection between governance and society, creating of false wellbeing picture
Traditionally developed resort, emergence of	Balneology system disfunction, lack of	Strengthening of resort medicine, education and	Difficulties of medical equipment and
governmental interest in the resort medicine revival issue; increase of the role of education and science	qualified personal, expensiveness of the branch, lack of conference infrastructure	healthcare sector, development of affordable resort medicine, organization of large-scale medical science events	infrastructure, need for big investments; probably the quality of local service may not be worth the price; and it can happen that attracting tourists for this sector fails
Positive examples of green areas arrangement in Borjomi, high interest of the society to the ecological condition of the region	Heavy ecological problems, strong damage of forests, partly wrong planning solutions by the rehabilitation of the existing green areas	Improvement of ecological condition, extension of green areas in suburbs, arrangement of green areas and public spaces in abandoned industry objects	Irreversible processes, related to climate change, delay of green cover restoration measures, Forest regeneration difficulties, late effect

Table 1. Borjomi, SWOT Analysis

Strengths	Weaknesses	Opportunities	Threats
Regional development strategy [4]. Well developed trade and handicraft sector	Influence of Akhaltsikhe does not cover the entire region and it can not fulfill the role of real center of the region; its disposition and services are not equally interesting for all subordinated municipalities	Growth of the regional importance, Offering alternative services opposite to the Tbilisi direction, increase of the intellectual potential	Akhaltsikhe might not be able to fulfill all the functions of the real regional center
Key location for the tourist routes, connecting position between Borjomi and Abastumani	Insufficient intellectual and material-technical base, Fewer use of potential in the region	Strengthening of educational and healthcare sectors, restoring of spa-functions of Akhaltsikhe, strengthening of the University	The passive approach of the state and private structures towards the implementation of large investments in the field of healthcare

Positive examples of green areas arrangement in the country	Lack of general master plan of the city, lack of strategic documents and decisions	Ecology improvement, extension of green areas, arrangement of green public spaces, renewing of old protective planting along the roads	Only local measures of some green areas rehabilitation were implemented, protective planting is not used widely
-------------------------------------------------------------	------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------	-----------------------------------------------------------------------------------------------------------------

Table 2. Akhaltsikhe, SWOT Analysis

Strengths	Weaknesses	Opportunities	Threats
Formed and well-known brand, existence of development strategy document [4]	Peripheral location, weakness of the transport network, Lack of decision-making skills locally	Increase of the role of Abastumani as unique climate and balneology resort, improvement of the communications and spa infrastructure	There is a view, that the resort treatment can be replaced by the chemical drugs therapy. Therefore the quantity of guests can decrease
Planned large-scale rehabilitation of cultural heritage	Damage of architectural heritage for long years, big part is wooden, damaged by moisture and fungus	Preliminary study of cultural heritage, 3D scanning, searching for the best ways to rehabilitate	It may not be possible to restore in the primary form, or just the facade reconstruction without reinforcement will be
	and other irreversible negative processes		implemented and hidden destruction of buildings continued
Tradition of resort medicine, interest of the governmental structures to the revival of spa medicine, increase of the importance of educational and science system	Balneology system disfunction, lack of qualified personal, expensiveness of the branch, lack of conference infrastructure	Strengthening of resort medicine, education and healthcare sector, development of affordable resort medicine, organization of large-scale medical science events	Maybe, the organizational side could not be carried out well and the investment costs could not be covered
Excellent natural conditions, high solar insolation	High probability of wastewater pollution with bacilles	The strategy envisages improving ecological conditions	Expensiveness and difficulties by the implementation

Table 3. Abastumani, SWOT Analysis

Climatic conditions and resort features, number and chemical ingredients of springs should be investigated again to update existing researches that were performed in 60th-s and 80th-s of 20th century.

Medical tourism could build a chain of interconnected health-care and spa facilities in the surrounding, involving also places with underused or unused potential (thermal sources of Akhaltsikhe and Aspindza Municipality; Aspindza, Nakalakevi, Uraveli, Tskaltbila etc., eco-tourism in Gujareti valley etc.).

Fig. 4. Regional map of Samtskhe-Javakheti Tourism and Recreation Cluster, with water sources

As successful example of medical tourism development we consider the case of “Borjomi Palace” hotel. According to the data of medical center attendees, the number of guests increased from 12 at the very beginning than center was opened in 2013 up to 470 in high season per month last year. But for the moment this is the only one hotel in the region which offers such services like medical treatment and spa-wellness at the same time. Guests of the hotel, like in another luxury hotels of the same area are mainly foreigners from former soviet countries, in which professional unions and insurance companies cover the part of the expenses.

Another issue is to develop system which works like affordable health-care tourism possibilities for Georgian inhabitants. Programs, Plans and Projects should been developed for this purpose. Here the cooperation of the State, Government and self-government, and private sector as banks and insurance companies is important.

Many projects of balneology and spa infrastructure for the future development of medical tourism were elaborated by Georgian Architects in 20th century, but most of them were not realized. We found these works interesting to show as prospective examples that could be used for learning and planning purposes, if health-care tourism industry will develop in Georgia. The Balneology sanatorium for 250 beds was designed for thermal resort Nokalakevi, by the Students Planning Bureau of Faculty of Architecture, Georgian Polytechnic Institute, 1979. Architects: V. Davitaia, G. Kvitsinashvili, T. Kldiashvili.

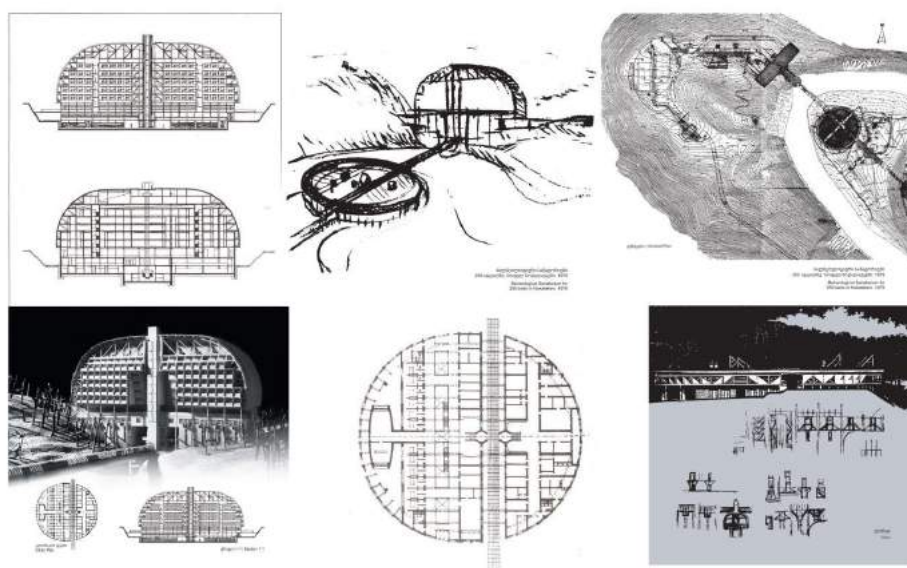

Figure 5. Project of Balneology Sanatorium in Nokalakevi. 1979. (Georgian Technical University archive)

Due to huge resort industry of Soviet Union, many standards and schemes of regional planning as well planning of different big and small touristic hotels and sanatoriums of resort areas were developed. (Urban Planning bases for development of resorts and recreation regions, Sroyizdat, 1990)

But for contemporary conditions old soviet standards, rules and schemes are not significant. According to Georgian building law, we are allowed to use standards of 37 countries by the planning.

Development of new schemes for resort regional planning and also schemes of hotels supported with medical tourism facilities is one of important tasks for the future.

From many world examples we have chosen Germany and Hungary, because of many similiaryties and good experience in the past. German examples of Baden-Baden were used by Romanov's for the arrangement of Georgian resorts, and in particular, for Borjomi and Abastumani facilities.

2.3 GERMANY

German examples: One of the best experiences is to manage resorts through resort unions. Deutsche Heilbäderverband is the agency which manages, gives information, cooperates with scientific institutions,

organizes trainings and workshops and cares for the resort development in Germany. There are the main and also several other similar unions in different parts of the country.

German experience shows the problems, new challenges and how they were solved. Modification of insurance system to private financing and crisis of spa industry because of this was one of the reasons. German state policies, some data, trends, and positive examples could be well used in Georgia.

2.4 GERMAN EXAMPLES, CURE IN GERMANY

In Germany people are getting a cure e.g. after a serious sickness, when over worked (burnout) or when getting sick for the same reason over and over again. Another reason why people visit a therapeutic bath nowadays is the movement of wellness and lifestyle, to take a so called "Kururlaub".

There are different ways of paying for it: health insurance, social pension fund or with privat money. The duration of cures lasts between 2-6 weeks, depends on the grade of sickness.

During the treatment there are staff members who look for special needs of the patients. If necessary they get helped to go back to the regular workplace after the cure, there are specialized people who help (e.g. what kind of work are you doing, perhaps different chair needed; shorter working hours to begin with).

Over the years the system of cures has changed. In 1996 the German health insurances stopped paying for the cure as it was before (10). Guest did not come as regular as it was, houses stood empty, people lost their workplaces. Because of that cure houses and cities had to reorganize to survive. Nowadays most of the "Kurkliniken" are specialized to persist, have modern rooms, old houses are remodeled or torn down and rebuild. Features like TV and Wifi, workout places and management of quality are important.

Two examples for different approaches are described in the following.

The clinic St.Peter (11) in northern Germany is well known for treatment of cancer patients. They put their focus on rehabilitation back to the regular workplace of the client. Specialist help to identify the critical points.

The network of Helios- Kliniken (12) sets the focus on enhancement of the quality of treatment. While surveying every treatment they do and publishing the operating figures everyone, from staff to patient or admitting doctor, can inform him/her self about the results

On other way of focusing in cures are spas, a speciality not only of Germany. They are called „Heilbäder“ (spa) or „Moorheilbäder“ (peat spa) (13). Around 6% of the spas with higher rating are peat spas. This type of spa uses peat/moor as treatment. The effect of the peat/moor is to appease pain and tension. Through the heat reservoir of the moor it operates depressant and stimulating. In Bavaria such spas are found often.

Figure 6. Resorts and baths in Bavaria.
(<http://www.kurorte-und-heilbaeder.de/karten/karte-bayern.html>).

It is obvious on the map, that the communication system is well developed, what supports development of local tourism. To give the customers facts for choosing the place they need/want to go, in German some institutions are evaluating cure clinic's and publish the results in different media.

There is a research institution, supported by the TU Berlin, called Minc (MINQ) (14) founded in 2010. It is independent and does surveys about the German cure clinics every year. The results are published not only in internet but also in a well-known magazine.

The German “Bäder- und Heilkundeverband” (15) (bath and medical science association), issues a quality label with four different focus. Gütesiegel des DHV.

DHV-Gütesiegel Die Kur®

- This label gives information about cure in general, what to expect, where to look for support, how to apply and so on. Three elements, earth, water and air, are the natural remedies of cures. Depending on the medical condition one of these or a combination of them can be chosen.

DHV-Gütesiegel Park im Kurort®

An important issue is the “Park im Kurort” label. As Catharine Ward Thompson said at the 5th Fabos conference in Budapest 2017 “the renewed interest in physical environment is now focused on identifying and understanding salutogenic environments (Antonovsky, 1979), that is, environments that support healthy behaviours and responses”. Presented surveys showed direct impact of green to the circumstances of life, people which are exposed to green environments are healthier than others, stress reduction included (ISBN 978-963-269-549-5, Landscapes and Greenways of Resilience, Catharine Ward Thompson: Greenways to health: the links between access to green space and healthy communities). Perhaps green surroundings enhance and speed up the rehabilitation of the cure-taking people.

- DHV-Gütesiegel Prävention im Kurort®
- This label shall give orientation mostly to private clients of cure houses. Their focus is the prevention of sickness, to enable people to live a healthier life. It combines three factors of exercise, nutrition and relaxation supplemented by communication and empowerment

- DHV-Gütesiegel Wellness im Kurort®
- Relax and enjoy is the motto for this label. In combination with the surrounding landscape and a cultural program it fosters a well-being of the client.

All of them stand for quality enhancement in a different field. Futur clients , patienten and doctors alike, can use this labels to find the place which fits their needs the most.

CONCLUSION

Cures are paying of after all because people are healthier, resilient and appreciated after a cure.

(For example, Siemens is financing to their employees health cures of 22 days at regular time intervals so that desease rate remains low. (<http://www.tagesspiegel.de/wirtschaft/karriere/kuren-wer-sie-bekommt-was-sie-bringen-urlaub-vom-job/1225054.html>). In return, they must spend 9 days of their annual leave. This is a Win-Win situation.

2.5 HUNGARY EXAMPLES

Hungarian Examples of thermal baths cluster, their management system and state policy, the huge and rapid development of Hungarian thermal spa facilities are positive example for Georgia, how the Health-care tourism industry became the major branch in the country. Examples of Hungary can be applied for Georgian health-care tourism cluster planning as well.

In Hungary green routes are strongly developed. This strengthens medical tourism branch. The baths are located in urban and rural spaces as well. Famous baths are also located in capital city Budapest. The Hungarian Health-care cluster is strong, because thermal potential is investigated and appropriated infrastructure is developed and arranged. In Georgia we have unique mineral and thermal water potential which is underused.

Nature has generously endowed Hungary thermal water. Due to the geographical location of the country's thermal springs are covering 80% of its territory. Altogether there are fifteen hundred sources and 450 thermal baths.

„Hungary has enormous natural potentials that could be beneficially exploited by health tourism. We have extraordinary and unique thermal water reserves, the amount of which places us among the first 5 countries with the greatest thermal water supplies“ (dr. Judit Visi, Geography of Health, (2013).

Figure 7. Composition of Georgian, German and Hungary resort landscapes.

3 CONCLUSION AND RECOMMENDATIONS

Strengthening Medical tourism seems to be one of the best ways for the sustainable development of South Georgian resorts. Due to the main objective of this article, improvement of health-care cluster in Georgia is possible using mentioned examples.

The main principle of resort planning is to insert healthcare facilities into the green spaces, with careful integration of green areas and buildings, with attention to cultural heritage buildings. Due to the above mentioned examples, spatial planning, appropriated communication system development is a future of regional planning of Healthcare clusters.

- Medical tourism should become the key issue for the regional development strategy.
- South Georgian health-care tourism cluster should be determined and strengthened.
- Existing resorts like Borjomi, Akhaltsikhe, Abastumani should be developed to green, smart, well managed cities; and resort places with unused potential should be involved.
- Good foreign examples of famous spas like German, Hungarian and similar should be used, which includes not only healthcare facilities and resort planning principles, but spatial planning issues with its communication systems, the full complexity of urban planning factors.
- Programs, Plans and Projects should be developed.

ID 1690 | EXAMINING THE POTENTIAL IMPACTS OF 2017 EUROPEAN YOUTH OLYMPIC WINTER FESTIVAL (EYOWF) IN ERZURUM, TURKEY

Tuna Batuhan¹
¹Ataturk University
tunabatuhan@gmail.com

ABSTRACT: This paper examines the perception of international visitors and athletes of 2017 European Youth Olympic Winter Festival (EYOWF), which will be held in Erzurum-Turkey. EYOF is one of the top multisport events for young European athletes where they have their first Olympic experience. As a relatively new concept, the EYOFs are organized in two-year cycles as summer and winter editions. Even though EYOF bears in general ambience of Olympic, it is far smaller in size than Olympic Games from many perspectives and its effects are more limited for the host city. However, for the host cities, EYOF can still serve as a serious organizational experience and as a reference point for hosting similar events. EYOWF is a new concept for Olympic tradition and this paper discusses the potential impacts of EYOWF 2017 in Erzurum, Turkey case. Turkey is awarded both the winter and summer EYOFs. First, Trabzon hosted the 2011 Summer EYOF and then with the positive legacy of the 2011 Winter Universiade, Erzurum is selected as the host city for the 2017 EYOWF. The 13th edition of Winter EYOF will be held in Erzurum from 11 February to 18 February 2017. Approximately 1,500 young athletes from 45 European countries will compete in different sporting events. EYOWF 2017 will also attract thousands of spectators, journalists, and volunteers along with the athletes, coaches and staff members. EYOWF is not just a sporting event, but also an important event with a potential to leave significant legacies to the host city. EYOWF is a unique opportunity for Erzurum to increase the recognition of the city as a winter sport center and to leave significant legacies to the city. A successful staging of EYOWF will serve as a catalyst to activate the potential of Erzurum, especially reinforcing city image, promoting and branding Erzurum as a winter sport destination, attracting more tourists and encouraging them to stay for a longer time, and increasing local economic activities. EYOWF will also bring out the winter potential of the city with a positive impact on other alternative types of tourism, and will open other doors for Erzurum. In this sense, this paper seeks to discover; the perceptions of international visitors and athletes towards EYOWF 2017 Organization and towards the city of Erzurum; to discuss the impacts of EYOWF on Erzurum; to examine the success of EYOWF planning process; and to identify potential issue areas from the visitors' and athletes' point of view. In this paper, the data will be gathered from personal observations, primary and secondary resources, and surveys, which will be conducted on EYOWF sites in order to identify the perceptions of international visitors and athletes as well as to examine the tangible and intangible benefits of EYOWF for Erzurum. The survey form includes several items including the questions dealing with EYOWF planning, transport to the EYOWF site, accommodations, security, variety of activities, Erzurum city image and infrastructure. Although EYOWF is a new concept for Olympic tradition, it is still one of the sporting events with a potential to impact the host city in several aspects in both short and long term. The impacts of EYOWF on host cities have largely remained understudied. This study represents an initial attempt to explore the potential benefits and possible impacts of relatively less studied EYOWF on Erzurum city case and this study hopefully will lead to new studies and projects in this area.

KEYWORDS: European Youth Olympic Winter Festival, Erzurum, sporting event organization, event planning, winter sports, event legacy

1 INTRODUCTION

This paper examines the potential impacts of EYOWF -which is one of the prestigious sporting events-for Erzurum, Turkey. EYOWF is a far smaller event in size than other international sporting events such as Winter Olympic Games from many perspectives and the potential impacts of EYOWF are relatively more limited for the host city. However, EYOWF still can serve as a serious organizational experience for the host city and as a reference point for hosting similar events in the future. Within this respect, in this study: first, a brief history of both winter and summer editions of EYOF is provided; second, Erzurum's experience on organizing sporting events is examined; and finally, the potential impacts of EYOWF 2017 for Erzurum is discussed along with suggestions to increase the positive effects of the event for the city.

2 EYOF AT A GLANCE

EYOF is one of the top multisport events for young European athletes between the ages of 14 and 18 across Europe and more than 3,000 participants take part in the summer edition and more than 1,000 participants take part in the winter edition of the festival (EOC website). EYOF is an important stage where young European athletes have their first Olympic experience. EYOF is relatively a new concept for Olympic tradition. The EYOFs are organized in two-year cycles as summer and winter editions on behalf of the European Olympic Committees (EOC) under the patronage of the IOC (EOC website). The idea of organizing EYOF was first proposed by Jacques Rogge, the President of the European Olympic Committees (EOC) at that time and the first edition of EYOF was held in Brussels, Belgium in Summer 1991 (Lucidarme ve Maes, 2009). The first winter edition of EYOF was held in Aosta, Italy in 1993 and it has been growing since then. Several European cities hosted EYOF and Table 1 shows the list of the host cities of both summer and winter EYOFs up to this point.

Turkey is also awarded both the winter and summer EYOFs. First, Trabzon -a city on the Black Sea coast of northeastern Turkey- hosted the 2011 Summer EYOF and then Erzurum - a winter city in eastern Turkey- is awarded to host the 2017 Winter EYOF. 2017 Winter EYOF had initially been planned for Sarajevo and East Sarajevo, Bosnia and Herzegovina and EYOWF 2019 was awarded to Erzurum at the 43rd General Assembly of the European Olympic Committees (EOC) on the 21st of November 2014 in Baku. However, Sarajevo had some difficulties to get ready in time for the EYOWF 2017, while Erzurum already had the facilities in place after hosting the 2011 Winter Universiade and was ready to host the events two years earlier than originally planned (Mackay, 2015). Erzurum agreed to swap with Sarajevo to host the EYOWF 2017 and the agreement between the two city officials was officially signed at the 2015 General Assembly in Prague (Mackay, 2015).

YEAR	Summer EYOF	Winter EYOF
1991	Brussels (Belgium)	-
1993	Valkenswaard (Netherlands)	Aosta (Italy)
1995	Bath (Great Britain)	Andorra la Vella (Andorra)
1997	Lisbon (Portugal)	Sundsvall (Sweden)
1999	Esbjerg (Denmark)	Poprad (Slovakia)
2001	Murcia (Spain)	Vuokatti (Finland)
2003	Paris (France)	Bled (Slovenia)
2005	Lignano Sabbiadoro (Italy)	Monthey (Switzerland)
2007	Belgrade (Serbia)	Jaca (Spain)
2009	Tampere (Finland)	Szczyrk (Poland)
2011	Trabzon (Turkey)	Liberec (Czech Republic)
2013	Utrecht (Netherlands)	Brasov (Romania)
2015	Tbilisi (Georgia)	Vorarlberg/Liechtenstein (Austria/Liechtenstein)
2017	Győr (Hungary)	Erzurum (Turkey)
2019	Minsk, Belarus	Sarajevo & East Sarajevo, Bosnia and Herzegovina

3 ERZURUM AND SPORTING EVENTS

Erzurum is located in the eastern part of Turkey with a population of 367,250 in the 2010 census. The city is situated 1757 meters above sea level with the Palandoken Mountain in its background. Erzurum has huge potential for tourism development with its climate, cultural and historical amenities. However, Erzurum is not able to attract significant amount of local and foreign tourists mainly because the city is not well known as a winter sports center. Erzurum has substantial experience on organizing sporting events. For those events hosted in the past, the central government played an active role and heavily involved with

the event planning process along with the support from different local governments, business sector, and the public. The investments on winter sports facilities have increased along with the interest on winter sports. International Palandoken Cup as the first international winter sports organization has been organized since then. Additionally, Alpine Skiing Turkey Championship was organized in Erzurum four times. Finally, Erzurum organized the biggest sporting event in its history: 2011 Winter Universiade. For such a huge organization, when considered the size of the city, public investment reached maximum in the history of the city in order to complete proposed facilities to be used during the Games. As the result of such a big organization, the city was provided chances to renovate city stadium and other sportive facilities, own modern winter sports venues from ski jumping towers to biathlon fields.

At present, Erzurum has the highest preparedness level for large extended or international organizations due to completed infrastructure among other Turkish cities. With the positive legacy of the 2011 Winter Universiade, Erzurum selected as the host city for the 2017 EYOWF. The EYOWF requires serious planning and organization skills and the event has potential impacts and provides several opportunities for the host cities, even though the event is far smaller than the Winter Olympic Games in terms of their size and scope. In this respect, the potential benefits and opportunities provided by the EYOWF along with suggestions to increase the positive effects of the event for Erzurum will be discussed in the next section.

4 POTENTIAL IMPACTS OF EYOWF FOR ERZURUM

The 13th edition of Winter EYOF will be held in Erzurum from 11 February to 18 February 2017. Approximately 1,500 young athletes from 45 European countries will compete in nine different sporting events. The programme of the EYOWF 2017 consists of nine sports including Alpine skiing, biathlon, cross-country skiing, curling, figure skating, ice hockey, short-track, ski jumping, and snowboarding (EOC Website). EYOWF 2017 will also attract thousands of spectators, journalists, and volunteers along with the athletes, coaches and staff members. EYOWF is not just a sporting event, but also an important event with the potential to leave significant legacies to the host city and the success of the event will be an important reference point for the host city to be able to plan and organize similar sporting-events that are likely to be staged in the future.

Major sporting events have both tangible and intangible legacies on host cities. Tangible legacies are the improvements on infrastructure, new sporting venues and other investments, while intangible legacies include the changes on organizational and administrative skills, community spirit, socio-cultural impacts, increased recognition, promotion of the host city, and sports participation. EYOWF is one of major prestigious sporting-events with a potential to benefit the host city in both short-and long-terms. For Erzurum, EYOWF is an important prestige element and also an important international practice for the city to test its sporting-event organizational skills. Staging the event without any major problems is crucial for Erzurum to increase the positive impacts of the event for the city. Through the potential of EYOWF, recognition of Erzurum will dramatically increase, and with the EYOWF experience Erzurum is likely to come into prominence and become an important winter sport center. EYOWF is also expected to bring some benefits to Erzurum, especially reinforcing city image, promoting and branding Erzurum as a winter sport destination, attracting more tourists and encouraging them to stay for a longer time, and increasing local economic activities. However, the host cities should start promoting the event and the city years before the event with a carefully and thoroughly planned vision in order to increase the impact of these intangible legacies.

Long-term tangible benefits of EYOWF will be limited since Erzurum is not investing on infrastructural improvements for EYOWF. Erzurum already has the facilities in place to successfully host EYOWF in 2017 and the city is not likely to make more investments to increase tangible legacies of the events. Sporting benefits of EYOWF to Erzurum will be very limited as well, since winter sports culture is weak in the city and it does not reach to locals for some reason. As a result of this fact, EYOWF will not result in increased participation to winter sport organizations or strengthened winter sport organizations in Erzurum. In this respect, it is more critical for Erzurum to invest on intangible legacies of EYOWF for the city. Erzurum has the dream of hosting the Winter Olympics some day in the future and EYOWF 2017 is a great opportunity for Erzurum to show the world that the city has the capacity and skills to host those types of major sporting events. EYOWF is also a good chance for Erzurum to increase the recognition and reputation of the city as a winter sport center.

EYOWF is not a big organization to leave dramatic tangible or intangible legacies on host city, but it can still serve as a reference point for potential future organizations. A successful staging of EYOWF will bring out the winter potential of Erzurum and this will have positive impact on other alternative types of tourism such as ecotourism, cultural tourism, health/medical tourism etc. Spreading the touristic activities year-round will increase the economic and social-cultural activities, thus EYOWF will serve as a catalyst to activate the potential of Erzurum. EYOWF will add value to the city's identity and brand building. However, lack of information and advertisement concerning the EYOWF 2017 and Erzurum itself on Internet and on other sources makes it even harder to approach the targeted tourists. As of now, no website is dedicated to the EYOWF 2017 to provide information about the event itself and details about Erzurum. Someone interested in coming to Erzurum for EYOWF will not be able access any information regarding the details of EYOWF 2017 program (competition sports and how to access to each competition) or information about Erzurum as a touristic destination (transportation, accommodation, activities to do etc.). For the summer edition of EYOF 2017, Győr (Hungary) created a website with detailed information about the event and the city both in English and Hungarian (EYOF 2017, Győr Website) and Erzurum needs to create a similar website for EYOWF 2017 as soon as possible.

EYOWF might also lead to a change on planning perspectives in terms of the projects proposed and built, which has the potential to change the perception for the future of the city. Future policies might prioritize improving the infrastructural capacity in order to promote tourism and finally create a strong economic base for Erzurum. With the catalyst impact of EYOWF, Erzurum might promote the local winter sports industry and achieve the goal of establishing an international winter sports center. Accordingly, the increased tourism potential will affect the way of thinking about the importance of tourism and will shape the future of Erzurum city as an attractive international touristic destination.

EYOWF will have more intangible legacies than tangible legacies on Erzurum and the strategies should focus on increasing the intangible legacies such as organizational and administrative skills, socio-cultural impacts, increased recognition, and promotion of Erzurum. A successful staging of EYOWF in Erzurum will open other doors for the city and the dream of hosting other important sporting events like Winter Olympics will come true in the near future. The future of the city and the dream of hosting other sporting events should be melted in the same pot with a holistic planning strategy. EYOWF is also another important turning point for Erzurum to integrate and spread other touristic activities year-round in the same holistic planning approach. Staging the EYOWF 2017 successfully will also increase the recognition of Erzurum and help promoting the city as an alternative, attractive winter sport center.

Erzurum has considerable winter-sport-event organizational experience and hosting EYOWF 2017 in Erzurum provides substantial hopes and opportunities for the city. EYOWF 2017 organizing committee should think seriously, carefully and holistically in order to get the most out of the event. The committee's way of analyzing the EYOWF preparation and planning processes should be a comprehensive approach, which entails a goal-oriented view and long-term vision of using the resources to show how a successful event can be blended with the long-term needs of Erzurum. In addition to the organizing committee's effort, other stakeholders' involvement and participation in the planning and organizing phases of EYOFW will increase the success level of the event. Additionally, transfer of knowledge is also a critical mechanism to benefit from earlier host cities' experiences to increase the success of staging the EYOWF.

5 CONCLUSION

EYOF is one of the top multisport events for young European athletes where they have their first Olympic experience. As a relatively a new concept, the EYOFs are organized in two-year cycles as summer and winter editions. Even though EYOWF bears in general ambience of Olympic, it is far smaller in size than Winter Olympic Games from many perspectives and its effects are more limited for the host city. However, for the host cities, EYOWF can serve as a serious organizational experience and as a reference point for hosting similar events in the future. Turkey is also awarded both the winter and summer EYOFs. First, Trabzon hosted the 2011 Summer EYOF and then with the positive legacy of the 2011 Winter Universiade, Erzurum is selected as the host city for the 2017 EYOWF. For Erzurum, EYOWF is an important prestige element and also an important international practice for the city to test its sporting-event organizational skills. The success of the event will be an important reference point for Erzurum to be able to plan and organize similar sporting-events that are likely to be staged in the future.

EYOWF is not just a sporting event, but also a good opportunity for Erzurum to increase the recognition of the city as a winter sport center as well as to leave significant legacies to the city. EYOWF is also expected to bring some benefits to Erzurum, especially reinforcing city image, promoting and branding Erzurum as a winter sport destination, attracting more tourists and encouraging them to stay for a longer time, and increasing local economic activities. Erzurum already has the facilities in place to successfully host EYOWF in 2017 and the city is not likely to make more investments to increase tangible legacies of the events. Sporting benefits of EYOWF to Erzurum will be very limited as well, since winter sports culture is weak in the city and it does not reach to locals for some reason. In this respect, it is more critical for Erzurum to invest on intangible legacies of EYOWF for the city and the strategies should focus on increasing the intangible legacies. A successful staging of EYOWF will serve as a catalyst to activate the potential of Erzurum, will bring out the winter potential of the city with a positive impact on other alternative types of tourism, and hopefully will open other doors for Erzurum.

EYOWF is a new concept for Olympic tradition and the impact of EYOWF on host cities has largely remained understudied. This study represents an initial attempt to explore the potential benefits and possible impacts of relatively less studied EYOWF on Erzurum case. Further studies in this subject area should focus on comparative cases to see the positive and negative legacies of EYOWFs on different host cities for short-and long-terms.

1 INTRODUCTION

The emerging sharing economy is an extremely interesting phenomenon in the context of major cities, impacting them on several dimensions, ranging from social to economic, from cultural to environmental. "The sharing economy is an emerging economic-technological phenomenon that is fueled by developments in information and communications technology (ICT), growing consumer awareness, proliferation of collaborative web communities as well as social commerce/sharing" (Botsman & Rogers, 2010), (Kaplan & Haenlein, 2010), (Wang & Zhang, 2012), (Hamari et al., 2015). The concept of sharing economy is very simple: it allows to rent out anything that is under-utilized or not used at all. The contact between supplier and customer is established through an online platform. Sharing economy platforms, in the last few years, have become very popular and changed our consumption patterns (Quattrone et al., 2016). On the one side, suppliers can short-term rent their goods (or services); on the other side, consumers can rent goods or services at a lower cost than a traditional provider (Zervas and Proserpio,

2014). Airbnb, a peer-to-peer accommodation website, is one of the most successful sharing economy platforms. Airbnb is a platform where people can offer for short term, discover and book houses all over the world, from a pc or smartphones and tablets. The company was founded in 2008 and by now (May 2017) it lists over 3 million properties in over 191 countries, over 65.000 cities, accommodating 150 millions of guests. Spaces rented on Airbnb vary from a couch in someone's living room to an entire island (Wortham, 2011), but generally there are few typologies of accommodation: private or shared room and entire houses. The host may live in the property at the time of the rental or not. Airbnb claims that 57% of listings are entire apartments or homes, 41% are private rooms and 2% are shared rooms (Guttentag, 2015). Airbnb has been adopted on a massive scale worldwide and also in Italy: in 2015 the country had the third largest number of Airbnb listings in the world, with 83.000 hosts and 3.6 millions of visits per year, according to data published by Airbnb Italia. A press event in Rome (2016) saw the participation of the Italian minister of Culture who spoke with great enthusiasm of the affordances of the platform and the great benefits that it supposedly brings to urban economy. Nevertheless, in typical Italian fashion, there has been very little debate over the long term consequences of a relatively new phenomenon, especially one associated with novelty, entrepreneurialism and "new" technologies, and the only intervention that the government has deemed necessary has been that of imposing a tax on homes rented through the platform. However questions about the impact of an upsurge of short term rentals ('STR' onwards) over the delicate environment of Italian historical urban centres, as an example, have hardly been asked. Italians also seem to be ignoring the controversy that Airbnb's fast rise has generated around the world, with accusations of driving up rents, depleting the residential housing market and, as is the case in Barcelona, turning entire neighbourhoods into 24h party zones, to the bewilderment of residents. Currently, in Florence and Venice just like in Barcelona, the risk to turn the historic centres into "cathedrals of consumption" where what had been grown naturally is replaced with a superficial and tourist-oriented veneer (Thani and Heenan, 2016) – is a very present one. The consequence of this process might be, at best, the loss of authenticity of such places (Zukin, 2009). In this context, the present contribution provides a more in-depth insight on the mechanics of Airbnb in Italy, focusing on two dimensions of the phenomenon, related to (1) the spatial distribution of STRs; (2) the economic impact of Airbnb on city centres and residential rents. After a brief recollection of the academic production on Airbnb (section 2), we describe our data and method of analysis (section 3); in Section 4 we present the spatial patterns of Airbnb supply and demand across 13 towns and cities in Italy, focusing on three archetypical patterns; we then hypothesize on the possible drivers of the Airbnb offer and suggest a possible way to assess whether Airbnb supply could be driven by an economic advantage of STR over long term letting (Section 5). In Section 6 we discuss the way the benefits of the sharing economy are... shared. Finally, we conclude by presenting a possible alternative way of regulating Airbnb.

2 RELATED WORK

While the topic of the sharing economy in general is widely analysed, the phenomenon of Airbnb in particular, despite having arisen interest in recent times, hasn't been investigating so much. It has been noted that legal issues are the most examined, for example Quattrone et al. (2016) focus on the regulation of Airbnb. They claim that the platform is either completely allowed or totally banned by municipalities, underlining the lack of regulations in any case. The authors suggest possible innovative policies that the city of London could implement, based on a stringent analysis of spatial and economic patterns of accommodation supply and demand. Similar focus is provided by Lee (2016) who employs legal and statistical analysis to explore how short term rental affects the price and the supply of housing rental in Los Angeles, and how municipalities and policy makers could regulate the phenomenon. Furthermore Guttentag (2016) examines the rise of Airbnb through the lens of disruptive innovation theory and investigates, again, certain regulatory issues related to Airbnb, considering the current tax flow and possible interventions. He also analyses the potential of Airbnb to disrupt the residential accommodation sector, and the impacts -both positive and negative -that Airbnb may have on cities. McNamara (2015) examined the same topic: she first analyses the development of the community marketplace and the perception of Airbnb within society, afterwards she concentrates on regulatory issues that Airbnb arises, how proponents and critics react to them, and advances some proposals to regulate the platform. A different outlook is provided by Edelman et al. (2014). They examine a diverse aspect of Airbnb, racial discrimination among landlords. The authors confronted a large dataset of pictures of all New York City hosts on Airbnb with the corresponding prices and user feedback. They found out that non-black hosts are

able to charge about 12% more than black ones for comparable properties, highlighting the existence of a form of racial discrimination in online marketplaces.

In the context of hospitality Zervas et al. (2015) focused on Airbnb as a touristic phenomenon. They analysed the ratings of over 600.000 properties listed on Airbnb worldwide and compared them with the ratings of about half a million hotels listed on Tripadvisor. Ikkala et al. (2015) explore Airbnb presenting a qualitative study of hospitality. They consider the motivation of hosts to monetize network hospitality. They found out that hosts are motivated to monetize network hospitality both for economic advantage and social interaction. The authors discuss the implications of their findings on the fields of social network analysis and sharing economy. Another study on hospitality (Zervas et al., 2014) focuses on the hospitality industry in the state of Texas, and tries to identify the impact of Airbnb on such industry. The authors collected all Airbnb listings in Texas and information on all Texas hotels to estimate the impact of Airbnb on hotel revenues. They found out that such impact is distributed unevenly across the industry, but generally lower-end hotels are those most affected. Finally, they simulated certain regulatory interventions, such as limiting Airbnb hosts to one single listing, and argued that this intervention alone would greatly reduce Airbnb's impact on hotel revenues. Yannopoulos et al. (2013) use a different approach, examining brand identity construction of user-generated brands (UGBs) through a visual analysis. They explore Airbnb and Couchsurfing to underline the peculiarities of identity construction and visual representation of UGBs. They found authenticity, access to the private sphere, a more human dimension, and meaningful inter-personal discourses, to be the distinctive features of UGBs. Dudas G., et al. (2017) use additional indicators (distance, attractiveness) and a 3-band raster layer visualisation method to map the spatiality of Airbnb in Budapest. Celata e. al. (2016) offer a comparative analysis of the main sharing platforms in the accommodation domain, looking at the relationship between trust, reciprocity and belonging across different sharing economy platforms. The rise of Airbnb has recently started generating some interest in the field of urban planning. Gurran and Phibbs (2017) looked at the impact of Airbnb in Australian cities and the implications for the local housing markets.

These works do an excellent job in defining diverse critical aspects of the phenomenon of Airbnb, some of them do also concentrate on the spatial distribution of the phenomenon and the economic impact of Airbnb. There have been no systematic investigations of the impact of Airbnb in Italy, we believe data from this platform can be extremely useful to explore dynamics related to the changes of Italian city centres.

3 METHODOLOGY AND DATA SOURCES

The data employed in this investigation were obtained scraping the Airbnb website at two different points in time in 2016 and 2017. We implemented a crawler¹ and collected all the listings existing on the website in the second weeks of February 2016 and February 2017 relative to 13 Italian cities (Bari, Bologna, Catania, Firenze, Genova, Matera, Milano, Napoli, Roma, Siena, Torino, Venezia, Verona). Specifically, for each property listed in the considered cities, we collected the data resumed in the table below.

Code	Description
uid	host id
ppn	price per night
bd	number of bedrooms
r2015	number of reviews posted in the year 2015
r2016	number of reviews posted in the year 2016
lat	latitude
lon	longitude

Table 1 - Data collected for each Airbnb listing

We estimated the gross revenues (R) generated in 2015 and 2016 by each listing according to the formula

¹ The crawler was based on code released online in 2014 by Tom Slee (<http://tomslee.com>) and Murray Cox (<http://insideairbnb.com>)

$Ry = (ry * 1.30) * ppn * 3$ (with $y=2015$ or 2016). We adjust the estimation assuming a 30% of stays without a corresponding review (as Airbnb itself maintains) and an average stay of three nights (following the approach of insideAirbnb.com). For entries listing an entire apartment/house we also estimated the size in square meters of the property offered according to the mapping in Table 2.

bd	0	1	2	3	4	5	>5
size in m2	35	50	65	80	95	120	180

Table 2 – Estimation of property size based on listed number of bedrooms

To the purpose of comparing the STR market with the regular long term rental market we obtained official data on average rental prices from the Italian Revenues Agency (Agenzia delle Entrate). The dataset made available to us includes the average monthly price paid per square metre in each “OMI Area” of the Country. OMI Areas are defined as areas with homogeneous market conditions, with larger cities generally being subdivided in at least 50 OMI. OMI Data allow us to compare revenues generated via STR with the revenues that the same property would generate if offered on the long-term market. We discuss our results in Section 5. Finally, data from the 2011 Census (ISTAT) were employed to account for resident population changes and number of individual dwellings existing in each census area of the cities considered (housing stock). In the following we try to analyse the dynamics of supply and demand of Airbnb accommodation. We consider the number of reviews that a property has received as the most immediate indicator of the demand for that property. Similarly, we group listings and the corresponding reviews geographically, to assess the areas in cities that are high and low in demand.

City	Population	Listings 2015	Entire Place 2015	%	Listings 2016	Entire Place 2016	%
Bari	320741	397	195	49	490	320	65
Bologna	382728	1095	587	54	2577	1690	63
Catania	313944	1055	570	54	1305	977	75

4 SPATIAL DYNAMICS OF SUPPLY AND DEMAND: THE AIRIFICATION OF HISTORICAL CENTRES

The three tables above (Tables 3,4,5) summarise the data that we gathered. Confronting year 2015 and 2016 some considerations can be drawn:

- The absolute majority of Airbnb listings consists of entire homes/apartments, over private and shared rooms. This is true for all the cities considered, regardless of size and number of listings (Table 1). • This trend seems to be reinforcing over the years, as more entire properties have been listed in 2016 than 2015: the proportion of entire homes over the total number of listings increases in all cities (Table 2).
- Within historical cores (Table 2) the trend is even more pronounced: the proportion of entire homes over the total number of listings is higher in the centres than elsewhere in all the cities considered. This proportion increased further between 2015 and 2016.
- The proportion of entire places listed in historical cores vs. the total number of entire places is decreasing in many cities. This signals that the Airbnb habit is spreading to areas of towns and cities other than historic centres (last two columns of Table 2).
- The proportion of the housing stock devoted to STR in historic centres is increasing and, in some places, has reached levels unseen in the world: 18% in Florence, 25% in Matera, 8% in the vast historical core of Rome (Table 3).

In most cities considered, the supply of Airbnb accommodation is concentrated in or around the historical cores. This is understandable, as most attractions in Italian cities are of historical and artistic nature, and tend to be concentrated in the centre. However, the scale of STR concentration in historic centres is, to the best of our knowledge, unmatched in the world. A 7% of all housing units in districts such as Venice Beach and Abbott-Kinney Boulevard in Los Angeles listed on Airbnb rose alarms among the local authorities¹. This number is almost doubled in places like Florence (18%), while in cities such as Rome and Venice Airbnb accounts for more than 8% of all housing units of their historic centres. A staggering one in four homes in the Sassi area, the historic core of Matera, Italian city of culture 2017, are offered on Airbnb. This particularly high number is very significant, especially in relation to a multi-decade old phenomenon that researchers have pointed out – the touristization and social desertification of Italian historical centres. Population has been lost, and city residents increasingly tend to perceive these areas with a certain detachment, as no longer belonging to their daily experience of the city (Rossi, 2003). This is a phenomenon that pre-dates Airbnb by far, but the availability of Airbnb data allows us to effectively visualize part of the dynamics at play. The three larger cities frequently recurring in the touristization discourse -Florence, Venice, Rome – all have a proportion of their centres’ housing stock on Airbnb above 8%. This figure could be considered a sort of canary value for the disneyfication of the centre. Cities

¹ <http://www.latimes.com/business/realstate/la-fi-airbnb-housing-market-20150311-story.html>

approaching it should seriously reflect on whether touristization and disneyfication are desirable conditions for their historical centre. However, the data show that not everywhere Airbnb accommodation is predominant towards the historical cores. On the contrary, the distribution of the Airbnb offer and demand is fairly variable among cities. Figures below show the distribution of offer and demand in Florence, Rome and Milan, exemplifying three recurring patterns.

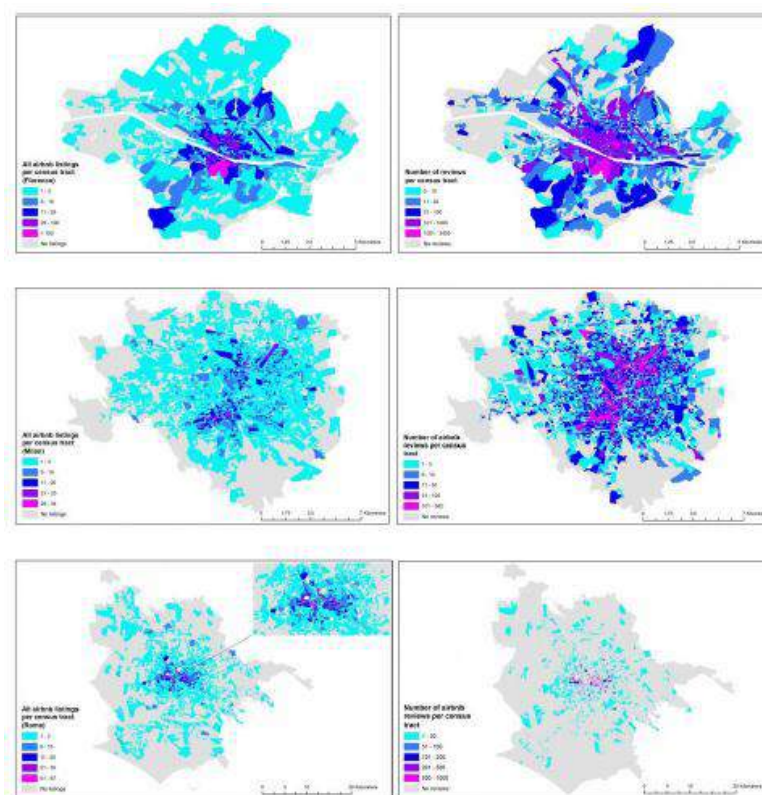

Fig. 1 – Distribution of offer (left) and demand (right) in Florence (top), Milan (middle), and Rome (2016).

Florence epitomizes the typical art city with an enormous concentration of the offer of STRs within the medieval walls of the historic centre, where 63.5% of the total listings are located (2016). As mentioned, 18% of entire housing stock of the city centre of Florence is listed on Airbnb (as entire homes) and the proportion has been increasing steadily over the last years. On the demand side, however, the figure shows that the listings outside of the historical centre are also capable of attracting a certain demand, likely thanks to the reduced prices, which we discuss further. In Florence (Fig.2) both offer and demand decay in parallel as a function of the distance from the town centre (identified with the location of the Town Hall); Milan displays an entirely different pattern, with a much more sprawling distribution of Airbnb properties. Here the STR phenomenon started outside of the historical centre: the fashionable districts of Isola and Navigli have been the areas with the highest concentration of Airbnb listings. In this regard Milan is more remindful of European capitals like London and Berlin, with recognizable and attractive districts outside of the centre. Despite an 88% increase in the offering of entire homes in 2016 vs. 2015, the old centre is still relatively blank compared to the neighbouring districts. Note how the historic centre of Milan is represented as a sort of depression in the Airbnbscapes diagram (Figure 3). Rome shows a pattern with elements of both Florence and Milan. In the Capital most of the offering is concentrated in the central Municipio I -which includes most of the great archaeological sites and the historic districts of Monti, Trastevere, Testaccio. Here the Airbnb offering of entire homes accounts for 8% of the entire housing stock, but Rome also shows hot spots outside of the centre: in proximity to the Vatican, in the student district of San Lorenzo, east of the central railway station, and in the residential district of San Giovanni, immediately to the south of the centre. An interesting trend that our data show is that, in the last couple of years, the phenomenon of renting out entire homes on Airbnb is extending far beyond historical centres. Between 2015 and 2016 the number of homes on offer outside of historical cores has increased faster than that within historical cores. In most cities this increase in offer seems to have met some demand: we plotted the variations in offer and demand between 2015 and 2016 within and without historical centres (Figure 4). While in cities like Rome and Naples the centre keeps being more attractive, producing a higher

number of new reviews for every home added, there are places, like Siena, where an increase in the offer of accommodation outside of the central core generates an increase in demand disproportionately higher.

Fig. 2 - Offer and demand decay. Florence, Milan, Rome (2016).

Fig 3. – Density of Airbnb listings (2016)

Fig. 4 - 2015-2016 variation in offer vs variation in demand of entire homes in centres and outside

5 DRIVERS OF AIRBNB SUPPLY

Critics of Airbnb often point out that the readily available opportunity of offering a property on the the STR market, often tax-free, has the extremely unpleasant side effect of depriving the long term rental market. A hotelization effect seems to be at play in several cities across the world (Lee, 2016). We asked ourselves whether our data would support such claim for the cities in our study. What are, in other words, the drivers of Airbnb provision? We obviously looked into tourism, but we also asked ourselves whether landlords offering their property on Airbnb and not on the long term rental market may be driven by economic considerations.

5.1 TOURISM

Fig. 5 – Tourist flows and Airbnb listings

The offer of Airbnb accommodation across the studied cities correlates almost perfectly (adjusted $r^2=0.95$) with tourist presence in the same cities. Tourist flows seems to be the best single predictor of the volume of Airbnb offering across cities.

5.2 ECONOMIC ADVANTAGE OVER LONG-TERM RENTAL

Fig. 6 – Airbnb index 2015 plotted against the 2015-2016 variation in the proportion of the housing stock listed on Airbnb (historic centres only). There is an almost perfect correlation, bar two outliers, Bari and Genoa.

Apart from the somewhat obvious relationship with tourist flows, we were interested in exploring whether the dynamics of the Airbnb offering could be explained in terms of the economic advantage that STR may enjoy over regular long term rental contracts. This is a crucial point, since the risk of tourist rentals depleting the housing market is a very realistic one, often very high in the agenda of local administrations across the world. To assess whether the provision of entire homes on Airbnb could be, at least partially, driven by the economic advantage over normal rent we estimated the revenue that each home listed on Airbnb would generate if offered on the regular long-term rental market. Such estimation was performed on the basis of rental market data described in Section 3. The ratio between Airbnb revenues (the estimated revenues of every entire home offered in a given area, pN) and the estimated long term rental revenues (RH -derived estimating the size of a property according to the mapping in Section 3) forms the basis of an "Airbnb index" that we produced. The index also includes a value proxying for the saturation of the offer and one for that of the demand: we considered the number of listings not receiving any review in the year (E) as a good indicator of the lack of demand in a certain area, whereas the density (r $2=0.95$) of listings per square km counts as an indicator pN of saturation in the offer. The resulting index $i = \frac{pN}{RH} \div E \div d$ is normalized in the 0-1 interval. Its correlation with the RH increase in the proportion of the housing stock of historical centres listed on Airbnb is shown in Figure 6. The correlation is quite high (although not as high as that with tourism), $r=0.73$, meaning that where the index relative to the previous year is higher, the increase in homes devoted to STR in the next period is also higher. Two strong outliers are there, Genoa and Bari. Without them the adjusted r jumps to 0.97, matching almost perfectly. This result leads us to believe that the factors considered -an economic advantage versus long term letting, the density of existing listings, and the existence of some demand in the previous period -are good predictors of the number of new listings that we can expect in a given area. Ideally, the index could also serve as a predictor of the possible evolution of the system. For next year we would expect a great increase in the proportion of the housing stock ending up on Airbnb in the centres of Genoa and Bari, since the conditions seem to be there for further expansion.

6 THE INEQUALITY OF AIRBNB

Somewhat contrarily to the rhetoric generally attached to the notion of "sharing", we found the Airbnb ecosystem to be a profoundly unequal one. In terms of income generated on the platform, the inequalities are twofold: an "inequality proper" between hosts, and a spatial inequality between centre and periphery of cities.

6.1 INCOME INEQUALITY BETWEEN HOSTS

Since its inception Airbnb has seen a profound change in the nature and demographic of participants. The original intended audience of young people renting out a spare room in their flats is long gone as the main income generator for the platform. As we have shown, as of today, entire flats make up, by a good margin, the majority of listings in all the cities considered. At the same time, among those who list entire homes for STR, hosts listing multiple properties seem to have increased substantially. We looked at how incomes from Airbnb are spread across the thousands of hosts that list entire homes on the website, suspecting that revenues wouldn't be shared in a particularly inclusive way between participants.

Table 6 shows the inequality of the distribution of Airbnb revenues for the 13 cities considered, in the form of the Gini index, a commonly used measure of inequality. Figure 7 plots the distribution of Airbnb revenues among hosts in four of the considered cities. Inequality is extremely high in all the cities, and has increased between 2015 and 2016 in ten of the thirteen cities examined. In most cities a handful of operators listing several properties are capable of amassing more than two thirds of the total revenues generated on the website. To what extent this phenomenon is due to businesses operating as agencies listing third-party properties for STR should probably be the subject of further investigation. However, for comparison, we note that the inequality (Gini) index of Airbnb revenues in all the cities considered – ranging from 51 in Genoa and Bari and 70 in Milan -exceeds of at least two times the nationwide Gini income inequality index (36). This suggests that the supposed benefits of the platforms are appropriated very disproportionately by a small number of users.

6.2 SPATIAL INCOME INEQUALITY

If revenues differ substantially among hosts, they also differ widely among different areas of the same city. The figure below shows how the average earnings from a property listed on Airbnb decays as the distance from the centre of town increases. This dynamic is consistent with that highlighted in other countries: Gibbs et al. (2017) note that each additional five kilometers away from City Hall were associated with price decreases ranging from 4.0% (Ottawa) to 20.7% (Montreal). Our analysis confirms the function of distance to centrality (we also measured distances from the City Hall) in the three cities observed. This confirms that a disproportionately high share of Airbnb earnings flows towards the central areas of cities.

City	Gini Idx 2015	Gini Idx 2016
Bari	52	51
Bologna	54	63
Catania	58	67
Firenze	65	66

Fig. 8 – Average Airbnb revenues by distance from the centre of town in Florence, Milan and Rome. Note how earnings in the centre are substantially higher than elsewhere.

7 CONCLUSIONS: REGULATING SHORT TERM RENTALS

As other “sharing economy” platforms such as Uber, Airbnb has spread unchecked and unregulated for almost ten years. Protests and criticism arose around the world, especially on the part of residents and businesses in the hospitality industry, the latter accusing Airbnb of unfair competition. The Italian Government has ignored the matter for most of the decade, deciding to intervene and “regulate” online accommodation platforms only in 2017, when Italy had already become the country with the second highest number of Airbnb listing in the world. A flat rate tax of 21%, operational from 1 June 2017, was introduced on all rentals of less than 30 days. It is interesting that, in the view of Italian policymakers, the need to regulate a phenomenon often instinctively translates into the mere taxing of that phenomenon; more often than not, with a flat-rate tax. What outcomes is a 21% flat-rate tax going to have on a phenomenon that we have shown to be extremely complex and unequal? In our view, it is safe to assume that hosts in the long tail – the many collecting a very small share of Airbnb revenues – will be disproportionately affected. The same is true of hosts listing properties outside of the very profitable historic centres. The risk of such taxation, then, is, on the one hand, of favouring the growing hotelization of historic centres, where the profitability of staying on Airbnb would persist, even after the tax. On the other hand, it could further increase inequality, because many small hosts with only one listing could withdraw from the platform, not finding it advantageous enough to stay. The net result would be an even more unequal system, with an even higher concentration of the offer towards the delicate and already

compromised environment of the historic centres. We believe that a less short sighted intervention could have exploited the opportunities offered by Airbnb to the benefit of local economies, instead of simply penalising those that participate. Quattrone et al. (2016), for instance, suggest a dynamic, data-driven attribution of “sharing rights” to hosts, based on the saturation of different areas of a city. In section 5 we showed that the offer of Airbnb accommodation, to a certain extent, generates its own demand. A city administration, therefore, could decide to encourage the provision of Airbnb accommodation in areas less popular and saturated – with a different tax regime, or with variable restrictions in licensing -driving tourists to those areas, thus benefiting local neighbourhood economies, instead of overcrowding the “usual suspect” areas: historic centres.

T13 | MOBILITY POLICIES, TRANSPORT REGULATION AND URBAN PLANNING

CO-CHAIRS: ENRICA PAPA; XAVIER DESJARDINS; FERNANDO NUNES DA SILVA

Human rights movement theorised that the concept of dignity could be used as a lens through which to explore the relationship the well-being status of individuals and communities and the human rights achievements or failures of the societies in which they live.

This session track aims at applying this rights-based approach, directed to protecting human rights, to the transport field. Its elements include participation, accountability, non-discrimination, empowerment and linkage to the European and international standards. Nowadays, transport systems and urban structures play an even greater role in providing accessibility to opportunities like public services, social facilities and jobs. So, this session track focuses on the role of accessibility planning, transport equity and justice to contribute to the creation of 'spaces for dialogue for places of dignity'.

The track will also accept paper of the following topics: governance and decision-making processes in transport planning and policy, cultural and social issues in transport, national, regional and local transport planning and policy, the role of new technology in transport, sustainable accessibility planning, land use and transport planning and policy, active transport, transport justice, complexity and mega-projects, transition studies for mobility.

ID 1307 | EVALUATING JOB ACCESSIBILITY FOR DIFFERENT TYPES OF TRANSIT ORIENTED DEVELOPMENT AREAS IN BEIJING

Guowei Lyu¹; Luca Bertolini¹; Karin Pfeffer¹

¹University of Amsterdam, Department of Geography, Planning and International Development Studies
g.lyu@uva.nl ; l.bertolini@uva.nl ; k.pfeffer@uva.nl

1 INTRODUCTION

Growing levels of urban mobility provide many noticeable benefits, but they also produce negative effects on the environment and society, such as higher energy consumption, CO₂ emissions, air pollution, traffic noise, and reduced traffic safety (Bertolini and Le Clercq, 2003; Banister, 2005; Ferreira et al., 2012). In order to find a better balance between the benefits and costs of urban mobility, a shift from mobility-based to accessibility-based transport and land use planning has been advocated (e.g., Cervero, 1996; Levine and Garb, 2002; Bertolini and Le Clercq, 2003; Bertolini et al., 2005; Curtis and Scheurer, 2010; Bos and Lee, 2012; Levine et al., 2012; Papa et al., 2014; Martens, 2016; Levine et al., 2017). Accessibility-based strategies focus more on people's direct demand for participation in activities (e.g., housing, working/schooling, shopping, visiting people/places, entertainment etc.), in contrast to the focus on derived travel demand that mobility-based strategies mostly focus on. Among several accessibility-based strategies, Transit Oriented Development (TOD) aims to fulfil people's need to participate in activities by concentrating relatively high-density, mixed-use, cycling- and pedestrian-friendly development in transit station areas (Bertolini and Spit, 1998; Cervero, 1998, 2004; Curtis et al., 2009). Under favourable conditions, TOD can deliver multiple benefits, such as providing access to diverse activities, creating liveable or attractive places, helping renovate the built environment, and mitigating urban sprawl. In order to measure the actual effects, it is particularly crucial to assess accessibility for TOD. This is because many expected impacts of TOD, for example, reduced passenger transport costs (Litman, 2007), reduced CO₂, air pollution emissions, and energy consumption (Kimball et al. 2013; Nahlik and Chester, 2014), and increased land/property values (Cervero and Murakami, 2009; Duncan, 2011) – are closely associated with the enhancement of accessibility, as accessibility significantly shapes these impacts by influencing individual travel behaviour (Kockelman, 1997) and business' decisions (De Bok and Sanders, 2005; De Bok and Van Oort, 2011). Recently, the assessment of accessibility with respect to TOD strategies has generated considerable interest in academic and professional circles (e.g., Papa et al., 2013; Papa and Bertolini, 2015; Qviström, 2015; Palmateer et al., 2016). Studies have also shown large differences in the application of TOD strategies, resulting in different TOD types, even within the same city (Atkinson-Palombo and Kuby, 2011; Kamruzzaman et al., 2014; Vale, 2015; Lyu et al., 2016). This means that deeper insights into the association between different types of TOD areas and accessibility are necessary. To our knowledge, this association has not been empirically measured yet.

The paper aims to address this gap by studying how various TOD types within the same city are related to accessibility. The main focus is accessibility to jobs, because this is closely related to key policy debates about the functioning of the

labour and housing markets, social equity, and personal emancipation (Kawabata and Shen, 2006; Matas et al., 2010; Zhao and Howden-Chapman, 2010; Reggiani et al., 2011). Moreover, access to jobs is one of the main inhabitant demands in cities, requiring adequate responses in transport and land use systems. The study presented in this paper addresses the following research questions: Does TOD deliver higher job accessibility? How does job accessibility differ across different TOD types? By answering these questions, we aim to provide insights that can help develop targeted strategies to improve job accessibility for the entire built-up area or for specific types of urban areas.

Beijing, China was selected as the case study for the following reasons. On the one hand, mobility-based strategies – e.g., road building (increasing road density in Beijing's urban districts, see Beijing transportation research centre, 2015), vehicle ownership number control (Zhao et al., 2014), and driving restriction (Viard and Fu, 2015) – have shown unable to fundamentally or effectively address Beijing's major urban problems, such as road congestion, long commuting times, high rates of traffic accidents, air pollution and traffic noise (Li and Tao, 2004; Anas et al., 2009; Beijing transportation research centre, 2015). On the other hand, accessibility-based strategies, in particular TOD strategies, have been proposed (or applied) to address Beijing's urban problems for many years. In Beijing's Urban Master Plan 2004–

2020, TOD strategies proposed commute corridors connecting Beijing's central area to the former satellite towns, now part of Beijing's continuous built-up area, and improving accessibility to meet inhabitants' housing and job needs (Beijing Municipal Government, 2003). Since then, TOD has been officially considered as one of the key policy tools to address Beijing's transport problems (Beijing municipal commission of transport, 2012; Beijing municipal commission of transport, 2016). Despite these policy initiatives, an assessment of job accessibility for different types of urban areas is yet to be conducted.

The paper is organised into five sections. Following the introduction, in Section 2, we develop a methodology to evaluate job accessibility for any given place in Beijing. Section 3 presents the result of the job accessibility assessment for different types of urban areas. Section 4 discusses some potential policy implications, while Section 5 draws conclusions, reflects on the limits of the study, and provides future research directions.

2 METHODOLOGY

2.1 INTRODUCTION OF THE CONTEXT

2.1.1 DIFFERENT TYPES OF URBAN AREAS IN BEIJING

Beijing Municipality is home to 21.5 million residents, with 86.4% urban population and 1,385.6 km² urban built-up surface (the main continuous urban areas) in 2014 (Beijing Municipal Statistics Bureau, 2015; Ministry of housing and urban-rural development, 2014). In 2014, the metro (18 lines, 268 stations and 527 km of tracks) served 10 million passengers each workday in 11 of Beijing's 16 districts (Beijing Mass Transit Railway Operation Corporation Limited, 2015; Beijing Infrastructure Investment Corporation Limited, 2015). Our research examines TOD areas around metro stops. Previous studies delineated TOD precincts according to geographical distances from the transit stop. Specifically, most European researchers (e.g., Bertolini, 1999; Reusser et al., 2008; Zemp et al., 2011; Vale, 2015) propose a 700 m Euclidian distance from the transit stop as the TOD precinct boundary, while most American studies use a range of ¼ mile (400 m) to ½ mile (800 m) (e.g., Atkinson-Palombo and Kuby, 2011; Austin et al., 2010; Schlossberg and Brown, 2004). Most TOD radii in European and American case studies are based on a 10-minute walking distance from the station (assuming walking as the main access and egress mode and 10 minutes as an acceptable walking time). In addition, some studies proposed that segments up to 1,500 m (Schütz, 1998) or half a mile (American Public Transportation Association, 2009) can include a secondary catchment area that might profit from the transit connection, substantiated by evidence that some walking trips to a transit node are generated in this secondary catchment area (see García-Palomares et al., 2013; El-Geneidy et al., 2014).

The study area in this paper was set as the entire built-up area of Beijing (the boundary uses Yang et al., 2013), and divided into 1,651 regular grid cells (1 km by 1 km). Given the modifiable areal unit problem (Openshaw, 1984), the choice of grid cells at this spatial scale may influence the results of the analysis. Our choice was made according to two main criteria: the size of the grid cell (1) can sufficiently distinguish between different types of urban areas to be investigated in this paper (compare definitions of area-types below) and (2) is around the average size of the original dataset (the economic census data at community level, also see Section 2.2.2). Moreover, grid cells are comparable spatial units. Next, based on the above-mentioned TOD studies, we identified cells whose centroids are less than 700 m Euclidian distance away from the centroids of metro stations as the TOD cells. Furthermore, we identified cells whose centroids are between 700 m and 1,500 m Euclidian distance from the centroids of metro stations as TOD secondary catchment (SC) cells. Beyond¹ 1,500 m, most studies record only a few walking trips to a transit node, thus we identified cells whose centroids are beyond 1,500 m distance from the centroids of metro stations as non-TOD cells. Based on this methodology, we identified 375 TOD, 548 secondary catchment, and 728 non-TOD grid cells. Furthermore, we also defined six types of TOD cells (TOD_C1 to TOD_C6) and their corresponding secondary catchment cells (SC_C1 to SC_C6) (Figure 1), based on the work of Lyu et al. (2016), who classified 268 metro station areas of Beijing into six types (C1 to C6) by means of a principal-component cluster analysis. Prior the further analysis, a validation of their TOD classification (Lyu et al.,

¹ Here a TOD area refers to a 700-meter buffer from the centroid of a metro station.

2016) was conducted using variance analysis (ANOVA) and Tukey's Honest Significant Differences (HSD) Test (Tukey, 1949). The result shows that their TOD clusters are highly distinguishable from each other.

2.1.2 SELECTION OF GRID CELLS FOR ANALYSIS

We selected 261 TOD cells (classified into six types) and 182 secondary catchment cells (classified into six types) for the analysis. The TOD cells were selected if the centroids of TOD areas¹ are located in such cells. Since some distances between the metro stations in Beijing's inner city are less than 700m, a few of the centroids of TOD areas are located in the same grid cells, resulting in a slightly smaller number (261) than number of metro stations (268). The secondary catchment cells were selected when the centroids of secondary catchment areas¹ were located in these cells. However, we only selected 182 secondary catchment (SC) cells for two reasons: (1) a few of the centroids of secondary catchment areas are located in the same grid cells; (2) a few of the centroids of secondary catchment areas are not located in secondary catchment cells². A selected TOD/SC cell was attributed the features (i.e. category C1 to C6 and TOD indicators scores³) of its closest⁴ metro station area. The locations of the selected cells and the numbers for their categories are presented in Figure 1. We also randomly selected 252 non-TOD cells (see Figure 1) to represent the entire population of non-TOD areas (728), calculated according to Formula 1 (Israel, 1992):

$$S = \frac{\frac{Z^2 pq}{e^2}}{1 + \frac{Z^2 pq}{N}} \quad (1)$$

S is the sample size; Z2 is the abscissa of the normal curve that cuts off an area α at the tails ($1 - \alpha$ equals the desired confidence level, in this case 1.962 for 95% confidence level); e is the desired level of precision (in this case $\pm 5\%$ precision); p is the estimated proportion of an attribute that is present in the population (we assume $p=0.5$, i.e. maximum variability); q is $1-p$; and N is the entire population (728).

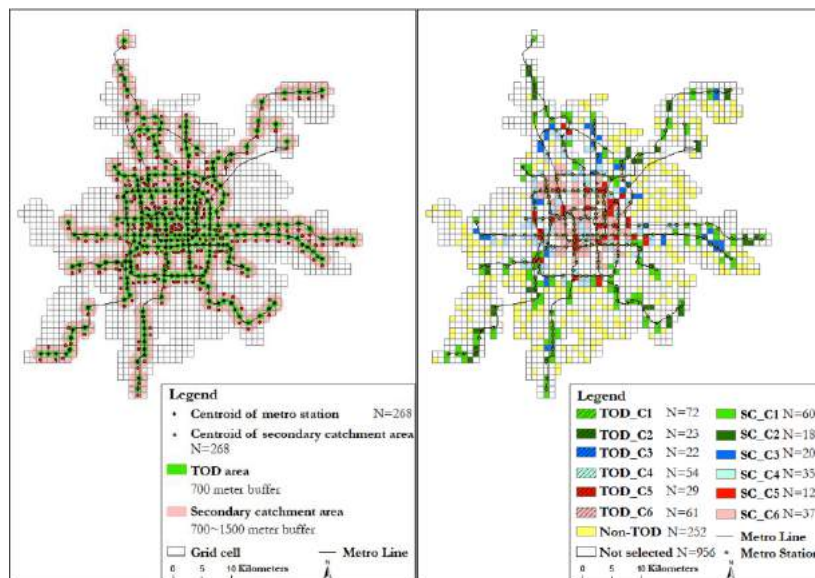

Figure 1 - TOD area and Secondary catchment area buffers (left) and selected cells of different types of urban areas for analysis (right) Based on: Lyu et al., 2016 and selection rules of this paper

¹ Here a secondary catchment area refers to a segment of 700- up to 1,500-meter buffer from the centroid of a metro station. The area has been cut out of the area that proximate TOD areas occupy. Its centroid is generated by the Feature to Point - a tool with an inside generation option in the ArcGIS 10.3.1 desktop platform. The output point was located inside of the polygon as its centre of gravity (centroid).

² See Figure 1 for the location of centroids of secondary catchment areas; some of them are located in the cells that have been identified as TOD cell in Section 2.1.1.

³ See the description in section 2.1.3

⁴ The distance is measured from the centroid of cell to the centroid of a metro station area.

2.1.3 TOD CHARACTERISTICS OF DIFFERENT TYPES OF TOD CELLS

Based on the work of Lyu et al. (2016) and the choices made in section 2.1.2, we summarised the TOD characteristics of different types of TOD cells, with 18 TOD indicators (see Table 1) used to cover 'Transit', 'Oriented' and 'Development' characteristics of urban areas. 'Transit' (T) indicators measured transportation features; 'Development' (D) indicators measured urban development features (e.g. land use density or diversity); and 'Oriented' (O) indicators drew attention to the functional and morphological interrelations between 'Transit' and 'Development' characteristics, focusing on relative proximity of residences and economic entities to the transit node and walkable urban design. All original TOD indicators were rescaled into the range of 0 to 1, with higher value means indicating a higher level of 'Transit', 'Oriented', and 'Development' features.

Of the six types of TOD cells, TOD_C2 cells, located in the periphery of the urban area (see Figure 1), show lowest values for the 'T', 'O', and 'D' aspects. TOD_C1 cells also have a peripheral location, but score higher on proximity to jobs and residences, functional density and diversity compared to TOD_C2. TOD_C4 cells are located at the periphery of the core urban districts; their TOD indicator scores are slightly lower than average, but the functional mix is at the highest level. TOD_C3 cells have similar 'T' characteristic to TOD_C4 cells, but higher 'O' dimension values (jobs and housing are located closer to the stations) and higher walking scores. The station areas in TOD_C5 cells and TOD_C6 cells are located at core urban districts and on the inner palm of the metro system. Although both score high on all TOD indicators, there are some notable differences. The 'O' values in TOD_C6 cells are highest among all clusters, suggesting that these areas are the most walkable and have the highest clustering of jobs and housing around stations.

TOD Characteristics	Indicators
Transit	T1 Number of directions served by Metro; T2 Number of directions served by bus; T5 Daily frequency of Metro services; T12 Number of stations within 20 minutes of travel by metro; T15 Travel times to major employment and activity centres by Metro; T19 Car parking capacity
Development	D1 Number of residents; D7 Number of establishments; D9 Number of establishments in retail, accommodation, and catering; D10 Number of establishments in education, health, and culture; D11 Number of establishments in public administration and services; D29 Degree of functional mix
Oriented	O1 Average distance from station to jobs; O2 Average distance from station to residents; O9 Length of paved footpaths per acre; O12 Intersection density; O14 Length of street network; O17 Walking scores

Table 1 - TOD indicators adapted from Lyu et al., 2016

2.2 METHOD OF MEASURING JOB ACCESSIBILITY

2.2.1 DEFINITION OF JOB ACCESSIBILITY

Job accessibility can be captured as the 'potential of job opportunities for interaction' (Hansen, 1959) or the 'ease of reaching workplaces' (Cervero, 1996). Based on these definitions, we define job accessibility as the potential job opportunities that can be reached from a given place, by travelling a certain time by means of a certain transport mode during a certain time period. With respect to travel mode, our focus is on public transport modes (bus, tram, metro, and walking or their combinations) for two reasons. One is that public transport is the main transport mode that TOD strategies build upon to affect job accessibility. The other reason is that public transport is an affordable and frequently used transport mode in Beijing. According to Beijing's annual transport report of 2014, 48% of all trips were made by public transport (Beijing transportation research centre, 2015). We set a travel time of one hour, because the average public transport travel time during peak hours (7:00–8:00 in the morning and 17:00–18:00 in the afternoon) is about one hour (Beijing transportation research centre, 2015). With respect to our specific study context, we thus capture job accessibility as the potential job opportunities that can be reached from a given cell by travelling one hour with public transport.

2.2.2 DATASETS AND MEASUREMENT

In order to calculate job accessibility in a given cell, two main datasets are needed. The first concerns travel times between the centroids of the cells. We retrieved the data by using Google Maps Distance Matrix API (Google Inc., 2016), which returns travel times of the shortest travel route from multiple given places to other multiple places by a given transport mode for a given departure time. We selected 695 cell centroids as trip origins (all the coloured cells in Figure 1), while the trip destinations were all grid cell centroids of the built-up area, namely 1,651 points (thus including all TOD, secondary catchment and non-TOD cells in Beijing). The departure time was set at 7:00 in the morning Beijing local time on Wednesday, 9 November 2016, by using a timestamp code (departure_time='1478646000'). The transport mode was set as 'transit' (Google Inc., 2016), i.e. public transport (bus, tram, metro, and walking or their combinations). The travel time dataset is a table, 695 rows (origins) \times 1,651 columns (destinations) and 1,147,445 cells (=695*1651), with total travel times between pairs of origin and destination points. This travel time includes walking time from point of origin to public transit stop, waiting time for transport mode, riding time in public transport, and walking time from transit stop to destination point. If one or several transfers are required, the transfer times are also accounted for by the travel time returned by this API.

The other dataset measures job opportunities in a given grid cell. We used a dataset that contains numbers of employed workers in each community in Beijing (the number of jobs in each work place, Beijing Municipal Statistics Bureau, 2016). The boundary of communities and numbers of employed workers in each community were retrieved from Beijing's web application depicting the third economic census of 2014 (Beijing Municipal Statistics Bureau, 2016; also see Figure 2). In the built-up areas of Beijing, there are 3,045 communities, which have an average surface area of 0.71 km² and are thus smaller than the area of a grid cell.

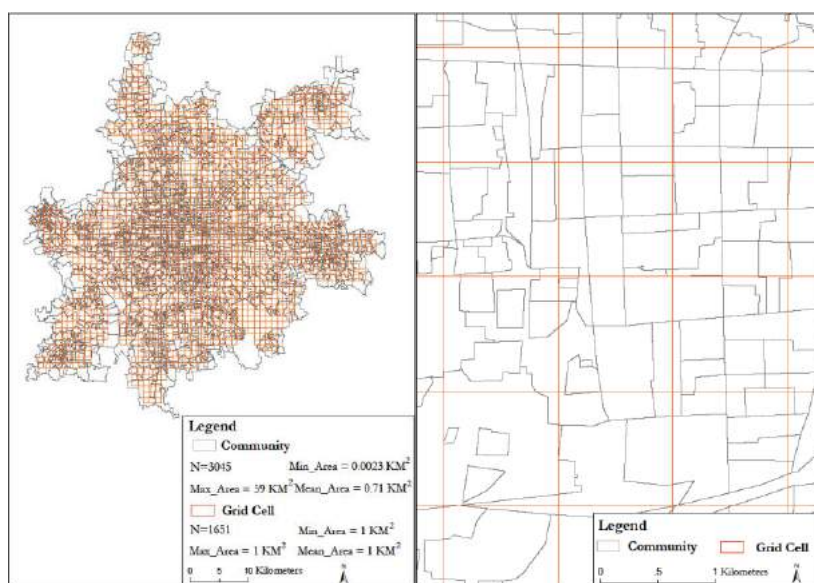

Figure 2 - Communities and grid cells in the built-up areas of Beijing.
Source: Beijing's web application depicting the third economic census of 2014

We selected three categories of jobs to be analysed, based on their relevance to policy intervention. The first is the type of all jobs¹ (no classification) because of its synthetic value. The second is type of jobs categorised by different economic sectors², using the Sectorial Classification System GB/T4754-2011 (National Bureau of Statistics of China, 2011), to provide insights into the differentiation of job accessibility across varying economic sectors. Third, we zoomed in on the jobs provided by central government-owned companies, because we assume that intervention in these jobs (e.g. establishing new or relocating existing

¹ It is not a sum based on the different types of jobs but an indicator for its synthetic value, which can be retrieved from the economic census database.

² We cannot analyse number of jobs by all different economic sectors because of data feasibility (e.g., the numbers of jobs on the sectors of agriculture, scientific research and polytechnic services, and international organizations are not available).

positions) can be accomplished more easily through direct policy choices (e.g. those suggested in our analysis).

The selected types of jobs for analysis	
All jobs	All-jobs (AJ)
By different economic sectors	Mining quarrying (MQ); Manufacturing (MF); Utilities(supply of water, gas, electric, heat, etc; UT); Construction (CT); Wholesale and retail trades (WR); Transport, storage, and postal services (TP); Accommodation and catering (AC); Information transfer, software and information technology services (IT); Finance (FN); Real estate (RE); Resident, repair and other services (RR); Education (EC); Health care and social work (HS); Culture, sports, and entertainment (CE); Public administration, social insurance, and social organizations (PS)
By capital source	Capital owned by the central government (CG)

Table 2 - Types of jobs selected for analysis

Based on the economic census data and the locations of grid cells, we computed the number of jobs within each grid cell. The processes were conducted in the ArcGIS 10.3.1 desktop platform. First, we calculated job density of each community by means of Equation 2:

$$Job_Density_{i,j} = \frac{Numbers-of-employed-workers_{i,j}}{Areas-of-community_j} \quad (2)$$

Job_Density_{i,j} is the job density of the community j on the category i; Numbers of – employed – workers_{i,j} is the number of employed-category-i workers in the community j; Areas – of – community_j is the surface area of community j. Second, we calculated the spatial overlap of ‘communities’ and ‘grid cells’ within ArcGIS. This resulted into 9,767 new polygons across the 1,651 grid cells. Third, we re-aggregated the number of jobs within each cell using Equation 3:

$$Job_Number_{i,k} = \sum_k Job_Density_{i,j,k} \times Area_Polygon_{j,k} \quad (3)$$

3 JOB ACCESSIBILITY IN DIFFERENT URBAN AREAS

3.1 SPATIAL DISTRIBUTION OF JOB ACCESSIBILITY

In order to illustrate the spatial distribution of accessibility of different kinds of job categories of the selected cells, we mapped all job accessibility, manufacturing job accessibility, wholesale/retail/trade job accessibility, and central government–owned-company job accessibility across these cells. The aim is to give the reader an idea about the spatial distribution of job accessibility according to all jobs, to different economic sectors, and to jobs of which the government may more easily determine the location. For the visualisation of the spatial pattern, we used the standard deviation method to classify accessibility values (ArcGIS for Desktop, 2016).

Regardless of the preferred job locations for different economic sectors, Figure 3 shows that the distribution patterns of job accessibility across different job categories are similar. First, it clearly shows a distinction between core and periphery (as defined by Friedmann, 1966). Job accessibility shows a marked decrease when moving from the inner city to the periphery. Second, Figure 3 also shows the influence of the historical distributions of job systems. For instance, job accessibilities in the northern part are generally higher than in the southern part, as the northern part is historically more developed than the southern part (Deng and Srinivasan, 2016). A third pattern is related to differences in TOD features, with job accessibilities in transit nodes and corridors being higher than in areas without transit connection. For example, even in the peripheral areas, job accessibilities are higher along the transit corridors (see light green or yellow coloured cells in the periphery in Figure 3). Potential implications for policy- and strategy-making

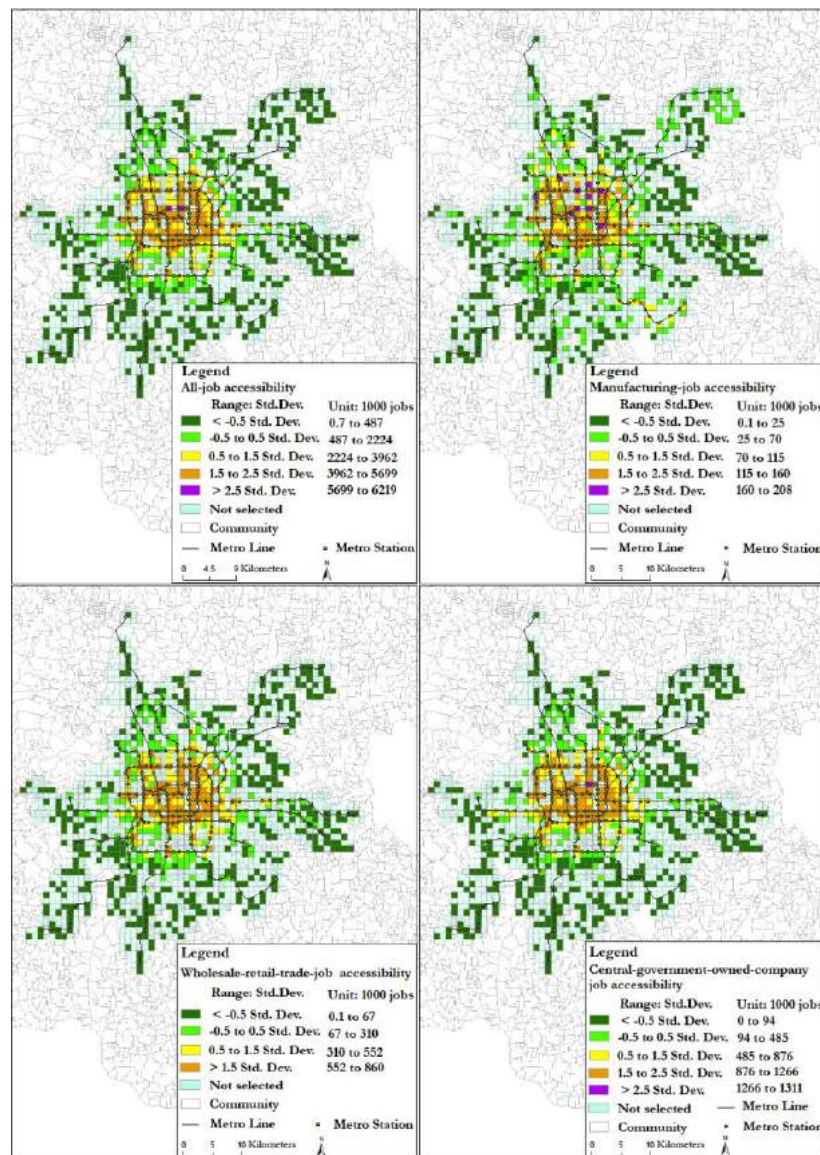

Figure 3 - Job accessibilities of the selected cells for the selected job categories. Source: Job accessibilities calculated, based on Economic Census 2014 and travel times obtained from Google Maps Distance Matrix API

3.2 TESTING SIGNIFICANT DIFFERENCES OF JOB ACCESSIBILITY IN DIFFERENT TYPES OF URBAN AREAS

In order to test whether job accessibility in each type of urban area is significantly different from other areas, we performed Tukey's Honest Significant Differences (HSD) Test (Tukey, 1949) after variance analysis (ANOVA), using the R Stats Package (R Core Team, 2017). Here we take a significance test for the difference in all-job accessibility across types of urban areas as an example. The 161.4 F-value (the ratio of the variance between groups to the variance within groups) in the ANOVA Test indicates that the means of all-job accessibility across different types of urban areas are different; however, it does not show exactly where those differences lie. Tukey's HSD Test provides detailed information about the significance of the difference between different types of urban areas on all-job accessibility. Table 3 shows the difference in all-job accessibility means between two types of urban areas. It also gives the adjusted P-value, indicating the significance of the difference. An adjusted P-value close to 0 means that the means of the two compared groups are significantly different, while an adjusted P-value close to 1 indicates that the means of the two compared groups are almost the same. Comparing, for example, the means of all-job accessibility between TOD cells and secondary catchment cells (TOD_Cell-SC_Cell) shows that the all-job accessibility in the TOD cells is on average higher than in the secondary catchment cells by 917,000 jobs. Their means are significantly different (adjusted P-value 0.00). The compared types in bold in Table 3

indicate that their means are significantly different, suggesting that in some types of urban areas, all-job accessibility is very much different than in the other types of urban areas. However, the result of this test is conservative by nature when applied to unequal sample sizes of compared groups. It means that all-job accessibility across various types of urban areas in Beijing may be much more different than what Table 3 shows.

Comparison between urban areas	Difference in means	Adjusted P-value	Comparison between urban areas	Difference in means	Adjusted P-value
TOD_Cell~SC_Cell	917	0.000	TOD_C2~TOD_C1	-433	0.719
SC_Cell~Non_TOD	1337	0.000	TOD_C3~TOD_C1	713	0.059
TOD_Cell~Non_TOD	2253	0.000	TOD_C4~TOD_C1	2145	0.000
TOD_C1~SC_C1	225	0.968	TOD_C5~TOD_C1	3562	0.000
TOD_C2~SC_C2	199	1.000	TOD_C6~TOD_C1	3514	0.000
TOD_C3~SC_C3	685	0.391	TOD_C3~TOD_C2	1147	0.001
TOD_C4~SC_C4	860	0.001	TOD_C4~TOD_C2	2579	0.000
TOD_C5~SC_C5	1358	0.001	TOD_C5~TOD_C2	3996	0.000
TOD_C6~SC_C6	1020	0.000	TOD_C6~TOD_C2	3947	0.000
			TOD_C4~TOD_C3	1432	0.000
			TOD_C5~TOD_C3	2849	0.000
			TOD_C6~TOD_C3	2801	0.000
			TOD_C5~TOD_C4	1417	0.000
			TOD_C6~TOD_C4	1369	0.000
			TOD_C6~TOD_C5	-48	1.000

Table 3 - Tukey's HSD Test for all-job accessibilities across six types of TOD cells, six types of secondary catchment (SC) cells, and non-TOD cells. Unit for difference: 1,000 jobs; adjusted p-values range from 0 to 1

4 POTENTIAL IMPLICATIONS FOR POLICY- AND STRATEGY-MAKING

The evaluation of job accessibility across different types of TOD areas, their corresponding types of secondary catchment areas, and non-TOD areas provides insights for policy- and strategy-making. First, the result that the means of all-job accessibilities in TOD areas are higher than those in secondary catchment and non-TOD areas can motivate urban planners, designers, and policymakers to develop more TOD areas in order to improve all-job accessibility. Second, the result that varying TOD characteristics substantially influences job accessibility suggests that from the perspective of job accessibility some type of urban areas with stronger TOD characteristics should be encouraged over other types, as elaborated below.

The internally similar but externally distinct characteristics of TOD types may allow planning professionals to develop a set of targeted strategies to facilitate a transformation of an area from one TOD type into another, which would serve to improve job accessibility for the targeted job category. For example, TOD_C1 areas that have broadly similar locations with TOD_C4 areas (Figure 1) can possibly be planned and designed to facilitate their transformation into TOD_C4 areas (shifts of means of 18 TOD indicators).

With respect to the associations between TOD types and the other types of job accessibility (e.g., manufacturing job accessibility or wholesale/retail/trade job accessibility), we can perform the corresponding Tukey's Honest Significant Differences (HSD) Tests (similarly to the process in section 3.2, the object of test becomes the targeted type of job accessibility). Such HSD Tests also provide insights for policy- and strategy-making in order to improve the targeted type of job accessibility of specific locations.

Furthermore, our work provides insights for actions on the metropolitan level. For instance, the spatial distribution of job accessibilities suggests that Beijing is still a single-centre city with a strong 'core-periphery' opportunity distribution pattern. Based on our work, policymakers can identify potential secondary cores (hubs) of job accessibilities to be strengthened. It seems useful to cultivate these future core urban areas to transform Beijing into a polycentric city, one of main stated planning goals of Beijing's Urban Master Plan 2004–2020.

5 CONCLUSION AND DISCUSSION

This research evaluated job accessibilities across different types of TOD areas, their corresponding types of secondary catchment areas, and non-TOD areas in Beijing. By comparing their job accessibilities, it confirmed that inhabitants of TOD areas enjoy higher all-job accessibilities than those living in secondary catchment or non-TOD areas. We also found that stronger TOD characteristics correlate with higher all-job accessibilities in these locations. This outcome provides insights for developing area-specific and targeted strategies to improve the all-job accessibilities of specific locations. It demonstrates the development of a methodology with future potential application in other geographic contexts, with both analytical and planning support value.

The study's methodology and findings are qualified by several limitations. First, the analysis is limited by the modifiable areal unit problem. It influenced the results on (1) the identification of different types of urban areas, and (2) the job attribution to cells. We took strong efforts to minimise its impact on the final result by using the most disaggregated census data and selecting a meaningful grid cell size for the analysis. Second, with respect to the association between TOD characteristics and job accessibility, we anticipated and confirmed its existence across different types of TOD areas. However, the hypothesised relationship may go in both directions, and it could be a dynamic and long-term relationship, across time or space, as captured by the notion of a transport–land use feedback cycle (Wegener and Fürst, 1999; Bertolini, 2012; and Kasraian et al., 2016). Third, since the results were based on publicly available datasets, namely Google Maps Distance Matrix API and Beijing's economic census of 2014, the level of detail or bias of these datasets also influences the result.

Based on these findings, we postulate the following potential research directions for future efforts. Considering the result that TOD characteristics have a strong effect on job accessibility of urban areas, we think it is worthy to evaluate TOD characteristics for the entire urban area of a city. This approach would entail extending TOD studies to urban areas without transit stops, but with 'T', 'O' and 'D' characteristics (here the 'T' refers to public transport). The next direction is to explore the relationships between specific TOD characteristics and the particular types of job accessibility (e.g., by sector or required skills). It would provide many valuable insights to policymakers for improving the targeted job accessibility in the specific urban areas. Considering the importance of job accessibility for access to the labour market, the third research direction could be to explore the spatial justice of job accessibility across different social groups of inhabitants.

ID 1322 | COMMUTING PATTERNS AND CAR DEPENDENCY IN URBAN REGIONS

Jake Wiersma¹; Luca Bertolini¹

¹University of Amsterdam

jake.wiersma@maastricht.nl ; l.bertolini@uva.nl

ABSTRACT: We have analyzed car dependency in urban regions in the Netherlands, focusing on the lack of alternatives for the car in daily commuting. As geographical factors like distance from home to work and accessibility of job locations shape important conditions for potential behavioral change in car use and ownership, we map out the alternatives to the car for commuting in urban environments in the Netherlands, with emphasis on the bicycle and e-bicycle for shorter distances and combined bike-train for longer distances. In 2014, in the three big cities and some medium-sized cities (30% of the Dutch

population), 60-80% of the commuters have jobs within an acceptable cycling distance (within 7.5 km on average). Moreover, in all big and medium-sized cities and most of the suburban areas in the Netherlands (61% of the population) 60-80% of commuters have a job within e-biking distance (within 15 km on average). These geographical conditions could allow a doubling of the share of the bicycle and the e-bicycle in commuting, becoming the dominant forms of commuting in urban areas in the Netherlands. Looking at trends over time, it appears that in the large cities there is a stabilization of the share of jobs within e-cycling distance, but the medium-sized cities show a decrease. The South Limburg case study examined the potentials of the bike-train combination and found that it provides a reasonable alternative to the car for approximately 5% of employees with jobs located beyond e-biking distances.

1 INTRODUCTION

In the area of transport policy and research there seems to be a wide consensus on the need for alternatives for the car as a daily means of transport in urban areas. The dependency on cars and the consequential massive car use and ownership seem to contradict the spatial and social characteristics of urban areas with respect to accessibility, health, safety, equity and quality of public space (Rogers 1997, Girardet 2004). In urban areas, the space required for driving and parking competes with space for leisure, walking and cycling, green areas, as well as residential and work space (e.g., on-street parking for residents, including room for maneuvering occupies more floor space than the average apartment). A shift to the use of environmentally friendly vehicles such as electric cars will not solve these spatial and social problems. The contributions of self-driving cars are at best uncertain in this respect (perhaps there is locally less parking space needed if self-driving cars are shared, but it may also lead to more car traffic).

In the light of the above, how feasible are changes in car use and ownership, especially in the more developed cities in Europe and North America where they are so ingrained? Although the spatial conditions for walking, the cycling, public transport and car-sharing seem favorable in urban areas – as shown by studies of travel behavior, modal split and car ownership (e.g., Geurs and Wee 2006, Hilbers and Snellen 2006, Kenworthy and Laube 1999, Van de Coevering 2013) – urban areas are increasingly becoming part of regional networks, with jobs and facilities located beyond cycling reach and often at transit poor, car-dependent locations (PBL 2014). The Netherlands, a country known for its relatively compact cities, has been scaling up urban networks, for several decades (Tordoir, 2015). The average commuting distance in the Netherlands has increased from 17.6 in 2003 to 18.6 in 2014 (CBS Statline). In areas with shrinking populations, the average commuting distance increases because there are fewer residents and jobs within the same space (Wiersma et al. 2017, Goudappel Coffeng 2015). Moreover, the biggest growth in jobs in the past 15 years has taken place on motorway sites (PBL 2014). The car seems indispensable for most weekly shopping and social recreational trips (Jeekel 2013).

The trends outlined above indicate increasing car dependency (CD), also including the urban population (Jeekel 2013, Harms 2008). CD does not only relate to car use, but also to car possession. Because both use (space for moving) and possession of cars (space for parking) claim urban space, not only the dependence on everyday use is important, but also the need of owning the car. In figure 1 the various levels of CD are shown. In yellow the car trips having alternative transportation modes that are competitive in terms of travel time and costs. This is the domain of what Jeekel (2013) refers to as 'subjective CD': a habit or lack of information about alternative transport modes. In the Netherlands, in urban, suburban and most rural areas, daily amenities, like schools and shops are within walking and cycling distance (Wiersma et al. 2015, CBS). They form part of the yellow sphere. In this sphere policy aimed at awareness of alternative transport modes, or offering more comfortable and safe bicycle paths, could be effective for behavioral change. Orange are the occasional car trips, for which the car is indispensable, such as a trip to the hardware store, or a holiday home. For this, the use of the private vehicle is necessary, but not the possession, renting or sharing a car being an option. In this sphere, policy aimed at offering attractive arrangements for rent-a car could be effective. Purple is the "hard core" of CD. These are everyday trips without an alternative transport mode, such as daily commuting trips to car dependent locations beyond cycling distance. Research shows that people rarely rent a car for their daily commute (Cervero 2006). The daily dependency on the use of cars for commuting creates thus a 'hard core' of the use and possession of cars, because 1) the trip is in most cases done with the private car, and 2) in addition to driving to work or school, the car is often part of a chain of other movements, for which alternative transport modes are often available (Harms 2003, Urry 2004, Baptista et al. 2014).

Figure 1. Levels of Car Dependency

Although in urban areas people aren't dependent on cars for trips to amenities, such as shops, health care or schools (Wiersma et al. 2015, CBS 2015), the dependence of using their own car for commute trips beyond cycling distance or to car-dependent locations seems to be an important determinant for a car-dependent lifestyle. Determining the extent of this 'hard core' of CD could show the extent of possible behavioral change (using alternative modes and sharing or renting instead of owning a car) in the existing spatial context, thereby giving insight into the possibilities of policies aimed at this behavioral change, not requiring a different location of homes and jobs.

Our study seeks to answer the following research question: How CD are employees in the Netherlands in their daily trips from home to work, and how does this evolve over time? While in the Netherlands' data are largely available on the development of average commuting distances (CBS 2016, PBL 2014, KiM 2013) and the accessibility of jobs (Goudappel Coffeng accessibility map <http://www.bereikbaarheidskaart.nl/>, PBL 2014, Tordoir 2015), there is no specific overview of the CD of existing and potential future commuting patterns of the urban population. Our study aims to fill this knowledge gap.

We have focused primarily on the potential of the bike or e-bike as an alternative to the car, because in the Netherlands 1) for most people this is the most attractive alternative to the car for short distances (Harms 2006), 2) more jobs are accessible within 30 minutes by e-bicycle than by public transportation (Wiersma et al. 2017, Goudappel 2015), and 3) the potentials of the e-bike for medium distances (5-15 km) seems promising (KPVV 2012, KIM 2016). For longer distances the alternative to the car must include some form of public transport. In this study, we focused on the bike-train combination, because in the Netherlands the bicycle as a transport mode has an ever-growing share of the ride to the station (Kager et al. 2016), and this combination seems to be most competitive alternative to the car in travel time, as it avoids time-consuming and inconvenient public transport transfers (Kager et al. 2016, Schakenbos et al. 2015, Staps 2014). This specification leads to the following sub-questions: 1) To what extent are commuting distances in urban areas within cycling or e-cycling distance, and how do they evolve over time? 2) To what extent is the combination (e-) bicycle-public transport an additional competitive alternative to the car in commuting? 3) Which are the potentials for behavioral change, in relation to the current modal split of commuting? In the next sections we define our case, the research methodology, findings and conclusions.

2 THE NETHERLANDS AND SOUTH LIMBURG CASE STUDY

The broader case is the current and future situation in urban areas in the Netherlands, especially municipalities of 100,000 inhabitants or more and their interwoven suburban areas (see Figure 2). Within the European context, the urban areas in the Netherlands are relevant because size and density are typical of many urbanized parts of Europe. At present, almost half of the people in the Netherlands live in medium-sized cities, ranging from 50,000 to about 1,000,000. This reflects the situation in most of Europe, where only a minority live in larger metropolitan areas such as Paris, London or Berlin (Giffinger 2007). This share is increasing at the expense of peripheral and rural areas. Second, most cities in the Netherlands are part of polycentric regions where daily urban systems are becoming intertwined, as is the case in many urban areas in Europe, such as Northern England, parts of Germany and northern Italy. In one respect the Dutch situation is atypical: the widespread use of bicycles in everyday life, in comparison with in size and density comparable urban areas in other countries. Nevertheless, although behaviors may

be different, the spatial conditions for bicycle use, as determined by urbanization patterns, are similar to many urban areas in Europe. We investigated commuting distances across the entire territory of the Netherlands, and looked at the bicycle-train combination specifically in the South Limburg region.

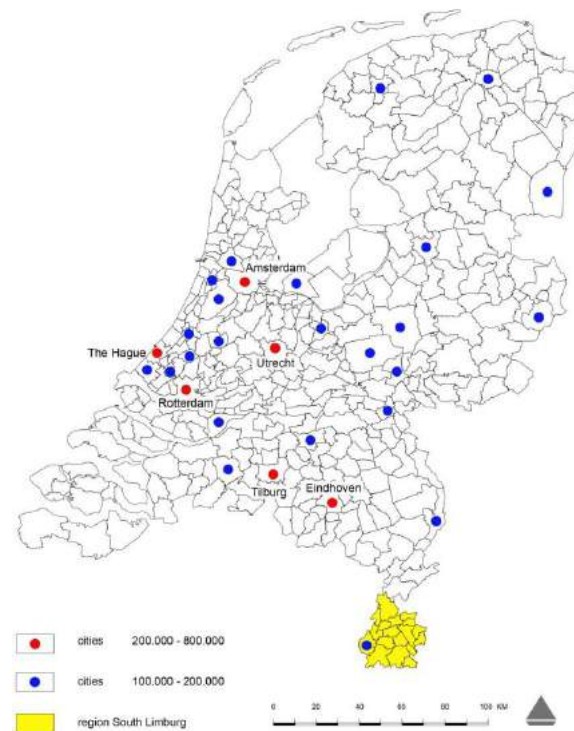

Figure 2. Cities of more than 100,000 inhabitants in the Netherlands

3 RESEARCH METHODOLOGY

3.1 COMMUTING DISTANCES WITHIN (E-)BICYCLE DISTANCE

The basis for this study consists of data on commuting distances, measured between the geographic centers of the commuters' home and work municipalities (CBS 2014). We have defined 5 km Euclidian distance one-way (or about 7,5 km real, on-the-network distance) as the maximum acceptable distance to cover daily by bicycle, 10 km Euclidian distance each way (or about 15 km real distance) for the e-bike (based on KiM 2016). For each municipality we have mapped out the percentage of employees who have jobs within cycling distance and e-cycling distance in 2014. We assumed that employees who have jobs in their own municipality live within bicycle distance from their jobs, given the geographical size of most urban and suburban municipalities in the Netherlands. Of course, there is a minority of people who work in the opposite side of the city. This would still be within a maximum of 15 km (10 km Euclidian distance), and therefore still be within e-bicycle distance. Furthermore, we assumed that employees with jobs in a nearby municipality, with a geographical center within 10 km of the geographical center of their home town, are within e-bicycle distance. Figure 3 shows a schematic view of the geographical size of municipalities in the Netherlands and corresponding commuting distances. We have distinguished two possible situations: people who hold jobs within their own municipality and those who have jobs in another municipality. The left side shows that commuting trips for people living in municipality A and working in A are on average within bicycle distance. The right side shows that commuting trips for people who live in municipality A or B and hold a job in B or A, respectively, are on average within e-cycling distance. In all other the job is located beyond bicycle or e-bicycle range.

Figure 3. Schematic view of the geographical size of municipalities in the Netherlands and corresponding commuting distances

3.2 POTENTIALS OF THE BICYCLE-TRAIN COMBINATION

Given the fact that the average distance from home to a train station in urban areas in the Netherlands varies between 2 and 4 km (KPVV 2017), we can deduct that the travel times from home to and from the station by bicycle would take on average about 15 minutes. Against this background, we assume that one can store the bike without significant delay; there is a 15 minutes train frequency; no train–train transfers are needed; and the job location is within 500 m from the destination rail station. Under these conditions the bike–train combination could be competitive – though not in all cases – in terms of door-to-door travel time, and a reasonable alternative to the car (especially taking considering parking costs and occasional effects of congestion in rush hour into account) (See figure 4). We explored how many employees would benefit from this combination, using data from the E'til (<http://www.etil.nl/contact/>) for South Limburg, available from the Province of Limburg (Vaessen and Knoors 2015). These data show the number of employees per municipality working in economic centers, on the level of zip code 4. This indicates how many people per municipality in 2014 had jobs at transit locations, defined as within 500 m from a train station.

Figure 4. Schematic view of the components of the bike–train combination in urban areas

4 FINDINGS

4.1 THE RELATION BETWEEN URBAN DENSITY AND POTENTIALS FOR THE (E-)BIKE

Figure 4 compares the densities of the municipalities in the Netherlands, defined by the number of addresses per square kilometer (left-hand side), with the percentage of commuting trips within bicycle distance for those municipalities (right-hand side). The cities with more than 100,000 inhabitants and some satellite towns ('groei-kernen') mostly have densities above 1,500 addresses per square kilometer, while smaller towns and suburban areas mostly have densities between 1,000 and 1,500 addresses. There is an urban concentration in western, central and the southeastern Netherlands, sometimes described as an 'urban field', as opposed to some smaller and less dense conurbations towards the north and southwest. The right side shows municipalities where more than 50% of their residents live within an acceptable cycling distance (7.5 km) from their jobs, on average, per municipality in 2014. As expected, it shows high scores (above 60%) for the big cities and some medium-sized cities with high densities. However, most cities with high densities in the heart of the above described 'urban field' seemingly have moderate (50–60%) scores. The satellite towns (groei-kernen) mostly have scores below 50%. Of the entire population of the Netherlands 8% lives in municipalities with between 70% and 80% reach, 22% in municipalities with scores between 60% and 70%, another 20% in municipalities with scores between 50 and 60%, and the rest (50%) in municipalities with scores below 50%.

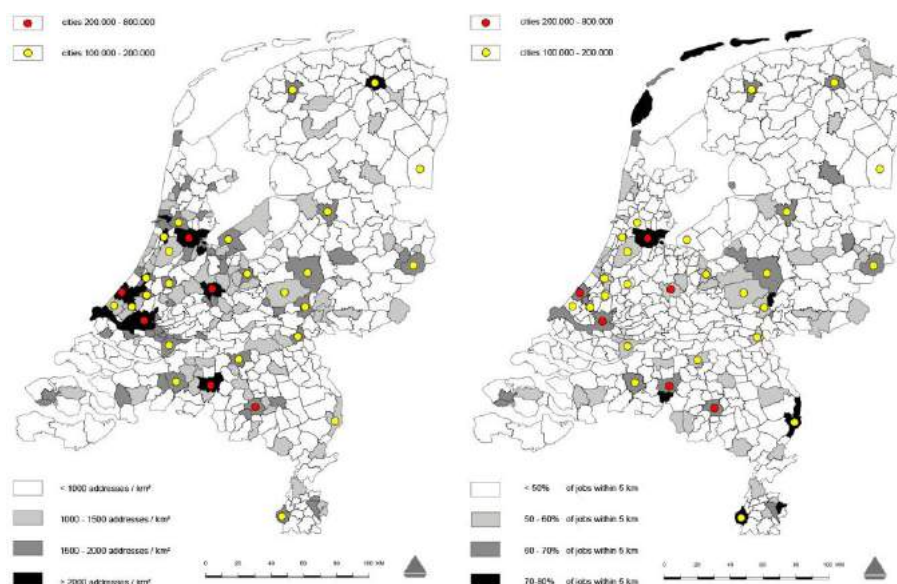

Fig. 5. Urban densities and potentials for the bicycle in commuting, Source: CBS 2014

Figure 6, right side, shows the percentage of workers living within an acceptable e-bicycle range (15 km) from their work, on average per municipality in 2014. As expected, there are more municipalities with high scores than in Figure 5. However, apparently there is no direct relation with density. Apart from the big cities in the west, high scores (above 60%) are found in suburban areas with lower densities, sometimes even below 1,000 addresses/km². In some cases, the scores of suburbs are higher than the adjacent medium-sized central cities (see the black areas next to cities, marked with yellow or red dots). Also remarkable are the extensive areas with high (more than 60%) e-bicycle potentials in the less populated periphery of the country. Finally, it appears that almost the entire southern wing of the Randstad and almost the whole of South Limburg, in urban as well as in suburban areas, where three-quarters of people live on average within 15 km of their workplace, thus within e-bicycle distance. Of the entire population of the Netherlands, 31% live in municipalities with between 70% and 80% of the workforce having a job on average within 15 km, 30% in municipalities with scores between 60% and 70%, a quarter (26%) in municipalities with scores between 50% and 60%, and the rest (13%) in municipalities with scores below 50%.

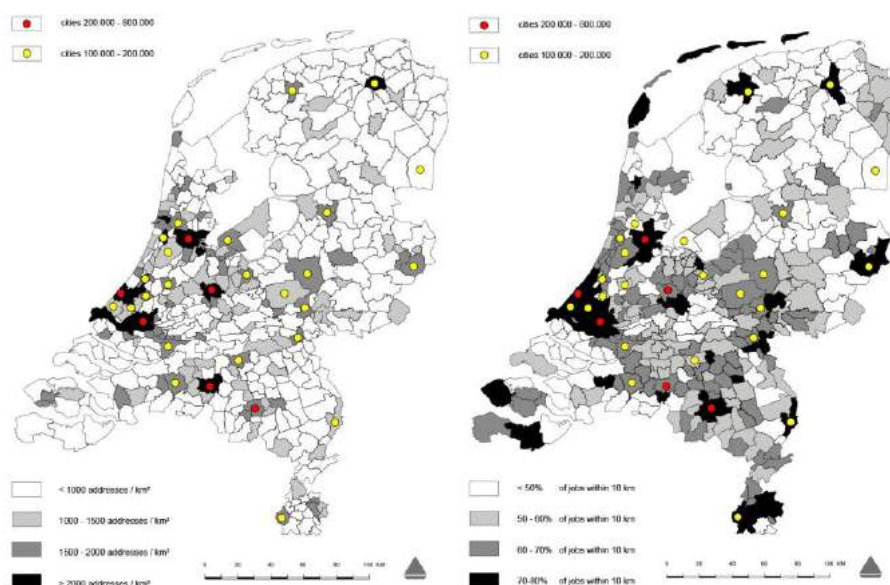

Fig. 6. Urban densities and potentials for the e-bicycle in commuting, Source: CBS 2014

4.2. DEVELOPMENTS IN COMMUTING DISTANCES

To explore how commuting distances evolve over time, we considered the changes in home–work distances in cities with populations over 100,000, between 2005 and 2014 (Figure 7). Except in the big cities, in most cities the percentage of people holding a job within an average distance of 15 km is decreasing, resulting in an average decrease of 4% between 2005 and 2014. This seems consistent with the observations of Tordoir (2015) regarding the upscaling of urban networks in the Netherlands. It is slightly less, however, than the increase in average commuting distance across the Netherlands from 17.6 km in 2003 to 18.6 km in 2014, which amounts to 6% (CBS 2016).

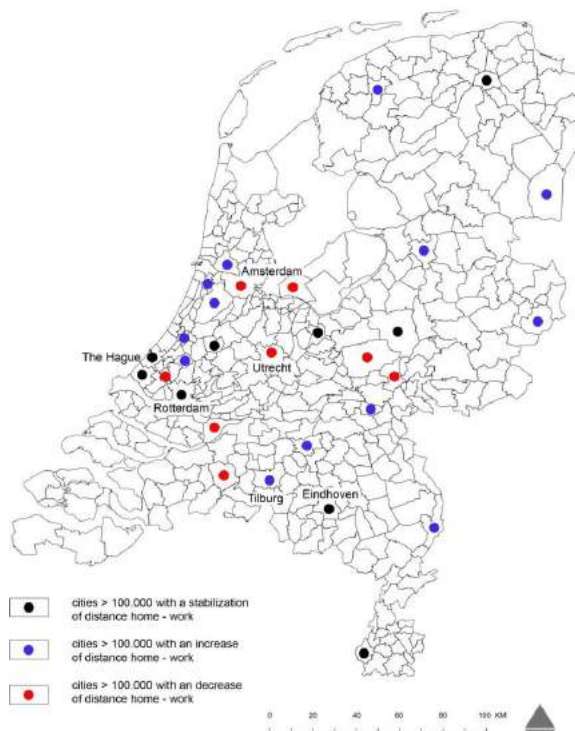

Fig. 7. Developments in home–work distances 2005-2014, in cities with over 100,000 inhabitants, Source: CBS 2014, 2016

4.3 POTENTIALS OF THE BIKE-TRAIN COMBINATION IN SOUTH LIMBURG

Figure 8 (left hand side) shows the percentage of people with jobs within acceptable e-bike distance in the South Limburg region. In Figure 8 (right hand side) this percentage is added up with the percentage of employees with jobs on rail-oriented locations beyond 15 km, having thanks to the bike-train combination a reasonable alternative to the car (following our assumptions, see above). This results in a gain of approximately 5% to 6% of commuting trips that have a reasonable alternative to the car. Compared with the scores of the (e-)bicycle, shown on the left side, this has almost no visible effects in the figure. Only two municipalities score above 70% thanks to this addition, but that is because the score of the e-bicycle for these municipalities was already close to 80%. It must be also kept in mind that these figures only reflect the potential use of public transport as an extension of the (e-)bicycle, and not as a transport mode in its own right, which might of course for some travelers and trips be an important option to have.

Fig.8. Left hand side: Percentages of employees living on average within e-bicycle distance from their work, per municipality. Right hand side: Percentages of employees living on average within e-bicycle distance from their work, added up with the potential bike-train combination, per municipality (2014), Source: CBS and E'til

4.4. ACTUAL VS. POTENTIAL TRANSPORT MODE OPTIONS IN COMMUTING

4.4.1 ACTUAL VS. POTENTIAL USE OF THE (E)-BICYCLE FOR COMMUTING

So far, we explored the geographical conditions for the potential use of bicycle, e-bicycle, and bike-train mode for commuting. An interesting question is to what extent the potentials for bicycle, resp. e bicycle use are currently being used. Table 1 shows the percentages of employees having jobs within bicycle distance, compared with the actual bicycle use for commuting, on average in four groups of municipalities, also showing the parts of the Dutch population living in these four groups in 2014. (based on own calculations on Netherlands Travel Survey-data (OVIN), CBS 2014).

Percentage of employees having jobs within 7.5 km	Actual bicycle use for commuting	Percentage of population
70-80%	39%	8%
60-70%	37%	22%
50-60%	35%	20%
0-50%	28%	50%

Table 1. Percentages of employees having jobs within bicycle distance, compared with the actual bicycle use for commuting, on average in four groups of municipalities, also showing the parts of the Dutch population living there, in 2014 (OVIN, CBS 2014).

It seems that, viewing home–work distances as conditional for potential behavioral change, about 30% of the Dutch population lives in municipalities in which a doubling of bicycle use for commuting would be possible.

Percentage of employees having jobs within 15 km	Actual bicycle and e-bicycle use for commuting	Percentage of population
70-80%	36%	31%
60-70%	33%	30%
50-60%	30%	26%
0-50%	27%	13%

Table 2. Percentages of employees having jobs within e-bicycle distance, compared with the actual bicycle and e-bicycle use for commuting, on average in four groups of municipalities, also showing the parts of the Dutch population living there, in 2014 (OVIN, CBS 2014).

4.4.2 ACTUAL VS. POTENTIAL MODAL SPLIT FOR COMMUTING IN THE SOUTH LIMBURG REGION

Following the results for South Limburg, we compared the current modal split in South Limburg (OVIN, CBS 2014) with the potential modal split, adding up the potentials for e-bicycle and bicycle-train combination. This results in the following potential modal split for commuting in South Limburg (see Table 3), as shaped by home-work distances and accessibility of job locations through the bicycle-train combination.

Actual modal split South Limburg region		Potential Modal split South Limburg region	
Car:	60%	Car:	23%
Alternatives for the car:	38%	Alternatives for the car:	75%
Other:	2%	Other:	2%
Total:	100%	Total:	100%

Table 3. Actual and potential modal split for commuting, as determined by geographical factors, and with the use of the e-bicycle and the bike-train combination, in the South Limburg region in 2014. (OVIN, CBS 2014).

5 CONCLUSIONS

To determine the 'hard core' of CD in urban areas, we addressed the following questions: 1) to what extent are commuting distances in urban areas within cycling or e-cycling distance, and how do they evolve over time? 2) to what extent is the combination (e-)bicycle-public transport an additional competitive alternative to the car in commuting? 3) which are the potentials for behavioral change, in relation to the current modal split of commuting?

The findings indicate the following conclusions:

1. Although distances from home to work have been increasing, reaching an average of 18.6 km in the Netherlands in 2014, in the three big cities and some medium-sized cities, 60-80% of the commuters have jobs within an acceptable cycling distance (on average within 7.5 km). Almost one-third (30%) of the Netherlands lives in these cities. Next, in all big and medium-sized cities and most suburban areas in the Netherlands (61% of the population) 60-80% of the commuters has a job within e-bicycle distance (on average within 15 km). Looking at trends over time, between 2005 and 2014, it appears that in the large cities there is a stabilization or a decrease of the home-work distance within e-cycling distance, but in most medium-sized cities there is a modest increase. In all cities with over 100,000 inhabitants there is an average increase of about 4% in the home-work distance, compared to an average 6% increase across the Netherlands in the same period.
2. We selected the South Limburg region as a case to examine the potential of the bike-train combination for distances beyond 15 km. At present, in the South Limburg region, approximately 5% of employees with jobs outside e-bike distance have a reasonable alternative to the car in their daily commute with the bike-train combination.
3. In urban environments (61% of the total population) the current home-work distances shape conditions for a potential doubling of the use of the (e-)bicycle for commuting, from about one-third to about two-third of commute trips, thus potentially becoming the dominant transport mode for commuting in urban areas.

Our overall conclusion is as follows: In the Netherlands the urban fabric seems appropriate for the daily use of the e-bicycle for commuting. In urban areas and their interwoven suburban areas the (e-)bicycle currently has a remarkable potential for increasing its share in daily work commutes, even replacing the car as the dominant transport mode. Looking at the specific case study of South Limburg, the added potential of the bicycle-train combination currently seems modest.

6 REFLECTIONS AND FURTHER RESEARCH

Although current home-work distances shape conditions for a doubling of the use of the (e-) bicycle in commuting in urban areas, this is of course not a sufficient factor for behavioral change. Extensive research has been carried out, addressing the non-spatial factors of behavioral change (see e.g., Van Acker et al. 2010). The differences between potential and realization shown in Table 1 and 2 underscore this challenged.

Nevertheless, for the sake of discussion, it would be interesting to try to estimate some implications for car dependency in urban areas. Only looking at the (e-)bicycle as an alternative to the car (without the use of public transport) and considering that about 50% of the population of urban areas commutes daily, it follows that only 10-20% of the urban and suburban population currently are dependent of the daily use of a car, due home-work distance in excess of 15 km. The rest of the population should be considered to lie outside the 'hard core' of CD, and in the second or third level of CD (see Figure 1). Assuming that dependency on the car for commuting can be considered as the major determinant for car ownership and that everyone might need access to a car occasionally, this results in a theoretical market for car sharing or renting – or the 'car as a service' – for at least 80% of the urban and suburban population.

Although potentials for alternative transport modes as determined by geographical factors will not necessarily lead to behavioral change, it is informative for the resilience of urban structures in the Netherlands in relation to possible desired or necessary behavioral changes in relation to e.g. climate change (reduction of the use of cars) or the livability of cities (reduction of use and ownership of cars). It

appears that this resilience is not dependent on high densities; the e-bicycle seems well suited for medium-size and even suburban areas as an alternative for the car. A question for further research would be to examine to what extent the urban structures and resulting commuting patterns in the Netherlands are representative for Europe at large.

Although the added potential of the bicycle-train combination currently seems modest, this does not reduce the importance of public transport: due to the increasing home–work distances, especially in medium-sized cities, the importance of regional public transport as an alternative to the car will increase on distances beyond 15 km. Next, and beyond this study, the importance of the availability of public transport options that do not depend on a good inter-modality with (e-) bicycles for certain trips and travelers should be acknowledged.

7 LIMITATIONS

We have assumed that people who work within their municipality on average live within 7.5 km of their workplace, given the geographical size of most Dutch municipalities and due to the concentration of residents and jobs in the more central parts of those municipalities. An analysis on a finer scale would obviously lead to a more nuanced picture. For instance, in the northwestern peripheral and rural areas of the country there are municipalities with a large geographical size, but without an urban core. Although it appeared from the model that in some of these municipalities the score of employees having a job in their own municipality was between 50% and 60 %, we adapted the score in these cases as being below 50%, as it was obvious that the average commute distance in these cases was beyond 7,5 km. A special position is taken by the big cities of Amsterdam and Rotterdam, in particular because their urban area is significantly larger than the medium-sized cities. As a result, on the basis of this analysis it is uncertain whether residents who work in these cities live on average less than 7,5 km from their work. On the other hand, it seems that precisely in these cities, through a well-developed urban transport network, alternatives to car commuting are in abundance. As stated above, looking at the specific case study of South Limburg, the added potential of the bicycle-train combination currently seems modest. Partly this is due to our research method: 1) We have assumed that all commute trips within 15 km potentially could be undertaken by the (e-) bicycle – on average around 70% in the South Limburg region – leaving as potential for the bike-train option only the rail-oriented jobs beyond 15 km. 2) We didn't take into account the rail-oriented job locations outside the region of South Limburg. Finally, we did not study the potential impact of technological and socio-economic developments, such as an increase in telecommuting or flexible work contracts, on the future commuting patterns.

ID 1342 | INFLUENCE OF URBAN MORPHOLOGY ON THE USE OF BRT TRANSPORT SYSTEM

Alba Nuñez¹

¹Universidad Politécnica de Madrid
alba.nbasantes@alumnos.upm.es

ABSTRACT: Urban planning has the responsibility for defining the territorial and urban models of cities, this determines the distribution of the demand for mobility in the cities. Hence, it is important to affirm the character of the two-way relationship between the spatial distribution and public transportation systems. Using the primary and secondary data with multiple regression model, the present study analyses the relationship of the built environment with the number of passengers registered in the year 2014 in the Bus Rapid Transit in the city of Quito, Ecuador. The delimitation of the service area in the built environment of stops is carried out with the support of the Geographic Information System (GIS). The results show the importance of no-resident population density and diversity of land uses and road density at the time of explaining the number of users of the system at each stop. Research allows to estimate both the future transportation system demand, as well as the impact that can have urban variables on the use of the Bus Rapid Transit in future growth of the urban area.

KEYWORDS: urban variables, Bus Rapid Transit multiple regression model, GIS

1 INTRODUCTION

Urban planning has a great responsibility in the management of urban mobility demands and conditions it (Pozueta, 2000), therefore this influences the mobility and transport system that serves, in the same way, the changes in the transport network and mobility generate territorial transformations (Miralles, 2002). In this sense, the spatial planning is a tool for generating an urban model that promotes public transportation.

In fact, this urban model has been promoted as a strategy within the sustainable planning of cities, as is the case of the European Union (EU, 2011). On the other hand, this urban model in the United States began to spread based on the Transit Oriented Development (Cervero, 1996, Boarnet and Copin N., 1999). In Latin America, the pioneer city was Curitiba, which BRT Oriented Development (BRT-OD), becoming a worldwide reference.

In the case of the city of Curitiba two elements facilitated the mobility, on the one hand the distribution of the activities of the city along the zones served by the transport, and on the other, the implementation of the Bus Rapid Transit. This system is efficient, flexible and low-cost system to meet the demand for mobility in cities (Rabinovitch and Leitman, 1996). For these qualities, this transport has expanded rapidly around the world. Currently there are 205 cities that have implemented this transportation system (GlobalBRTData, 2016).

However, not all cities that have this transport system have managed to integrate the built environment with transport. In this line of reflection some research has emerged of these urban models that were not planned as a support to the BRT, several of these analyses were carried out in cities of Latin America. The results show that the demand behaviour of the transport system depends on the supply of the service and the built environment (Estupiñan and Rodríguez, 2008, Rodríguez and Vergel, 2013, Vergel, 2014).

Notwithstanding these contributions support the relationship between the built environment and the number of users, it is difficult to determine the behaviour of some variables, especially the influence of design. These analyses determine the area of intervention within a range of 250 meters in all stops, 500 meters in the terminals and stations. This delimitation does not consider the actual distances travelled in the pedestrian networks of the built environments.

On this basis, this paper aims to analyse the built environment of the service area within distance of 300 meters at stops and 600 meters at stations and terminals. Starting from the question How does the urban form promote the use of Bus Rapid Transit in Quito? The main objective was to analyse the urban

variables no-resident population density, land use diversity and road density. The hypothesis is supported by the statistical empirical analysis of the urban variables and the number of users of the Bus Rapid Transit.

For this, the research is structured in four sections. First the introduction in which review of the literature, secondly the data and the methodology used based on GIS tools, third the model is explained and finally the conclusions and contributions of the work.

2 BUS RAPID TRANSIT AND BUILD ENVIRONMENT

The Bus Rapid Transit (BRT) are high-quality surface buses that provide comfortable mobility through the use of exclusive lanes and a favourable cost-benefit ratio. These systems have performance characteristics similar rail transit, but at a lower cost. A BRT could cost from 4 to 20 times less than a tram system (LRT) and 10 to 100 times less than a metro system (Wright and Hook, 2007). For these qualities, the BRT system has gained worldwide popularity. To date, more than 200 cities around the world have implemented some form of BRT-type system, comprising about 5568 kilometres in length and more than 30 million passengers per day (GlobalBRTData, 2016). Despite the popularity of this type of transport, the fact that these systems can promote a development in the next building environment, and that this environment becomes a support for this system remains a topic of discussion. The empirical evidence shows that the built environments can be a contribution at the Bus Rapid Transit, as well as the transport system can generate significant activities in the built environment.

These studies have analysed the urban variables proposed in the TOD, which is the urban form considered inherent, efficient and sustainable (Calthorpe, 1993; Curtis et al., 2009). In other words, they analysed residential and employment population density, the diversity of land uses and urban design (Cervero and Koceliman, 1997, Cervero, 2007, Badoe and Miller 2000, Cervero and Duncan 2003). Thus, the city of California identified correlations between population density and number of passengers, however, this also depended on the proximity factor (Cervero, 2007). Similar was the behaviour of the employment density variable located in the environment close to BRT transport (Frank and Pivo, 1994).

In relation to the diversity of land use, this variable and accessibility are considered relevant for the behaviour to ridership, even more than the characteristics of the residential density (Badoe and Miller, 2000). The Portland study found that the diversity of land use in residences decreased the likelihood of private vehicle travel, while in residential exclusive use areas the number of private vehicle journeys increased. Similar to the result was obtained in the bus stop of Florida (Chu, 2004). However, it depends on the willingness of the residents to walk. Thus, they found that local commerce located within a radius of a mile (1.6 km) may have a greater chance of displacements pedestrian (Cervero and Duncan, 2003)

On the other hand, urban design is one of the variables with broad meaning depending on the context, in general, understood as the form that acquires the connection space that allows the integration of different land uses in cities. Under this concept, the variable acquires its importance when considering that, the displacement does not end at the entrance or exit door of the transport system but includes the urban environment to capture the clients (Wright, 2007). Thus, the study of the city of San Francisco concludes that, the landscape and the urban form directly affects nonmotorized modes, especially by design factors such as the distance between blocks, the perception of safety or other factors as Topography (Cervero and Duncan, 2003; Kitamura et al., 1997).

In this sense, the demand of the Bus Rapid Transit has a similar behaviour to other types of transport analysed in other contexts, in which the demand of the transport system depends both on the supply of the system (speed, Service and frequency) and of the characteristics of the near urban environment (Cervero and Koceliman, 1997; Cervero, 2007).

3 BUS RAPID TRANSIT IN QUITO-ECUADOR

Quito is the capital both Republic of Ecuador and province of Pichincha. Due to its characteristic of centrality it welcomes the majority of the population of the Metropolitan District. The city is located on a plateau at 2850 m a.s.l., in an area of 18,860 hectares (DMQ, 2009). The urban area is articulated by public transportation that facilitates the movement of the population through the integrated Bus Rapid Transit known MetrobúsQ, conventional buses, vans and informal buses (EMQ, 2011). The system

integrated BRT(Metrobús-Q) was built and implemented gradually in some phases since 1995. At present, the trunk corridors Trolebús, Ecovía, Suroriental, Central Norte, Suroccidental have a total of 135.70 kilometres of length between exclusive lanes and mixed traffic. In the exclusive corridors articulated buses circulate while in the mixed traffic corridors the conventional buses circulate (EPMT, 2016; Barrera A. and EMBARQ, 2013).

The Trolebús system is the central corridor. It is also known as the "green line", which covers an approximate distance of 18 km from the south of the city with the El Recreo terminal to the north of the city in the terminal La Y (Guía, 2012). These articulated buses run through exclusive corridors, has 31 stops,

two stations and four transfer terminals (EPMT, 2016). The Ecovía corridor is known as "red line", the fleet is composed of articulated buses. It travels a distance of 9,5 km in exclusive lane, that goes from the transfer station the Marín (sector center) to the terminal Rio Coca located in the north zone of the city (Guide, 2012). This articulated bus system has 16 stops, one station and two terminals (EPMT, 2016). Regarding demand, the results of the mobility survey (2011) highlighted that 67.3% of the population depends on the supply of the public transport system. Of this percentage of trips, 22.7% correspond to the integrated transport of Metrobús-Q, of which 45.6% are Trolebuses, 19.7% to Ecovía and Eastern Southeast with 8,0% (EMQ, 2011).

In relation to the urban form, the city of Quito presents diverse characteristics. The city maintains a structure that concentrates equipment and services in the centre, whereas a tendency of distribution of the population is registered in the periphery of the city. This heterogeneous distribution has an impact on the mobility of the city.

Fig.1 Quito's Trole and Ecovia BRT stations audited

4 DATA AND ANALYSIS TOOLS

The study analyses the variables of the stopping environment in terms of no-resident population density, land use and network density in the surroundings near the shutdowns, stations and terminals of the transport system. Primary and secondary data are used for the 2008-2016. This period time is justified in the first instance by the sources provided. To obtain no-resident density, it uses the number of employees in public entities, the number of students and the number of employees in shopping centres. For the index land use, it uses the database (2008) available at the Secretariat of Territory of Habitat and Housing. This information is superimposed with available on the internet using the Google maps tool and also with the data obtained in situ. The road and corridors of the BRT system, stops, stations and terminals (2008) available in the Metropolitan Public Enterprise of Mobility and Public Works. The number of passengers per stop (2014) Metropolitan Public Transport Company of Passengers. In the case of the dependent variable (number of passengers), we use the data corresponds to he averages recorded in one day in the stops, stations and terminals of the Bus Rapid Transit obtained from the database of the year 2014, the base is used of data this year because in recent years the stops are in a process of remodelling, for such reason its operation has been unusual.

Table 1 shows the description of the data, the level of data collection, the source of information. In addition to the statistical descriptive analysis of the 53 stops, stations and terminals studied. In the case of the density variable, it analysed the number of people who are not residents of only those who work in public entities, shopping malls and educational institutions, the latter includes students. In relation at index land use are considered according to the current legislation (education, health, recreation, religious, administration, hotels, specialized commerce, malls, small scale commerce, and industry). Finally, the density of the network which is the result of the total length of the pedestrian network in kilometres divided for the service area.

Variable	Definition	Mean	Std. Desv.	Min	Max	Spatial Level	Source
Dependent Bornings 2014	Number of daily boarding per station for 2014	4897,04	3501,06	617,3	19940,83	Station	EPMTF
Centrality	Distance of Centrality activities form stop	5,73	4,5	0,58	15,41	Station	GIS
Density	Density (Persons do not live per hectare)	123,98	124,74	0	585,56	Station	MEC, MTRH
Land use	Land use index (0-100)	656,6	194,75	18	100	Station	EPMMOP
Road Density	Road density (linear kilometres in service area)	0,24	0,055	0,15	0,41	Station	EPMMOP

Table 1 Description of the variables used in the model and descriptive statistical analysis (N = 53)

For the calculation of the independent variables, it analysed the data within the service area of each stop, station or terminal. In the case of no-resident population density it superimposes the information of the number of public employees, students, teachers and number of employees of shopping centres with the service areas of each stop, thereby calculating the population number within the float population inside of the service area which is calculated in hectares. Using the land use layer (2008), the layer with the data obtained in the field is superimposed on google maps. These data are filtered into the tables and the number of uses in each service area is quantified. These activities were classified according to the current regulations, establishing a range of 0-100 for this indicator. In order to integrate the design variable into the model, it is considered the road density. For this, it calculated road density by means of overlap the layer road (length kilometres) and the service area. Once the independent variables are obtained, a multiple linear regression model is obtained from the statistical analysis system, this tool is available in the Geographic Information System (GIS).

5 METHODOLOGY

Using primary and secondary data, the present work combines the quantitative and qualitative analysis to explain the relationship between the built environment and the Bus Rapid Transit. For this, it selects the corridors Trolebús and Ecovía which the bus systems were the first to be implemented in the city. The Trolebús corridor began its operation in 1995, has 31 stops, 2 transfer stations and 2 terminals. The Ecovía corridor began operating in 2002, has 15 stops, one station and two terminals. These two BRT transport systems circulate through exclusive corridors. On the other hand, the built environments of these corridors have been analysed in previous studies (Rodríguez and Vergel, 2013, Vergel, 2014).

Another relevant issue for this study is the delimitation of the service area of the Trolebús and Ecovía corridor stops. For this delimitation, this paper considers the choice of critical service distance in relation to the demand capture in the built environment and the pedestrian route through the network. In this particular case, the critical service distance of 300 meters is established for the stops and 600 meters for the terminals. These thresholds correspond to the maximum distances of the sample of pedestrian routes registered in the environments near the stops in October 2016. These distances are similar distant identified in studies of the Metro Madrid, Spain (Gutiérrez et al. , 2010). The network analyst (tools GIS) is used for pedestrian distance. In this way, we intend to work with the actual distances travelled through the road (Gutiérrez et al., 2012).

Using overlays of layers within the delimited served areas, we calculated the urban variables. In the first part of the study, we analysed the variable density the variable density of non-resident population in 44 stops, 3 transfer stations and 6 terminals of the corridors of the Trolebús and the Ecovía in relation with ridership. This study also includes two variables, on the one hand the dummy because the stops and the terminals have different behaviour and on the other the distance of the stops in relation to the centre of activities of the city (Rodríguez and Estupiñan, 2008; Vergel, 2014; Gutierrez Et al., 2010). The second part analyses the relationship between the ridership and the attributes of the built environment, in this case the diversity indicator is calculated dividing the number identified in the service area for the total number of uses established and multiplied by 100. Finally, for the design variable, it calculated the road density within the service area (Rodríguez and Estupiñan, 2008; Vergel, 2014; Gutiérrez et al., 2010).

6 DESCRIPTION AND ANALYSIS OF RESULTS

In the first part of the model we consider the ridership relation to the density of the nonresident population in the service areas, with this variable it obtains R^2 0.149. Table 2 describes the results of the model fitted with the first factor analysed, which includes the distance to the stops, service stations and terminals and the dummy, with these variables it obtains R^2 0,43

Variables	Coefficient	Std error	P-value
Dummy	0,43	0,131	0,000021
Centrality	-0,02	0,091	0,004405
Density	0,189	0,008	0,001774
N	53		
R2	0,44		

Table 2 Multiple regression model (N = 53)

$$Y_i = \text{PoFlot Density} + \text{Centrality} + \text{Dummy}$$

Y = ridership at each station i

PoFlot Density = not-resident population in the service area

Centrality = Distance between stops to the centre of activities of the city

Dummy = terminal BRT = 1; 0 = other type.

The second part of the model analyses the relationship between ridership, land use and design.

$$Y_i = \text{Dummy} + \text{Diversity} + \text{DenRed}$$

Diversity = variable number of uses divided by the total number of uses multiplied by 100.

Dummy = terminal BRT = 1; 0 = other type.

DenRed = Road density

Variables	Coefficient	Std error	P-value
Dummy	0,14	0,095	0,09
Centrality	-0,019	0,007	0,008
Density	0,08	0,048	0,07
Land use	0,05	0,001	0,0019
Road Density	0,07	0,022	0,0010
N	53		
R ²	0,66		

Table 3 Regression model of station boarding

Table 3 shows the bivariate correlation coefficients obtained between each of the independent variables studied and the number of passengers recorded in the stops. The results show a significant statistical correlation between the variables, except for the variable density of the network. The coefficients have low values, with significance values below 0.01.

7 CONCLUSIONS

This proposed model shows the information of the users volume that could have the station of simple way. Relating the variables in the Geographic Information System, we analyse a direct estimate of the demand for BRT transport at the station level. This model involves the variables of the built environment known as the 3D (Density, diversity and design). Variables become important when explaining the use or not of the BRT transport system because the built environment is the pedestrian connector to the transport system.

To estimate the demand, the multiple regression model has been adjusted, where the dependent variable is ridership at stops, stations and terminals, and the independent variables reflect the characteristics of the built environment in the service areas delimited with the networks analyst tool of the GIS, reaching R²0.66. The procedure allows to make estimates of demand quickly facilitating to the transport planners. In addition, it is a tool of interest to planners when establishing urban plans. Despite the goodness of the model, there are weaknesses and one of the main is that, it considers the pedestrian movements in the stations and it is not applicable in the stations and terminals where the access can be through feeders.

The adjustment of Bus Rapid Transit model in the city of Quito (R²0.66) confirms that urban variables are explanatory in relation to the number of passengers at stops, stations and terminals. Although this study has not been considered the resident density, because it has little explanatory value. However, the incidence of no-resident density can be identified as a variable with greater explanatory value and not applied in other works. This variable acquires greater value when integrating the variables distance to the centre of economic activities and Dummy.

The distance from the stations to the city centre is also a variable that has an explanatory value in relation to ridership. The stations near the activities of the city tend to catch more passengers than in the peripheries. This information is a tool at the time of planning both to predict future demand for new peripheral stations and to restructure the distribution of existing activities in the city. Including the variables land use road diversity, the results confirm the importance of the 3D the time to explain the demand of the Bus Rapid Transit. The design in this model is identified only through the road density. Under the criterion that the increase of the density of the network directly affects an increase of the area of coverage to the stops. A dense road facilitates the pedestrian mobility of the population. In spite of this assertion, to define that they comply with characteristics to be spaces known as pedestrian-friendly spaces, other variables are required that will be considered in the next stage of the investigation.

Finally, it is concluded that this model that relates the variables through the multiple regression analysed in the GIS contributes to strengthen the existing knowledge regarding the urban form and the demand of the

Bus Rapid Transit. From the point of planning it allows establishing future demands and also becomes a tool that can contribute information for the design of new development and the rehabilitation of existing ones.

s.oppido@iriss.cnr.it

ABSTRACT: The research aims at discussing the potential role of reusing abandoned built heritage as driver for place-based regeneration processes in inner areas. The study focuses on disused railway heritage in Italy because of its relevant size, the low percentage of effective initiatives, and its strategic position into the territory. In European context, successful initiatives show the considerable role of political agenda and economic programmes as well as shared interests among institutional subjects, associations, entrepreneurs and local communities to achieve common goals. In Italy, these necessary components are often lacking, especially in terms of strategic initiatives and dialogue between policy makers, activists and socio-economic stakeholders, although the National Railway Company (RFI) has promoted institutional initiatives in the last decades. In this field, could activist planning have a key role for regeneration processes by recycling unused heritage? Could activist planning contribute to new territorial metabolisms, especially in deprived and marginal areas? The Southern case of Campania Region has been selected taking into account that it is included among the regions that need support to promote development and reduce regional disparities in European countries, according to European Structural Funds and Cohesion Fund. In this region, on one hand, the potentiality of railway heritage has been recognised for its being an existent infrastructure network on the territory that could link cultural, historical and environmental resources; on the other hand, the crisis of 2008 has cut down investments addressing main of them to sustain market-led processes. This conflicting scenario has induced social reactions such as civic movements, new local associations and community-based initiatives that have a proactive role in carrying out bottom up planning initiatives. To discuss that, the researchers have selected a case study in the Campania Region – the historical *Avellino-Rocchetta Sant'Antonio* railway – to reflect on the process induced by activist planning in reusing railway heritage. Through the consultation of indirect sources, fieldwork sessions, interaction with local key actors of the selected case study, the research group aims at verifying if bottom-up reuse initiatives are able to trigger place-based regeneration processes, producing positive impacts in terms of social, economic and cultural dimension.

1 INTRODUCTION

In many Italian Regions, inner areas represent about 60% of the national territory, where 25% of people lives, plagued by growing depopulation and marginalisation conditions, as described in the National Strategy for Inner Areas. The National Strategy defines these areas « [...] as territories substantially far from centres offering essential services and thus characterized by depopulation and degrade» but also « [...] with a wealth of key environmental and cultural resources of many different kinds, which have been subject to anthropisation for centuries». The Strategy is funded by Community funding programme for the period 2014-2020, and by national funds (Stability Law) and actually implemented at regional scale. As result of abandonment and emptiness processes, nowadays the inner areas often present a capital of unused built and infrastructural heritage. According with the National Strategy, the starting point for a local regeneration process is enhancing the “territorial capital” (Camagni, Borri, & Ferlaino, 2009): the natural and cultural capital and the social capital and social cohesion. In this perspective, unused capital should be considered as a measure of development potential. The ongoing research is developing within the research project “Place-based Regeneration Strategies and Participatory Processes”, coordinated by Gabriella Esposito De Vita, and funded by the Italian Research Council (CNR) and aimed at combining community engagement and participatory approaches within a cooperative and place-based regeneration process. A thematic focus regards abandoned heritage and reuse strategy as driver for local regeneration processes, analysing the role of bottom up initiatives ad social activation in implementing these processes. At present, the study deals with reusing abandoned railway asset in Italian inner areas as catalysts for valorising and networking environmental, historical, cultural and socio-economic resources, and guaranteeing a sustainable accessibility to the inner areas. What can be the opportunities arising from the railway network asset in the field of place-based regeneration processes? In this framework, what can be the proactive role played by local communities? The research deals with this heritage considering building stations and tracks as integrated parts of an infrastructural system for verifying if reuse strategies of this network can contribute to cope with the challenges of marginalization in inner areas through place-based regeneration processes. In particular, while in urban areas reusing railways can produce new opportunities in terms of urban mobility (Xu, 2011), in inner areas it can support local development strategy, improving accessibility of environmental, cultural and historical resources (Oppido & Ragozino, 2014). This research deals with the enhancement and valorisation of disused railway heritage taking into account a systemic logic, coherent with this heritage features and territorial characteristics. The main goal of this approach is to highlight relationships that this network has with the territory and the opportunity in linking environmental, cultural, historical as well economic and social existent resources (Oppido, 2014). The selected method to facing adequately this issue is the case study approach (Andrade, 2009; Yin, 2009), by selecting a case study located in an inner area of Southern Italy, the historical *Avellino-Rocchetta Sant'Antonio* railway in Campania Region. The case has been selected taking into account different criteria, among which: with regard to national average, the Region of Campania has an high level of soil consumption and this highlights a need of strategies for the reuse of dismissed or underutilised heritage (ISPRA, 2016); the extent in this Region of internal areas (63% counter to 60% of national average) and high rates of depopulation of the *Alta Irpinia* area; the extent of the track (119 km) with its historical and engineering value; and the high value of the landscape that the track crosses as well as environmental and cultural heritage that it captures. In this phase of the research, the case analysis has double objectives:

- To give a systemic lecture of the context aiming at linking the railway path with the entire infrastructural system and territorial heritage;
- To reconstruct main steps, main actors and stakeholders, which have marked the process of social activation for the enhancement and valorisation of historical track of *Avellino-Rocchetta Sant'Antonio*.

For these reasons, empirical analysis has been led starting from a consultation of direct and indirect sources and a set of site visits aimed at producing a visual analysis and a constant active observation (Gaber & Gaber, 2007). Then the work has carried on with the interviews to main local stakeholders, with a particular focus dedicated to actors involved in the social activation process, thanks to which several initiatives has been planned and put to the test for the enhancement of the track and for contrasting its closure. Geographic Information System (GIS) has supported this phase of the research for the construction of a geographic database. Other strengthens points have been added to these formers ones in order to consider possible future strategies of enhancement and valorisation of the track as well regeneration of its context:

- The project *"Binari senza tempo* [Timeless Tracks] and the Memorandum of Understanding between the Minister of cultural goods and activities and tourism, the Region of Campania, the *Rete Ferroviaria Italiana S.p.A.* [Italian rail network] and the Foundation *Ferrovie dello Stato Italiane* [Italian State railways] for a new opening of the track with tourist destinations (14 July 2016).
- The inclusion of the *Avellino-Rocchetta Sant'Antonio* case among the Italian historical tracks objects of the law proposal for the declaration of "Tourist railways" now collected from the Senate.
- The starting of the declaration procedure as good of architectural and landscape interest.
- Campania Region Strategy for inner context has selected this area as pivotal for regional inner contexts.
- The recent declaration of the *Distretto Turistico Alta Irpinia* [tourist cluster] with the Ministerial Decree 321/2016.

The last but not the least element of strong interest is the relevant civic activation emerged. In this context, associations and citizens have struggled to contrast the closure of the railway and to implement the process of enhancement and valorisation for the entire area. This engagement has anticipated and stimulated the following public action. Both strengths and weaknesses points of the *Avellino-Rocchetta Sant'Antonio* case arouse an interesting fieldwork for investigating potential effects of its reuse – with the final goal of supporting regeneration processes in vulnerable and marginal territories – and for checking the power of social activation. The paper includes four sections. Following this introduction, the background to frame the issue of place-based regeneration and enhancement of unused railway lines with a specific focus on social activation; case study analysis and first findings to the discussion about proactive role of social capital in regeneration; conclusions and perspectives for implementing research activities.

2 ENHANCING RAILWAY ASSETS FOR PLACE-BASED REGENERATION PROCESSES

Place-based regeneration processes «may be more accurately understood (and more efficiently practised) as an innumerable range of place-based economic strategies – each one connected by some common attributes, which could form an ideal-typical place-based policy model, although each approach to place-based development is likely to be contextually distinct. Actualising a place-based mode of thinking shapes how places are understood, conceptualised and codified, which can have significant implications for the formulation of policy and the implementation of development initiatives» (Pugalis & Bentley, 2014:561). These context-rooted approaches aim at improving partnership, involving and empowering local community in decision processes to achieve common goals. The main challenge is to build widespread collaborative arena among institutions, experts, stakeholders, local communities and all key actors for inclusive policies and practices in urban planning. They can support regeneration processes in historical centres, neighbourhoods, brownfields or abandoned areas that needed new development strategies based on inclusive and participatory processes. Indeed, place-based regeneration processes aim at building long-term development strategies that overcome inefficiency and inequality in the territory by solving the underutilization of resources and by reducing social exclusion (Barca, 2009). In this framework, cultural heritage represents a strategic resource and potential driver for triggering local development processes, improving quality of life and socio-economic and cultural environment, supporting heritage led regeneration processes (Ferilli et al., 2016; Fusco Girard, De Rosa, & Nocca, 2014; Horizon 2020 Expert Group on Cultural Heritage, 2015). This goal is even more relevant in inner areas, defined as territories at considerable distance from hubs providing essential services (education, health and mobility), and characterized by depopulation and degrade. In Italy, these areas cover approximately 60% of the national territory and hosting nearly 13,540 million people (Barca, 2016). This condition caused marginalisation processes, aging population, and, consequently, land maintenance reduction, hydrogeological instability and environmental risks, and decay and abandonment of the historical heritage. Nevertheless, on the other hand, the inner areas – excluded by globalization processes – contain major environmental resources (water, agricultural systems, natural and human landscapes), and relevant material, and immaterial cultural heritage. Because of this heritage, together with strong sense of community and sense of places, these areas represent a resource for recovering and enhancing local identity and promoting sustainable development. This perspective is consistent with the National Strategy for Inner Areas in Italy, which identifies natural, cultural and landscape diversity enhancement as the main goal for development processes, competitiveness and attractiveness, by increasing the use of territorial capital and by strengthening territorial cohesion (Atkinson, 2013; Camagni et al., 2009; Camagni & Capello, 2013). For this purpose, local communities and place-based leaderships can play a pivotal role in recognizing and enhancing local resources and in bringing up initiatives for bottom up local development and regeneration processes (Hambleton, 2015). With regard to this topic a new figure has been coined by Sager, the "active planner" (Sager, 2016). She is engaged in developing an alternative planning proposal not being a professional planner but a person informed about facts and involved proactively in the process by going beyond possible institutional participatory process and starting grassroots-initiatives, mainly when the institutional decision-making process is not sufficiently inclusive and transparent. She is aware of the potentiality of territorial resources and is engaged in bottom up struggles to enhance underused or unused goods for collective use. Place-based approaches and active planners could be a key to face issues of inner areas. Starting from valorising underused heritage it is possible to build new scenarios for their future. In particular, enhancing disused railway infrastructure can represent an opportunity for a new sustainable accessibility and for tourism promotion (Taylor, 2015), generating positive impacts on economic, social and cultural terms, as evidenced by a number of national and international experiences. For this goal, the railway heritage must be evaluated through a systemic approach, considering disused railways and stations as integrated parts of a system, a network able to improve accessibility and connections among environmental, cultural and historical resources (Oppido & Ragozino, 2014). In international context, many experiences demonstrate opportunities arising from enhancing disused railways for tourism, pointing out the role of a cooperative governance and dialogue between policy makers, stakeholders and local communities. The main initiatives concern, on one hand, national greenway design for implementing a slow mobility, such as *Sustrans Program* in England, *Vias*

Verdes in Spain, *Ecopistas* in Portugal; on the other hand, tourist trains for recreational activities. This second case is the topic of the research, aimed at designing a new life cycle for historical railway lines linking landscapes, and cultural and historical heritage. In many countries, local government bodies and community groups are developing these outdoor recreational trails and this tourism experience represents a growing trend (Taylor, 2015). In some cases, the tourist railway also represents historical and civil engineering values, such as Semmering Railway in Austria, added to the list of the UNESCO World Heritage sites. In Italy, these tourism initiatives started in the 90s thanks to voluntary associations, such as *Ferrovie Turistiche Italiane* [Italian Tourist Railways] in the cases of *Treno Blu* [Blu train] in the area of the Iseo Lake and the Norcia Valley railway. Then, starting from the 2013, the tourism train has been implemented also by institutional initiatives of *Ferrovie dello Stato FS Group*, in particular by *FS Foundation* that provides to enhance historical and technical heritage of Italian railways. For this purpose, in the 2014 it has launched an initiative named *Binari senza tempo* [Timeless railways], aimed at valorising historical rail tracks by converting them in touristic routes across Italian landscapes. Data by *FS Foundation* highlight over 60 thousand of visitors in touristic railways in 2016, with an increase of 45% over the previous year.

THE CASE STUDY OF AVELLINO-ROCCHETTA SANT'ANTONIO

The research deals with the case of Campania Region, where appropriate strategies for reuse of disused railway heritage can contribute to reverse the trend of high soil consumption, to activate valorisation processes of cultural, historical, environmental resources and to reduce gaps between the inner and the coastal areas. With regard to internal areas, the Campania Region has identified the delimitation of four internal areas among which has selected the *Alta Irpinia* as Pilot Area (resolution 600/2014). In March 2016, the Preliminary of Strategy of the Pilot Area *Alta Irpinia* was published on the site of the Territorial Cohesion Agency. The historic *Avellino-Rocchetta Sant'Antonio* railway, before its suspension, represented a strategic infrastructure between Campania, Basilicata and Puglia Regions crosses this area. Data highlight the ongoing marginalization process in the area; between 2000 and 2011, the population decreasing was 5,8%, higher than the regional average of internal areas (1,4%) and the national average for the same type of area, equal to 2,3%. In 2011, population over 65 was 23,7%, higher than the regional and national average for internal areas (21,2%). All these data are included in the Preliminary of Strategy - Pilot Area *Alta Irpinia* (Agency for Territorial Cohesion, 2016), which, among the whole actions for the development of the area, indicates the reuse for tourism of the suspended *Avellino-Rocchetta Sant'Antonio* railway. The railway was built starting from 1889, and it was inaugurated in 1895, with the engagement of Francesco De Sanctis – Minister of Public Education of the Kingdom of Italy – that described in his book *Viaggio elettorale* [Election trip] the landscapes crossed by the railway. The line is 119 km long with 31 stations and 2 terminals (Figure 1).

Figure 1 – The closed terminal of Avellino: new infrastructure and historical warehouse - (Source: Authors)

The tricky orography of the territory, and the need to overpass three rivers - *Sabato*, *Calore* and *Ofanto* – required the built of 58 bridges and viaducts, some of them are above 50 meters long and entirely of masonry (Pane, 2008). Among these relevant infrastructures, the *Principe Bridge* is renowned for its technologic and dimensional features. Considering this heritage, in 2014 an agreement has been signed between Department of Architecture (DIARC) of University of Naples Federico II and Regional Direction for cultural and landscape heritages of Campania; it aims at protecting and valorising the historic railway *Avellino-Rocchetta Sant'Antonio* with the proposal of declaration of architectural and landscape interest. This nineteenth-century-line crosses the main landscape resources such as *Conza della Campania* (Figure 2) natural reserve, *Monti Picentini Regional Park* - in which there are a SIC (Site of Community Importance) and a ZPS (Special Protection Area) zones - and Mephite area with a sulphurous lake and an archaeological site. The landscape excellence is testified by the high quality of local food-and-wine production such as registered designation of origin white wines - *Fiano* and *Greco di Tufo* - and Taurasi DOCG red wine. Nevertheless, in last decades national and regional policies did not recognise and valorise resources of this territory, local communities have believed in local identity value and understood potential future scenario based on their territorial capital.

Figure 2 – Landscapes of Conza della Campania, an abandoned post-earthquake village (Source: Architect Emanuela Di Guglielmo (2013), Degree Thesis "La Ricostruzione di Conza della Campania, Alta Irpinia. 1980/2013. Attraverso la Fotografia di Paesaggio")

3.1 ACTIVIST PLANNING FOR AVELLINO-ROCCHETTA SANT'ANTONIO RAILWAY

The sense of belonging that characterises *Alta Irpinia's* communities is widely evident in the case of *Avellino-Rocchetta Sant'Antonio* railway. During the middle 2000, has been in sight the closure of the railway because it was underused. Because of this real possibility, a group of people organised an event-trip using the railway. Several people participated at the event so that an idea born: to build a permanent network having the main goal of demonstrating potentialities of the railway, mainly in tourist terms. In 2009, one year before

suspension of the line, the association *In_Loco_Motivi* was established by a network of associations, organisations and citizens, together with trade-union observatory (CGIL), to renew and give the right value to the *Avellino-Rocchetta Sant'Antonio* railway. The project was the *Treno Irpino del Paesaggio* [Irpinia's Landscape Train], Sunday's train trips to discover territory and its cultural, landscape, historic and food-and-wine resources. *In_Loco_Motivi* book from *Ferrovie dello Stato* tickets and organised a tourist package in which were included an excursion with lunch, cultural entertainment and guided tours, with the aim of telling the story and identifying local resources through a slow mood. This initiative was recognised really well done and interesting and the Campania's Agency for Sustainable Transport funded two trains per month. The high number of participants certified the success of this initiative in terms of tourism, socio-economic issues and territorial valorisation: during one year of activity, 27 excursions organised with 2,051 visitors, which have paid a ticket from 15 to 30 Euros. Among these trips, three were organised with educational goals (63 students per trip) and the others with tourism purposes (76 visitors per trip) by crossing 17 small villages and visiting more than 30 monuments (*In_Loco_Motivi* archive). On December 2010, the railway was suspended but not dismissed thanks to the engagement of *In_Loco_Motivi*'s activism started in 2009 to keep high attention to the *Avellino-Rocchetta Sant'Antonio* railway and on usage opportunities for the valorisation of the area. The association organised national level events (National Day of Forgotten Railways, www.ferroviedimenticate.it), meetings and debates to facilitate communication among local administrators, stakeholders and citizens, and awareness activities in schools involving pupils and students in knowing territorial history and resources. A rail trip from Rocchetta to Conza was organised for the last edition of the Sponz Fest of Calitri (22-27 August 2016, www.sponzfest.it); it is an artistic kermesse directed by Vinicio Capossela that is programmed also for this current year during August. They are active also in contrasting not shared ideas and projects, such as the 2014-adopted Territorial Plan of Provincial Coordination that have proposed the conversion of the *Avellino-Rocchetta Sant'Antonio* railway to a greenway. This would have meant to delete the historical railway heritage substituting it with a new green infrastructure; this idea did not encounter favours of the *In_Loco_Motivi* Association, who, recognising its historical, cultural and engineering value, submitted comments to the plan in order to oppose to this conversion.

3.2 GIS inventory AS SUPPORT FOR territorial analysis

In order to analyse the territorial complexity and overlapping nature characterising *Alta Irpinia* area, a Geographical Informatic System (GIS) supports the research. Being the object of research a network linked (or potentially linked) to other territorial systems (environmental, historic, cultural and socio-economic), the GIS permits to analyse this complexity by identifying clusters and homogeneous areas – both critical and potential – to trigger a place-based regeneration process in the *Alta Irpinia* pilot area. Starting from these reasons, a GIS inventory has been elaborated to systematise information about railway and territorial structure. This tool can provide a support both in the case study analysis – reading the space-time context in a systemic logic and railway relations with environmental, cultural, socio-economic heritage (Eizaguirre-Iribar, Etxepare Igiñiz, & Hernández-Minguillón, 2017) – and in decisions making process to develop a place-based regeneration approach for the area. The use of GIS tool permits, indeed, to manage process, analyse, and then update and implement, a significant amount of georeferenced data and alphanumeric dataset. The analysis have focused on the railway line and crossed territories, particularly in the *Campania* Region, with attention to *Avellino* Province; considered that railroad crossed also *Puglia* and *Basilicata* Regions, the study model has also been extended to neighbouring territories of *Foggia* and *Potenza* Provinces. Spatial reference system is WGS84-UTM-zone 33N. About the project of the study model, systems have been identified taking into account context features in order to think about a place-based regeneration process: accessibility system, environmental system, historical-cultural system, socio-economic system, production system and tourism hospitality system. The model, then, takes back both information and maps about single systems, and integrated readings. This study model has been divided in systems to identify features and resources of territorial context, and to highlight relations of this one with railway:

- Environmental and historical-cultural systems include data about the existence and typology of natural and cultural resources;
- Accessibility system aims at highlighting some integrations between transport systems and different types of roads, the distance of the railway line and stations from urban centres and sites of interest and accessibility conditions;
- Socio-economic system aspires to analyse the marginalization of these areas, especially that crossed by the railway line in the previous and subsequent period by suspension (population density, age range, occupancy, commuting, etc.);
- Production system includes the identification of the main productive sectors and their location; finally, the tourist reception system identifies the current type of tourism that affects the area, and the hospitality capacity of the area.

Data to build GIS inventory have been found from different territorial information systems – particularly from, among other sources, Geoportal of public administrations, primarily from the *Campania* Region and the *Avellino* Province – and from official statistical sources, particularly *ISTAT* (Italian National Institute of Statistics). These databases have been integrated with information about environmental and cultural heritage, found by national and local authorities, and supplied by the *In_Loco_Motivi* association; also, fieldwork campaigns have been aimed at verifying and integrating information. By the use of GIS tool, graphics and thematic maps regarding territorial information have been worked out. In the subsequent steps of the research, moreover, this tool will be used for spatial and topological analysis to determine information about spatial relations. Therefore, it is clear that the use of GIS tool has a double function: the use as an analysis tool during the study step and as a decision support system for future valorisation strategies of the territory through the reuse of the *Avellino – Rocchetta Sant'Antonio* railway.

4 A DIFFUSED ENHANCEMENT THROUGH SHARED STRATEGIES

In the current initial phase of research, case study analysis has been structured in two areas of complementary investigation aimed at understanding the potential of the territory, the role of social actors and the expectations of local communities. For this purposes, an analysis of the track and its stations in relation to the context and territorial heritage has been carried out, through a systemic approach and building data collections. In parallel with this research activity, a listening campaign has been carried on for integrating the reading of the territory and identifying the expectations of local communities and key stakeholders. In the first five months of activity, initial case study evidences have been collected to define a first framework analysis:

- The importance of the territorial heritage of the context crossed by the track, with its historical, cultural, landscape and precious resources, and excellence productions;
- The strategic position of the railway to access landscape and main resources of the territory;
- Railway role as hinges between three Italian regions that amplify its range of action and consequent effects of a valorization strategy;

- The number and position of stations along the track reinforces this role as a linkage among the main territorial resources and as points for a diffused accessibility;
- Not critical conditions of the infrastructure that need not too expensive investments for the railway rehabilitation.

The listening campaign conducted so far has highlighted:

- The sense of belonging, social and territorial cohesion, which represented humus for the effectiveness of a broad social activation process;
- The presence of a group of key actors able to exercise leadership in civic activism;
- The community's awareness of the historical memory value of this railway line and the prefiguration of its potential for regenerating the territorial context, which has anticipated and urged the subsequent choices of public action;
- Proactive role of involved actors that have highlighted potentialities of the railway for a regeneration process, have anticipated and stimulated current public intentions.

In the face of public action absence, bottom-up initiatives undertaken by activists have highlighted the potential of the railway in tourism terms through the re-use of a benefit perceived as a collective and considered part of the historical memory of local communities. The data provided by the *In_Loco_Motivi* association regarding the attendance of users during Sunday walks with "*Il Treno Irpino del Paesaggio*" before the suspension of the line highlights the appropriateness of the initiative and the willingness to pay for this kind of tourist service. After seven years of exclusive civic activation, starting from 2016 institutional actors had showed their practical intentions for tourist reuse. In particular in 2016 the Avellino-Rocchetta Sant'Antonio railway has been inserted in the Foundation Timeless Tracks of FS Foundation, and in the same year the Campania Region has signed a Memorandum of Understanding with FS Foundation, Minister of cultural goods and activities and tourism, *Rete Ferroviaria Italiana S.p.A.*. For this current year, Campania Region has committed to fund the reopening of the railway for the Sponz Fest – scheduled for August – and to support accessibility to the WWF's Oasis *Conza della Campania*. The last but not the least result is the reuse of this railway with tourist and cultural destination among main interventions declared with the Preliminary of Strategy of the Pilot Area *Alta Irpinia*. Starting from these initial results, from completion of the analysis phase and the listening campaign, next steps of the research could be developed in order to verify opportunities offered by the railway as a field in which it could be tested approaches for place-based regeneration. In particular, it will be possible to highlight the impacts on the territory resulting from the reuse of the railway, in terms of environment (soil consumption reduction, sustainable accessibility), socio-economic dimension (new services for local communities, new profitability), cultural dimension (valorisation and promotion of environmental, cultural and historical heritage). In this integrated perspective, by overlapping environmental, socio-economic and cultural dimensions, it becomes necessary to consider a reuse approach based on mixed usages in order to guarantee not only a tourist destination but also new proactive synergies for internal areas. New activities in railway stations and sustainable mobility system are strategic points for this goal, with a particular regard to the role of the railway in accessing vulnerable areas, supporting Management Plan for Site of Community Importance, WWF areas and archaeological sites. The main goal of this proposed approach is to explore the reuse of railway as a device for diffused enhancement and valorization in terms of tourist development, building and sustaining excellence productions and activation of new economic and social synergies.

ACKNOWLEDGMENT

We thank the association *In_Loco_Motivi* and in particular Pietro Mitrone, Valentina Corvigno and Luca Battista for the material provided, useful for analysing the historic of *Avellino-Rocchetta Sant'Antonio* railway and its tangible and intangible heritage, and for the reconstruction of the social activation process of which they were and are protagonists. Thank also to Emanuela Di Guglielmo for her landscape photographs of *Conza della Campania* area. This contribution is the result of the collaborative work of the authors. However, Stefania Oppido specifically worked on §1, 2 and 4, Stefania Ragozino worked on §1, 3 and 3.1 and Serena Micheletti worked on §3.2.

ID 1754 | RESILIENCE ASSESSMENT TOOL FOR PUBLIC SPACE REGENERATION

Antonia Gravagnuolo¹, Roberta Iavarone², Ines Alberico³, Gabriella Esposito De Vita¹
CNR National Council of Research, Institutes 1 IRISS, 2 IBAF, 3 IAMC
a.gravagnuolo@iriss.cnr.it

ABSTRACT: The reacting capacity of a territorial system to multiple stresses can be described as its “resilience”. It expresses the ability of a system to absorb, recover from and successfully adapt to stressing circumstances. To make cities more resilient to natural disaster risks, international initiatives, such as the UN Agenda 2030 for Sustainable Development and the Sendai Framework for Disaster Risk Reduction (2015-2030), recommend the application of risk management measures and procedures, and stress the importance of preserving and safeguarding cultural heritage as a key element of safe, inclusive, sustainable and resilient cities. Urban planning and regeneration can be opportunity to design safe and resilient public spaces according to risk management, enhancing the overall city resilience to natural disaster risks. In this work, we develop a methodology to assess resilience to natural disaster risk in cities and public spaces, allowing the integration of risk management into ordinary planning tools. We identify which are the drivers that make cities and public spaces resilient to natural disaster risks, adopting a systemic approach that interprets cities as complex, dynamic, self-organizing systems, continuously changing under the pressure of perturbing factors caused by internal processes or external factors. A set of *drivers* (4), *driver descriptors* (15) and *sub-drivers* (36) were identified. A single sub-driver was associated to one or more phases of disaster risk management and to one or more goals of resilience. The method allows to overcome the sectorial approaches of territorial management through an integrated decision support tool for resilience-oriented planning. Particular attention was posed to the role of cultural heritage because it enhances the sense of belonging to the place and thus can enhance the response of citizens to adverse natural events. The territory of the Ischia Island, in Southern Italy, was identified as a suitable case study for future testing of the methodology. In Ischia, the presence of natural and cultural heritage coupled with the exposure to many natural hazards (seismic, volcanic, landslide, coastal erosion and marine inundation), and the intensive urbanization, could favor the validation of the methodology here proposed.

KEYWORDS: urban resilience, public space, urban design, risk management, cultural heritage.

1 INTRODUCTION

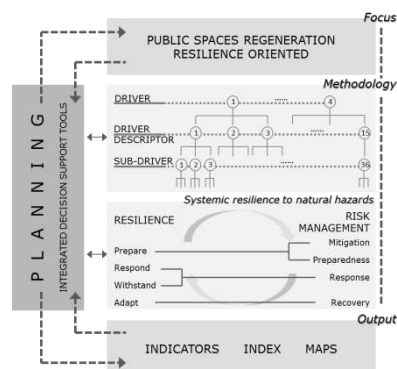

Public spaces should be designed to provide cities with beautiful, human-scaled and walkable open areas, creating a unique atmosphere, sense of place and identity. Furthermore, public spaces should be “safe”, both in the daily use and in the face of hazardous events and emergencies that threaten people's life. The Agenda 2030 for Sustainable Development (United Nations, 2015) advocates the development of safe, inclusive, resilient and sustainable cities (Goal 11), by protecting and safeguarding the world's natural and cultural heritage (Target 11.4), reducing the number of deaths and damages caused by disasters (Target 11.5), and increasing the number of cities and human settlements adopting and implementing integrated policies and plans towards resilience to disaster and holistic disaster risk management, according to the Sendai Framework for Disaster Risk Reduction 2015-2030 (Target 11.b). In order to achieve these fundamental aims at global scale, cities should implement feasible, economically viable, easy-to-use and effective tools to enhance their ability to cope with natural disaster risks. A set of integrated actions to increase city resilience to natural disaster risks should include information and preparation of citizens, cultural and natural heritage protection, and the design and equipment of public spaces. It requires a large effort in terms of human and economic resources. However, public resources are more and more scarce, particularly at the local and municipal level. Moreover, the integration of risk management into ordinary urban planning presents many difficulties due to the sectorial education and skills of urban planners and risk management officers. Thus, the enhancement of cities resilience can become extremely challenging, preventing the achievement of global goals. Existing funding provided for urban regeneration processes can be an opportunity, if sectorial approaches are overcome in favor of more integrated, multidisciplinary and systemic approaches. The concept of urban regeneration includes actions improving the economic, physical, social and environmental condition of an area that could be subject to changes (Roberts & Sykes, 2008). Thus, the synergy between risk management and urban

regeneration strategies can be the key to achieve safe and resilient cities. In recent years, the concept of resilience emerged as an important quality of natural and man-made systems (Folke, 2006) to cope with the effects of stressor events. The term resilience expresses the capacity of a system to withstand, respond to, adapt and prepare more readily to shocks and stresses to emerge stronger after tough times, and live better in good times (The Rockefeller Foundation & ARUP, 2015). This perspective highlights that resilience should not be interpreted as a static equilibrium, because urban systems can change and become different from their original conditions, in response to strains (Ahern, 2011; Carpenter et al., 2001). The needs pointed out in the Agenda 2030 were highlighted by the international scientific community since the end of eighties. The International Decade for Natural Disaster Reduction (IDNDR, 1989) recommended to integrate disaster-mitigation programs, land use and insurance policies for disaster prevention and to establish education and training programs to enhance community preparedness. The Yokohama Strategy and Plan of Action for a Safer World (United Nations, 1994) and the International Strategy for Disaster Reduction (1999) highlighted that managing disaster in the response phase alone is not sufficient, because it yields temporary results at a very high cost, thus underlining that all the phases of risk management should be considered integral parts of policies and urban planning at regional, national and international scales. The recommendations were received by Hyogo Framework for Action (2005-2015) which stressed the importance of innovative and proactive approaches to involve people in all stages of disaster risk reduction (UNISDR, 2005). It also pointed out the need of building a culture of safety and resilience at all levels, improving international collaboration on resilience issues and allocating proper resources to reduce the impacts of natural hazards. Recently, the Sendai Framework for Disaster Risk Reduction (2015-2030) has emphasized the different concepts of disaster risk management and disaster management (UNISDR, 2015). Disaster risk management assumes the implementation of actions that allow the city to cope with dangerous events and reduce their effects, while disaster management applies when events have already occurred. Aiming at enhancing the resilience of cities to disasters, this document suggests to develop a new concept of disaster risk, which can be seen as part of a multidimensional and systemic framework including also the preservation of natural and cultural heritage in the face of natural hazards. The Sendai Framework recognizes thus the positive role of cultural heritage to improve urban resilience, since it has historic, aesthetic, social, scientific and spiritual values for past, present, and future generations. The international frameworks recognized the importance to consider the resilience goals (prevent, prepare for, cope with, respond to, and recover from) in ordinary planning to manage the impacts of natural shocks and stresses (UNISDR, 2015). All the measures adopted before, during and after the occurrence of a dangerous event, to ensure human security, well-being, quality of life, resilience and sustainable development are part of risk management phases (*mitigation, preparedness, response, recovery*) (IPCC, 2012). *Mitigation* phase focuses on increasing the capacity to withstand natural hazards; *preparedness* phase addresses the process to get ready the population to the event occurrence; *response* phase aims to ensure a scalable, adaptable, and flexible reactions; and *recovery* phase aims to apply measures to rebuild and revitalize the affected communities. In this work, starting from previous literature review regarding categories and indicators of systemic urban resilience (Iavarone, Gravagnuolo, Esposito De vita, & Alberico, 2017), we identify which are the drivers that make cities and public spaces resilient to natural disaster risks and propose an evaluation framework to assess resilience of cities and public spaces exposed to natural hazard. In addition, we point out the key role of natural and cultural heritage as element enhancing urban resilience. This frame includes 4 *drivers* and 36 *sub-drivers* of urban resilience and recognizes for each *sub-driver* the resilience goals (prepare for, respond to, withstand, adapt to) and risk management phases (mitigation, preparedness, response, recovery). The proposed resilience assessment tool allows overcoming the sectorial approaches of territorial management thanks to the integration of disaster risk management measures into territorial plans in force (e.g. Regional Territorial Planning, Provincial Territorial Planning, Municipal territorial planning) and to the identification of priorities for intervention for resilient cities and public spaces.

2 METHODOLOGY

Disasters caused by dangerous events and environmental stresses such as climate change have a critical impact on the public space of the city, affecting the natural and built environment, but also the economy and society. The ability to absorb, adapt, transform and prepare for shocks and stresses is influenced by the institutional capacity and availability of critical resources at local scale, thus the management of risks requires a highly multidisciplinary and systemic approach. Evaluation tools can be useful to ensure the identification of features of a resilient urban system exposed to natural hazard, to assess the present territorial status, provide guidelines for its enhancement and monitor its evolution in the future. The evaluation framework proposed in this work integrates sectorial approaches of territorial planning and disaster risk management, identifying *drivers* and *sub-drivers* of urban resilience and recognizing their locations in all phases of risk management (Figure 1).

Figure 1 –Evaluation framework scheme. A brief description of logical model (focus, methodology, output and planning), the risk management tools (indicators, indexes and maps) and the key role of data integration (dark gray box) are shown.

The *drivers* can be defined as elements of the complex territorial system (economic, social, environmental, institutional) that drive urban resilience. The *sub-drivers* represent specific aims of resilience-oriented urban regeneration, which can be used not only to “measure” and map resilience through the selection of suitable indicators, but also to produce evidence of the weaknesses of public realm that need to be enhanced through urban regeneration tools. The framework is structured into three main parts:

- 1) Identification of focus (public space regeneration resilience oriented);
- 2) Development of the methodology (identification of *drivers* and *sub-drivers* that make cities and public spaces resilient to natural hazard);
- 3) Identification of links between risk management phases (mitigation, preparedness, response, recovery) and resilience goals (prepare, respond, withstand, adapt).

2.1 IDENTIFICATION OF DRIVERS AND SUB-DRIVERS OF URBAN RESILIENCE

According to OECD (2016), four *drivers* help to enhance urban resilience: economic, social, environmental and institutional. *Economic driver* requires innovation and diversification of economic activities; *social driver* ensures inclusive society, active citizens networks and access to opportunities, infrastructures and services; *environmental driver* requires that urban development is sustainable, natural resources and adequate infrastructures are available; finally, *institutional driver* requires clear leadership and long-term vision, proper

resources at local scale, governments cooperation and openness to participation. For the single *driver*, the conditions that lead to a resilient city (field *description* in Table 1) and related *driver descriptors* (e.g. E1 - Employment and workforce, E2 – Entrepreneurship, E3 - Local productivity) were defined and listed in Table 1. Specific *sub-drivers* representing the optimal characteristics that a resilient urban system may have, at the scale of the public space, were identified. They were deduced from a broad literature review (Iavarone et al., 2017) and the “Resilient Cities” framework (OECD, 2016), which has been already tested in ten cities worldwide and can be considered a robust evaluation structure. A total of 36 *sub-drivers* have been proposed (table 2), which express the qualities that cities and public spaces should achieve to be considered resilient to natural shocks and stresses. Specifically, 7 *sub-drivers* are related to the economic *driver* (more broadly intended to express resilience at the city scale); 8 *sub-drivers* pertain to the social *driver* (expressed at the city and public space scale); 12 *sub-drivers* express the environmental aspects of resilience (specifically expressed at the public space scale); and 9 *sub-drivers* are related to the institutional *driver* (at the city scale).

Driver	Description	Driver Descriptor
Economic	All productive activities, trade and services in a specific territory; it includes economic sectors (primary, secondary and tertiary) and their diversification, the level of innovation and creativity, vitality of entrepreneurial environment, skills and education of workforce, which influence the overall capacity of response of a community to adverse events.	E1 - Employment and workforce
		E2 - Entrepreneurship
		E3 - Local productivity
Social	Includes socio-economic characteristics of population such as age, gender, employment, education, income, health and wellbeing; it also includes the access to communication means, transport means and health services; also, social cohesion and cultural aspects such as the relationship of community with its environment, which influences the inclination of a community to recover from adverse events.	S1 - Socio-economic
		S2 - Services (communication, transport, health)
		S3 - Socio-cultural
Environmental	Includes the characteristics of the natural and built environment, land uses and infrastructures; it also includes natural and cultural heritage as element of particular value of the environment, but also as factor of increased vulnerability if adequate mitigation measures are not implemented.	En1 - Natural environment
		En2 - Built environment
		En3 - Infrastructures (streets, energy, ICT)
		En4 - Land use
Institutional	The capacity of institutions at all levels to manage the territory, also in case of natural dangerous events, through urban / territorial planning tools, risk management tools and emergency management tools; it includes financial resources available at local level for risk management, and the capacity of institutions to be open and inclusive, promoting active participation of the community to emergency planning and risk management decision processes.	I1 - Leadership and long-term vision
		I2 - Territorial management
		I3 - Institutional collaboration
		I4 - Financial resources
		I5 - Citizens' engagement

Table 1 – Drivers of urban resilience to natural disaster risk

2.2 RESILIENCE AND RISK MANAGEMENT

The evaluation framework proposed in this work poses particular attention to the key role of relation between the urban resilience goals and the four phases of disaster risk management. Mitigation focuses on the impact of a hazard and encompasses the structural and non-structural approaches taken to reduce the interaction of human, property and environment with dangerous events and to limit their vulnerability. Mitigation actions differs from these applied to survive during an emergency because they are programmed for a long-term and can take place before and after emergencies. Mitigation measures can involve changes in local building codes to fortify buildings, revised zoning and land use management, strengthening of public infrastructure, retrofitting structures to withstand natural hazards, construction of defences and other efforts to make the community more resilient to a dangerous event (FEMA, 2010). Preparedness addresses the process for developing and maintaining capabilities for the whole community both pre and post event through the education, outreach and training of the population. It includes engaging the business community, evacuation planning and other logistical readiness activities such as stocking food and water (FEMA, 2010). Response addresses the actions taken in the immediate aftermath of a dangerous event to save and sustain lives, meet basic human needs (food, shelter, clothing, public health and safety), reduce the loss of property and limit the effect on critical infrastructure and on environment. Right after the solution of the immediate emergency issues, the focus shifts to planning action aiming at reparation of property, restoration of utilities, stabilization of public services and conclusion of clean-up process. Response planning provides rapid and disciplined incident assessment to ensure a quickly scalable, adaptable, and flexible response (FEMA, 2010). Recovery encompasses both short-term and long-term efforts for the rebuilding and revitalization of affected communities, aiming at the return to a degree of physical, environmental, economic and social stability and to future sustainability and resiliency. The short-term phase involves delivering immediate services, including the restoration of interrupted utility services, the reestablishment of transportation routes and the provision of food and shelter to displaced persons, while the long-term phase requires thoughtful strategic planning and action to address more serious or permanent impacts of a disaster. Particularly a recovery plan should address prewritten emergency ordinances that facilitate recovery operations, such as those dealing with road closures, debris removal and expedited permitting; it also should incentive community efforts aiming at the improvement of mitigation processes and should develop strategies for including civic leaders and the public in the recovery decision-making process (FEMA, 2010). Taking into account all aspects considered in these definitions, each *sub-driver* of urban resilience was correlated to one or more phases of risk management (Table 2).

Driver	Driver Descriptor	Sub-Driver	Goals Of Resilience	Risk Management Phase
Economic	E1 Employment and workforce	The population in working age is actively employed	Ability to adapt	Recovery
		Workforce has diverse skills	Ability to adapt	Recovery
		Workforce is employed in sectors useful to cope with natural hazards	Ability to respond, withstand and adapt	Response Recovery
		Industries are diverse	Ability to adapt	Recovery
	E2 Entrepreneurship	Innovation takes place	Ability to prepare for and adapt	Mitigation Preparedness
		The entrepreneurial ecosystem is vital	Ability to adapt	Recovery
	E3 Local productivity	Adequate stock of primary resources is ensured	Ability to respond, withstand and adapt	Response Recovery

Social	S1 Socio-economic	Society is inclusive	Ability to adapt	Recovery
		Resources are equally distributed	Ability to respond, withstand and adapt	Response Recovery
	S2 Services (communication, transport, health)	People have access to communication devices	Ability to prepare for and adapt	Preparedness Response
		People have access to transport means	Ability to respond and withstand	Response
		People have access to health services	Ability to respond and withstand	Response
	S3 Socio-cultural	People recognize and feel proud of their city's identity	Ability to prepare for and adapt	Mitigation Recovery
		The Heritage Community takes care and valorises cultural heritage / landscape	Ability to prepare for and adapt	Mitigation Recovery
		Citizen's organizations are active in the community	Ability to prepare for, respond, withstand and adapt	Mitigation Preparedness Recovery
Environmental	En1 Natural environment	Adequate Green Infrastructures are realized to cope with natural hazard	Ability to respond and withstand	Response
		Natural heritage is preserved	Ability to adapt	Recovery
	En2 Built environment	Buildings are robust and safe to cope with natural hazards	Ability to prepare for, respond and withstand	Mitigation Response
		Inhabited areas are not overpopulated	Ability to prepare for, respond, withstand and adapt	Mitigation Response Recovery
		Buildings are covered by insurance	Ability to adapt	Recovery
		Adequate equipped and safe spaces are available for emergency	Ability to prepare for	Preparedness
		Cultural heritage / landscape is well-conserved	Ability to prepare for and adapt	Mitigation Recovery
		Cultural heritage / landscape is safeguarded from natural hazards	Ability to prepare for and adapt	Mitigation Recovery
	En3 Infrastructures (streets, energy, ICT)	The infrastructures are well distributed over the territory	Ability to prepare for, respond, withstand and adapt	Mitigation Response
		The infrastructures are well maintained	Ability to prepare for, respond, withstand and adapt	Mitigation Response Recovery
	En4 Land use	Degraded areas are absent or in phase of regeneration	Ability to prepare for and adapt	Mitigation Recovery
		The city/territory carries out urbanization rates	Ability to prepare for and adapt	Mitigation Recovery
Institutional	I1 Leadership and long-term vision	Leadership and long-term vision are clear / include learning from past natural events	Ability to prepare for and adapt	Mitigation Preparedness
	I2 Territorial management	Urban planning is regulated	Ability to prepare for and adapt	Mitigation Recovery
		Risk management plans are available and periodically updated	Ability to prepare for and adapt	Mitigation Preparedness
	I3 Institutional collaboration	Local governments cooperate with regional and national governments	Ability to prepare for, respond, withstand and adapt	Mitigation Response
		Local governments, institutions and civil society organizations cooperate	Ability to prepare for, respond, withstand and adapt	Mitigation Preparedness Recovery
	I4 Financial resources	Adequate financial resources are available at municipality level	Ability to prepare for and adapt	Mitigation Recovery
	I5 Citizens' engagement	People are informed about the natural hazards that may affect the city	Ability to prepare for	Preparedness
		People are able to apply emergency plans directives	Ability to prepare for, respond and withstand	Preparedness Response
		Government is open and citizens' participation takes place	Ability to prepare for and adapt	Mitigation Preparedness Recovery

Table 2 - Structure of drivers and sub-drivers of urban resilience related to risk management

3 DISCUSSION AND CONCLUSIONS

The methodology proposed in this work identifies 4 *drivers* and 36 *sub-drivers* to assess the resilience of cities and public spaces for urbanized areas exposed to natural hazard. Each *sub-driver* represents the optimal conditions that cities and public spaces should have to cope with natural disaster risk. They were associated to one or more phases of disaster risk management and one or more goals of resilience. The assessment framework proposed overcomes the sectorial approaches of territorial management providing a decision support tool useful to enhance daily territorial management though resilience-oriented guidelines for planning and design. Particular attention was posed to the role of cultural heritage, which highly contributes to social resilience, providing in communities a sense of belonging to the place that can enhance the response of citizens to adverse natural events, particularly in the phase of reconstruction, recovery and adaptation to a new equilibrium, without losing the cultural inheritance of the past. Moreover, it can positively influence city creativity, innovation and the vitality of the entrepreneurial environment, indirectly enhancing economic resilience. The assessment framework takes into account the key role of natural and cultural heritage. In fact, it comprehends the following 5 *sub-drivers*:

- Social (Socio-cultural): People recognize and feel proud of their city's identity
- Social (Socio-cultural): The Heritage Community takes care and valorises cultural heritage / landscape
- Environmental (Natural environment): Natural heritage is preserved
- Environmental (Built environment): Cultural heritage / landscape is well-conserved
- Environmental (Built environment): Cultural heritage / landscape is safeguarded from natural hazards

Moreover, some specific *sub-drivers* were added to the list proposed by OECD (2016), which ensure the achievement of resilience goals (ability to prepare for, respond, withstand and adapt):

- Environmental (Built environment): Buildings are covered by insurance (*ability to adapt*).
- Environmental (Built environment): Adequate equipped and safe spaces are available for emergency (*ability to prepare for*).

- Environmental (Infrastructures): The infrastructures are well-distributed over the territory (*ability to prepare for, respond, withstand and adapt*).
- Environmental (Land use): Degraded areas are absent or in phase of regeneration (*ability to prepare for and adapt*)
- Environmental (Land use): The city / territory carries out urbanization rates (*ability to prepare for and adapt*).

Sub-driver labelled “Adequate green infrastructures are realized to cope with natural hazard” (e.g. green space created around the southern edge of Manhattan after hurricane Sandy in 2012) has been also considered to improve the resilience of large parts of the city (Iavarone et al., 2017). The assessment framework proposed in the present work can be a valid decision support tool in planning processes, enhancing resilience in a territory through the integration of urban regeneration and risk management tools. It can be further developed through the identification of multidimensional evaluation tools (quantitative and qualitative indicators, indexes and draw maps) useful to enhance the urban liveability through resilience-oriented plans. The methodology will be tested in a real case study to identify possible weaknesses and refine the assessment framework. Possible limitations due to data availability, particularly for qualitative data, need further investigation through case study application. Specific selection criteria led to the identification of the Ischia Island, located in the north-western zone of Napoli Bay (Southern Italy), as a suitable area for the pilot test. They were the presence of both natural and cultural heritage, exposure of the territory to multi-hazard, and the availability of institutional quantitative and spatial data for a first assessment of the territorial structure. Ischia Island territory includes six municipalities: Ischia, Barano d'Ischia, Casamicciola Terme, Lacco Ameno, Forio d'Ischia and Serrara Fontana. Its local economy is based mainly on tourism in urban coastal areas, while the cultural landscape in mountain areas still preserves wide forests and agricultural terraces characterized mainly by vineyards and fruit trees (Gravagnuolo, De Rosa, Ronza, Di Martino, & Fusco Girard, 2017). Natural and cultural heritage such as lava domes, headlands, cliffs, pocket beaches, castles, towers, chapels and villas, are hotspots in the waterfront landscape (Figure 2). The presence of such elements in coastal areas, exposed to many natural hazards (seismic, volcanic, landslide, coastal erosion and marine inundation) and intense urbanization (Alberico & Petrosino, 2014, 2015), make the Ischia Island a relevant case study to test the proposed resilience assessment tool.

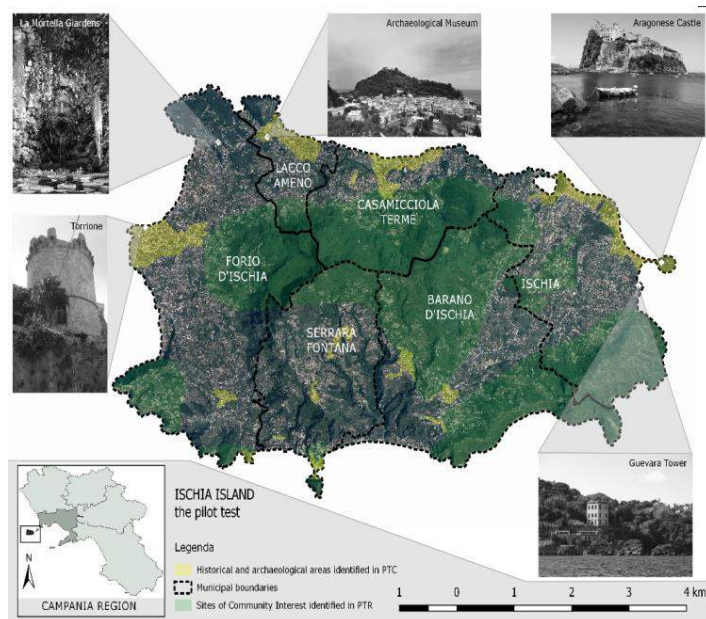

Figure 2 – Ischia Island. Map of key elements of the current territorial structure: cultural heritage, areas of high nature value, institutional municipal boundaries

Future research will focus on the development of a matrix of suitable quantitative and qualitative indicators, applied in the spatial dimension in the Ischia Island case study, which will be used to rank the territory in different resilience classes, identify weak areas that need resilience-oriented regeneration and produce specific guidelines for the enhancement of public spaces. For the four phases of risk management urban resilience maps can be drawn, which could support the identification of priorities for interventions at the municipal and inter-municipal scale and at the scale of public space.

ID 1363 | “MIND THE MINDEMYREN” A NEW SPATIAL ANALYSIS TOOL FOR LINKING BUILDING DENSIFICATION STRATEGIES TO PUBLIC TRANSPORT AND STREET NETWORK ACCESSIBILITY IN BERGEN CITY

Remco E. de Koning¹; Akkelies van Nes¹

¹Western Norwegian University of Applied Sciences

rek@hvl.no ; avn@hvl.no

1 INTRODUCTION

The population in Bergen city is growing fast. There is a need for areas for facilitating such a population growth. However, the availability of land is scarce, as the city is squeezed between seven mountains on the hilly west coast of Norway. Today, about 279 000 inhabitants live in Bergen. The population is growing with 4000 inhabitants per year. This is 2,5 times higher than the Norwegian bureau of statistics predicted in 2007 (www.bergen.kommune.no).

Old industrial areas and existing low density areas located adjacent to the city centre are becoming attractive for urban transformation. The industrial area Mindemyren is one of the urban areas with the largest transformation and densification potentials. Today this area functions as a barrier between surrounding dwelling areas by roads, old railways, fences, large long buildings and a lack of cross connections for pedestrians. The size of the area is comparable to the city centre. Bergen municipality has a policy to transform this area into a new urban centre in the next 25 years. At this moment, the area is the largest urban transformation area in Norway. This gives the opportunity on the one hand to create a new centre for the surrounding dwelling areas and to facilitate population growth on the other hand.

Population growth implies pressure on the existing infrastructure network. After a half a century of road building and facilitating the private car in city centres, the emphasis is currently shifting towards improving the public transport network and to implement a second light rail line in Bergen. A light rail line opened in 2009. The last part of the line has recently been finished. During the last 5 years, this light rail contributed to densification around the stations and to an increase of the property prices in the stations' vicinity.

At present, a proposal for the location of a second light rail line is now on the drawing table. The track of light rail line 2 goes through the Mindemyren area, and connects the Fyllingsdalen area on the other side of a large mountain with the city centre with a tunnel. The location of this light rail shapes a unique possibility to establish integrated urban design solutions in the Mindemyren area.

A land use plan has already been made. The plan has a flexible solution. Due to strong property rights in Norway, development depends on the will of the various property owners. Therefore, the challenge here is to facilitate with a proper infrastructure to trigger densification.

In addition, a change in Norwegian planning practice is currently taking place. Until recently, rigid street and road dimensions, minimum parking standards, the making of rigid land use plans with a land use

fulfilling one single function and high private car accessibility everywhere was the standard. Now, the aim is to create car-free city centres, promote a high degree of walkability, implement bicycle lanes, strengthen public transport and promote a diverse land use in new land use plans. However, large highway infrastructures for private cars outside the city centre are still implemented with the aim to remove the through-transport from city centres.

This development is in line with trends that are already taking place in other European cities. Current planning policies in Europe are putting smart growth, high building density and high diversity of urban functions within short walking distances on the agenda to create compact cities. However, the social and environmental sustainability of building a compact urban form is disputed (Rådberg 1996:385). The compact city has the advantage of short walking distances between buildings containing its various activities. The ecological footprint is relatively small due to a reduction of urban sprawl. There are advantages to social and economic intensity because a high number of people live close to each other. From an environmental perspective, energy usage of transport between functions in compact cities is low. However, there is a lack of green spaces for recreation or for agricultural activities. Green and sustainable cities on the other hand have positive connotations in terms of well-being, attractiveness and sociability. The green city has the advantage of being able to provide its inhabitants with recreation and possibilities to produce food. In contrast, green cities contribute to urban sprawl into the countryside when the city expands.

This contradiction between green cities and compact cities continues to prevail in urban design and practice (Rådberg 1996).

High building density is considered to contribute to sustainable development because it implies sharing of buildable space, facilities and infrastructure, as well as the reduction of travelling distances. This sharing implies a reduction of land use and energy resources required to perform all kinds of urban activities.

The degree of success of this sharing can thus be seen as an indicator for an area's degree of urban quality.

If density is desirable as one of the requirements for urban quality, then urban development projects should always facilitate for maintaining, and where possible, further increasing density. Jane Jacobs (2000) and Jan Gehl (2011) argue that sufficient density is a requirement for life between buildings. More importantly, life between buildings is "potentially a self-reinforcing process", in which, "once this process has begun, the total activity is nearly always greater and more complex than the sum of the originally involved component activities" (Gehl, 2011:73). In other words, a successful urban area is self-propelling by merit of the amount and duration of outdoor activities, which requires both sufficient density and high-quality public spaces to ensure that a high number of people enjoy using these spaces.

Therefore, if density is a prerequisite for sustainable use and the amount of outdoor activities an indicator for the degree of success of performing these activities, then a spatially integrated urban street network is the primary generator of sustainability in the context set out here (Hillier et al., 1993). The next step is now to reveal how public transport accessibility plays a role in the natural urban transformation process. Therefore public transport accessibility is included in the calculations of street network accessibility by mapping the angular step depth from public transport stops.

One obstacle for large scale urban planning and transformation of urban areas in Norway is the strong legal issues related to private property rights. It is even stated in paragraph 105 of the Norwegian constitution law from 1814 that no one should be dispossessed of their private property, and if so, they should be given full compensation (Backer and Bull 2016, p. 12). Therefore, urban expansions in Norway tend to take place on large plots where one has to deal with a low number of property owners. Large-scale urban renewal projects or big inner city transformations thus involve time-consuming negotiations with property owners and adjustment of property borders, as well as high costs of changing property borders when a large number of owners are involved.

2 WHERE AND HOW TO DENSIFY?

The background for the research is a project set up by Bergen municipality that intends to explore where and how to densify in existing urban areas. The aim is to use the outcomes in future land use and policy planning as a strategy for densification in the central areas of Bergen. Inspired by the 'Denser Stockholm' project (Spacescape 2013), a Spacescape analysis is made using a densification rose to identify both the need for densification and where there is freedom to do so. How to densify in those areas depends on the degree of accessibility of the street network and public transport, as this inquiry shows. To that end, the Space Syntax method is included in the research project.

The project started with an identification of the types of densification actions proposed by the municipality. Three types of densification actions were identified: intensification, transformation and expansion.

The intensification strategy entails identifying densification potentials in existing urban areas without changing the whole built environment. The transformation strategy concerns identifying and assessing densification potentials of larger urban areas requiring a functional transformation, such as harbour fronts, goods terminals and industrial estates. The expansion strategy implies finding densification opportunities in previously un-built areas within the city borders. In the Bergen case, these are often found on the mountain slopes, where development had not previously been considered due to costly technical challenges. According to the theory of the natural movement economic process, the spatial structure of the street and road network influences the flow of movement from everywhere to everywhere else as well as the location of economic activities (Hillier et.al, 1993 and 1998). A change in this kind of mobility network, such as a new road or street link, influences the location of various urban centres (van Nes 2003).

During the last years, the use of GIS has contributed to combine the results from spatial analyses with place-bound socio-economic data. GIS has made it possible to operate with big data and to combine them with one another. The combination of building density (the correlation between FSI with GSI), degree of function mix (MXI) and Space Syntax in old and new towns has contributed to knowledge on how these aspects are interrelated (Ye and van Nes 2013 and 2014; van Nes et al., 2012). Already now, an outline is formulated for a theory of the natural urban transformation process. According to this theory, the spatial configuration of the street and road network influences the degree of building density and the degree of multi-functionality in the natural transformation processes in neighbourhoods over time (Ye and van Nes 2014). Lively and vital urban environments are thus dependent on a combination of a highly spatially integrated and well-connected street pattern, high building densities and a high degree of function mix. Following the theory of the natural movement economic process, it is to be expected that the highest potentials for densification outside the city centre are found around the main routes, the local centres and the public transport stops. Local discrepancies may be found which can likely be attributed to the unique landscape elements such as the mountain slopes and fjords surrounding the city. They are also responsible for the characteristic capricious road pattern, which follows height lines to keep gradients acceptable from a road-engineering point of view.

2.1 DATA SETS AND METHODS

The Space Syntax method, developed by Bill Hillier and his colleagues at University College London, is able to calculate how a street relates to all others in a town or city. The recent versions of the Depthmap software are able to calculate topological distance (how integrated a street is in relation to others in terms of the number of direction changes), geometrical distance (how integrated a street is in relation to others in terms of the angular relationship between them), and metrical distance. Moreover, the software is able to both describe and visualise spatial inequalities within a built environment.

Johan Rådberg developed the Spacematrix method, whereas its name is introduced by Meta Berghauser Pont and Per Haupt. The Spacematrix method contributes to quantify density and various building types. This classification makes it possible to quantitatively describe the combination of intensity, compactness, pressure, non-built space and height, which can be used to differentiate urban form in a more efficient way than before. Spacematrix correlates the following measures with one another: floor space index (FSI), ground space index (GSI) and the average number of floors or layers (L). Here, FSI on the y-axis gives an indication of the building intensity in an area and GSI on the x-axis reflects the coverage, or compactness of the development. The L represents the average number of storeys. The building types are classified into

low-rise, mid-rise and high-rise based on floor numbers. The building types are also separated into point type, stripe type and block type based on building forms.

The Mixed-Use Index (MIX) method, developed by Joost van den Hoek, deals with the degree of functional mix in a quantitative manner in terms of the percentage of dwellings, working places and amenities, measured in building spaces. The function Housing includes various buildings for residential living, such as apartments, condominiums and town houses. The function Working implies places of work such as offices, factories and laboratories. The function Amenities implies all kinds of commercial facilities such as shopping and retail, societal facilities such as schools and universities and leisure facilities such as sports, cinemas, concerts and museums. A triangle matrix is made on how these three functions can be correlated and divided into high, middle and low ratios of multi-functionality. The three corners of the triangle represent one single function, which are either 100% amenities, 100% dwellings or 100% working places.

With the aim of producing maps in which Space Syntax, Spacematrix, Mixed-Use Index and property ownership data are combined, two new ways of visualising integration levels have been tested. This method goes further than the raster method introduced by van Nes, Ye and Mashhoodi (van Nes et al., 2012; Ye and van Nes, 2013, 2014) (see figure 1).

With the first method, the integration levels contained within the line segments are projected onto the building plots adjacent to these segments. This is achieved using an Overlay operation in ArcMap. The method is chosen because the building plots themselves contain the data that the integration levels are aimed to be combined with, i.e. the data on density and functional use as well as information on ownership of the plots.

Figure 1 - Examples of raster-based, polygon-based and buffer line-based Space Syntax maps in GIS

The second method combines Space Syntax data with Spacematrix and the Mixed-Use Index with a buffer area around the line segments, since there are a number of inaccuracies in the initial results from the grid-based method. The overlay method works well for smaller plots, especially if they are connected to only one or two line segments. However, in particular on larger plots, values are found that often do not represent the actual degree of integration based on their position in relation to the street network.

The best example of this inaccuracy is the plot belonging to the goods terminal east of Bergen's railway station (figure 2). Directly connected to the globally and locally highly integrated street Strømgaten, this large plot thus receives a "highly integrated" classification. In reality, however, the plot is for the larger part flanked by line segments with much lower integration values than the map suggests. Moreover, the plot today is isolated and difficult to approach, and elongated to such an extent that only a limited percentage of people would approach it from Strømgaten, but most others from other streets located closer by.

To avoid this deviation from actual integration values on larger plots, a buffer operation is tested out as a second method. With a buffer of 75 meter around each line segment, a surface area is created that contains the corresponding integration value of that segment.

To identify the segments with high potential for both to- and through-movement, the global and local integration values have been multiplied with each other and combined with the multiplied metric step depth values with both high and low radii. The result is an aggregated map that reveals the overall integration

values based on the location in relation to the street network. In addition, the building function is visualised by colour according to the Mixed-use Index and simultaneously, the building height is indicated by the gradient of the colour in question.

2.2 RESULTS

In figure 2 and 3, the global and local integration values have been projected onto the building plots. The highest global values are found in the city centre area where there is an orthogonal street structure, introduced in the first decade of the twentieth century. The high values extend out of the centre along the main axis that leads past the Danmarksplass area. This axis has evolved over time by different road upgrades to facilitate the rapid growth of vehicle transport. Since 2009, Bergen's first light rail line runs parallel with the highway. The highest density and degree of function mix is found along this highway axis.

The orthogonal street network structure yields the highest local integration values in the city centre around the Smålungeren area (figure 3). However, there are no other local areas outside the city centre where equally high values are found. This lack is not only limited to the built-up slopes, where both the road structure becomes more parallel to limit the gradient and there is an edge effect, but is also found throughout the urbanised valley.

It becomes clear that the street pattern throughout the city (outside of the city centre) has been constructed for facilitating car traffic through the large topographic variations in the landscape. This has produced a curvier road pattern with fewer cross connections than in cities situated in a more level landscape. Moreover, road engineers have the largest influence in Norwegian urban planning. In detailed land use plans, all new streets and roads are planned in detail, whereas the land usage along these streets and roads is merely indicated with a function and with a degree of building density.

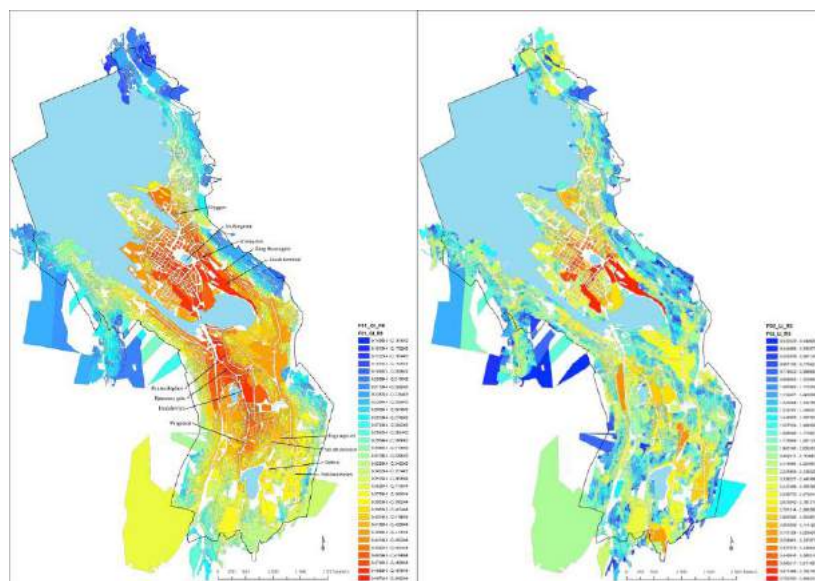

Figure 2 - Global integration map projected onto building plots
 Figure 3 - Local integration map projected onto building plots

Taking into account that Bergen's street pattern is imposed on an extreme sloping landscape, the aggregated map in figure 4 was produced to reveal the areas with the best accessibility on both city level and local level, whilst including choice of route based on angular deviation. Again, the highest values are found in the city centre. Moreover, several main streets are well-integrated on a local level, such as Bryggen and Kong Oscars gate in the centre, Bjørnsons gate and Inndalsveien leading up to Wergeland, Slettebaksveien and Hagerups vei north of Sletten, and Natlandsveien as the main road on the east side of the valley.

These red areas are undergoing a considerable degree of urban transformation in terms of increased density of the built mass. Ground prices in these areas are rising. New building projects have larger floor space and more storeys than the old buildings. The amount of commercial establishments is also increasing.

The trajectory of the light rail line has subsequently connected these centres with each other. Most areas around these centres, marked in orange, are relatively well-integrated, although further away, the values drop sharply.

Figure 4 - Aggregated integration map using 75m buffer lines

A close-up study was done of Danmarksplads and Bergen centre. The goal was to reveal how building density and degree of multi-functionality are strongly influenced by the degree of spatial accessibility of the street and road network. These two areas have developed incrementally over many years without any overall urban planning. In line with earlier studies from other cities in Europe and Asia (van Nes et al 2012, Ye and van Nes 2013 and 2014), the higher spatial integration on all scale levels on Bergen's mobility network, the higher the degree of multi-functionality and the higher the density of the built mass.

2.3 THE NORWEGIAN PLANNING REALITY

It turns out that developments in Bergen city take place in line with the natural urban transformation process. Well-integrated streets have more to- and through-movement than poorly integrated streets. Shops and businesses cluster around these streets and densities increase considerably in comparison to the situation prior to the new situation.

Seemingly, cities in Norway are currently transforming on an "anti-urban" track. Even though the intentions are to make compact cities, there are three drivers for urban sprawl in Norway. For the first part, urban developments are still steered by a strong emphasis on private car accessibility. New buildings are equipped with parking garages in the basement and often at ground floor level. As a result, building projects create poor urban qualities for pedestrians and cyclists. This stands in strong contrast with the municipality's formal ambitions to reduce the growth of car traffic with 50% by improving the walking and cycling conditions in urban areas.

The second cause for the continuation of the anti-urban tradition is Norwegian property legislation. Although private property developments do result in space-efficient exploitation of building plots with high short-term profits, the flexibility and adaptability to adjust to changes in the long-term is lacking. Moreover, these private owners have the last word concerning the degree of multi-functionality on their properties. In addition, property owners tend to plan and build their properties to the current context rather than being future-oriented. Access from the public domain is hardly taken into account and private car accessibility is prioritised. Attitudes like these strongly affect the organisation of public spaces that link the properties to the public street network. Disappointingly, this often results in an incoherent, anti-urban structure with inward oriented buildings that lack active frontages towards the public streets.

The third aspect is the hilly Western-Norwegian landscape. Technical innovations now give way to previously impracticable or unrealisable plans, although they are expensive. Carrying out functional changes in a later stadium would thus be much more demanding. Therefore, any possible short-sightedness from private developers could produce a building stock that is hard or expensive to adapt to new uses.

The method of projecting integration values onto building plots can be a useful tool in Norwegian planning. By linking integration values directly to building plots, the authorities can take measures that oblige privately owned properties to be developed with the urban qualities related to accessibility for pedestrians, cyclists and public transport, flexibility, multi-functionality and, in the near future, energy production, smart communication and sustainable mobility means.

The second method, using buffer lines, is more usable to locate densification potentials based on the position in the urban fabric. In addition, this method allows for quick identification of areas that are segregated as a consequence of the street pattern layout. The municipality and road authorities can use this method as input for overall development plans as well as infrastructural improvements, and subsequently predict the effects on building density and degree of diversity of such plans and measures.

2.4 WHERE AND HOW TO DENSIFY FROM TODAY'S SITUATION

How can this research be used to make recommendations for Bergen municipality on where and how to densify? Evidently, the street network configuration influences the degree of building density and degree of function mix. Four types of urban areas were identified based on street network integration on local and global scales:

- Type A: High local and high global integration of the street and road network - Where extra space becomes available, these areas can be transformed with a high density of built mass. This can include high-rise buildings. The aim is to provide land use plans that allow a wide range of different usages, in particular on ground floor level. Areas suitable for this kind of development in Bergen are the city centre, the harbour areas around the city centre, Danmarksplass and the old industrial area Mindemyren.
- Type B: High local, but low global integration of the street and road network - Where there is space, these areas can facilitate high density of dwellings with ground floor spaces for shops, small businesses and services. Depending on the local circumstances, high-rise buildings can be considered as an option. As an example, the Sandviken area has many 2-3 floors high old wooden houses. The type and style of buildings give this area a particular place character. New buildings will have to adjust to the existing building stock in scale and style to avoid damaging the place-identity of that area. Areas suitable for this kind of densification are the various local centres outside Bergen centre. Most of these small local centres are situated along the main routes leading through various urban areas. Areas located along the light rail line also fit in this category.
- Type C: Low local, but high global integration of the street and road network. These locations are suitable for high densities of housing. Where possibilities exist to create a locally integrated street network, local shops on the ground floor can be facilitated. An example of such an area is the southern part of industrial area Mindemyren.
- Type D: Low local and low global integration of the street and road network. Where there is space to develop, high densities of only dwellings are desirable. These areas have a low degree of accessibility, and are therefore little attractive for shop owners. Examples of these kinds of areas are found around the lake Store Lundgårdsvannet such as Møllendalsveien, and harbour areas located along the fjord Puddefjorden.

Figure 5 shows the principles on how and where to densify in one map. The colours in the diagram in the upper right corner are applied in the combined integration map. Four groups were used in this inquiry.

It is also possible to use nine different groups where high, medium and low values of global and local integration are combined. This would enable the application of more detailed strategies. In this case, however, being in the beginning stage of collaboration with the municipality and in a planning process where multiple NGO's, property owners and stakeholders are involved, operating with four different categories rather than nine is more practical. In addition, the various densification strategies for each of the nine categories would need to be defined.

Figure 5 – Strategies for where and how to densify

The experiments with the buffer line method are still in a test stage. The next step is to find ways to combine density, MXI and Space Syntax data into one buffer line model. The raster model is useful for overall strategic land use planning in whole urban regions or in regional planning. Professionals such as spatial planners and urban geographers may find this model useful. The polygon model is useful as a guide for urban designers and architects who work on plot level. Finally, the buffer line model can be useful for road engineers to make them aware of the spatial potentials of their planned road and street links. After all, the degrees of building density and function mix depend on the spatial integration of the mobility network.

3 CONCLUSIONS: THE MINDEMYREN EXPERIMENT

According to the theory of the natural urban transformation process, a change in the road and street network system implies a change of the densification potentials and degree of multi-functionality. An experiment is carried out on Mindemyren's street and road network. A few new cross-connections were added between east and west and made an orthogonal street grid inside the whole area. This proposal is analysed with the Space Syntax method. Figure 6 shows global and local angular integration analyses of Mindemyren today and with our proposal. These street and road network changes can extend Bergen's main centre to Mindemyren. The degree of street life depends on a well-connected fine-grained local street network, whereas the new cross-connections contribute to give this new centre a strategic location for the whole city.

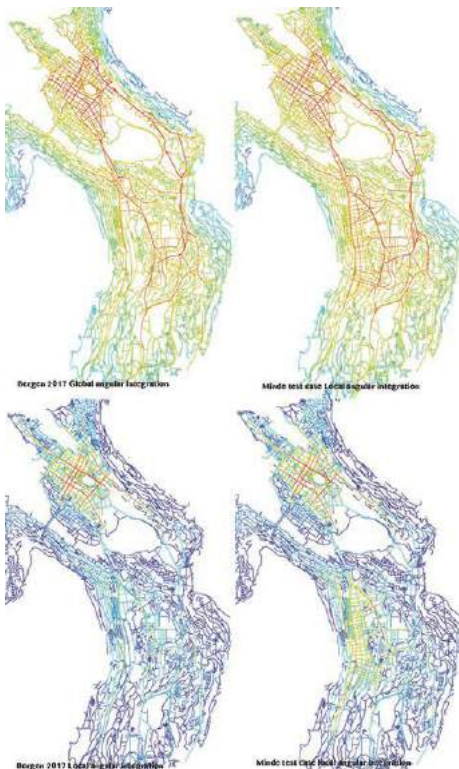

Figure 6 – Spatial analyses of the street and road network showing changes with Mindemyren as a test case

The test analysis of public transport stops as a backbone for densification reveals that the influence of bus routes is insignificant in comparison to that of the light rail. This might be due to the comparatively long-term character of light rail lines, creating a certainty of passenger flows along these routes. The municipality is currently developing plans for three new light rail routes aimed at improving the accessibility to and from the city centre to the districts further away. It can therefore be expected that redevelopments will intensify more along these lines than the integration values based on the street pattern would otherwise suggest.

Figure 7 – Angular step depth from light rail stops showing changes in public transport accessibility with Mindemyren as a test case

Figure 7 shows an angular step depth analysis from all light rail stops. The light rail is running frequently. In the Mindemyren test case, the stops of light rail number 2 (which is now on the drawing table) are added into the model. As can be seen in our proposal, two light rail lines surround the new Mindemyren area. The area has in the proposal a higher public transport accessibility than in the historic city centre. Seemingly, a natural densification process depends on the degree of accessibility of the street and road network on various scale levels. If this degree of accessibility changes as an effect of new street and road links, the potentials for a natural densification process will change too. Therefore, these aspects have to be taken into account when making densification strategies for Bergen municipality. In particular, planners have to mind Mindemyren's hidden spatial potentials in the making of densification strategies.

1 INTRODUCTION

In order to better understand the impact of infrastructural improvements on spatial development, we can make the illustration of our planet as our own body: the skeleton is made of roads, railways, air and sea ports; the vascular network consists of gas and oil pipelines and electric grids, while the nervous system is based on internet cables, satellites, data scanners, etc. In sum, infrastructure, being it an instrument of physical connection, energy supply or information share, is an underlying factor generating the connectivity – the key asset class of the 21st century. Thus, the infrastructural upgrading, as it enables all other sectors to function properly, is recognised as one of the 19 UN Sustainable Development Goals.

Looking back through the history of European ‘rise and fall’, after each critical period Europe started to renew itself by improving the transport corridors. In other words, Europe has a long tradition in understanding the infrastructure, in particular the railway transport infrastructure, as a tool for achieving prosperity and stability – first transnational initiatives date back to the end of the 19th century. However, the coordinated action regarding the development of transport infrastructure in Europe started in the 1980s with the European Union (EU) TEN-T (Trans-European Transport Network) policy clearly addressing the main objectives of European development – economic, social, and territorial cohesion. The first initiative was the PEC (Pan-European Corridors and Areas), developed during two Ministerial Conferences – in Crete (1994) and in Helsinki (1997), with the aim of connecting the EU-15 with the then neighbouring countries. At the same time, the TINA (Transport Infrastructure Needs Assessment) process started in 1995 focused on strengthening the linkages within the eastern part of Europe (EC, 2011a; Commission of the European Union 2011b).

In order to better understand the impact of infrastructural improvements on spatial development, we can make the illustration of our planet as our own body: the skeleton is made of roads, railways, air and sea ports; the vascular network consists of gas and oil pipelines and electric grids, while the nervous system is based on internet cables, satellites, data scanners, etc. In sum, infrastructure, being it an instrument of physical connection, energy supply or information share, is an underlying factor generating the connectivity – the key asset class of the 21st century. Thus, the infrastructural upgrading, as it enables all other sectors to function properly, is recognised as one of the 19 UN Sustainable Development Goals.

Looking back through the history of European ‘rise and fall’, after each critical period Europe started to renew itself by improving the transport corridors. In other words, Europe has a long tradition in

understanding the infrastructure, in particular the railway transport infrastructure, as a tool for achieving prosperity and stability – first transnational initiatives date back to the end of the 19th century. However, the coordinated action regarding the development of transport infrastructure in Europe started in the 1980s with the European Union (EU) TEN-T (Trans-European Transport Network) policy clearly addressing the main objectives of European development – economic, social, and territorial cohesion. The first initiative was the PEC (Pan-European Corridors and Areas), developed during two Ministerial Conferences – in Crete (1994) and in Helsinki (1997), with the aim of connecting the EU-15 with the then neighbouring countries. At the same time, the TINA (Transport Infrastructure Needs Assessment) process started in 1995 focused on strengthening the linkages within the eastern part of Europe (EC, 2011a; Commission of the European issue of integrated railway and spatial development along European corridors, illustrated through two examples: 1) the Rhine-Alpine corridor (the Rotterdam-Genoa corridor) as the crucial north-south axis of developed Europe, and 2) the Orient/east-Med corridor (the Hamburg-Athens corridor) as the most challenging corridor of entire Europe, connecting both developed and developing countries. Therefore, the concluding remarks provide the lessons learnt from the Rotterdam-Genoa corridor development, and their possible adaptation and implementation in the case of the Hamburg-Athens axis.

2 THE COOPERATIVE APPROACH FOR INTEGRATED SPATIAL AND TRANSPORT DEVELOPMENT

Integrated spatial and transport development is considered a challenging task. This is particularly true if we take into account the territorial scope associated with such a development, different contexts (political, social, economic), and finally different ways of 'how thing are done' (Faludi, 2005), i.e. the planning cultures. Therefore, one of the most demanding issues, besides the compliance of infrastructural equipment and technical specificities, is the question of the governance of such a development (Peric, 2016b). How to achieve effective cooperation among a number of nation states? How to integrate the visions of various sectorial departments at the state level? And, how to make the consensus-based decisions among the various parties involved in certain urban development? The following lines describes the most important levels and types of cooperation needed to be taken in due account when in comes to the integrated spatial and transport development, as provided in Figure 1.

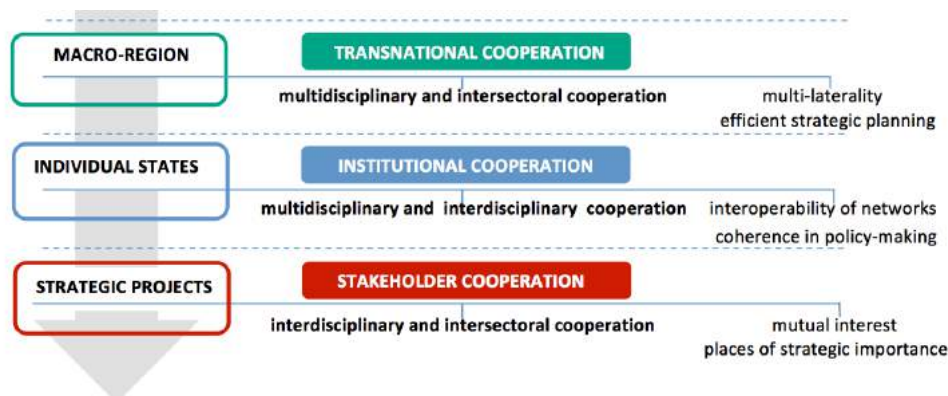

Figure 1 – A cooperative approach to integrated spatial and transport development
(Source: Peric, 2016b)

2.1 TRANSNATIONAL SCALE: MACRO-REGION

According to the research in the field of transnational (macro-regional) projects, the main problem is that there is no sufficient cooperation among numerous countries, which participate in these (Colomb 2007; Perkmann, 2003; Scholl, 2012). In a narrow sense, all the achievements and project results usually stay within one country, without their effective dissemination among other project participants. Briefly put: transnational projects are not truly transnational, since they usually remain at the level of 'exchange of experiences' on domestic issues (beginning phase) and seldom reach the final phase of the process – making a transnational strategy (Colomb, 2007). Therefore, it is necessary to implement multi-lateral and strategic approach, which, on the one hand, includes relevant representatives stemming from various expertise domains (transport, spatial planning, economy, sociology), and various sectors (public, private,

and civil). Usually, at the transnational scale, only the voice of official government representatives and public enterprises are heard, neglecting the fact that large-scale development usually depends not only on public money, but more likely on private funding.

2.2 NATIONAL SCALE: INDIVIDUAL STATES

Transnational cooperation and its outcomes affect the institutional and policy change, observed at the national level and lower levels of governance (regional, local). Actually, transnational cooperation has an impact on the extent of synergy between different governance levels within the nation states. The changes can be seen in formulating the new integrated policies (e.g. integrated spatial and transport policies) or stronger cooperation among existing institutions (e.g. spatial and transport agencies). Nevertheless, the implementation of decisions made at the transnational level often depends on the planning culture – the way of understanding the problem and the usage of specific planning methods and instruments of the individual state (Scholl, 2012; Getimis, 2012; Friedmann, 2005). The compatibility of national policies with the transnational strategic planning goals is very ‘state-sensitive’ and demands knowing the broader context of socio-political circumstances in which spatial planning policies are made (Savini and Ovink, 2012). Therefore, in order to achieve the coherence in policy-making, a multi- and interdisciplinary cooperation (at the entire national scale, or among the regions within the state) is a must.

2.3 LOCAL SCALE: STRATEGIC PROJECTS

The easiest way to understand the close relationship between the improvements in transport infrastructure and its effect on spatial development is to observe their interconnection at the level of strategic nodes, i.e. specific, flagship projects in particular places (Scholl, 2012). An example of such a project can be the redevelopment of the railway station and, consequently, urban growth of its catchment area. More precisely, such infrastructural developments contribute not only to creating the transportation hubs, but also to generating the new city landscape. The synergy between the mentioned two fields usually transcends local, often national, and, in some cases, integrated project can be of international concern. One of the criteria for identifying such projects is certainly the firm commitment by the country concerned to implement the project (EC, 2005). Nevertheless, it is not only about the readiness of the authorities to tackle such issue – the identification of strategic projects depends on the extent of stakeholders’ involvement and their cooperation. This is particularly relevant for the states without the tradition of cooperation among relevant stakeholders and with the non-transparent decision-making procedures (Peric, 2016a).

3 INTEGRATED SPATIAL AND TRANSPORT DEVELOPMENT ALONG EUROPEAN CORRIDORS

Before we proceed with an analysis of integrated spatial and transport development on the case of two European corridors, it is important to clarify what is actually understood as a corridor. A corridor is a bundle of infrastructure and adjacent settlements and landscapes linking regions spread over a certain physical space (cf. Witte, 2014). From such a definition, it is clear that infrastructure development cannot be considered without taking into account the spatial dimension. Moreover, due to its axial nature, the issue of corridor development usually goes beyond the national borders (Scholl, 2016a). The main indicators assigned to the topic of corridor development are: 1) mode (road, rail and inland waterway), and 2) scope (freight and passenger) (Priemus and Zonnenveld, 2003).

Two main factors that determine the approach to be used when dealing with corridor development are its multidimensional and multi-scalar nature (Chapman et al., 2003). Multidimensional nature refers to various dimensions appropriate for further analysis, such as: 1) infrastructure (physical and organisational infrastructure), 2) space (functions and morphology), 3) governance (politics and institutions), and 4) economy (finance and market conditions). Although there can be difficulties in combining various aspects to gain the synergetic developmental effects, the improvement of its spatial and infrastructural dimension certainly have no negative impact on other two factors. When it comes to the multi-scalar nature of

corridors, it is logical to mention three main levels of observation: 1) transnational, 2) national/regional, and 3) local.

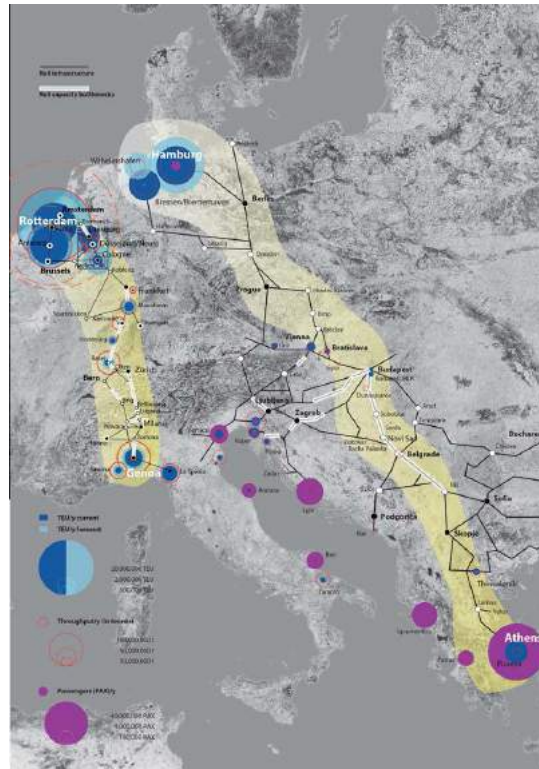

Figure 2 – Rail and port infrastructure along two European corridors (Source: Scholl, 2016b)

In the following lines, the main features of the Rhine-Alpine (Rotterdam-Genoa) and the Orient/east-Med (Hamburg-Athens) corridors (Figure 2) are to be elucidated, being observed from various levels according to the cooperative approach described in the previous section.

3.1 THE RHINE-ALPINE CORRIDOR

The corridor from Rotterdam/Antwerp to Genoa, which was designated as Corridor 24 by the EU TEN-T policy, now operates under the name Rhine-Alpine corridor as one of nine core European corridors. In its length of more than 1200 km, it travels through European regions that have the highest economic value – from the large North Sea harbours in Belgium and the Netherlands, across Germany and Switzerland, to the prospering economic centres of northern Italy, as well as the Italian Mediterranean area. In terms of transport, 700 million tonnes of freight are transported along this north-south link, while 70 million people, roughly nearly a fifth of the entire population of the EU, live in the catchment area of this important European north-south connection (Drewello and Scholl, 2016).

The corridor demonstrates which connections and conflicts between spatial and transport development at the macro-regional scale are to be observed and how the tasks to be solved can be identified and solved in steps. More precisely, the analysis provided below stems from the project entitled CODE 24, conducted in the period 2010-2013 within the framework of the European Commission supported INTERREG programme. Results and interim project results are reported in detail in other publications (see Scholl, 2011, 2012, 2014).

3.1.1 GLOBAL TRENDS

A strong increase in transport in the north-south direction of Europe can be expected for 2030 as globalisation continues to grow. The world is changing slowly but steadily into one single large market. In particular, the economic growth in Asia and the increase of goods exchange within the EU plays a vital

role. The Mediterranean Sea has taken over from the Atlantic as the main shipping route for maritime exchange. In the long term, it will be important to take the opportunity to use the port potential situated on the Mediterranean and the Adriatic coasts in order to achieve a balanced European goods exchange. Highly productive hinterland connections, in particular, those on railway systems, as are the northwest European ports, will as before play a decisive role (Scholl, 2016a). At present, the main parties dealing with sea transport in Europe are the ZARA ports (Zeebrugge, Antwerp, Rotterdam, Amsterdam) and the German harbours of Willemshafen, Hamburg, and Bremen/Bremerhaven.

3.1.2 TRANSNATIONAL OVERVIEW

Antwerp and Rotterdam alone had a turnover in 2010 of over 16 million TEU (Twenty-foot Equivalent Unit). By 2020, a redoubling of capacities to over 36 million TEU is expected. Such a preference for northern harbours over the Mediterranean ports is indicated by the financial capacities of these regions and the much larger and more effective cargo handling facilities as well as better hinterland connections, e.g. waterways, railways, and high capacity roads. The container capacities of Rotterdam are five times larger than those of the Ligurian harbours (Savona, Genoa, and La Spezia) together. The harbours in Northern Europe, particularly in Rotterdam, have invested massively in the extension of their harbour infrastructures. Rotterdam will increase its cargo handling capacity with a harbour extension 'Maasvlakte' from about 450 million tonnes at present to about 700 million tonnes in 2035. However, the harbour extension will make it increasingly difficult to guarantee a smooth hinterland transport (Günther, 2015). In the Netherlands, the launch of the Betuwe line was achieved in 2007 under considerable pressure. Starting in 2015, a full use of this line between Oberhausen and Emmerich will mean the need for a third track and block concentration which will not be available because the German railway network has other priorities. From now on, commissioning and costs of around 2 billion euro will be expected for the year 2023 (Scholl, 2016a).

3.1.3 NATIONAL CHALLENGES

With such a foreseen port development and their extra capacity, more bottlenecks are to be expected. Today, there is a great request from the Rotterdam port to transfer the share of the container hinterland traffic (4 million TEU in 2009, and 18 million TEU expected in 2035) to the waterways and railways.

Another bottleneck is the strategic railway section Frankfurt-Mannheim in Germany. It is highly significant for the approach to the Brenner Tunnel and the Main East-West Railway, as well as the missing continuation of the four-track extension of the Rhine line from Offenburg to the area south of Freiburg. It should be mentioned that despite all financial difficulties, the 17.6 km long Katzenberg Tunnel was launched in time for the time table change in December 2012. The building work for the Raststatter Tunnel could also begin in 2013 after a nearly ten-year postponement due to missing financial support. The launch is now expected to be in 2022, with construction costs of around 700 million euro. According to prognoses, the finalisation of the extension of the Rhine Valley route will not take place until after 2030, although according to the contract, a timely launch with the Gotthard Base Tunnel had been secured (Scholl, 2016b).

In addition, the opportunity arises, supported by new planning approaches, to achieve the separation between goods transport and passenger transport in some densely populated areas, for instance, by using goods transport bypasses. Route sections where this should definitely be tested are: Germany – the section between Frankfurt and Mannheim, from Offenburg to just south of Freiburg, and Switzerland – Basel to Central Switzerland, a bypass for Bellinzona, and south of Ceneri to the Italian border. Transferring dangerous goods transport not only decreases railway noise and eliminates unsatisfactory noise reduction installations, it also plays a significant role in creating relevant planning considerations (Tosoni, 2015). This transfer would also create additional experimentation space for local and regional development where smaller distances to the railways are possible (Scholl, 2016a). It will be necessary therefore to create sensible priorities, together with the national and regional authorities, and find integrated solutions through innovative forms of cooperation. This can only happen on the basis of an assessment of the entire situation. CODE 24 has created an important foundation for these (Scholl, 2012, 2014, 2016a).

3.1.4 LOCAL ISSUES

Eliminating bottlenecks is of major significance for the redevelopment of cities and regions, whereas the catchment areas of the railway stations are considered the crucial redevelopment nodes (Peric, 2016b; Scholl, 2016a). This encourages the need to keep, or actually improve the availability of public transport. With redevelopment, the share of public transport's part of overall traffic can be increased when relevant attractive offers for public transport are available. Its decrease or reduction through increasing goods traffic, which would compete with the passenger transport on rails, is counterproductive. Of all these reasons, the integrated development in the triangle of passenger transport, goods transport and redevelopment is of central importance (Scholl, 2014).

The catchment areas of nearly all mayor railway stations offer special opportunities for redevelopment. The city of Frankfurt is a good example: near the central railway station and several metro stations, a new city area, the Europaviertel, is being created on a 100 ha-site where about thirty thousands of people will have the unique opportunity to modernise and expand the Messe Frankfurt in its inner city location.

Estimates of the available settlement potential along the north-south axis show a grand total of around 150,000 ha. Some of these potential areas, e.g. in the German state of Rheinlandpfalz, in the regions of Rhein-Neckar and Upper Rhine-Bodensee, and in the Swiss cantons of Basel-Landschaft, Schwyz, Uri and Tessin. A conservative estimate would mean that around 50% of the sites would be available immediately. Applying an average gross floor ratio of about 0.5 would, and filling the area with apartments at a rate of 50 m² of floor space/inhabitant, around 7 million additional inhabitants could be housed along the corridor (Scholl, 2016a,b). These are significant figures for a potential settlement area, which can be actively implemented in the coming decades.

3.2 THE ORIENT/EAST-MED CORRIDOR

The Hamburg-Athens corridor, defined as the Corridor 22 in the TEN-T policy and as the Orient/east-Med(iterranean) corridor within the more recent EU Core Network programme is one of the key north-south transport corridors in Europe. In its length of more than 2,500 km, it connects the ports of northern Germany with the Adriatic and the Danube ports, as well as the seaports in Thessaloniki and Athens. Hence, by strengthening its transportation features, the Hamburg-Athens corridor is considered an axis with a huge potential for triggering off spatial development, which would finally lead to territorial cohesion in Europe (Scholl et al., 2016).

However, the Hamburg-Athens corridor is currently an example of genuine shortcomings in various domains: it runs through the states with traditionally low economic performances in comparison with the developed Western European countries; there is also a significant lack of efficient infrastructural network – seen in numerous missing links and bottlenecks; the corridor nowadays coincides with the so-called migrants' route; finally, administrative obstacles caused by mistrust among stakeholders are common practice in cross-border issues, as well as among various authorities of the nation states (Peric and Scholl, 2017).

The findings presented below stem from the ongoing three-year project titled “Spatial and Transport Development in European Corridors: Example Corridor 22, Hamburg-Athens”, being conducted currently by the German Academy for Spatial Research and Planning (ARL). Since the ARL members recognised the necessity to take also the needs and challenges of the non-EU states affected by the official corridor into consideration, and since the route from Budapest to Thessaloniki via Belgrade is the shortest (400 km) and the most logical way of connecting the north and south of Europe, the axis covered by the ARL project slightly differ from the official EU route – it runs through Serbia as a primary line, while the way through Romania and Bulgaria is of secondary importance.

3.2.1 GLOBAL TRENDS

Since the development of the large-scale projects is affected by global factors (trade, economy, demography), it is important to stress the relevance of the Hamburg-Athens corridor in trans-continental circumstances. Firstly, 80% of global TEU traffic appears between Europe and Asia, reaching the most important European ports of Rotterdam, in the north, and Piraeus, in the south. Secondly, the New Silk

Route is constantly upgrading through the Chinese investments, mainly through constructing the new high-speed railway network not only in Asia, but also in Europe. Its most important section in Europe is a route from Athens to Budapest via Belgrade. Finally, until 2050, the population rate in Europe will shrink to only 5.7% of global population (in comparison to 10.1% today), with a constant loss of people in Eastern Europe, mainly due to socio-economic reasons and, hence, the huge brain drain (Scholl et al., 2016). Hence, demographic decline in Europe together with boosting factors in terms of trade and economy actually trigger us to think about sustainable ways of overcoming such challenges.

3.2.2 TRANSNATIONAL OVERVIEW

Improving the conditions along the Hamburg-Athens corridor can be seen as contributing to a better territorial cohesion along this axis and reducing the gaps between Western and Eastern Europe. Nevertheless, the challenges are numerous. In terms of economy, the countries along the corridor have 21% lower performance comparing to Western Europe. Although EU provided a great support (also in financial terms) to the less developed European regions, the problems and limitations that the socialist countries had to face during the period of the Cold War are still felt nowadays. Through the lens of the traffic analysis (goods export/import, passengers/goods on rail/road, network density), the performance is even 50% lower looking at the section from Vienna towards the south. This makes a great inconsistency in the railway schedules, thus practically disabling any efficient passenger and/or freight transfer along the corridor; e.g. the passenger travel time from Hamburg to Athens is 52 hours (Scholl et al., 2016). Finally, in terms of population along the corridor, there is 128.4 million inhabitants counting only NUTS-1 regions along the corridor route and excluding these in Germany and Tirol in Austria (Scholl, 2016b). Such a limited population potential creates one of the biggest challenges for the creation of an effective rail connection. However, recent incentives in various projects (transport infrastructure, pipelines, etc.) provide an important stimulus for the research on possibilities for raising the competitiveness level of the Hamburg-Athens corridor.

3.2.3 NATIONAL CHALLENGES

In addition to the historical differences between the countries on the corridor route (i.e. only Germany, Austria and Greece were not part of the Soviet bloc), there is also a high discrepancy between the corridor member states today. Except Germany, which is still one of the leading European countries in economical terms, Greece is faced with recent economic downturn, Romania and Bulgaria are dealing with numerous problems despite their joining to the EU, while Serbia still tries to fulfill all the necessary pre-accession conditions.

In terms of transportation quality indicators, the current assessment is as follows. There is an asymmetry in the freight distribution through the maritime transportation mode. Sea freight is mainly concentrated in the northern ports of Hamburg and Bremerhaven, while maritime passenger figures are low in Germany. In contrast to this, both in the Greek and the Adriatic ports, the main flows using ports are the passengers, denoting a much more tourist-oriented economy than in the north. Secondly, the rate of freight transport is the highest in Austria, while particularly low rate (in both freight and passenger transport) is observed in the case of Greece. Finally, the quality and density of the rail network is better in the regions northern from Vienna – especially in Germany. In contrast to this, there are no railway lines with a speed more than 160 km/h along the southern part of the corridor. In some of the regions (parts of Serbia and Bulgaria), the train speed is only 40 km/h (Scholl et al., 2016).

3.2.4 LOCAL ISSUES

The local scale of the Hamburg-Athens corridor project relates to identifying the hot spots – places with major spatial implications of transport infrastructure development. Moreover, it is interesting to observe some 'good-practice' examples of integrated spatial and infrastructure development as well as more challenging case studies. The result is directed towards mutual learning finally aimed at improving the collaboration among various stakeholders with different interests.

The main differences are again observed between the cities along the northern part of the corridor and the hot spots in the south. The 'best practice' examples of integrated spatial and transport development are found in the cities of Hamburg, Berlin and Vienna. Each city succeeded to make certain transportation Mutual engagement of all interested parties in the problem screening and identifying the complex points for future actions.

- Preparation of regional conferences and the annual project conferences, whereby the results and findings are introduced to the public, representatives of all governmental levels and political committees, as well.
- The findings, together with the outcome from the debates with the public and political representatives, should consolidate a common strategy for the corridor development.
- The European Grouping for Territorial Cooperation (EGTC) is considered one of the follow-up aims, as it will continue to be the organisational body for future project related activities.

ID 1467 | MOBICAMPUS-UDL: COMBING WEB-BASED TRAVEL SURVEY AND SMARTPHONE APP DATA COLLECTION TO UNDERSTAND AND MANAGE URBAN MOBILITY BEHAVIOUR

Ayman Zoubir¹

¹Transport Urban Planning Economics Laboratory
ayman.zoubir@entpe.fr

ABSTRACT: Reducing car dependence in general and driving alone in particular has become an important public policy issue. Universities are recognised as special generators in transportation planning processes. Large university campuses contribute in a variety of ways to the travel demand. However, university populations are underrepresented in travel behaviour studies in particular regular household travel surveys. The aim of MobiCampus-UdL research is to understand Lyon's university communities daily travel behaviour characteristics not just from a travel demand modelling perspective but as well to help campuses managers in planning coherent measures prioritising various range of mobility management strategies/urban design solutions appropriate to the diverse mobility needs and fulfil sustainability goals. The data used specifically was generated by an online travel survey conducted among several higher-

education institutions. Another issue of the project is exploring the potential of smartphone travel data collection. As we know university populations are tech-savvy, that was a good opportunity to plan a panel recruitment of voluntary participants who will respond to the first wave of the web survey. The objective of this experimental approach is to verify if this new method of data collection can improve quality/accuracy in temporal and spatial data. This paper aims to report on first findings from and experiences gained in the conduct of a comprehensive travel survey at University of Lyon (UdL). The paper offers a very preliminary results of an ongoing research project MobiCampus-UdL. A detailed description is dedicated to research method and data collection. Preliminary analysis on surveyed campuses shows when compared to the employees from the same university, university students are more likely to share favourable modal split towards active transport modes that include public transport and sustainable travel modes.

KEYWORDS: Lyon, student travel behaviour, mobility management, travel survey, planning, policy, transport regulation and urban planning, sustainable accessibility planning, active transport

1 INTRODUCTION

As education and employment destinations, universities are important generators of travel demand on local transport networks. Understanding travel behaviour is essential to informing transport management and planning (Akar, et al., 2012). Travel survey is often adopted as a method to understand individual travel behaviour. However, university students' mobility patterns are weakly investigated in conventional household travel surveys (HTS) surveys (Khattak, et al., 2011).

This paper investigates travel behaviour of the students, faculty and staff of the UdL campuses. A first experiment was undertaken by research team in spring 2015 among ENTPE-ENSAL Vaulx-En-Velin campus' population. The aim of the survey was to contribute to the reflection in the campus redevelopment framework in particular accessibility and parking issues. Insights gained from this pilot study served as a springboard for the next step with the ambition to set up a permanent "mobility observatory" on overall UdL's community by collecting longitudinal data including socio-economic, demographic, spatial and travel activity data.

The remainder of the paper is organized as follows. Section 2 describes the background of the project by a presentation of the research context. A detailed description is dedicated in Section 3 to research method and data collection. Section 4 presents some very preliminary results while Section 5 concludes and gives perspectives for the next research objectives.

2 BACKGROUND

Considered as the main French higher-education and scientific centre outside the Paris metropolitan area, The Université de Lyon (UdL) is a so-called ComUE (community of universities and higher-education institutions), federating 26 institutions of higher education and research (12 members and 14 associate members), located in the cities of Lyon (about 1.3 million) and Saint-Étienne (400,000 inhabitants) and spread over 7 campuses with different urban settings (Figure 1). Over the past several years, UdL has experienced considerable growth in enrolment and this growth has contributed to substantial increases in travel demand. An estimated population of 150,000 students & staff attend different UdL' campuses.

In an attempt to increase their environmental sustainability, part of UdL's campuses are benefiting since 2008 of an important program of energy-efficient renovation known as Lyon Cité Campus. Strategies aimed at reducing the dependence on private cars and at increasing the use of alternative transport modes are also part of UdL's sustainability goals as car-traffic is considered a major source of CO₂ emissions in particular campuses presenting a high car-oriented environment. As legislation has changed, the Energy Transition for Green Growth Act (2015) made it compulsory for businesses and public institutions (with at least one hundred employees working at a single site) to set up a mobility scheme to support behaviour changes and encourage use of alternative modes.

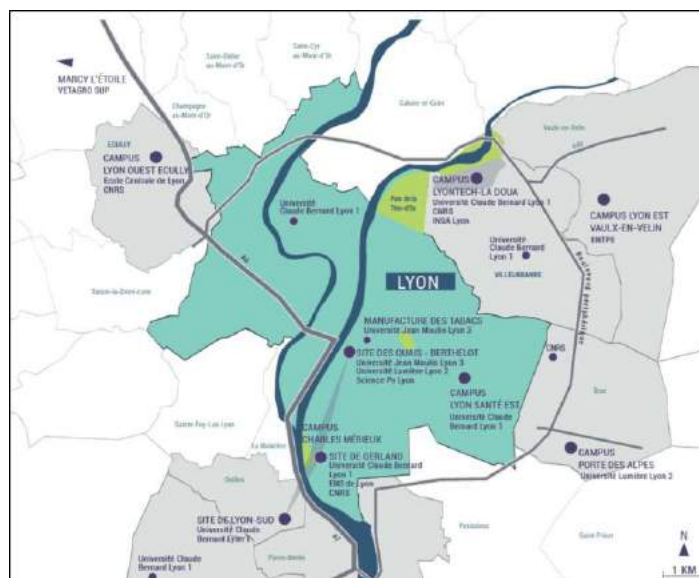

Figure 1 - Location of the different campuses part of Université de Lyon

In this paper we will focus on Lyon's university campuses, actually Jean Monnet University located in Saint-Étienne has already drawn up a mobility plan to increase the level of sustainable accessibility of its campuses. At present two campuses were object of the first wave of MobiCampus travel survey:

LYONTECH-LA DOUA CAMPUS

As one of the largest campus in the city of Lyon (about 25 000 students), LyonTech-la Doua campus has an objective to reduce the campus's energy consumption by 40% by 2021. The campus is located in dense urban settings and well serviced by a various public transport options: two tram lines are connecting the campus with the city centre with 5 stations on campus. There are also 3 bus routes connecting the campus with the rest of the city.

Actually the campus is engaged in an ambitious rehabilitation project jointly sponsored by the Métropole de Lyon and the UdL. The project involves the rehabilitation of some 20 buildings on 140,000 m² and 100 hectares. Due to the rehabilitation project the campus will face a severe parking shortage during and after works. About 25% of the actual parking capacity (4650 places) will have to be removed.

VETAGRO SUP CAMPUS:

The veterinary campus of Lyon is located in Marcy-l'Étoile a western suburban area in metropolitan Lyon approximately 16 km from the city centre. The campus is hosting about 1200 students & staff and accommodates academic, hospital and residential functions for students.

3 RESEARCH METHOD

DEVELOPMENT OF THE SURVEY INSTRUMENT

The questionnaire was developed by MobiCampus research group. Questions were then adapted to better fit the populations of interest and to be more relevant to different UdL's urban campus setting. We perform a web-based survey to collect the dataset to understand travel patterns to, from and on campus. This survey mode (web) was chosen because it is attractive to the target population (students) and the costs are lower than other survey modes (face-to-face or phone survey). There have been a few studies in the recent past focusing on measuring and analysing university students' mobility behaviour. Greene, et al., (2013) provide a meta-analysis of three separated university population travel surveys, include a survey of eight universities and colleges in Arizona, Utah and a survey of Texas A&M University and Blinn Junior College in Texas. Insight from this analysis conclude that the web-based instrument was the most successful technique to collect travel data

One of the challenges associated with a web-based online survey is that the survey administration team has no direct contact with the survey respondents. Thus the survey should meet appropriate standards and be compliant to specificities of a university environment to improve the quality of data collected, encourage participation and reduce participant burden. To ensure that erroneous and miscoded data are minimised, review, refinement, error checks and logical consistency checks were built into the survey instrument during the test of the beta version. Also, to minimise the non-response rate, our questionnaire was configured to allow respondents to skip questions they don't want to answer, except those that are crucial for mobility analysis such as travel patterns and socio-demographic characteristics.

The first set of questions involved collecting information about the academic institution affiliation of the respondents. Participants were asked to identify the campus where they went to study or work (primarily). They were also asked to identify their mean residential and work locations (both on-campus and off-campus for students) and mean frequented places linked to their activity. A user-friendly map-based interface (Google Maps API) was integrated to the online questionnaire to identify locations using point-and-click features. Locations could also be identified by typing an address, cross streets, or landmark if participant do not want to use the map-based interface. The deployment of the survey through a web-based interface made it possible to implement complex skip patterns and logic flows without unduly burdening the respondent. A second set of questions concerns basic information about usual travel to and from campus. Participants were asked to provide the usual mode of travel, travel time, departure and arrival times and parking location for their regular daily travel. A third set of questions concerns detailed socio-economic and demographic information about themselves and their households. Data was collected on such items as personal income (household income if living with family, parents, or guardians), race, gender, age, living arrangements, driver license holding, and public pass holding. Some additional questions were asked to determine whether the respondent could also be part of a qualitative interview or/and participate to a GPS mobility tracking experiment.

SAMPLING PROCEDURE

The student travel survey's reference population comprises all active students, faculty and staff attending targeted campuses. These lists of active students and staff was provided by the participating academic institutions through the support of UdL staff. A list of students, faculty and staff email addresses was drawn by Information system staff by processing complete and recent data from HARPEGE and APOGEE tools (respectively human resources and student management softwares). A confidentiality agreement was signed with each academic institution to insure rules of use and guarantee protection of personal data transmitted for the sampling purpose. The administration of a survey to the entire university community can be accomplished only with the cooperation and consent of the considered academic institution and its various administrative units. A confidentiality agreement was signed with each university to insure rules of use and guarantee protection of personal data transmitted for the sampling purpose.

SURVEY ADMINISTRATION AND RECRUITMENT OF PARTICIPANTS

To ensure that the university community was informed about the purpose of the survey and encouraged to participate, the initiative was advertised through multiple forms of university media and announcements were placed on the university weekly newsletters and student's web portal. The administration of a travel survey to the entire university population requires close coordination with university administrative authorities. A deliberate and collaborative process-oriented approach is actually followed by the project team to ensure that all constituents are engaged and supportive of the effort specially to enhance response rates. To give the survey good exposure advertising was designed in partnership with communications department, with a strategy developed that included a visual branding design which was publicised across campus using digital teasers and paper flyers (Figure 2). The IT department was also informed to authorized to send out mass e-mail messages requesting participation in the survey.

Figure 2 - example of publicity materials used during the survey advertising

The survey was hosted on our own reliable and high power server to facilitate ease of access and retain greater control of the online survey system by the project team. The email message provided a brief description of the survey and the ways in which the data would be used by our project team and the university administration for mobility planning and analysis. The message included a link to the survey instrument (LimeSurvey software), requested participation from community, assured respondents of the safety and privacy of all information provided, and furnished contact information if anyone have comments or concerns about the survey.

A first wave of the web-survey was carried out from January to May 2017. Successive waves will be achieved in the next 3 years with the aim to establish reliable travel behaviour data for the university community across all UdL's academic institution members. The 1st wave of the survey was deployed by a mass-email to a stratified sample belonging to the following institutions:

- VetAgro Sup: during 6 weeks from January to February 2017;
- UCBL University¹: during 8 weeks from March to May 2017;
- UdL (staff): during 5 weeks from May to June 2017; (ongoing survey)

As our survey questionnaire collect data about travel means used the day before or the last time for joining the campus/workplace, the survey mailing process was spread over weekdays (from Tuesday to Friday) applying a proportionate stratified sampling method thanks to the R statistical software and its package 'SamplingStrata'. As in the survey questionnaire we are asking respondents about their usual mean of transport to access their mean studyplace/workplace, we wanted also to verify trough the survey if there is any variation in preferred modal choice linked to period of the survey administration.

SAMPLING RATES

As expected we found that response was higher among some role groups (faculty & staff) and lower among others (students). Table 1 shows that sampling rates for the students vary from 7 to 25 % between the two surveyed campuses. It is important to note that for our survey, no incentives were offered. In general, university student populations are younger aged and may not be fully engaged with survey processes compared to staff & academic members. As such, they are more likely to ignore surveys for which they do not personally identify and see an immediate or direct benefit to themselves. Furthermore, and according to UCBL's Communication Department, students used to be checking less their academic email compared to their personal email account. This was not the case of VetAgro Sup students who

¹ UCBL University welcomes more than 40,000 students and represent the largest university in number of students enrolled in the Lyon's metropolitan area and the region.

joined the survey with a relatively high response rate (25%). It appears that reminder messages did have an appreciable impact on the response rate for staff & faculty community group.

UdL's academic institution	Category of population	Baseline population ¹	(%)	Sample size	(%)	Sampling rate (%)
VetAgro Sup campus	Students	707	66%	179	57%	25%
	Faculty & staff	370	34%	134	43%	36%
	Overall	1077	100%	313	100%	29%
UCBL University	Students	36640	90%	1917	60%	5%
	Faculty & staff	3987	10%	1279	40%	32%
	Overall	40,627	100%	3196	100%	8%
UCBL University LyonTech-la Doua campus ⁴	Students	16,414	88%	1214	60%	7%
	Faculty & staff	2274	12%	824	40%	36%
	Overall	18,688	100%	2038	100%	11%

Table 1 - Population and samples for surveyed campus

Despite the best efforts and intentions of the project team, response rates for student community group has been identified to be a serious concern in student segments surveys. However, based on our own experience, email survey remains nevertheless the most effective channel of communication for our survey. We found that our survey rates of return are generally consistent with response rates from similar travel surveys:

- Université de Lille (2014): 6% (120,000 students)
- Université fédérale de Toulouse Midi-Pyrénées (2015): 8% (27,000 students)
- Université de Poitier (2010): 15% (18,600 students)

SAMPLE ADJUSTMENT

Due to the differential response rates across market segments, staff members were over-represented in the dataset while students were slightly under-represented in the dataset relative to the true university population (Table1). Therefore, we weight the responses by role (undergraduate students, graduate students, faculty, and staff), age range, gender and distribution of university population across campuses and sites for multi-sites institutions so that the proportion of respondents in each group reflects their proportion in the university population (raking ratio method, using XLSTAT 2014.5.03). Access to higher resolution data during to sampling frame step participate to improve the adjustment process.

We voluntary do not include residential location as a weighting factor in the sample adjustment process. University students tend to be a mobile group with a-typical mandatory activity schedules, frequently changing their residential locations and residential living arrangements. Available data issued from university information system (APOGEE) includes generally zip codes given by students when enrolled. Important part of those zip codes are corresponding to parent's house and thus do not fit with common student's residential location during term time (Monday until Friday).

DATA PREPARATION AND QUALITY ANALYSIS

A very extensive filtering, cleaning and coding process of the raw data has been performed. A quality control and assurance process was implemented wherein all records were subjected to a number of consistency checks to see if the records would pass through the quality filters especially for travel patterns data. In a number of instances and with extreme care, it was able to apply logical imputation techniques and fix obvious errors, thus minimising the loss of data due to incorrect entries. As data preparation is still an ongoing step we invite to take with extreme care preliminary results presented in this paper.

4 PRELIMINARY RESULTS

Preliminary analysis on surveyed campuses shows when compared to the staff & faculty group from the same university, university students are more likely to share favourable modal split towards active transport modes that include public transport and sustainable travel modes. Figure 3 shows that students do indeed differ from other adults. This is especially noticeable in the analysis of travel patterns.

5 CONCLUSION AND PERSPECTIVES

This paper has attempted to present part of UdL's campuses travel survey design and administration, analysis of observed university community travel behaviour. However, there are some limitations to the research as the data collection and analysis still an ongoing process. At present this paper will be updated as additional data processing will be done.

ACKNOWLEDGMENTS

We acknowledge the financial support of IMU-Labex "Intelligences of Urban Worlds Lab". We thank our colleagues for their contribution to the elaboration of the questionnaire and UdL's staff for their coordination support with surveyed academic institutions.

ID 1499 | COLLECTIVE TRANSPORT. A SPATIAL ANALYSIS IN THE CITY OF RECIFE, BRAZIL

Claudia Alcoforado¹; Anabela Ribeiro¹

¹University de Coimbra

alcoforado.claudia@hotmail.com ; anabela@dec.uc.pt

ABSTRACT: Developed countries have related the lack of access to public transport to disadvantage and social exclusion, and many methods have been developed for the spatial measurement of the public transport supply aimed at equity in relation to socially disadvantaged groups, and for improvements in transport systems. These methods are still incipient in Latin America, although interventions to improve transport quality are an essential political requirement in urban governance. This paper is part of a PhD thesis, aiming the methodological development for the identification and evaluation of spatial gaps in the supply and demand of public transport causing social disadvantage in the Brazilian city of Recife. It is based on methodologies such as Needs-gap (Currie, 2010), PTAL (Transport for London, 2010), PTAI (Saghapour et al, 2016), and other methods analyzed. The objective of the paper is the critical analysis of the approaches that deal with these aspects, both in terms of social disadvantages due to the difficulty in accessing or even having public transport, as well as in the part related to the detection and analysis of spatial gaps in the supply and demand for public transport in urban areas of large cities. Based on the review carried out, it is possible to base the methodological development intended for the thesis study area, which can also be used for other cities in the world.

KEYWORDS: Public transport. Needs-gap. Social exclusion.

1 INTRODUCTION

Social inequality has been interpreted in several ways. It is most commonly explained as being the effect of income concentration and disparities in quality of life. In a study published in 2015, the OECD shows that the gap between rich and poor has widened in developed countries over the past 30 years, consolidating disparities between classes and affecting gross domestic product. What, then, can be said of the countries of Latin America that have reduced poverty, but in absolute numbers have millions of people in this situation in urban areas and high levels of unemployment strengthening informality? Considered the most urbanized region in the world, its cities are spatially and socially segregated (UN-Habitat, 2012). In Brazil, the appropriation of the urban space by private interests with the support of the State has been well-known and thus the challenge of overcoming the unequal conditions of citizenship is constant. The socially disadvantaged population moves away from the main centers of cities and the difficulty of access to public transport in carrying out basic activities such as work, school and health, compromises freedom and social progression. In view of the importance of the theme, several methods have been developed for the spatial measurement of the public transport supplied, aimed at identifying lack of equity in relation to socially disadvantaged groups.

This article focuses on the bibliographical review aimed at framing and sustaining the methodological development to be proposed for the current PhD thesis. The critical analysis of the approaches prepares the mainstay of the methodology for the study area of the thesis, the Brazilian city of Recife, and that can be used mainly for other cities of Latin America and also of the world, with adaptations to each reality.

Thus, the paper is formed by this section, containing the objectives and showing an overview of the framing for this work; section 2, which deals with the social needs and social exclusion that is due to the disadvantages in public transport; section 3, which presents the main and most recent methods for investigating spatial failures in the provision of public transport, and section 4, which presents the analysis and discussion of results concerning the content reviewed in the paper. Finally, in section 5, are the conclusions and the methodological proposal to be used in the thesis.

2 DISADVANTAGES IN TRANSPORT AND SOCIAL EXCLUSION

Social exclusion has a broad and multi-pronged concept, sometimes being addressed in a general context as a synonym for poverty, which is not real. For Kenyon et al. (2002), poverty mainly incorporates recognition of material and social deprivation, while social exclusion perceives unequal access and need for inclusion and participation of the individual in society (Levitas, 2007).

In the face of the concepts that translate social exclusion, when referring to transport in the face of a perspective on how its scarcity in diverse bias can bring losses to the lives of individuals in various social strata, one begins to perceive what the disadvantage in transport is. If social exclusion is encompassing in its structure, with factors such as poverty, ethnicity, gender, disability, age, employment status, among others, it is natural to understand that people who do not have or have difficulty accessing to achieve the normal activities of life such as education and employment, health, food and leisure shopping, do not have the same opportunities as others who have access to public transport and are thus disadvantaged. The disadvantage in transport is one of the causes of social exclusion.

Latin America and the Caribbean are mainly characterized by urban public transport, walking and cycling, while private motorized transport is composed by cars or motorcycles. It is important to note that for those who live in peripheral areas, transportation costs are higher, which is natural because of the greater mileage traveled and this corresponds to a considerable portion of their salaries. This picture portrays the great Brazilian cities, including the city of Recife, which also suffer from the inadequate supply of public transport, which made the use of private motorized transport attractive (IPEA, 2011). There is still a lack of adequate infrastructure for the so-called active means of transport, besides being sustainable, such as cycling and walking (Malatesta, 2007, UFRJ, 2016). Thus, having a motorized vehicle has become an important element for the level of accessibility and not owning it has become a factor of social exclusion (Rodrigue et al., 2006).

Investments in urban roads in order to improve their capacity have been only temporary in Brazil (Ministério das Cidades, 2007), increasing the additional capacity of the roads without privileging urban public transport and the active means of transportation. Transport, while not taking into account criteria for urban development in harmony with demand to improve urban mobility, is totally counterproductive, aggravates congestion and privileges individuals that can own a car (Vasconcellos, 2010).

According to Jaramillo et al. (2012), in the most traditional line of planning methods for urban transport systems, the demand has been the main object of study, not taking into account the spatial or socioeconomic equity (Banister, 2005). It should be noted here that spatial equity in focus is embedded in vertical equity because, according to Litman (2016), "transportation policies are equitable if they favor economically and socially disadvantaged groups, thus compensating for inequalities."

It is in this context that some of the methodologies developed for the identification and evaluation of the spatial gaps in the provision of public transport are presented and that they bring in their structure the problem of the disadvantages in transport relative to the disadvantaged social groups, trying to find the proper methodological support for the case study of the current thesis, as already mentioned.

3 METHODS FOR THE GAP ASSESSMENT IN PUBLIC TRANSPORT

Methods that associate the measure of supply to disadvantage in transport using geographic information systems (GIS) have been developed for a long time in Australia (Currie and Wallis, 1992; Currie et al., 2003; Currie, 2004; Currie, 2010; Delbosc and Currie, 2011). In the studies for Hobart (Currie, 2004), which is in the Australian state of Tasmania, the already refined approach has been called 'needs-gap'. The designation of this approach is due to the fact that needs-gaps are the spatial failures between transport and social deprivation, after comparing measures of supply and demand. Currie (2010) used the methodological development needs-gap in Melbourne, which is in the State of Victoria, Australia, for all 5,839 census collection districts (CCDs) -which will be called 'bairros' (neighborhoods) in our study - in order to test how this approach would respond to the case of larger localities within the Australian context. Greater Melbourne already had a population of 4,530,000 inhabitants in 2015, to the detriment of the population of Greater Hobart, which in the same year (2015) had 221,000 inhabitants (Australian Bureau of Statisticians, 2016).

Delbosc and Currie (2011) also presented a new approach to the metropolitan Melbourne region, with a visual representation of the shortcomings in the provision of public transport in relation to population and employment.

Also aimed at Greater Melbourne, in a differentiated bias, the methodological development of Saghapour et al. (2016) considered the frequency of public transport services, with the incorporation of population density, an innovation considering previous studies.

Also in the context of the quality of public transport provision, the work of Wu and Hine (2003) studies the supply and the disadvantage in transport, in the city of Belfast, Northern Ireland. It uses the geographic information system and the Public Transport Access Level (PTAL) method (Transport for London, 2015).

The revisions of the aforementioned methodologies regarding supply and demand measures are shown below, observing the social needs due to the transportation disadvantage.

3.1 MEASURE OF SUPPLY

In the treatment of supply, Currie's study (2010) considered a combination of the level of service provided by public transport in metropolitan Melbourne and the conditions to access it through the existence of buffers in the neighborhoods of the study area. The frequency was evaluated by the number of arrivals per week in each neighborhood and the measurements of typical walk catchments (Currie, 2010) were used for public transport modes. For the calculation of the supply index, a combined measure of the above parameters was used, as shown in the equation below. GIS software was also used.

$$SI_{bairro} = \sum N \left(\frac{Area_{Bn}}{Area_{bairro}} * SL_{Bn} \right) \quad (1)$$

Where: bairro is the neighborhood under analysis; SI_{bairro} is the index of the supply corresponding to each neighborhood; N is the number of walk access buffers for the stops/stations in each neighborhood; B_n is the buffer n for each stop/station in each neighborhood; Area_{bairro} is neighborhood area in square kilometers (km²); SL_{Bn} is the measure of the level of service (number of arrivals per week of buses, trams and metro in buffer n). The approach then considered the territory of the neighborhood taking into account its coverage by walk catchments to access public transport beyond its relative service levels.

Delbosc and Currie (2011) used the same index for the supply developed by Currie (2010), corresponding to equation (1), in each census tract (CCD) or 'bairro' for metropolitan Melbourne. The main focus was on the distribution of supply in relation to population and employment. The approach consisted in the use of Lorenz curves as a measure of the relative supply of transport to the population, as well as the Gini coefficients for the representation of the equity measure, allowing a visual representation of the gaps in the public transportation supply relative to the population and employment. They reported in their research that service levels were calculated based on the walk catchment overlap of the stop and not based specifically on the catchment centroid, where the stop is located, noting that the public transport stop does not have to actually be within the neighborhood so your service contributes to the supply of this neighborhood.

In the studies of Wu and Hine (2003) the PTAL-Public Transport Access Level method (Transport for London, 2015) was used to determine the quality of the Citybus network's supply in Belfast, Northern Ireland. The purpose was to assess the spatial impacts that would be caused on the population under the influence of that network in the case of hypothetical networks, by comparing relatively the access to the localities in Belfast, as well as verifying the relative effects on access with the introduction of new schedules or levels of service. Among the main parameters of the research were the age structure of the population, the possession of the car and the fact of belonging to the Roman Catholic religion or the Protestant religion. The PTAL translates into a scale of levels that show the amount of service provided, including measures such as frequency, reliability and walking time to access public transport.

In the methodological development of Saghapour et al. (2016) an index for classifying public transport access levels (PTAI) for metropolitan Melbourne's Statistical Areas Level 1 (SA1s) was formulated. In the elaboration of this index, two factors were calculated for each SA1 district and for each buffer, that is, the weighted equivalent frequency (doorstep frequency) and the proportion of population density. In the approach, Mesh Blocks were used to calculate the population density of SA1s and buffers. According to ABS, the Melbourne region contains 53,074 Mesh Blocks and 9,510 SA1s. The PTAI index for each SA1 in the service level part follows a similar approach to the London PTAL method (Transport for London, 2015). In this way, the buffer areas were overlapped on the SA1s, using ArcGIS, in order to calculate their population density. Figure 1 illustrates the overlapping areas of a SA1 selected with walking catchments of tram stops and mesh blocks. In this figure the authors assumed a homogeneous distribution of the population within the mesh blocks. The SA1 population is then obtained through the population in the mesh blocks that compose it. The population within buffer areas was calculated based on the proportion of these areas in relation to their overlap in the mesh blocks. Thus, the area or population of each SA1 corresponds to the sum of the areas and population of the respective mesh blocks.

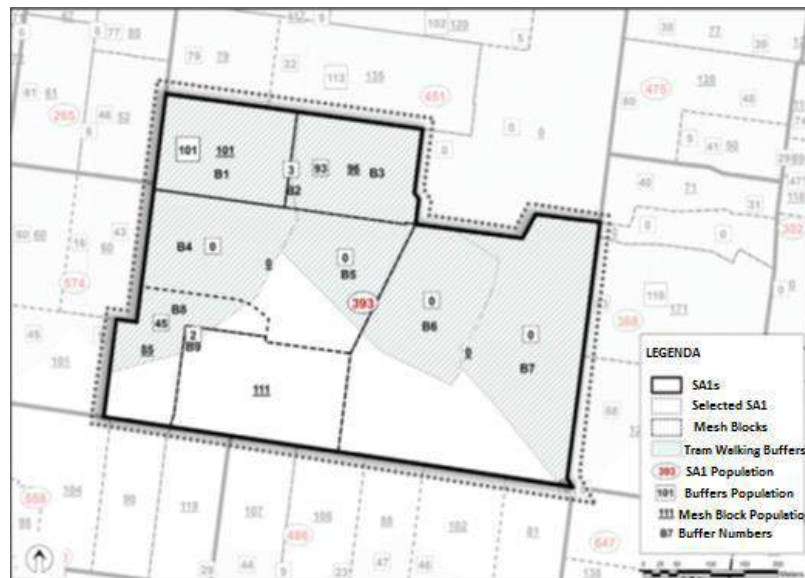

Fig. 1. Illustration of calculation of population density for buffer areas and SA1s.
(Adapted from Saghapour et al, 2016)

It is possible, therefore, to calculate the population density, for both study areas, that is, those of buffers and SA1s. Since the PTAI index is the composition of the combined measure of the weighted equivalent frequency of the SA1s and the incorporation of the population density ratio of the buffers' areas in relation to their respective SA1s, then,

$$\begin{aligned}
 \text{if } DB_{ij} = 0; \text{PTAI}_{SA1i} &= \sum_{j=1}^3 \sum_{i=1}^I \left(1 + \frac{DB_{ij}}{DSA1i} \right) * WEFS_{A1i} \\
 \text{if } DB_{ij} \neq 0; \text{PTAI}_{SA1i} &= \sum_{j=1}^3 \sum_{i=1}^I \left(\frac{DB_{ij}}{DSA1i} \right) * WEFS_{A1i}
 \end{aligned}$$

Where: PTAI SA1i is the index of access to public transport for each SA1; DBij is the population density of buffer i for transport mode j; DSA1i is the population density of SA1i and WEFS_{A1i} is the weighted equivalent frequency of the corresponding SA1.

Finally, a measure of the provision of public transport is obtained through the same evaluation technique of the London PTAL, that is, the PTAL is grouped into 6 bands with levels of quality of the offer ranging from very poor to excellent. The result equal to zero indicates that there is no accessibility or there is no population in an SA1.

3.2 THE MEASURE OF TRANSPORT NEEDS (DEMAND)

In the methodological development of Currie (2010) for Melbourne, two groups of indicators were presented for calculating the needs index in the socioeconomic context, and the analysis could be based on one group or another. The first group was composed of variables primarily of socioeconomic characteristics and weighting values according to the level of importance of each one in the social analysis of the study area. The second group concerns the more specific indicators of transport demand, and was based on an earlier 'need-gaps' approach developed by Currie & Wallis (1992); Travers Morgan (1992) and Currie (2004). These indicators are shown in table 1.

<u>Need indicator</u>	<u>Source</u>	<u>Weight</u>
<u>Adults without cars</u>	<u>Census 2001^a</u>	<u>0.12</u>
<u>Accessibility</u>	<u>Distance from Melbourne - CBD^b</u>	<u>0.15</u>
<u>Persons aged over 60 years</u>	<u>Census 2001</u>	<u>0.14</u>
<u>Persons on a disability pension</u>	<u>Centrelink^c</u>	<u>0.12</u>
<u>Low income households</u>	<u>Census 2001^d</u>	<u>0.10</u>
<u>Adults not in the labour force</u>	<u>Census 1996^e</u>	<u>0.09</u>
<u>Students</u>	<u>Census 2001^f</u>	<u>0.09</u>
<u>Persons 5–9 years</u>	<u>Census 2001</u>	<u>0.12</u>

Table 1 Transport need indicators and weights applied. (Adapted from Currie, 2010)

- Based on the number of cars per household and the number of persons aged 18 and over (Census 2001).
- Based on the straight line distance to Melbourne central business district (GPO) from the CCD centroid.
- Based on the number of persons on a disability pension in a postcode grouping (Centrelink 2006). This was then spread across CCDs based on number of persons in each CCD within that postcode (Census 2001).
- Based on the number of households with a weekly household income of \$499 or less (Census 2001).
- Based on persons over 15 not in labour force in 2001 (Census 2001).
- Based on persons enrolled in an educational institution – including primary and secondary school, university and technical and advanced further education.

Currie used the group listed in table 1 to elaborate the measure of social needs due to transportation disadvantages. For the measure of accessibility, the direct distance from the center of each neighborhood to the central business district (CBD) in Melbourne was considered. Thus, for calculating the transport needs index, the following equation was used, highlighting the fact that the values of the indicators should be standardized beforehand, since a single need score will be produced for each neighborhood.

$$NI_{bairro} = \sum (SI_{1bairro} * W1) + (SI_{2bairro} * W2) + \dots + (SI_{nbairro} * Wn) \quad (2)$$

Where: NI_{bairro} is the index of need for the neighborhood; $bairro$ is the neighborhood under analysis; $SI_{ibairro}$ is the standardized indicator of each indicator of need, where $i=1, \dots, n$ and W_i is the assigned weight for each indicator of need.

In order to calculate the measure of transportation disadvantages, Currie and Delbosc (2011) developed their research in the perspective of an equity analysis in relation to public transport, both horizontal and vertical, using, for this, the Gini coefficients, calculated using the following equation:

$$G1 = 1 - \sum (X_k - X_{k-1}) (Y_k + Y_{k-1}) \quad (3)$$

Where: X_k is the cumulative proportion of the population variable, for $k = 0, \dots, n$, with $X_0 = 0$, $X_n = 1$; Y_k is the cumulative proportion of the public transport service variable, for $k = 0, \dots, n$, com $Y_0 = 0$,

$Y_n = 1$.

In order to evaluate the horizontal equity, the index of the public transport supply was compared to the population and also later compared to the employment. Data from Australian census of Melbourne 2006, at the district level, were used. Demographic data from that census were obtained for the evaluation of vertical equity.

Wu and Hine (2003), on the other hand, used the multiple deprivation index of Northern Ireland, the so-called Noble Index, to measure transport disadvantages in the approach developed for Belfast in that country. This index was based on the demographic census of 1991, allowing an understanding in the spatial analysis of the most distinct aspects, whether of deprivation or disadvantage. Among the deprivation indicators considered by the Noble Index were income, employment, health and physical or mental incapacity, education, social environment, housing and geographical access to health services, postal services, among others.

3.3 THE NEED-GAPS

As explained above, the methodological development of the thesis is based on the identification of spatial gaps in the provision of public transport for people who are socially disadvantaged.

Before the measurement of the supply and of the one referring to the disadvantage in transport, the two are compared using the geographic information system and in this way the need-gaps are obtained, according to the method of Currie (2010). Following this approach to Greater Melbourne, he calculated the supply index by arranging it into seven groups, one in the zero supply category and the other categorized as three above average (above average, high, very high) and three below average (below average, low, very low). The groups that are below the average, are those that suffer of greater social necessity. In this context, we found the results shown in figure 2, which presents the spatial distribution of supply in the categories mentioned.

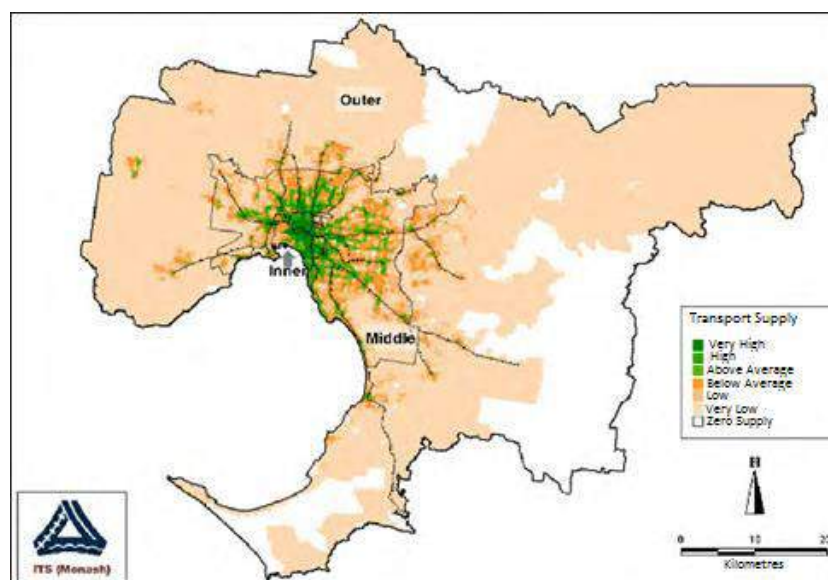

Fig. 2. Distribution of supply measure scores – Metropolitan Melbourne. (adapted from Currie, 2010)

With regard to the index of disadvantages in transport, it is seen in figure 3 below, the spatial distribution of social needs due to disadvantage in public transport. Groups were separated into a needs scale with scores ranging from low need to high need, in the context of three levels below average (below average, low and very low) and three levels above average (above average, high and very high).

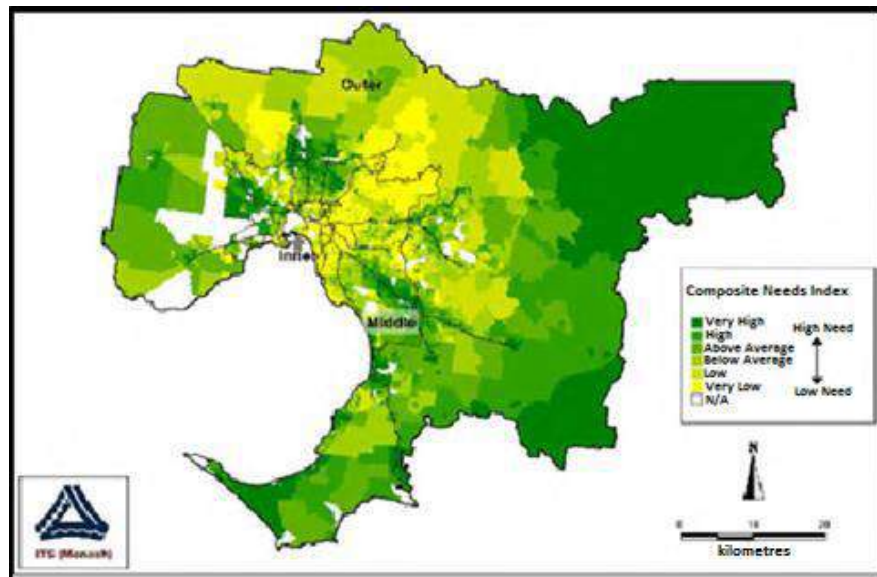

Fig. 3. Distribution of categories of composite social need index scores.
(Adapted from Currie, 2010)

In Currie's methodology, as mentioned previously, need-gaps are obtained through the comparison between the measure of supply and the measure of social needs (or demand). As an example, figure 4 below presents spatial gaps due to the disadvantage in transport (need-gaps) in the category of very low supply or zero supply and in the category of social disadvantage by transport, very high.

Fig. 4. Melbourne needs-gap – very high transport need areas with zero or very low public transport supply. (Adapted from Currie, 2010)

In the study of Delbosc and Currie (2011), as already discussed in section 3.1, the approach was developed in a perspective of horizontal and vertical equity. Using the Lorenz curves for the measure of supply and the Gini coefficient for the measure of equity, it is possible to graphically represent the results of the relationship between transport supply and population and employment, since, according to the authors, “while the Lorenz curve is a visual interpretation of equality, the Gini coefficient is a singular measure of the representation of the degree of inequality”. Figure 5 below shows that 70% of the population of Melbourne shares only 19% of public transport, while 30% of this population shares the remaining 81% of the public transport service. In this case, the Gini coefficient obtained was 0.68, which suggested relatively low horizontal equity, since services are only available for a small proportion of the population. In order to map the gaps for horizontal equity, the differences between the supply and the population are detected, and the inequalities of the service are identified.

Fig. 5. Lorenz curves of population and employment (Adapted from Delbosc and Currie, 2011)

The approach of Wu and Hine (2003) using the PTAL method (Transport for London, 2015) focused on the analysis of the existing Citybus Network and the assessment of the spatial impacts that would be caused in the population under the influence of the network, in the case of Implementation of hypothetical networks by comparing the access to localities in Belfast, as well as by checking the relative effects on this access with the introduction of new schedules or levels of service. The PTAL levels were calculated for different periods of time, so that it was possible to examine the relative access in different locations, as well as the relative effects on access to public transport in view of the proposed changes. In this way, the gaps were identified when comparing the variations of the local PTAL index and the spatial distribution of the deprivation indexes.

4 ANALYSIS AND DISCUSSION OF RESULTS

The methodological development of this work follows a research line similar to Currie's Need-Gaps method (2010); however, in the perspective of an innovative bias, adaptations will be carried out in search of consolidated results, in addition to being a study focused on Recife, in northeastern Brazil, while Currie's studies were primarily in developed countries.

Considering the documents analyzed, it is observed that in Currie's approach (2010) the analysis was able to detect significant gaps for the metropolitan area of Melbourne. Considerable differences have been found between the service levels of the public transport supply in Inner and Middle Melbourne with space areas covered by walk catchments at a much greater advantage than Outer Melbourne. It was observed that in addition to having much lower levels of service, the suburbs of this part of the outskirts of Melbourne have characteristics of sparse population of low density, and thus, the overlap of walk catchments is also limited when compared to the more central region and surrounding (Inner and Middle). In the analysis of the social needs index for transport disadvantages, it has been found that there are large spatial concentrations in Outer Melbourne with high levels of transport necessity and even in Inner and Middle Melbourne, despite the better conditions in relation to the urban periphery, yet they have sectors with high and very high social needs. When comparing needs/spatial gaps, the analysis identified that 1.1% of residents were in locations with no public transport provision, and were included in the group with needs scores rated very high. Overall, 8.2% of the population of Melbourne, according to the Need-Gaps methodology, were included in the group with very high needs score and with public transportation in the zero, low and very low supply categories.

In a different context, Saghapour et al. (2016) in the development of the PTAL included the population density as an indicator of the spatial distribution of the population in the neighborhoods and in the walk catchments areas and for this it was introduced the 'mesh blocks'. The mesh blocks represent a closer estimate of the reality, because being smaller measures, make possible a calculation of the population in

SA1s (neighborhoods) or buffers, more accurate. A homogeneous distribution of the population within the mesh blocks was assumed, which allowed a better analysis of the spatial distribution, which was not done in Currie (2010), since it was considered a uniform population distribution throughout the study area.

Wu and Hine (2003), using the PTAL (Transport for London, 2015) method, with the benefits of GIS and transport networks, strategically analyzed the spatial impacts caused in the population with the hypothetical networks in Belfast, in view of changes in the original Citybus network. PTAL levels were produced at different time periods, so relative access could be examined at different sites. In all the hypothetical options a strong impact was observed on the age groups, mainly harmful to the elderly. Families without cars would be more disadvantaged, as they would have more difficulty accessing the network especially at the peak of the morning. The users of each religious group, Catholics and Protestants, would have many problems in the periods between peaks and off-peak. A contextualized research on vertical equity was observed in Wu and Hine. The PTAL methodology is pertinent in the approach of the authors, as it develops a measure that reflects the connectivity between the different modes of public transportation and thus, the availability of access to them.

Delbosc and Currie, verified the practicality of their method, with the use of the Gini coefficient to obtain a simplified value of the equity of the system as a whole. When the (population + employment) curve was also taken into account in relation to supply, the situation was not very different from the (supply x population) curve, mentioned in section 3 (because 70% of jobs and population share only 23% of the service (Gini = 0.62)). For the authors, “perfect horizontal equity is not attainable or even desired, but the fact that 77% of public transport is concentrated for only 30% of the population and employment in the city, seems quite unfair”. With respect to vertical equity, there are features of it in Inner Melbourne, where young people and low-income groups have much higher transport supply than other groups and in Outer Melbourne, where older people have a slightly larger offer. However, in Middle Melbourne there is little difference in supply between groups. In the three areas of Melbourne, households that do not own cars are located in places with much higher rates than those with one or more cars.

5 CONCLUSIONS AND METHODOLOGICAL PROPOSAL TO BE USED IN THESIS

Some failures were detected during the review of the analyzed methods, as well as positive and value aspects.

In the case of the Need-Gaps methodology, Currie (2010) pointed out as fragility of this approach, the fact that supply allocation has been assumed to be uniformly distributed spatially within the neighborhoods. This issue could present more consistent results with the incorporation of population density to the method, as Saghapour et al. (2016) in the methodological development PTAL. In this case, the population density served as an indicator of the spatial distribution of the population in the neighborhoods and in the walking catchment areas, and for this purpose ‘mesh blocks’ were used. The population of the neighborhood was obtained through the existing population in the mesh blocks that composed them and the population in the buffer areas was calculated based on the proportion of their areas in relation to the overlap in the mesh blocks. Thus, the area or population of each neighborhood corresponded to the sum of the areas and the population of the respective mesh blocks and the homogeneous distribution of the population was assumed to be within these neighborhoods instead of being throughout the study area as was done in Currie (2010). In this way a closer analysis of reality in terms of spatial distribution is possible.

The method of calculating the Currie supply index (2010), pointed out by Delbosc and Currie (2011), presents deficiencies, one of which is that the frequency of the service does not have a measure of access to specific destinations. This same failure in relation to the PTAL methodology itself is identified by Transport for London (2015) because the PTAL does not take into account the destinations to which the individual can travel. PTAL, on the other hand, is limited in terms of connectivity between modes, which certainly has a great influence on access, the object of its approach, especially in areas where it is inappropriate.

The other methodological deficiency in the measure of Currie's supply (2010) perceived by Delbosc and Currie (2011) is in relation to walk catchments. They pointed out that most of the important points that are in larger neighborhoods than those around them are sometimes identified as being of low supply. What

happens is that sometimes the point shares its catchment with the neighborhoods bordering it, thus reducing its level of service.

In view of the above, given the positive aspects and the detected failures, it is expected that the methodology of this thesis will cover the following directions: the use of a methodology similar to Currie, considering the index of the public transport supply and the index of the social needs (demand) due to the disadvantage in transportation, for the identification and analysis of spatial/need gaps, according to the standard of the Need-Gaps method, but considering, however, the system of Saghapour et al. (2016) when the population density was included in his PTAI, in order to distribute more properly the population in the walk catchments and in the neighborhoods, making the results closer to reality. In this case, due to the fact that Brazil does not have the 'mesh block' measure unit, the Brazilian Institute of Geography and Statistics (IBGE), the so-called 'census sector', would be used as the smallest measure. Another adaptation in Currie's methodology (2010) that this thesis can add is the incorporation in the index of the supply of a measure of access to specific destinations, that in the case of Recife study would be the hospital of the 'Restauração' and the hospital 'Santa Joana', and that in the framework of this study was already foreseen the redistribution of the frequencies for these equipments.

1 INTRODUCTION

In recent decades, the effectiveness of positivistic approaches in transport planning has been growly contested by academics and practitioners (Innes and Booher, 2010). The idea of planning for a single model of reality is becoming obsolete when considering the fast and radical changes that society is experiencing at present and in the near future (e.g. ICT advances, environmental concerns, social inequalities, changes in mobility behaviour, etc.) (Batty et al., 2012; Lyons and Davidson, 2016; Marsden et al., 2014). The

discussed crisis of the rational-planning model has generated a great deal of interest in those rationalities pursuing “alternative realities” of planning, rooted in critical realism, constructivism and pragmatism (Khisty and Arslan, 2005). However, practitioners and policy-makers are still comfortable with the idea of planning as “enlightening the future”, also reinforced by traditional planning cultures, legal frameworks, and political institutions (Lyons and Davidson, 2016). Placed in a crossroad of approaches, motivations and

perspectives, the issue of unveiling uncertainty has been gaining relevance among transport-planning researchers (Martens and van Weelden, 2014).

Attempts at understanding uncertainty have mostly been made from a decision-making perspective, especially from the transport-modelling field (van der Pas et al., 2010; Walker et al., 2003). However, those approaches face what is known as the “uncertainty paradox”: the recognition of higher levels of uncertainty goes hand in hand with the expectations of positivistic science and knowledge to tackle them (van Asselt and Vos, 2006). Moreover, despite multiple dimensions of uncertainty having been explored in literature (Brown, 2004), they seldom encompass the plurality of perspectives (and also languages) involved in transport planning. At this point, previous systematization and conceptualization efforts need to converge into common overarching frames, which are flexible enough to embrace this plurality of uncertainty dimensions.

Such attempts may help in improving the perception and communication of uncertainties in planning. This paper addresses the following research question: how can uncertainties faced by transport planners and policy makers be framed and compared? To explore potential answers: (i) a heuristic framework has been developed to summarize a set of existing sources and levels of uncertainty in transport planning; (ii) this heuristic framework has been used to carry out a literature review of situations of uncertainty, that is, specific perceptions and consequences of uncertainty in planning; illustrative examples of those situations were provided, with the implementation of a new public-transport infrastructure (i.e. a Light Rail Transit systems) as a background.

Section 2 outlines the research design. Section 3 shows the bases of the proposed heuristic framework to identify situations of uncertainty in transport planning. Section 4 further develops the description of the framework according to different dimensions of planning, using references from transport literature and some examples. Section 5 closes the paper with reflections and some concluding remarks.

2 RESEARCH DESIGN

The research design consisted in a literature review comprising two main phases: in the first phase, a review was conducted on academic publications under an open search basis, aimed at identifying uncertainty, complexity and risk concepts (i.e. how uncertainties are represented, located, and assessed); two perspectives were explored: i) the planners’ perspective on uncertainty, involving how and where uncertainties are perceived and communicated; and ii) the policy-makers’ perspective on uncertainty, involving how uncertainties are analysed, assessed and managed. In the second phase, the previous concepts were used as keywords for a systematic search of references in the Scopus database. The resulting selection of 364 references was manually refined to 44 papers according to their relevance (i.e. mostly, discarding offtopic references, insights on mathematical modelling and research on operational processes and transport engineering) and their availability in consulted sources. After a first scan of the content of the final selection of papers, a heuristic framework was proposed (Section 3) for connecting different levels of uncertainty with features and dimension of planning represented by authors (Section 4).

To facilitate the understanding of the theoretical insights during the literature review, some situations of uncertainty have been pictured with examples involving the implementation of a Light Rail Transit system (LRT) (Section 4). LRT projects have cast claims and doubts over the potentials of such systems for transforming existing urban spaces and upgrading the transport system of medium and small urban regions (Babalik-Sutcliffe, 2002; Priemus and Konings, 2001). The examples provided here are mostly inspired in the recent implementation of an LRT project in Granada (Spain), close to the authors’ experience.

3 A HEURISTIC FRAMEWORK FOR UNCERTAINTY IN PLANNING

The heuristic framework was built as a thinking device for identifying different situations of uncertainty in planning. Those situations are described linking two questions: (i) where uncertainties are located (i.e. object and subject); and (ii) how important they are (i.e. their impact).

Concerning the object of uncertainties, information, knowledge and decisions have been central to their study. Uncertainty manifests when something is unknown, or cannot be known, due to certain limitations related to the very nature of knowledge (i.e. “what we know”), how it is processed (i.e. “how we know”) and how knowledge is used (i.e. “what we do”). In literature, these aspects have been related to different locations or sources of uncertainty (Enserink et al., 2013; Hansson, 1996). Nonetheless, a more complete understanding of uncertainty sources in planning also requires attention to their subjects, highlighting how perceptions and actions of planners and policy-makers are inherent to their confidence, expectations and state of surprise (Hutter, 2016).

The heuristic framework conceptualises the possible sources of uncertainty in transport planning according to three overlapping layers. Uncertainties are generated as interactions or tensions between pairs of features in each layer (Figure 1):

Layer 1 or “planning reality” (context – environment): this layer corresponds to the notion of the world outside the planning process, as perceived by both planners and policy-makers. It involves the planning context, as the less or more complex “physical reality”, which planners cannot directly control or influence (e.g. infrastructures, transport systems, flows, demography, economic cycles, technological changes, behaviour of travellers, etc.); and the planning environment, or the “social or organisational reality”, as the network of actors which links material reality and the planning process by gathering information and practical experience and sharing information and knowledge with other actors.

Layer 2 or “planning process” (concepts – artefacts): this layer would be embedded in the transport planners’ side, regarding how disperse information and knowledge from the planning reality is actively screened, processed and interpreted by them to define and solve planning problems. Concepts stand for those planning problems and premises steering the transport-planning process to its resolution (e.g. restraining car traffic volumes, reducing traffic emissions, promoting TOD, etc.). Artefacts are the devices or knowledgebases which help planners to describe, explain and validate concepts (e.g. judgements or argumentations, simulations, planning-support systems, decision-support systems, etc.). At the same time, the definition of concepts motivates the choice of those artefacts that can interpret them.

Layer 3 or “planning products” (outputs – outcomes): this layer would be embedded in the policymakers side, considering how planning knowledge is effectively used. Outcomes characterize the available options of the plan and their expected impacts (e.g. decisions it expects to influence, objectives to achieve, policies it delivers, alternatives it proposes, etc.). Outputs are the real planning impacts, as decisions are made according to outcomes. At the same time, outputs are used for validating and questioning planning outputs.

The implications or impacts of uncertainty are addressed in our framework through the addition of levels of uncertainty. Levels have been used in other works to measure or express the severity of uncertainty, or its consequences, within a spectrum from completely deterministic knowledge to ‘total ignorance’ (Bertolini, 2007; Enserink et al., 2013; Lyons and Davidson, 2016; Walker et al., 2010). Here, we also consider levels as related to the main nature of uncertainty (Enserink et al., 2013; Hansson, 1996): epistemic, originating from lack of knowledge about phenomena; ambiguity, a type of epistemic uncertainty coming from the plurality of frames under which reality is understood; and ontic, originating from the limits of cognition and representational systems. We distinguish four levels (Figure 2): Reducible uncertainty (level I): information may be eventually incomplete, but known causal relationships (deterministic knowledge) can help to retrieve the “missing parts”. Shallow uncertainty (level II): knowledge is incomplete but still reliable, linked to a single frame, in a way it can effectively bridge the information gaps.

Deep uncertainty (level III): it corresponds to conditions of incomplete and unreliable knowledge, in which information gaps cannot be properly bridged, due to the existence of conflictive frames (i.e. different perceptions of the same issue).

Radical uncertainty (level IV): this level exacerbates the limits of knowledge and the lack of reliability on past experience. Therefore, information gaps cannot be even defined, as previous knowledge frames turn useless.

Figure 1 - Conceptualization of the three layers of the heuristic framework.

Figure 2 - Levels of uncertainty.

4 SITUATIONS OF UNCERTAINTY IN TRANSPORT PLANNING

In this section, situations of uncertainty are described according to intersections between layers and levels of the heuristic framework (in each sub-section). The features of planning at different layers (i.e. context, environment, concepts, artefacts, outcomes and outputs) are further developed in 14 dimensions, concerning different aspects relevant in transport-planning literature. Tables 1 to 6 summarize key situations of uncertainty, and offer some examples picturing the planning and implementation of an LRT system.

4.1 UNCERTAINTIES FROM THE PLANNING REALITY

The situations of uncertainty authors acknowledge within the notion of reality of planning (layer 1) are mostly associated to the planning context (physical reality) and the planning environment (social reality) (see Section 3).

Uncertainties in the context have been linked to planners and policymaker's perceptions of past change (see Table 1). Objects of change in transport planning seldom work in isolation (level I), but they involve different components and their mutual relationships, usually arranged in systems: transport systems, land-use systems, social systems, etc. Uncertainties are related with different types of complexity in systems, which range from the complexity due to increasing number of components and properties (e.g. a transport network growing in nodes and links) (levels I and II) to the complexity of dynamic systems, shifting behavior and functions (level III), or interacting with outside drivers (level IV) (Bertolini, 2007; Dimitriou et al., 2013; Koppenjan et al., 2011; Martens and van Weelden, 2014; Ramjerdi and Fearnley, 2014; Salet et al., 2013). On parallel, nature of change refers to the pace, continuity, reversibility and dynamicity observed in transformations of the context (Bertolini, 2007; Lyons and Davidson, 2016; McDowall, 2014). Accumulation of change dominates transport planning, for instance, in the inherited urban forms and infrastructures. From a level-II perspective, fixed elements, such as infrastructures, may help to retain structures and deliver stability (Gifford, 1994); nonetheless, under a level III perspective, such elements are perceived as irreversible and path-dependent (i.e. the sequence of historical events influences future possibilities) (Bertolini, 2007; Herder et al., 2011; Ramjerdi and Fearnley, 2014). Combination of reversible

and irreversible elements is usually associated with transitional and discontinuous changes (levels III and IV).

<i>Dimension of planning</i>	<i>Level 1</i>	<i>Level 2</i>	<i>Level 3</i>	<i>Level 4</i>
Object of change (<i>what changes?</i>)	components of systems	structure of systems	regime of systems	external conditions of systems
Nature of change (<i>how does it change?</i>)	incremental	stable	transitional	discontinuous
<i>e.g. What changes will LRT bring to Granada's context?</i>				
<i>Levl. 1</i>	Plans claim that the LRT will extend the public transport coverage (a simple physical dimension of transport systems). As a consequence of this increase in coverage, public transport demand is also expected to rise.			
<i>Levl. 2</i>	LRT implementation generates new components into the previous transport systems (e.g. new stations, transfer nodes, etc.); these new components and structures are also intended to "create order out of chaos", concerning the multiple transport services operating in Granada (i.e. urban and inter-urban public buses), as well as reinforcing the functionalities and complementarities of those services (e.g. the metropolitan dimension of metropolitan transport systems).			
<i>Levl. 3</i>	LRT will induce new mobility behaviours in public transport users. At the same time, the new travel dynamics induced by LRT will transform the corridor functionality, which will create pressures and interests in developing spaces with new roles, which, again, will generate additional travel needs and, therefore, new infrastructure demands.			
<i>Levl. 4</i>	LRT has been an opportunity for channelling external investments in Granada (i.e. regional and European funds), which have been dependent on the economic context over the last two decades (the property boom and the economic downturn), and external political decisions.			

Table 1 - Uncertainties from layer 1: context.

Uncertainties within the planning environment are linked to barriers on knowledge exchange, regarding planning actors and their modes of interaction (see Table 2). Firstly, uncertainties perceived in planning actors, as knowledge-sharers and knowledge-holders, have been connected to their organisational structure (Boelens, 2011; Gifford, 1994; Koppenjan et al., 2011; Marsden et al., 2012). Increasing levels of uncertainty are depicted as problems of fragmentation and coordination, moving from "top-down" (i.e. vertical, centralized, organization-based, institutionalized) (level I and level II) to "bottom-up" structures (i.e. horizontal, spontaneous, agent-based, networked, actor-relational) (level III); at the level IV extreme, the strong influence of independent actors, such as coalitions, lobbies or political champions, is also acknowledged (Dimitriou et al., 2013; Salet et al., 2013). Modes of interaction involve how exchange of knowledge occurs between actors in the planning environment. Uncertainties have been related to the quality of information formats, and transparency of knowledge exchange (Boelens, 2011; Grant-Muller et al., 2001; Isaksson et al., 2009; Khan, 1989; Koppenjan et al., 2011; Marsden et al., 2012; Tapio, 1996). In theory, while lack of information on level I and II comes from the assumption that well-defined information requirements have been previously set (format, procedures, standards...), higher levels of uncertainty are generated in the overwhelming amount and diversity of information managed within collaborative environments, often full of contradictions, misinterpretations, gaps and redundancies (level III), or in the lack of transparency or traceability of knowledge, mostly produced in informal interactions between actors (level IV).

Dimension of planning	Level 1	Level 2	Level 3	Level 4
Planning actors (who interact?)	institutions	organisations	agents (sectors)	individuals
Modes of interaction (how do actors interact?)	procedural	normative	collaborative	informal
<i>e.g. in which arenas have been the LRT discussed?</i>				
Lvl 1	LRT-system solutions (routes, designs, vehicles, etc.) were developed and promoted by regional government for different Andalusian cities. Communications involved specific features of the systems and in-detail issues, which should be integrated in local planning. They were implemented through formal technical documents (as part of the LRT-survey and project documents).			
Lvl 2	While local governments are expected to commit to the project provisions ("top-down" decisions), problems of coordination arise concerning land-use, other services, and infrastructures. In response, the regional government formally requested information from local departments and organizations concerning a close set of issues (e.g. about new developments, transport demand).			
Lvl 3	Local actors promoted modifications to the LRT route ("bottom-up" decisions), according to different conflicts of interest, preferences, etc. Those modifications are sustained in different types of communications, meetings, round tables, claims, etc.			
Lvl 4	The option of building the central part of the LRT route underground was finally taken as a consequence of pressure from local officials and political parties, disregarding other options recommended by local experts and supported by retailer associations and transport operators.			

Table 2 - Uncertainties from layer 1: Environment.

4.2 UNCERTAINTIES IN THE PLANNING PROCESS

Uncertainties within the planning process encompass two features: concepts (planning motivations, premises, and problems) and artefacts (knowledge constructs as mechanisms validating or supporting concepts) (see Section 3).

In reference to planning concepts (see Table 3), a first dimension of interest is their value as future hypothesis. A future hypothesis may be past-dependant, relying in few variations over known trends, theories, probabilities or policy pathways (levels I and II) (e.g. the "predict-and-provide" approach); or it may divorce from past and show higher tolerance towards alternative hypothesis (level III), even raising speculations (e.g. technological "hype") (level IV) (Lyons and Davidson, 2016). A second dimension of concepts is their contextualisation, which concerns the "policy transfer" of planning solutions (Marsden et al., 2012) and their "permeability" regarding context influences (Dimitriou et al., 2013; Gifford, 1994; Marchau et al., 2010; Tapio, 1996). In this sense, uncertainties can be related to the definition of universal planning concepts (in isolation from the context) (level I); to local exogenous factors that influence the use of certain concepts (e.g. problems of applicability in concepts underlying some transport analysis) (Ma and Lo, 2015; Malone et al., 2001); or to concepts surrendering to local forces and singularities (e.g. critical components, opportunities, barriers, vulnerabilities, events, community images...) (levels III and IV). In third place, the definition of concepts may rely on accurate expressions (e.g. quantitative previsions of demand/capacity, accurate prescriptions, etc.) (level I) or accommodate the higher variability and fuzziness of natural language and statistical science (e.g. time-travel intervals, "higher/lower" accessibility, spatial arrangements, road levels of service, scores...) (Kikuchi and Pursula, 1998; Lambert et al., 2013) (level II). In addition, concepts can take the form of parameters (level I) and closed categorical properties (level II), or be based on loose structures concepts lacking a single underlying categorisation, but retaining some meaning or purpose related to the issue (levels III and IV).

Dimension of planning	Level 1	Level 2	Level 3	Level 4
Future hypothesis (how are concepts preconceived?)	as predictions	as assumptions	as possibilities	as speculations
Concept contextualisation (where do concepts come from?)	global	local-influenced	local-oriented	singular
Concept definition (how are concepts expressed?)	as parameters	as categories	as meanings	as thoughts
<i>e.g. how is the LRT concept introduced in Andalusia and Granada transport planning?</i>				
Lvl. 1	LRT solution relies on the hypothesis of increasing travel demands, supported by forecasts in the metropolitan area of Granada. These needs are based, at the same time, on universal (i.e. formal/mathematical) definitions of service demand and capacity. Along the same line, parametric premises are proposed in the LRT project, such as reducing car travel by over 10%.			
Lvl. 2	LRT is a solution for satisfying a range of projected mobility demands and preferences, associated with promoting public transport use. Concepts of capacity must be reconfigured to address more complex spatial and social factors in the context, such as car dependency and modal preferences. Categorical qualities of multi-modality (modal share) and PT competitiveness (concerning travel times, priorities, use of street section etc.) are associated with LRT.			
Lvl. 3	LRT is a critical factor for future transformations towards more sustainable mobility patterns. Such transformations involve multiple local issues and options, such as reducing traffic impact in the city, encouraging city center regeneration, etc. Moreover, the model of "sustainable urban mobility" is ill-defined in plans, and there is a convergence of many conflictive meanings (local visions).			
Lvl. 4	LRT is associated with the idea of a modern transport system, both as a solution to mobility demands and as a symbol of city prosperity in the future. At the same time, despite the external origin of the LRT, it has been deliberately given the nostalgic appeal of the old electric tramway system, which worked in Granada until 1975.			

Table 3 - Uncertainties from layer 2: Concepts.

Concerning planning artefacts (see Table 4), their knowledge requirements are directly connected to the levels of uncertainty. Thus, artefacts operating under lower levels would require conditions close to perfect information to perform (level I), or, at least, in which information can be externally validated (by technical expertise, institutional support, etc.) (level II). On the other hand, artefacts under level III assume some degree of fundamental ignorance, caused by the impossibility of gathering sufficient evidence to support planning concepts by "natural" laws or probabilities (Kikuchi and Pursula, 1998; Kronprasert and Talvitie, 2015). Other important dimension is the artefacts structure. Structures at level I are analogical, that is, they resemble physical and economic laws (level I) (e.g. gravity models and impedances, cost-demand laws, laws of human behaviour, etc.) (Batty et al., 2012; Khan, 1989); higher uncertainties admit more flexible and diverse structures, either systematic/structurally closed (level II) or holistic (level III), allowing a greater variety of qualitative techniques (e.g. stakeholder panels and workshops, narratives and intuitive scenario-planning techniques, open indicators, direct transfer of planning ideas...) (Schippel and Fleisher, 2012). Level IV artefacts, despite their lack of proper deliberative structures, can still be powerful instruments to change public opinion (Richardson, 2001). Finally, uncertainty has been connected with debates about prevalent rationalities in planning approaches and methodologies (Martens and van Weelden, 2014; Richardson, 2001; Tapio, 1996). Situations of uncertainty are inherent to the particular knowledge mechanisms or grounds which allow artefacts to validate concepts: strong cause-effect explanatory logics (level I); judgements resting on a coherent structure of thinking (e.g. experts and expert systems, etc.) (level II) (Berritella et al., 2008; Khan, 1989; Rayner, 2004); heuristics and bias mechanisms for supporting arguments (e.g. case similarity, lessons of success and failure, common sense, rules of thumb, etc.) (level III); or even non-rational use of artefacts built in rhetoric, legitimacy, fairness, public trust or fear, etc. (level IV) (Isaksson et al., 2009; Martens and van Weelden, 2014). Higher uncertainty levels relax the conditions of expertise required (Kronprasert and Talvitie, 2015), and also lead to more sophisticated uses of artefacts (e.g. instruments for contestation, narratives, etc.).

Dimension of planning	Level 1	Level 2	Level 3	Level 4
Knowledge requirements (what do artefacts need?)	complete series of information	comprehensive information	incomplete/contested information	no information
Artefacts structure (how are artefacts built?)	analogical	systematic	systemic	unstructured
Rationalities (how are artefacts used?)	to validate cause-effect logic	to generate judgements	to support arguments	to support discourses
<i>e.g. how has the LRT concept been supported?</i>				
Lvl. 1	LRT implementation has been supported by transport demand models, whose generations/attractors logic relies on gravity models (analogy with physical model). These transport-demand models link causal factors with the positive effects of LRT (increasing PT use, reducing traffic, etc.). They also rely on a predefined set of variables and data.			
Lvl. 2	Alternative LRT routes have been compared in various project stages using MCA, concerning not only functional features (demand), but also encompassing economic, urban integration and environmental objectives. These methods admitted the use of multiple indicators, and qualitative and quantitative attributes (especially from the report on the environmental impacts of the LRT project) for assisting final decisions. In parallel, multidisciplinary technical boards were asked to draw up expert judgements on some key decisions, such as building part of the LRT route underground, considering similar criteria.			
Lvl. 3	Arguments on the systemic evolution of Granada towards a metropolitan area have supported the idea of a metropolitan rail system, addressing the future growth of suburbs and the loss of population and activities in the city center. However, the strength of these assumptions (only relying on observed demographic trends) has been weakened by the prevailing importance of the city center.			
Lvl. 4	The LRT solution has been justified with discourses on improving citizens' quality of life, with no information support or structured argument.			

Table 4 - Uncertainties from layer 2: artefacts.

4.3 UNCERTAINTIES IN THE PLANNING PRODUCTS

Planning products ("plans", to abbreviate) (layer 3) include two planning features: outcomes (planning options) and outputs (planning effects) (see Section 3).

Uncertainties from planning outcomes are observed in the content of plans, as well as in how plans are expected to accommodate future change (adaptations) (see Table 5). Firstly, uncertainties in contents obey to how planners foreclose the list of problems and alternatives before moving to decision-making. On level I, all decision-related aspects are expected to be foreclosed, leaving policy-makers with a complete set of descriptions, statements and designs of future systems (planning as blueprints). On level II, only the list of planning problems is foreclosed, and contents consist on all-encompassing guidelines and statements still anchored in a complete end-state image of the future (i.e. statutory planning, comprehensive planning or master planning) (Bunker and Searle, 2007; Gifford, 1994; Khan, 1989). In levels III and IV, policy-makers confront ill-defined problems, either with an underlying idea or motivation toward their resolution (e.g. an urban or transport program) (level III) or without it (i.e. "wicked problems") (Dimitriou et al., 2013; Batty et al., 2012; Martens and van Weelden, 2014). Secondly, planning adaptations involve how uncertainties are handled by policy-makers through a balance of adaptability, flexibility and robustness in planned systems (Bertolini, 2007; Dimitriou et al., 2013; Ramjerdi and Fearnley, 2014; Salet et al., 2013). In the lower levels (I and II), this balance lean towards protecting outcomes from external changes (i.e. "closing systemperspective"), trading off robustness against overall flexibility. On the contrary, flexibilities are prioritized against robustness in most aspects of decision-making (e.g. systems scale, definition of components, reversibility, etc.) on the higher levels (III and IV), to mitigate their negative consequences and amplify the positive consequences (Herder et al., 2011; Van De Riet et al., 2008). Level IV would only leave room for improving resources and learning capacities of actors following their actions (e.g. "policy experiments").

Dimension of planning	Level 1	Level 2	Level 3	Level 4
Contents (what kind of options exist?)	blueprints	guidelines	programs	actions
Adaptations (how options accommodate changes?)	isolating from context	increasing robustness/resilience	increasing flexibility	increasing adaptability
<i>e.g. which options were considered for implementing the LRT in Granada?</i>				
Lvl. 1	Some features of line 1 of the LRT, such as itinerary and stations near city center, were fixed at great detail from the early planning phases (as evidenced in regional infrastructure plans and spatial plans). Such planning decisions were also isolated from later events (e.g. the substitution of the line 2 project with a high-capacity bus line), building trust amongst land developers, property owners, retailers, etc.			
Lvl. 2	Regional infrastructure and spatial plans created a set of guidelines for fostering the multi-modality of LRT with other transport modes in Andalusian cities. Own right-of-way systems (including LRT and tramway) were part of a strategy of protecting adaptations of future public-transport systems against traffic problems.			
Lvl. 3	Among the final LRT project definitions, a set of general measures and orientations for re-structuring traffic flows and urban-bus network was proposed. These measures took advantage of the potential flexibility of the urban bus system, operated by a city company (if compared with the rigid concessional system of metropolitan buses).			
Lvl. 4	While the LRT project has not yet produced great changes, local master and transport plans have learnt from previous actions implemented in Granada at the beginning of the 1990s, on the whole pedestrianisation projects and car-access restrictions. These individual actions have led to a complete overhaul of mobility patterns in the historic city-centre, including the reduction of car traffic and the improvement of urban bus system reliability.			

Table 5 - Uncertainties from layer 3: outcomes.

In relation to planning outputs (see Table 6), uncertainties are associated to planning expectations (success conditions) and where are they materialized (implementations). Uncertainties on implementations are intrinsic to the aspects of decision focused by plans (Koppenjan et al., 2011; Marsden et al., 2014): control over material outputs (e.g. planning of daily transport operations) (level I); directions on decisions to be made by organizations and actors (level II); indirect influence over the way actors make decisions (level III); or, in broad terms, recommendations on general issues that should be engaged (level IV). Uncertainties over success conditions of plans are linked to the nature and range of those expectations, or, in other words, how unexpected effects are managed (Schippl and Fleischer, 2012). At level I uncertainty, success conditions assume that changes observed in reality must fit all previsions of the plan as close as possible (e.g. definition of targets). At level II, success conditions are set in terms of progress and achievement towards more general planning goals; decisions are governed by preferences towards intended effects, while unintended effects are managed as risks. At level III, success conditions relate to the capacity of plans for creating agreement frameworks, in such a way that potential surprises related to policy-maker actions can be overcome (Boelens, 2011; Koppenjan et al., 2011). At level IV, the success of plans is limited to basic acknowledgement of issues, which can set the difference between being prepared or not to address the most unexpected consequences of decisions.

Dimension of planning	Level 1	Level 2	Level 3	Level 4
Success conditions (what expectations exist?)	targets	achievements	agreements	acknowledgements
Implementations (where are expectations placed?)	applications	directions	influences	discussions/ references
<i>e.g. what transformations are plans expected to make in Granada following the LRT implementation?</i>				
Lvl. 1	Infrastructure plans incorporate monitoring indicators related to number of public-transport stops per inhabitant; in addition, they fix quantitative targets related to LRT average frequency (8 minutes).			
Lvl. 2	Multi-modality guidelines are promoted in regional infrastructure-plans, which create a directive framework for city interventions in transport systems, such as park-and-rides, multi-modal facilities, inter-service coordination, etc.			
Lvl. 3	The LRT project is expected to influence the definition of corridors and services-sharing conditions for the next concession of metropolitan bus services. In this sense, the LRT has created a background for setting agreement between urban and metropolitan transport operators.			
Lvl. 4	Regional-infrastructure plans include broad references to a "sustainable urban mobility model", which, without more in-detail specifications, aims to raise concern and stir up debate before future environmental challenges (e.g. peak-oil, climate change, etc.).			

Table 6 - Uncertainties from layer 3: outputs.

5 CONCLUSIONS

The recognition of uncertainties in transport planning has been traditionally used as a provisional closure for technical questions, for avoiding conflicting topics or, on the other hand, as a call for straight action (Marsden et al., 2012; Rayner, 2004; Salet et al., 2013). Conversely, this research argues that many useful interrogatives can be opened after uncertainty has been acknowledged. But, how can uncertainties faced by transport planners and policy-makers be framed and compared? To address this, a heuristic framework was developed to explore situations of uncertainty at four distinct levels (reducible, shallow, deep and radical), concerning three layers of planning: planning reality, planning process and planning products. Some concluding remarks are made:

Framing uncertainties. Compared with theoretical insights to uncertainty, both conceptual (Brown, 2004; Hansson, 1996) and mathematical (Kikuchi and Pursula, 1998; Kronprasert and Talvitie, 2015), a rather practical and intuitive approach was used. This heuristic character has been proven useful for processing and comparing references from a wide and disperse range of research fields within transport planning (i.e. decision-making, modelling, scenario planning, transport policies and governance, etc.). Furthermore, the understanding of uncertainty across methodological boundaries and planning paradigms is considered central here (Khisty and Arslan, 2005; Martens and van Weelden, 2014; Tapio, 1996). This framework offers an excellent platform for (re)formulating further research questions on how specific situations of uncertainty are perceived and handled by actors involved in transport planning.

The communicative approach. Positivistic approaches seldom explain uncertainties beyond levels I or II (reducible or shallow), ignoring the more extreme and complex situations described by transport-planning literature (i.e. “black swans”, “wicked problems”, adaptive or flexible planning approaches...) (Lyons, 2016). While the “uncertainty paradox” (see Section 1) prevents any effort from actually “knowing uncertainty”, it leaves space for creating a common language for understanding its implications in planning. This research contributes to making explicit differences between grounds and values in planning actors, and to creating flexible frameworks for communicating uncertainties within a transactional planning environment, that is, where conditions of “truth”, expertise and knowledge validity are constantly bargained (Abbott, 2005).

Lastly, this study was motivated by the challenge that emerged during the search for new scopes on scenario building in transport policy. Such insights demand new theoretical and practical foundations for understanding the role of scenario exercises in building meaningful futures (i.e. plausible, consistent, desired, challenging, etc.), while managing the uncertainty deriving from its conceptualization, expectations and use in practice. In addition, a framework for exploring uncertainties may enable new branches of research, focused on empirical and experiential exercises (in real planning conditions or controlled experiments) about how actors relate specific layers, features and dimensions of transport planning with uncertainty and how comfortable they feel under different levels of uncertainty. In this way, more suitable context-sensitive planning tools can be offered in the future.

1 INTRODUCTION

Sustainability is a concept that has become entwined with planning of the future, since it means the capacity to endure. It is a balance between the use of resources and productivity, allowing the process to continue uninterrupted. The organizing principle of this concept is called Sustainable Development and its definition was firstly conceived by the World Commission on Environment and Development (WCED), on March 20th, 1987. WCED defined Sustainable Development as the "Development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED, 1987). Sustainable Development stands on three principal pillars: environment, society and economy, where the latest two are restricted by environmental limits (UCLG, 2008).

The transport sector is responsible for 23% of the total GHG emissions, with about three quarters coming from road traffic (Ribeiro, et al., 2007). In addition to this problem, transportation has also other negative impacts on sustainability such as noise pollution, devaluation of public spaces, public health and safety, development and urban sprawl, etc., all of which involve a high cost for societies (Fenton, 2017). Given this situation, the concept of sustainable mobility arises, which can be defined as the one that, responding to people's travel needs, is carried out through sustainable modes of transportation (Portuguese Environmental Agency, 2010).

In order to properly formulate a plan for sustainable mobility, studies are required to assess the situation and the suitable course of action. Unfortunately, traditional data collection implies long periods of time and associated heavy costs. In Portugal, many mobility decisions are only supported by the Census, which only provides information on work/school related trips. New solutions must arise to meet the needs for supporting data and the requirements of feasible practical applications.

Technology is advancing at an alarming speed, providing an enormous quantity of data in a rate that cannot be processed. It's the age of Big Data. From small quantities of information taken directly from willing participants to huge amounts of complex and unorganized data retrieved automatically in digital processes, the collection of information is rapidly migrating from straightforward and direct methods to an undetected part of everyone's life and becoming an increasingly prosperous market.

Striving for a sustainable urban management requires solid foundation on reliable data collection to construct achievable plans for the future. Mobility, being a core subject in urban systems, entails extensive data to properly characterize its patterns and to evaluate its impact in a city's sustainability.

Therefore, Big Data shows potential in becoming an important tool in the decision making process of improving mobility systems. It is in this sense that falls the present study, in which the main objective was to evaluate the sustainability of mobility in the Faculty of Engineering of the University of Porto (FEUP) using carbon footprint as the main tool and operationalizing this concept for awareness campaigns on the sustainability of individual mobility intended for the general public and to compare traditional and modern data collection to validate its transition. The secondary objectives consisted on:

- Studying the different methods of mobility data collection;
- Reviewing the phenomenon of Big Data and its applications in mobility;
- Analysing relations between sustainability and mobility;
- Assessing the potential for a more sustainable mobility of FEUP's community.

2 STATE OF THE ART

2.1 CARBON FOOTPRINT

A carbon footprint, is a Life Cycle Assessment (LCA) limited to the analysis of emissions that have an effect on climate change, including carbon dioxide, methane, etc. This limitation makes this method easier to apply on integrated systems, such as an entire house or automobile, facilitating its application on mobility sustainability studies (Wachter, 2008). It allows the calculation of global warming gases emissions from transports and, consequently, their energetic efficiency (Davies, Jefferson, Longhurst, & Marquez, 2000).

The carbon footprint measures CO₂ emissions mainly associated with fossil fuel use. In order to calculate this footprint, it is necessary to be aware of the Global Warming Potential (GWP) of each gas to be able to add the emissions of different gases and reach a single result on the overall impact on global warming of an activity, often called "CO₂ equivalent emissions" (Myhre, et al., 2013). The usual GWP is estimated for a time period of 100 years. Carbon Dioxide is the reference gas, hence the name of the method, and it has a GWP of 1. The latest IPCC Assessment GWP values for the three most important gases (Carbon Dioxide, Methane and Nitrous Oxide) are shown in Table 1. Even though the emitted Methane lasts about a decade on average, which is much less than the Carbon Dioxide that lasts for thousands of years, it can absorb a lot more energy. This effect plus the indirect influence on being a precursor to ozone (also a greenhouse gas) is quantified in the GWP.

The complete list can be reviewed in the original report, however only these three gases were considered in the carbon footprint calculation of this study. The inclusion of climate-carbon feedbacks means it is considered the response of the gas to emissions of the indicated non-CO₂ gases (Myhre, et al., 2013).

	Lifetime (years)	Climate-Carbon feedbacks	GWP ₂₀	GWP ₁₀₀
Carbon dioxide (CO ₂)	-	-	1	1
Methane (CH ₄)	12.4	Yes	86	34
		No	84	28
Nitrous oxide (N ₂ O)	121.0	Yes	268	298
		No	264	265

Table 1 – Main GWP with and without inclusion of climate-carbon feedbacks
(Adapted from Table 8.7, IPCC Fifth Assessment Report, 2013).

By quantifying all emissions from each gas, it is possible to apply the GWP and translate to CO₂ equivalent, all the process being in units of mass, not volume, as shown in the formula below (Gillenwater, 2015).

$$\text{Mass of CO}_2\text{e} = \sum(\text{mass of gas}) \times (\text{GWP}) \quad (1)$$

The emissions of each gas depend on the activity, being its specific values called emission factors. The default emission factors are averages based on the most extensive data sets available.

2.2 MOBILITY DATA COLLECTION AND PROCESSING

To implement measures to improve mobility it is necessary to collect information about mobility patterns and population's behaviour, usually following established indicators. The most traditional method is directly through surveys and interviews, more recently including travel diaries. While surveys usually gather general information about a person's mobility, a travel diary is a collection of real travel information throughout a period of time, usually a week. These methods can consider individual data or household data and generally evaluate the main indicators of mobility: mode of transportation, frequency, time and distance (by considering the destination and purpose of the trip).

With the evolution of new technology, like the smartphones and other location detection devices, the last decade has been the stage of the development of two different fields determined to understand how individuals move in space and time: the traditional field of mobility researchers, who have been working in this field for decades, and the new comers from a variety of disciplines, especially computer scientists in

particular due to the crescent source of digital information. They both use different approaches, different methodologies and different datasets. This presents an opportunity for the evolution of mobility data collection and processing by working together for a common goal (Chen, Ma, Susilo, Liu, & Wang, 2016).

From paper, travel diaries are reaching the digital world, which are less prone for errors. Many people around the world share their travel experiences every day, but this informal information goes unprocessed. The digital information differs and separates from the analogical one for its quality and fidelity, its independence of nature of the data, the flexibility for the transport, compression, cipher, communication and manipulation of the basic sources and, especially in the data space and economic demands for the massive store of information (Hoyuela, 2002).

Nowadays, the Internet of Things connects us more than ever, yet the Big Data that constantly produces presents many challenges that need to be tamed so we can reap the benefits of connectivity (Li-MinnAng & PhooiSeng, 2016). The biggest problem with Big Data (massive, less structured, heterogeneous, unwieldy data up to, including and beyond the petabyte range) is that it is incomprehensible to humans at scale. Machines in the cloud are simply tools and they cannot understand the information they process as humans do. They can amplify noise or errors in the data just as easily as amplify signal or provide insight, consequently a human input is always necessary. And yet Big Data keeps getting bigger and unprocessed in a useful manner (Morrison, 2015).

The Big Challenge of Big Data is turning it from technology oriented to user oriented, because in the end what truly proves its value is its usefulness. The success of an information system is to transform a data set into comprehensible information (Hoyuela, 2002).

Most online social networks nowadays allow the identification of the location of the user. Facebook and Twitter, for example, exploit the GPS readings of user's phones to tag posts, photos and videos with geographical coordinates. This generates enormous amounts of data, which can be useful for the study of mobility behaviours. Comito, Falcone and Talia (2016) attempted to analyse the time and geo-referenced information associated with online posts to detect typical trajectories and discover common patterns, using the tweets in the urban area of London as a case study. By assuming people tend to follow the same routes daily, like going to work using the same roads, they had enough information to model behaviours and identify top interesting locations and travel sequences (Comito, Falcone, & Talia, 2016).

Another more direct way of collecting mobility data is through smartphone specialized applications. Mobility apps have been increasing as alternatives to traditional travel diaries. Nonetheless, most still present both characteristics. An application called "MoveSmarter" used automatic trip detection with a web-based prompted recall survey. This app is particularly unique due to its sample size (about 600 respondents) and representativeness of the sample for the Dutch population. After an in-depth comparison between automatic detections and reported trips, most trips were detected correctly without strong biases in trip length or travel time distributions. However, 20-25% of the trips could not be detected due to a problem with inaccuracy when activity times at the trip destination are small, creating lack of distinction between successive trips. Also, most missing trips were caused by inappropriate use of the app or empty batteries, a common problem in mobility applications (Geurs, Thomas, Bijlsma, & Douhou, 2015), unlike "SmartMo". The app "SmartMo" was designed in a multi-stage iterative development process and included a traditional travel survey modified to match mobile devices that could be completed any time the user wished. Trip distance and duration was automatically measured and calculated to prevent inaccuracies due to individual and subjective assessments. Additional map matching algorithms and filter criteria for identifying and eliminating outliers are implemented externally on a server, which in return made the app less demanding from the energetic point of view, since all the calculations were not run by the smartphone (Berger & Platzer, 2015).

Other study by Montini et al. (2015) used a dedicated GPS device to validate the results of the mobility app and to compare the best form of data collection. They concluded that even though meaningful diaries can be extracted from both data sources, if the high resolution data is needed, a dedicated GPS device is more efficient, since they do not have battery issues, which means more consistent data with a constant quality (Montini, Prost, Schrammel, & Rieser-Schüssler, 2015).

As proven, GPS-based data collection has gained popularity in the recent years, due to its ability to record accurate time and geographic information and easiness to add extra request for information through integrated surveys. While such methods have many advantages over traditional surveys, they suffer from

other limitations such as the dependency of the constant use of the smartphone and the unavailability of GPS signals in certain areas (Zhao, Ghorpade, & Pereira, 2015). They face the challenges of mode identification and stop detection with overlapping bus routes, distinguishing waits and transfers from non-travel related activities, and tracking underground travel in a Metro network, so in many situations they use small questionnaires as a support (Carrel, Lau, Mishalani, Sengupta, & Walker, 2015).

A recent study by Susilo et al. (2017) used different methods to measure travel satisfaction, which included two types of smartphone applications (a satellite navigation app and a game app), an on-line survey, a paper-based semi-structured questionnaire and a focus group. This resulted in 5275 valid responses from eight European cities and five FIA (Federation Internationale de l'Automobile) national networks. Although this study wasn't focused on mobility data collection, it allowed to conclude that every method has complex advantages and disadvantages when it comes to provide data on travel satisfaction to policy makers (Susilo, et al., 2017).

In this study, both a traditional survey with incorporated travel diary and a mobility app called "SenseMyFEUP" will be analysed, comparing the two methods and evaluating the sustainability of the joined results.

3 METHODOLOGY

The process applied to this study required three parts with subdivisions to reach the desired results and conclusions: the supporting study of the state of art and preparation of the next phase; the dissemination and data collection from the mobility survey and the app "SenseMyFEUP"; as well as the final data processing and inherent analysis.

The case of this study for both survey and mobile application is the Faculty of Engineering of the University of Porto. The University of Porto is the second largest Portuguese university by number of enrolled students, after the University of Lisbon, and has increased its renown and reputation over the years, while at the same time striving to increase its sustainability. In 2015, it harboured 30 066 students, 1 542 staff members and 2 286 teachers and researchers spread among the 3 main campuses and 14 faculties (Universidade do Porto, 2015). From these numbers, the Faculty of Engineering of the University of Porto

includes 6 839 students, 340 staff members, 536 teachers and 315 researchers (FEUP, 2015).

Throughout the years, several studies have been carried out to evaluate sustainability and mobility patterns, especially since the creation of FEUP's Commissariat for Sustainability in 2015.

Figure 1 – Distribution of FEUP's community.

3.1 PREPARATION PHASE

The study of the art phase was a common base to both the survey and application. For the survey, the collection of both typical and traditional questions was needed in order to compare with the results from the app and expand further to evaluate the ability of this method to gather reliable information. For the smartphone application, the preparation phase required more effort due to the partnership with a team from the telecommunications lab, which was developing the Future Cities Project where the SenseMyFEUP app was included. This cooperation allowed the improvement and the moulding of an existing technology (SenseMyFEUP used the same code of an existing app from the same lab,

SenseMyCity) based on mobility and environment indicator's needs. It was necessary to operationalize the carbon footprint so it could become an integrated tool of both sustainability and dissemination.

To assess FEUP's sustainability regarding mobility, it was required data related to the society involved, economy and environment. The society parameter was satisfied by the interaction with the community through the survey and the SenseMyFEUP app, the resulting feedback and conclusions. Regarding economy, the balance of household income/mobility costs was made through the survey, but not with the app, even though in early discussions it was considered the inclusion of that measurement, however that would require a better mode of transportation detection system and some level of intrusion for the user to obtain sufficiently accurate results.

On the subject of environment, which we are focusing on, the elected tool to measure was the carbon footprint. The formula for its calculation changed according to the mode of transportation selected for each trip. To calculate the emissions of CO₂ equivalent of the car, motorcycle and bus we used the values regarding Portugal provided by the EMEP/EEA air pollutant emission inventory guidebook from 2013 (Ntziachristos & Samaras, 2013). The substances considered for the calculation were CH₄, CO₂ and N₂O. CO, NO_x, PM and CO₂ from lubricants were rejected for having little or too indirect influence in the overall carbon footprint (Intergovernmental Panel on Climate Change, 2013).

According to the IPCC Fifth Assessment Report of 2013, releasing 1 kg of methane (CH₄) into the atmosphere is equivalent to releasing 34 kg of CO₂ and if instead of methane it was nitrous oxide (N₂O) the equivalent would be 298 kg of CO₂ in the course of 100 years. The resulting CO₂e value was calculated with the following formula:

$$CO_2e = [CO_2 + (CH_4 \times 34) + (N_2O \times 298)] \times \text{Fuel Density} \quad (2)$$

Considering the bulk emissions for Portugal provided by the EMEP/EEA air pollutant emission inventory guidebook from 2013, updated July 2014, in the 1.A.3.b Road Transport Section, the resulting CO₂e (g/l fuel) values were calculated for cars, motorcycles and buses.

In order to use the required emission factors, it was necessary to know the fuel consumption of each transport to transform from CO₂e in g/l of fuel to g/passenger.km. While it is easier to acquire that information about personal means of transportation, like cars and motorcycles, public transportation proves itself more difficult to provide it. Considering that in Porto most of the transportation via bus is controlled by "Sociedade de Transportes Colectivos do Porto" (STCP) whose fleet is mainly fuelled by compressed natural gas, we used their Sustainable Development Report to obtain the data on their CO₂ emissions. In 2015, each vehicle emitted 1.385 kg of CO₂ for every kilometre covered. The same procedure was applied with the Porto's Metro and train (Comboios de Portugal – CP) information, which revealed that, in 2014, they released 41.674 and 27.03 gCO₂e/passenger.km respectively (CP Comboios de Portugal, 2014).

The results of the emissions from each vehicle need to be divided by the number of passengers to provide a more accurate value of the individual carbon footprint. The occupancy rate of passenger cars in Western European countries, like Portugal, is around 1.54 passengers per vehicle (European Environmental Agency, 2015), however in Greater Porto that rate is lower, consisting in 1.4 passengers per vehicle (Instituto Nacional de Estatística, 2002).

In regard to buses, STCP states that in 2015 the occupancy rate was 13.4% (STCP Sociedade de Transportes Colectivos do Porto, 2015), which, considering that the average capacity for a bus is 90.9 people (STCP Sociedade de Transportes Colectivos do Porto, 2016), means that it usually carries 12.18 passengers per vehicle.

For the metro and the train, the information on the occupancy rates were not required, because the provided data from the reports already took that detail into consideration and further calculations weren't needed. The final emission factors can be consulted on Table 2.

	Final emission factors (gCO ₂ e/passenger.km)
Car	Gasoline: $2420.20 \times \frac{\text{fuel consumption (l/100km)}}{1.4} / 100$
	Diesel: $2661.27 \times \frac{\text{fuel consumption (l/100km)}}{1.4} / 100$
	LNG: $1237.50 \times \frac{\text{fuel consumption (l/100km)}}{1.4} / 100$
Motorcycle	Gasoline: $2528.14 \times \frac{\text{fuel consumption (l/100km)}}{100}$
Bus	CNG: 88.939 gCO ₂ e/passenger.km
Metro	Electricity: 41.674 gCO ₂ e/passenger.km
Train	Electricity and Diesel: 27.03 gCO ₂ e/passenger.km
On foot or bicycle	0 gCO ₂ e/km (increase of CO ₂ production not considered)
Other means	Not calculated

Table 2 – Carbon footprint estimation

To calculate the individual carbon footprint through the survey and the app it is required information about the distance travelled with each trip and, in case of the car and motorcycle, the specific fuel consumption, so it is possible to apply the emission factor.

It is important to point out that even though vehicles that run on diesel create more CO₂ per litre, they usually can achieve higher fuel economy than similar vehicles that use gasoline, which generally offsets the higher carbon content of diesel fuel

3.2 DATA COLLECTION PHASE

3.2.1 MOBILITY SURVEY

This online survey was a combination of traditional questions to characterize the sample (occupation, age, gender, household information, income) and evaluate their general mobility habits concerning their trips to and from FEUP (distance, frequency, duration, mode of transportation) and a travel diary to give a consistent one-week detailed information that can be compared with the general answers that were given. The evaluation of sustainability will be based on the sample characteristics, their average travelling costs and their carbon footprint, which will be calculated using the data about mode of transportation, distance and fuel consumption in case of using a personal vehicle. With these results, the objective will be to assess the sustainability of FEUP's mobility and the potential of improvement.

Due to an initiative in progress by FEUP's Commissariat for Sustainability and the University of Porto called U-Bike, the mobility survey was sent to all University community with the addition of a question specifically about the susceptibility to the initiative, which promotes electric and conventional bicycles in Academic Communities.

In total, 340 people answered the survey, consisting of 4.1% of the total community, with several replies with suggestions and ideas about sustainability and mobility. Even though it is a low response rate to a normal Mobility Survey (the ideal being above 10%), it is high if we consider the usual rate for travel diaries, where it is not unusual having only 10 families in a city contributing to the travel diary.

3.2.2 SENSEMYFEUP APP

The mobile application called SenseMyFEUP was developed for Android Smartphones by a research team from FEUP's Institute of Telecommunications. For this purpose, they adapted another app of their creation, called SenseMyCity, which is part of the project Future Cities from the University of Porto. They both use crowdsensing to obtain data from the users, and, in SenseMyFEUP's case, it is more directed to retrieve

information about mobility's indicators (mean of transportation, duration and distance of a trip), using distance and chosen mode of transport to obtain the user's carbon footprint.

The data collection and the associated database was registered in the National Data Protection Commission. Each user is identified in the database by the hash used by Google Open ID and not even the database administrator could revert it, therefore being impossible to identify the emails of the participants. The users had access to their data through the app's website, but they were anonymous to everyone else. The raw anonymous data use individual id to be later processed in mass. All the data will be erased after 3 years.

To validate the mode detection algorithm that was still in progress, the users had to respond to a questionnaire each time the app sensed that they finished a trip, using GPS or other location sensor and detecting the variation of velocity between points. The interface of the app showed information about the user's mode of travel, carbon footprint and the comparison to FEUP's average, so the user could be aware of his or her own sustainability.

The SenseMyFEUP app was officially released to the public on March 29th and the dissemination consisted on the distribution of flyers and the exposition of posters throughout the faculty, considering that the target audience was all FEUP's community.

A Facebook page was created to help disseminate the project especially among the students. To raise interest, during the period of data collection (April 4th to April 29th), a FEUP's sweatshirt was sorted among the app's users each week and a smartphone in the end with the chances of winning accumulating with time since the installation and with each data contribution. Due to the impossibility of identifying the exact winner through his or her google email, the winner would be warned through an app notification.

In total, 239 people used the app, but only an average of 150 sent data consistently.

4 RESULTS AND DISCUSSION

4.1 SUSTAINABILITY

Sustainability stands on the pillars of society, economy and environment, but this study will focus on the environmental side, considering that the main tool was the carbon footprint. The key variables for its calculation were mean of transport and distance.

For the first variable, shown in Figure 2, the difference from the app and the survey results is based on the different sample of users, although they tend to become more alike during the same time the data was recorded. The car modal share, particularly the one assessed by the app, is similar to the value defined by the Census 2011 for work/school trips (62%) not only in Portugal but also in Porto, with the rest of the modal choices having a similar distribution, except the metro and bicycle, which are more frequently selected in this case study due to the proximity of metro stations and the larger number of short trips.

Figure 2 – Modal split according to the survey and the app.

For the second variable, distance, the app and the survey stray from each other in terms of results. While the average trip distance assessed from the survey was 13.6 km, the average shown in the app was 6.0 km, probably due to the difficulty of intermodal trip chaining, which included train travelling, to be discussed further ahead.

With the information of both methods, it was possible to calculate the final carbon footprint. Using the survey, it was concluded that the carbon footprint, on average, is 1.28 kgCO₂e per capita in each trip made from and to FEUP, which is consistent to a prevalent car user community. With the app the value is relatively similar, reaching 1.42 kgCO₂e/trip due to a higher share of car users.

Using the survey information on frequency of trips throughout an average week, the emissions were estimated around 13.80 kgCO₂e individually, which translates into 551.99 kgCO₂e during the 40 weeks of an academic year. In 2014, the average carbon footprint per capita in Portugal was 4.60 tCO₂e, with 1.51 tCO₂ being the share related to transportation emissions (World Energy Council, 2016). Even though our results constitute just a third of that value, we have to bear in mind that it was only considered trips from and to FEUP for 10 months. The contributions from other types of mobility will definitely increase, since that school/work travelling only represents 30% of a person's mobility in the area of Porto according to the Mobility Survey of Resident Population in 2000 (Instituto Nacional de Estatística, 2002). By considering the totality of mobility emissions of 1.84 tCO₂e per person in a year (considering that 0.55 tCO₂e is 30%), FEUP's community not only surpasses the national average, but also the world annual carbon emissions of 0.86 tCO₂e per capita (World Energy Council, 2016).

There are a few options within FEUP's reach to help decrease their carbon footprint. Studying the survey's results with more care, we concluded that from the 186 people (55%) who chose car as a preferred mode of transportation, 25 reported that they used any kind of public transport or other alternative for their travelling to or from FEUP in at least one day in their travel diary, meaning there is a feasible substitute to the car. On another note, 24 people use the car or public transportation for travel distances shorter than 3km, which can be considered a valid walking distance and an extra of 27 people, if we consider 5km, which could be travelled by bicycle.

In total, 65 people (19.1% of the sample) were identified to possess mobility habits that could be easily changed and become more sustainable. If those people decided to use a bus from now on and those within 5 km started walking or cycling, for example, the average carbon footprint would become 1.21 kgCO₂e/trip, a 6% decrease. Applying on the whole population, around 1535 people in FEUP (19.1%) are easily susceptible to improve the sustainability of their mobility which could be obtained and increased in number with more awareness campaigns, projects like car sharing, and even striving to improve public transportation around campus and in areas poorly serviced. On the other hand, if we consider SenseMyFEUP's results, 42% of car trips to FEUP and 34% of car trips from FEUP were less than 3km. If those trips were on foot, the total carbon footprint would decrease 22% from 1.42 kgCO₂e/trip to 1.10 kgCO₂e/trip.

Regarding the feedback of the U-Bike initiative, as cited previously, 8% claimed they would change their mobility habits to become more sustainable and 33% would consider it. This would mean that if all those who affirmed that they would start cycling keep their word, the average carbon footprint would decrease to 1.20 kgCO₂e/trip. If we add those who would think about it, the difference would be even more considerable, dropping to 0.69 kgCO₂e/trip, with a 46% decrease from the actual value.

The overall reduction of the carbon footprint can reach 48%, if we combine the population susceptible to change their mobility patterns and the answers for the U-Bike initiative.

4.2 COMPARISON BETWEEN METHODS

After analysing the sustainability results provided by both sources, the survey and the mobile application, it is time to review these methods and reach a conclusion on their effectiveness in obtaining useful results and their reach to the community.

The traditional method of studying mobility is simple and to the point, although it has its limitations. It matured through time into a standardized procedure based on surveys, which can take various forms, but

always presenting the same base questions to answer key points in mobility: mode of transportation, time, distance, frequency and purpose of the trip. Other information can easily be requested and inserted in the survey, as well as interviews for a more qualitative input.

The downside of this process is related to the length of the survey and the specific, extensive questions that are necessary to cover the information required to be able to gather useful statistics on the matter. The less specific a survey is, the less exact and informative the results will be, but on the other hand it will be faster and not as exhausting to people, which can lead to a higher number of responses. If, on the contrary, a survey is more complex and inquisitive, the opposite would happen. In the end, it reduces itself to a simple balance of extent of information gathered and the willing participation of the people.

Comparing both methods, there is a clear confrontation about declared mobility and revealed mobility. By relying on a survey to provide data means accepting the inherent errors related to generalization, perception of the respondent and willingness to provide thoughtful answers. An app based on a location sensor system gives more accurate answers, since it does not depend on the user per se to provide the data. This information is not a described behaviour but a perceived behaviour instead.

Regarding SenseMyFEUP, a source of app results errors can be during the answering of questionnaires. Some respondents stated they walked during the last trip, although the velocity sensed by the app was around the 45 km/h. Another common problem was with the detection of the exact user's location. The source of this error, however, can usually be traced to the phone itself. These represent the various different uncontrolled variables that can potentially cause problems.

Inconsistencies with the location system from the user's phone or online connection can incapacitate the app's ability to work correctly. Each trip must be correctly identified from its beginning to its end and that means movement recognition with variation of velocity. This process can be complicated because many trips are not simple: they can be intermodal, with stops along the way and other irregularities. If the automatic detection mode is not fully operational, questionnaires can be both a source of confirmation to compensate that weakness as well as a source of confusion, errors and frustration from the user's part. Having to answer a question about used mode of transportation every time a trip ends can be tedious if they pop up regularly.

Trip recognition is crucial, but most of it relies too much on the user's phone or if the user remembers to answer with each trip without letting them accumulate and probably give wrong feedback for mistaking trips. Another problem associated with trip recognition is the correct trip chaining, which can be a problem difficult to control, especially when public transportation and waiting periods are involved. SenseMyFEUP considered a trip complete when the user seized to move for a longer period than a normal metro or bus stop or the waiting time at a traffic light, therefore if it took longer than usual, like being stuck at a traffic jam or waiting for a bus or a train, the app would not chain the trips correctly. Also, if the location system stopped providing data for longer than 20 min or in a 200 m radius, the trip would end, which becomes a problem with metro underground tracks. To aid in correcting this problem, the help of the user would be necessary to select the registered trips and connect them, requiring a change of the app's interface choices.

Although SenseMyFEUP faced these challenges, in comparison with the survey, the app data is more detailed and each trip is unique, which is better for differentiation and accuracy. While in the survey, the distance analysis was based on the answers of the respondents and their opinion, the app automatically retrieved that same information with precise values and added details about origin and destination, not only gathering data on school/work mobility, but its total as well. For more accurate results for the survey distances, it would be necessary to calculate it through the given addresses, which would take a long time to process, and, even so, it would not reach the accuracy of the app because not all school/work trips start or end at home. The closest in detail that a survey can get to a dedicated app is through a travel diary, but that lowers the response rate, therefore the choice between both methods must be balanced by considering the requirements and the resulting consequences.

Regarding sustainability, the survey provided more specific data related to details about personal vehicles, including type of fuel and fuel consumption, both being important for the calculation of the carbon footprint, and also information about social situation and mobility costs. SenseMyFEUP, on the other hand, did not retrieve that information since that would demand more questions for the users and, for now, the intention was to remain simple, using average data to compensate the lack of information.

While the app had more immediate sustainability results which could create awareness about individual habits, the survey didn't offer direct results for the community, although many gave personal feedback revealing their concern about their sustainability, and explaining the limiting conditions that influence their choice of using the car.

In the following table, a final collection of advantages and disadvantages from both traditional and modern method according with different main topics is revised.

	SURVEY	APP SENSEMYFEUP
Costs	<ul style="list-style-type: none"> • Even though the survey did not present associated costs due to the fact that was email based, city or country level surveys require considerable investments. 	<ul style="list-style-type: none"> • The main costs of SenseMyFEUP were the prizes, the payment for the registry in the National Commission of Data Protection and, especially, the costs regarding data storage.
Time	<ul style="list-style-type: none"> • Although it requires a smaller amount of time to write a survey, in bigger scale the survey period is a lot more extensive, especially with a larger target community. Door-to-door surveys demand long periods of time and, as opposed to the app, the richness of the data is not increased with a longer data collection period, only the amount of answers; • It usually only requires a single fill of the survey, unless it is a travel diary. 	<ul style="list-style-type: none"> • The programming phase requires a lot of work and a lot of time, however, from the moment the algorithm is finished, the data collection is automatic and does not require further effort, unless problems are found; • The period for data collection is continuous until the app ceases to work, contributing with more information each day.
Human resources	<ul style="list-style-type: none"> • In this case, the method only needed the contribution of one person, since it was an online survey. However, if it is face-to-face, many teams are required on the field to conduct interviews and surveys. 	<ul style="list-style-type: none"> • Making and maintaining an app requires a specialized team with an increasing number of involved people according to the complexity of the app and the collected data.
Users	<ul style="list-style-type: none"> • It allows a better access to a larger portion of the population, since it does not exclusively depend on technologies to collect data, which could be a deterrent regarding old-aged people, for example; • The response rate depends of how the survey is conducted (online, face-to-face, by telephone) and the receptivity of those inquired. Face-to-face interviews have better rates, as well as having a target community that is more informed and interested in the matter. 	<ul style="list-style-type: none"> • It is limited by the required technology, which in SenseMyFEUP's case meant that only those who possessed an Android smartphone could install and use the app, narrowing the sample; • It is a more attractive and effective method for the younger population, who rely on a daily basis upon technology and are less likely to regard this method with distrust.
Results	<ul style="list-style-type: none"> • The collected data is a declared mobility, which is more prone to assumptions; • The provided information is generalized and limited to the questions; • The detail demanded in the survey influences negatively the response rate, which means that travel diaries, even though they collect more information, present lower response rates; • The errors of this method are mainly human, especially during the filling of the survey, due to distraction, imprecision, assumption, lack of memory (in particular regarding travel diaries, which require more details), etc.; • Most difficulties lie on dealing with response inconsistencies and unforeseen situations that are not considered in the questions of the survey. 	<ul style="list-style-type: none"> • The collected data is a revealed mobility, which is closer to reality; • The results are more exact and detailed throughout time, with a passive and continuous collection, even though privacy issues can limit some access; • SenseMyFEUP used a questionnaire to identify the transport mode, therefore, in similarity to the traditional method, it had to face human errors in its results; • Technical problems are intrinsic to technology and, especially if the users are not accustomed to this type of apps, situations like having the location sensor inactive, not turning the smartphone on while travelling or Wi-Fi problems are common; • The main difficulties of mobility apps are modal identification and trip chaining.

Table 3 – Advantages and disadvantages from both studied methods.

Both methods have advantages and disadvantages, with the choice depending on the available resources, the required richness of the results and the target population. The ideal scenario would be to use the strengths of both methods to collect data, especially in larger scale cases, allowing a smoother transition to a new era of mobility information. However, that is not always a viable option and a choice must be made.

5 CONCLUSIONS

The case study, supported by two methods, proved that the community of the Faculty of Engineering of the University of Porto follows the trend of favouring the car over public transportation. Its comfort and practicality in varied situations is still deeply valued, and it affects FEUP's sustainability negatively for being a favoured choice for long distances. The individual carbon footprint for each trip calculated with the data from the survey and the app was between 1.28 and 1.42 kgCO₂e, that translates to 0.55 tCO₂e at the end of the academic year.

The feedback from the survey demonstrated a wish for change from the community that revealed interest for sustainability, but inability to overcome daily limitations with other mobility choices. More initiatives are required to support this transition, including promoting walking or the use of bicycle for short distance trips, which showed interest from the community according to the U-Bike question, and carpooling/carsharing for people who live further away and have few or none public transport options. Encouraging better supply and quality of public transportation with supporting data about deprived areas is also important to diminish the advantage of the car. It is imperative to diminish the preference for motorized vehicles for short distances and to increase the use of public transportation for longer ones.

Regarding SenseMyFEUP, even though being a relatively new method of approaching data collection in this faculty, it sparked interest in the community and raised awareness about mobility and sustainability in a new way by using carbon footprint as a tool. Being a recent project, it requires further development to correct problems and increase interactivity with the user to encourage installation and continued use.

Both methods provide valid information, but the app has a greater potential for the future as a developing technology. The traditional method has a more established procedure that can be easily followed, but, unfortunately, studying big populations can be costly and take long periods of time. In the end, the results are slightly different: the survey method relies on what respondents say it is true and the app method collects real life information directly from the source, as long as it is not completely based on questionnaires. Each approach has its strengths and weaknesses and the choice to obtain data through one or another belongs depends on the situation, the target population, the final objectives and the available resources. For now, using both methods to balance their strengths and weaknesses is a good choice for the evolution of data collection.

elena.pede@polito.it; luca.staricco@polito.it

1 INTRODUCTION

Car sharing is nowadays commonly acknowledged as an innovative approach to the transportation problems of urban areas (Firnkorn and Müller, 2015). Scientific literature regularly discusses car sharing related to the context of sustainable mobility and environmental benefits, or in relation to consumer behaviours in the sharing economy rhetoric. The former approach is common in transport studies and concerns strategies to face mobility-related problems in urban context and potential solutions for the environmental impacts of car traffic due to CO2 emissions (Martin and Shaheen, 2011), number of vehicles per household (Martin et al., 2010) and vehicle-kilometres travelled (Firnkorn, 2012). On the other side, social studies are more interested in the changes of consumer behaviour and their implications on society and economy. These publications are mostly based on the shift from ownership to service use lifestyles (Kuhnimhof et al., 2011; Prettenhaler and Steininger, 1999; Schaefers, 2013): the concept of ownership is changing fast and determining lots of consequences on consumers' practices and business strategies (as, for example, the interest of auto companies in short-term rental like a way to balance the loss of purchases; Schwanen, 2016a).

Differently, poor attention has been so far focused in scientific literature to the social impacts of car sharing. This can sound quite surprising: the first car sharing organisation, the SEFAGE (Selbstfahrgemeinschaft, self-riding community), was founded in 1948 in Zürich by a housing co-operative, just to allow people, who could not afford to purchase an own car, to share one (Harms and Truffer, 1998). Shaheen and Cohen (2007) outlines that the main beneficial social impact of car sharing is the possibility for households (in particular, low-income ones) to gain or maintain vehicle access without bearing the full costs of car ownership. Litman (2000) reads it in terms of equity: car sharing can increase equity by improving the mobility options of people who are transportation disadvantaged.

But the spatial dimension can play a crucial role for these supposed social benefits, in particular in urban areas. On the one hand, the distribution of social deprivation problems in the city is not homogeneous, on the contrary it tends to increasingly polarize (especially in times of austerity and economic crisis; Cucca and Ranci, eds., 2016). On the other hand, car sharing services hardly cover all the territory of a city; private companies can choose the area where to operate, or can modulate costs and levels of service (e.g., the density of stations) in different neighbourhood of the same city. If these two spatial distribution patterns mismatch, car sharing can deepen rather than reduce socio-spatial injustice and inequity

As regards the spatial dimension of car sharing services, until now scientific literature has mainly focused its attention on models and tools to assess the market potential for new car-sharing operations in urban communities (Habib et al., 2012). For example, Celsor and Millard-Ball (2007) developed a methodology that supports car-sharing operators and transit agencies to assess the market potential for car sharing in different neighborhoods, according to their characteristics. Wagner et al. (2016) use a set of indicators for the attractiveness of certain areas (based on points of interest in their vicinity, such as shopping malls, movie theatres, train stations etc.) to identify promising regions for an expansion of car sharing business areas. However, the potential negative impacts of these approaches in terms of social inequity have not been considered.

Conversely, in this paper we will try to examine precisely if present car sharing services increase or reduce socio-spatial injustice. The paper focuses on three Italian cities (Turin, Milan and Rome), where private transport plays a key role in mobility choices of citizens (section 2). A deprivation index is calculated to identify in each city the neighbourhoods where potential car sharing benefits could be more significant, and levels of car sharing service are assessed in each of these neighbourhood (section 3). Positive or negative correlations between levels of deprivation and car sharing services are then calculated (section 4), and reasons for these results are hypothesised and discusses (section 5).

2 CASE STUDIES

In Italy, private motorized transport plays a key role in mobility choices of citizens: (its modal share is close to 70%; Isfort, 2016) and the Country has the highest motorization rate in EU, after Luxemburg and Malta, with 610 cars per 1,000 inhabitants. At the same time, road traffic is one of the main problems in urban areas in terms of air and noise pollution emissions, loss of public space, reduced efficiency of surface public transport. Despite these critical situation related to private transport, the diffusion of car sharing services inside most important Italian cities was considered, since the beginning, a potential advantage for solving mobility problems and an innovative “ethic” perspective of mobility (Fistola, 2007). Nowadays, car sharing is spreading quickly, especially in Northern Italy, whereas is less widespread in the South.

The first car sharing services started at the end of the 90’s thanks to the national Car Sharing Initiative (ICS) promoted by the Ministry of Environment, that financed station-based services in 12 cities and 4 provinces at the beginning of 2000s. Since 2013, several private free-floating services were set up in main urban areas, followed also by van and scooter sharing. The introduction of free-floating services is reducing the number of users of station-based services, which are more expensive and less flexible. At the same time, new types of station-based and free-floating services are emerging related to electric vehicles.

The case study analysis takes into account three of the four Italian cities with the highest number of inhabitants: Rome, Milan, and Turin. They have different types of car sharing services and more than one company interested to operate in this service (Table 1). Naples (the third city per population) was not considered because it has only one company that operates with a very limited car sharing services (only 4 stations in the whole city). Rome, Milan and Turin have both station-based and free-floating services. In general, each city has its public (station-based) car sharing initiative even if some of them have a limited number of cars or the service has stopped because of the high decreasing of customers. On the contrary, free floating mainly concerns private companies whose numbers of cars, costumers and services are increasing rapidly in the last 4 years.

Station-based services			
	number of car services	number of scooter services	number of electric vehicles
Rome	1	-	-
Milan	3	-	2
Turin	2	-	1
Free-floating services			
	number of car services	number of scooter services	number of electric vehicles
Rome	3	5	3
Milan	4	1	2
Turin	2	-	-

Table 2 – Details of the car sharing services analysed in the three cities

At the same time, it is important to consider the different dimensions, densities and spatial structures of Rome, Milan and Turin (Figure 1), which can influence the implementation strategies of car sharing companies.

Figure 1 – Spatial structure of the three case studies

Rome is the largest and most populated Italian city (and the fourth-most populated one in the European Union) with 2.873.598 residents (2016) on 1.285 square kilometres. Its urban boundaries are wide due to historical reasons: its surface is six times the size of Milan. Its territory is divided between highly urbanised areas, parks, natural reserves, rural areas, wetlands. The transport infrastructure is based on the radial network of roads that connected, already at the time of the Roman empire, the city with its surrounding region. Nowadays, Rome is cut in two parts by the Grande Raccordo Anulare (GRA), a ring-road that circles the city centre with a radius of about 10 km. Most inhabited areas lay inside the GRA, but there are also neighbourhoods outside of it and also up onto the Tyrrhenian coast (20 km far from the city centre). The city suffers from chronic road congestion, also because of the limited size of Rome's metro system (two underground lines) compared to other cities of similar size. Due to poor efficiency of public transport, citizens have become addicted to private vehicles and the ring-road has become the main transport infrastructure. Today the city has one of the highest motorized vehicle ownership rate in Europe: 613 cars every 1,000 inhabitants.

Milan is the second most populated city in Italy with 1,369,000 people in the proper city and 3,209,000 in the metropolitan area (2016). Its territory covers 181 square kilometres with a population density of 7.315 inhabitants per square kilometres. The urbanized area covers almost the entire city surface and has swallowed many municipalities of the metropolitan area, especially in the North. The city has a concentric layout and the public transport network consists of five underground lines and 154 surface bus and tram lines. Also in Milan, mobility problems are related to the private transport demand, due to the high number of people entering the city during the day and the absence of co-ordinated mobility management at the metropolitan level between the city and its hinterland. A congestion charging scheme has been introduced in 2011 in the central part of the city.

Turin counts 888,921 inhabitants (2016) and covers 130 square kilometres. The city has a natural limit on the Eastern front, where it is surrounded by high hills. On the Northern and Western fronts the urbanized area spreads far beyond the city limits and covers several municipalities up to the Alpine mountains, while the Southern front is wider due to the plain territory. The city has grown along the North- South railway axis that used to cut the territory in two parts; this trench was covered in the 90s and its transformation has allowed to build a 8-lines commuter rail system that connects the city to its metropolitan area. The public transport network consists of one underground line and several surface bus lines. Nevertheless, also in Turin private transport plays a leading role in citizens' choices of mobility.

These transport and morphological structures have influenced the car sharing models adopted in each city. For example, due to severe congestion problems, in Rome 5 companies were or are specialized in scooter sharing services. In the cases of Rome and Milan, the municipalities required to the companies to serve specific areas, while in Turin there is not specific demands (even if Eastern hills are not served because of their poor residential density and difficult accessibility). Rome limited the services to the region inside of the ring road (GRA) even if some of the companies have showed an interest in serving also parts of the surface outside the GRA, especially the coast during summer season. On the contrary, the municipality of Milan tried to impose spatial equity elements requiring to cover a certain percentage of the

municipal surface. As a consequence, one of the company operating in the city (Car2Go) has introduced an additional cost for outskirt zones because they registered a low utilization of the cars and the relocation of the vehicles by the company was considered non- economic.

In this paper, we will focus on the three car sharing services that are active in each of the three cities (Table 2): the already mentioned station-based ICS service, promoted by the State, and two private free-floating services, Enjoy (promoted by the Italian oil company ENI) and Car2go (promoted by the Dutch automotive Daimler group).

	Turin	Milan	Rome
ICS: number of station	67	84	131
Enjoy: operational area (square kilometres)	49	118	97
Car2go: operational area (square kilometres)	56	117	90

Table 2 – Details of the car sharing services analysed in the three cities

3 METHODOLOGY

3.1 DEPRIVATION INDEX

Data above driving licences of car ownership at sub-municipal neighbourhood level are not available for Italian cities. We have decided to use, as a proxy for these, a social deprivation index: the assumption is that people that cannot afford to own a car are more likely to live in neighbourhood where social conditions are worse, rather than in more richer ones. Therefore, a deprivation index (ID) was calculated for each census tract¹ of the three cities. The index is made up of four distinct indicators of social deprivation, for which disaggregated data at the census tract level were available from 2011 population census. These indicators are:

- Education (z1): percentage of people aged 15 years and over which has attained at maximum a primary or lower secondary level of education;
- Unemployment (z2): percentage of people aged 15 years and over which is unemployed;
- Living condition – overcrowding rate (z3): average number of people per dwelling;
- Living condition – housing condition (z4): percentage of people living in mediocre or poor condition houses.

For each indicator z, census tract variables x are standardized by subtracting the city mean μ_x and dividing the difference by the standard deviation σ_x :

$$z_j = \frac{x_j - \mu_{x_j}}{\sigma_{x_j}}$$

The deprivation index of each census tract is then calculated as the sum of the four indicators:

$$I_D = \sum_{i=1}^4 z_i$$

On the basis of the deprivation index values, census tracts are finally clustered in five “deprivation classes” through the Jenks natural breaks method, where “class 1” comprises the least deprived tracts and “class 5” the most deprived ones.

¹ The census tracts referred in this paper are the so-called ACE (“aree di censimento”), which are defined by the Italian national statistics Institute as municipality partitions hosting between 13.000 and 18.000 inhabitants.

3.2 LEVELS OF CAR SHARING SERVICE

For station-based car sharing services, each station is geo-referred and “attributed” to the census tract it is located inside. Two indicators are then calculated for each census tract:

- the absolute number of car sharing stations;
- the density of car sharing stations (i.e., the number of stations divided by the number of residents).

For free-floating car sharing services, the border of the operational area covered by the service is geo-referred, and census tracts (with their number of inhabitants) inside and outside this border are identified; the same is done for borders which separate operational areas covered by different service tariffs. If a census tract is partly inside and partly outside this border, the tract is divided in two sub-tracts and its total population is attributed to these portions proportionally to their surface. An indicator is calculated to measure the percentage of population living in census tracts that are covered by the car sharing service, and the percentage that is not served; in the case of diversified tariffs, the percentage of population covered by each tariff is calculated.

4 EMPIRICAL RESULTS

4.1 DEPRIVATION INDEX

Table 3 shows the mean values and the standard deviation of the four deprivation indicators for each of the three cities, as well as the range of values for the five classes of the derived deprivation index.

	Turin	Milan	Rome
N° of census tracts	57	86	147
ID dimensions:			
<i>Education</i>			
mean value	0,230	0,186	0,187
standard deviation	0,053	0,052	0,058
<i>Unemployment</i>			
mean value	0,071	0,054	0,064
standard deviation	0,016	0,013	0,014
<i>Overcrowding rate</i>			
mean value	2,140	2,065	2,302
standard deviation	0,159	0,143	0,217
<i>Housing conditions</i>			
mean value	0,122	0,096	0,123
standard deviation	0,074	0,069	0,099
ID classes			
1	-4,95 – -2,89	-4,27 – -3,04	-5,25 – -2,83
2	-2,89 – -1,22	-3,04 – -1,44	-2,83 – -0,67
3	-1,22 – 0,35	-1,44 – 0,30	-0,67 – 1,38
4	0,35 – 2,70	0,30 – 3,00	1,38 – 3,75
5	2,79 – 8,02	3,00 – 9,95	3,75 – 8,31

Table 3 – Details of the deprivation index in the three cities

Population is quite homogeneously distributed (Figure 2) among the five deprivation classes in Milan and Rome, despite classes 4 and 5 cover over the half (76% in Rome) of the municipality surface. In Turin residents are more concentrated in the first and in the two last classes.

Figure 2 – Distribution of population and surface among the five classes of the deprivation index

Conversely, from a spatial point of view, the distribution of the census tracts among the five deprivation classes is quite far from being homogeneous. As shown in Figure 3, in all the three cities deprivation levels generally tend to increase from the central area to the outskirts. In the case of Turin, less deprived areas are concentrated in the Northern part of the city and in the Eastern hills; in Milan, they cover the Western and Southern outskirts; in Rome, a wide deprivation “class 4” area surround the central city, while “class 5” census tracts are quite restricted in surface.

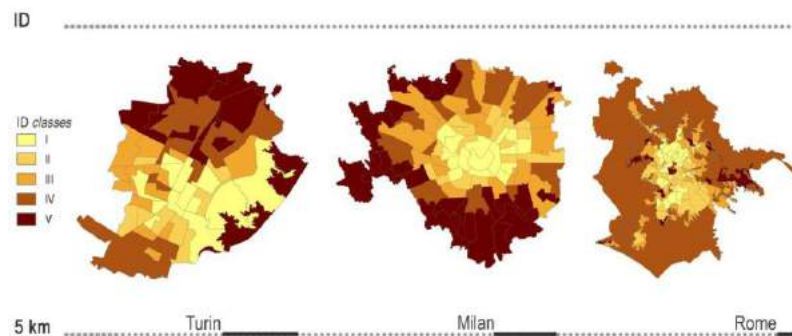

Figure 3 – Spatial distribution of the five classes of the deprivation index in Turin, Milan and Rome

4.2 STATION-BASED CAR SHARING SERVICES

In all the three cities, it is clearly evident (Figure 4) that the level of station-based car sharing service decreases significantly from less deprived areas to more deprived ones, either considering as service level the absolute number of stations in each class or their density (n° of station / inhabitants ratio). For example, in Turin 55% of stations are concentrated in census tracts of the first deprivation class. In all the three cities, two thirds of the stations or over are located in the census tracts of the two less deprived classes.

Figure 4 – Number and density of the fixed car sharing stations

4.3 FREE FLOATING CAR SHARING SERVICES

As regards Enjoy (Figure 5), the percentage of the population living in census tracts covered by the service decreases from less deprived tracts to more deprived ones (except in Rome, where population in the tracts of the fifth deprivation class is more served than in the fourth class). In Milan, the coverage range from 100% for the first class of deprivation to 74% for the fifth class; in Turin from 81% to 50%; in Rome, 83% of the population in the first deprivation class is served, but only 5% in the fourth class and 16% in the third and fifth classes.

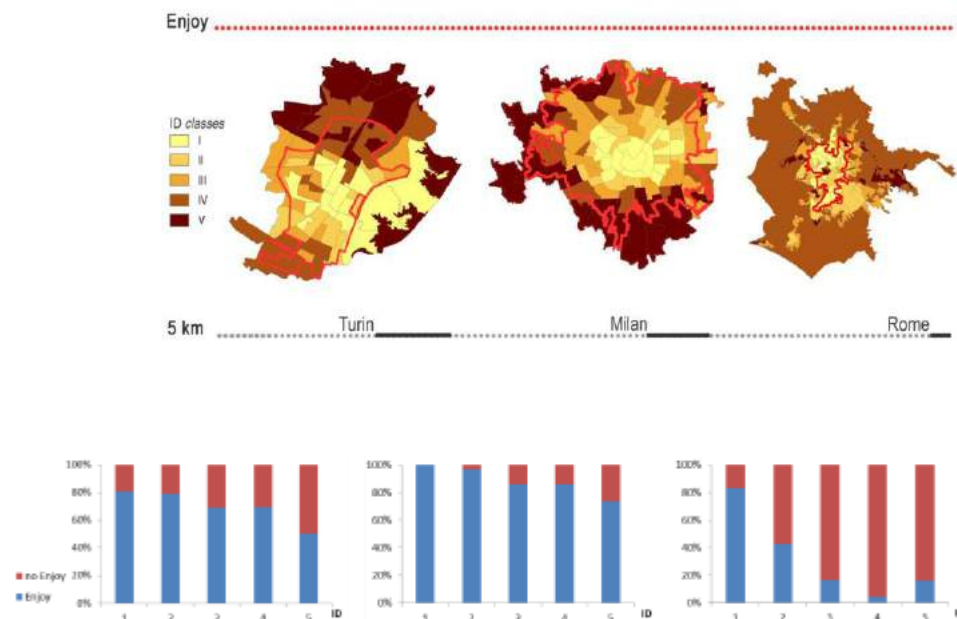

Figure 5 – Percentage of the population living in census tracts covered by the Enjoy car sharing service

As regards Car2go (Figure 6), a similar uneven spatial coverage of the service can be noted. In Rome, 76% of the population in the first deprivation class is served, compared to 6-7% in the fourth and fifth classes. In Milan, where the service has a dual tariff, in the first two classes over 95% of the residents are served by the less expensive tariff; in the fifth class, only 6% of the residents live in a census tract covered by this tariff, 61% are covered by the more expensive tariff and 33% are not served at all. In Turin the decreasing level of the service is less clean but anyway acknowledgeable: the coverage reaches 86% of the population for the second deprivation class, and only 65% in the fifth class.

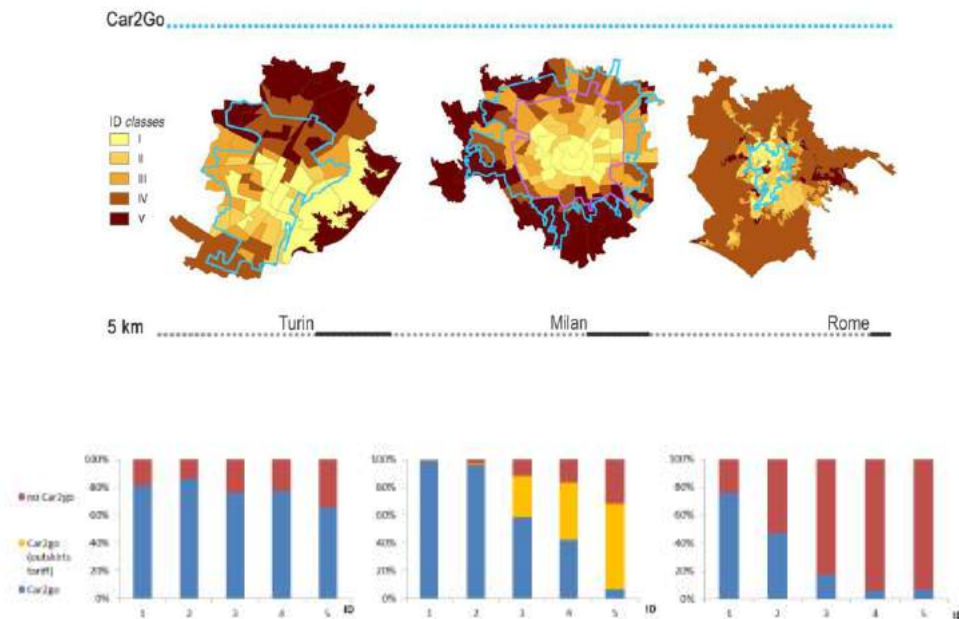

Figure 6 – Percentage of the population living in census tracts covered by the Car2go car sharing service

5 DISCUSSION AND FUTURE RESEARCH

The importance of transportation in spatial justice issue is still hardly considered (Martens, 2016) even if transportation systems, for their very nature, influence the urban structure and affect the accessibility from and to a specific place. For example, Schwanen (2016b) wonders whether the reconstitution of public transport as efficient and economical in neoliberal and post-neoliberal cities has reduced or intensified socio-spatial polarization.

Car sharing could be thought as a factor that improves socio-spatial justice and transport equity, since it offers people, who cannot afford to own a car, the opportunity to drive more or less occasionally. But the results of the analysis of car sharing services in three Italian cities clearly demonstrate that, because of their spatial distribution, these services (be they station-based or free floating) increase – at least in relative terms – social and spatial polarization in the city, rather than reduce it. As a matter of fact, in Turin, Milan and Rome car sharing is less developed in most deprived urban areas (where a greater share of residents is likely not to be able to own a car) than in less deprived tracts. In other words, car sharing services tend to give precedence to central urban areas, while most deprived tracts are mainly concentrated in the outskirts.

As Soja (2011) outlines, it is relatively easy to discover examples of spatial injustice descriptively, but it is much more difficult to identify and understand the underlying processes producing unjust geographies. In this paper, we do not examine the strategies that car sharing operators adopt in defining the spatial distribution and extent of their services. A few hypothesis can be done. As some studies have outlined, car sharing users are mainly urban, young and professional: they tend to be in their 30s or 40s, have middle-to higher-incomes, are primarily employed in professional occupation, live in one-person households (Bardhi and Eckhardt, 2012; Katzev, 2003; Millard-Ball, 2005; Schmöller et al., 2015). In order to maximize their profits, private companies can decide to intensify their car sharing services where this kind of potential users are more concentrated (typically, central urban areas), to the detriment of other areas (as the most deprived ones). Other studies (Celsor and Millard-Ball, 2007) show that car sharing has success in places where transit and walking are realistic alternatives, where a car is not needed for everyday travel and little off-street parking is available: again, these are typically central older, historic neighbourhoods. Finally, private operators can avoid to serve (or reduce their levels of services in) most deprived areas for fear acts of vandalism: for example, in Italy Car2Go allows to rent its cars in a city and park them in another one, but prohibits to drive them in the South of Italy.

Further research on the spatial strategies that car sharing operators adopt in defining their services could help to better understand the reasons of the socio-spatial injustice that car sharing can determine. Moreover, they could offer relevant information to public administration that aims at encouraging car-sharing operators to place their cars in low-income neighbourhoods (through co-funding, subsidies for households etc.) (Millard-Ball, 2005).

ID 1548 | UNSUSTAINABLE GROWTH OF URBAN TRANSPORT: QUESTIONING MAINSTREAM SUSTAINABILITY SOLUTIONS FOR TURKISH CITIES

Cihan Erçetin¹

¹Middle East Technical University
cihanercetin@gmail.com

1 INTRODUCTION

The automobile, supported by bus, has become the transportation mode which formed the urban physical structure after the beginning of the years of Second World War. By this technology, it was possible for the city to develop in any direction. Initially, urban development occurred between train lines, and then the cities started to develop fifty kilometers away from the central core for the average half-hour journey (Newman & Kenworthy, 1999). When the effects of car dependence are considered in urban areas in terms of sustainability concerns for the future of environment, society and economy, it is obvious that an automobile based urban pattern cannot be sustained.

As opposed to car dependency, mainstream solutions are put forth as public transport, walking and cycling. In addition, decreasing policies for car use such as congestion charging, traffic calming, disincentive tax measures for car entrances to city centers and awareness raising campaigns and policies have been seen as supplementary solutions to sustain the future of urban transport. The positive feed backs of those mainstream sustainability solutions have been observed in positive manner over years in especially U.S and Europe –in cycling friendly cities such as Copenhagen, Amsterdam, Strasbourg, Antwerp-. However, cities in Turkey has still been experiencing the hazardous outcomes of car dependency and unsustainable urban transport. Whether the policies has been taken consciously or unconsciously concerning making urban transport more sustainable, there have also been several sustainable solutions in particularly public transport in Turkish cities. These are new urban rail investments, pedestrianization projects, cycling lanes and bike-sharing systems. Therefore, the main question is that “Have sustainability precautions worked so far in cities in Turkey or not?”

In this research, firstly, unsustainable transport concept will be mentioned together with its sustainable solutions as public transport walking and cycling. Then, unsustainable urban transport, namely car dependency, in Turkey will be revealed to constitute a base for research question. Finally, sustainable transport solutions in cities of Turkey will be critically discussed concerning the effects of new public

transport, walking and cycling investments. Finally, the expected outcome of research will be that it has been so difficult to overcome the dominance of neo-liberal urbanization and transport policies through only sustainability impacts on transport.

2 WHY CAR DEPENDENCY IS UNSUSTAINABLE?

In the late 1960s, both public and policy makers tended to reconstruct central urban areas in order to create more space for traffic such as roads and parking spaces. In the early 1970s, many Western countries realized the negative urban and health impacts associated with the excessive use of automobile, and prepared regulations to reduce emissions of pollutants per vehicle kilometer for cars and other kinds of road vehicles together with considering noise emissions of them (Wee, 2007).

The use of automobiles has significantly increased during the last few decades. Between the years of 1970 and 1990, the number of passenger kilometers by private car per capita experienced an abrupt rise by 90 percent in Western Europe and 13 percent in the United States (Jakobsson, 2004). Road traffic that depends on motorized vehicles is a fundamental contributor to particularly environmental problems at a global scale. Steady growth of motorized traffic threatens the quality of life in urban areas, and private car use is an important source of these problems. In this instance, reducing negative effects per vehicle through new technologies cannot make a significant impact to completely control these problems; instead, changes in volumes of car traffic are necessary (OECD, 1996).

According to Newman and Kenworthy (1999) that problems of car dependence cover a wide range of issues, varying from economic efficiency, environmental responsibility, social equity, and human livability. The effects of automobile dependence on the efficiency of economy, firstly, start with infrastructure costs. A significant amount of costs for new urban infrastructure emerges, because older infrastructure in the city is underutilized. In fact it is obvious that, as long as the urban development is low density and sprawled rather than transit oriented, monetary sources will still be wasted. Then, transportation costs come for the issue of economic efficiency. It is important to mention that the total costs of an automobile-based urban transportation system exceed transit system costs by 30% to 40%. Moreover, this system could become completely automobile-based with a little focus on public transport; therefore, the land use structure has to be on the basis of more concentrated and non-motorized movements including public transport. In addition, time costs of an automobile based urban transport system also exist as a constraint. Urban traffic mostly creates congestion, and cities have been oriented their way out towards it. Therefore, people lose most of their time for travelling from one destination in a city to another, and it has to be reconsidered that the solution for the problem of time loss necessitates land use changes in order to reduce the need to travel. The last problem of economic efficiency on the basis of automobile dependence is land waste which refers to the use of urban land for car parking and new road construction. The loss of available productive land for excessive parking and road space is not only the concern of economic constraints, but social as well as environmental ones. Secondly, the constraint of social equity on automobile dependent cities stands initially together with inequalities in being car-less. In any city, a significant part of population cannot drive, because of being too young, too poor, too old, or just disabled and being thus disadvantaged. Then, the issue of inequalities in location comes. The people living in middle, outer and fringe suburbs created in the era of the car are access disadvantaged because of lack of transit, which is often the case in car-dependent cities. This kind of a disadvantage has two key characteristics: primarily, the policy makers focus on transportation rather than land use policy approach which reduce the need for car travel; and secondary, they give priority to private cars over public transport and non-motorized modes. Furthermore, there are constraints of automobile dependence on human livability. Initially, the issue of loss of community constitutes one of the significant automobile-related constraints. The interactions between neighborhoods and communities are decreased, because together with the domination of automobile on urban transport, pedestrian or transit system travels -which cause accidental or casual interaction between people-lessened. Therefore, it is evident that walking, cycling and public transport play crucial role in considering the quality, and more interaction of human oriented aspects of access and transportation. Moreover, loss of urban vitality stands as another part of constraints. The vitality and culture of the city is decreased when urban spaces are dominated by automobiles instead of people. The main problem here is structuring our cities according to car use and an emphasis on private rather than public space.

Urban transport is also highly related with injuries and deaths as a result of accidents and this probably have the most dramatic unfavorable influences on both objective and experienced quality of life of

survivors, their families and friends. Besides, it can be extensively considered that serious accidents have irreversible impacts on victims due to drunk or careless driver who fatally injures someone else (Gifford, 2007). Motor vehicle accidents constitute 44% of total accidental deaths in the United States; in addition, approximately about 45,000 people have been died every year in the last 30 years for that reason (Best, 2005). In Table 3, statistical data can be seen including population, number of people with driver license, total motor vehicle accidents, deaths and injuries between 2002-2011 for Turkey. When the number of people with driving license is considered almost in parallel with the number of motor vehicles in traffic, it can be obviously seen from the table that the number of total motor vehicle accidents -constituted much of them from car involvements- raised almost threefold in number between the years of 2002 and 2011. In those accidents, important numbers of them involved death or personal injury which increased also in parallel with the number of driver in traffic and total accidents. In addition, almost each year, an approximate average number of 4300 people were killed, and more people also injured. In this case, it is evident that motorized traffic has a direct effect on not only human health, but its existence, and if the increase in the use of motorized vehicles -especially private cars- continues, the condition will be very dramatic as expected.

YEARS	Population (Thousand)	Number of People with Driving License	Total Motor Vehicle Accidents	Accidents involving death and personal injury	Number of people killed	Number of people injured
2002	69 626	14,994,960	439 777	65 748	4 093	116 412
2003	70 231	15,488,493	455 637	67 031	3 946	118 214
2004	71 794	16,151,623	537 352	77 008	4 427	136 437
2005	72 065	16,958,895	620 789	87 273	4 505	154 086
2006	72 974	17,586,179	728 755	96 128	4 633	169 080
2007	70 586	18,422,958	825 561	106 994	5 007	189 057
2008	71 517	19,377,790	950 120	104 212	4 236	184 468
2009	72 561	20,460,739	1 053 346	111 121	4 324	201 380
2010	73 723	21,548,381	1 106 201	116 804	4 045	211 496
2011	74 724	22,798,282	1 228 928	131 845	3 835	238 074

Table 1 - Number of driver license, persons killed, persons injured, motor vehicles and population between 2002-2011 in Turkey - Source: (Turkish Statistical Institute, 2012)

Thus, the seriousness of the circumstance has to be stated that on the one hand, a car based urban transport system damages particularly the environment, climate, and nature; and on the other hand, it affects human health and quality of life in general. It is evident that car use has unfavorable results on three phases of sustainability: on economy, society, and especially environmental quality; therefore, the answer of the question about what we undoubtedly should not sustain anymore for urban transport appears more clearly. In short, a car-based urban travel pattern cannot be sustained, and some kinds of sustainable solutions have to be considered in policy making.

3 SUSTAINABLE SOLUTIONS TO CAR DEPENDENCY

According to the report prepared by International Economic Development Council in Washington (2006), the principles of Smart Growth can be listed as:

- Mix land uses
- Use land efficiently
- Create a range of safe, convenient, and affordable housing opportunities and choices
- Create walkable neighborhoods
- Foster distinctive, attractive communities with a strong sense of place
- Preserve natural lands, farmland, and critical environmental areas
- Strengthen and direct development toward existing communities
- Provide a variety of transportation choices

- Make development decisions predictable fair, and cost-effective
- Encourage community and stakeholder collaboration in development decisions (International Economic Development Council, 2006)

Calthorpe (1993) presented the urban design principles associated with Transit Oriented Development in his book as:

- A compact and transit supportive development urban growth on regional level,
- Location of housing, jobs, commercial activities, parks and civic uses within walking distance of transit stops,
- Formation of street networks that are pedestrian friendly and directly connected to local destinations,
- Provision of a mix of housing types, densities, and costs,
- Protection of environmental quality and high quality open spaces,
- Making public spaces the focus of building orientation and neighborhood activity
- Encouragement of infill and redevelopment along transit corridors in the existing neighborhoods (Calthorpe, 1993).

As expected, a variety of solutions to the problem of automobile dependence can be mentioned as restrictions for using cars, and improving public transport services and biking and walking conditions. This requires a careful management of the urban transport system. In the 1980s, concepts of congestion management and travel demand management were tried to be discussed referring to problems in cities, inter-city corridors, and activity centers that produce urban traffic (O'Flaherty, 1997). These management measures can help to accomplish one or more of the following targets:

- Reduce the need to make a trip
- Reduce the length of a trip
- Promote non-motorized transport
- Promote public transport
- Promote car pooling
- Shift peak hour travel
- Shift travel from congested locations
- Reduce traffic delays (OECD, 1994)

According to May (1997), there are some ways to restrict automobile use as vehicle ownership taxes, fuel taxes, parking measures, congestion charging, traffic calming and charging for road use.

3.1 IMPROVING PUBLIC TRANSPORT, WALKING, AND CYCLING

The most efficient passenger transport mode for long distances and at the corridors that travel demand is high in urban transport is public transport. In cases of short travel distances pedestrian travel and transport through cycling can also be efficient alternatives (Sutcliffe-Babalik, 2012). It can be seen that public transport systems provide significant advantages for passenger travel when compared to car use. At most five people can be carried by car; on the other hand, the passenger capacity of a bus changes between the ranges of 40 or 120 which means that 8 or 24 times more people can be carried by public transport. Automobile and public transport is also differentiated in terms of the necessity of road use. For example, a 12 lane road is needed for 40,000 people to cross over a bridge; on the other hand, only 4 lanes for bus, and two lanes for a light rail system is needed (Illich, 1992). In addition, another advantage of public transport systems compared to the car is the efficiency for energy consumption, that is, per passenger transported per kilometer automobile consumes five times more energy compared to bus and metro, and automobile creates 125 times more air pollution compared to bus. For these reasons, improving public transport plays a key role within the framework of sustainable development strategies. Consequently, sustainable urban development objective necessitates a high quality and sufficient capacity public transport system (Sutcliffe-Babalik, 2012). Another sustainable mode for urban accessibility is walking. Pedestrian oriented regulations -especially in city centers- can make people use their car less for transportation and, also it contributes to decreasing unsustainable impacts of automobile on the streets or open public spaces. According to Tumlin (2012), pedestrian planning principles include several critical issues including that most of the needs of daily life should be available within walking distance; buildings

should be in relation with sidewalks rather than parking lots; road traffic has to be calmed; lighting should be arranged for the benefit of pedestrians; people should feel safe. Even if all these principles are applied in the design of a walkable environment; at first glance, walking may not seem as an alternative transport mode compared to car or public transport; however, if urban planning and design of an area includes efficient regulation principles that focuses on facilitating pedestrian movements particularly in short distances, it can seriously affect the appearance of car in the areas in which the car existence is not desired -particularly in city centers- due to wishes for the efficient pedestrian use of urban space and for a less polluted, more equal urban social environment. Cycling stands as a transport alternative which can contribute significantly to sustainability of our urban transport future. Using bicycle as a transport mode has been common travel choice for many years in the globe: there are a number of cities where people ride their bicycle from their home to school, or to work, or to a leisure activity, or to the opposite direction, and now this can be considered as a permanent culture, in other words, "cycling culture". Learning from the experience of such cities with a cycling culture, many other cities in the world started to invest in cycling infrastructure by developing bikeways, bike lanes, and building bike parks. In order to further encourage the usage of this mode, which is one of the most sustainable modes of travel since it requires no energy and emits no pollution, many cities in the world also started to launch bike-share systems.

4 ANALYSIS OF TURKISH CITIES IN TERMS OF SUSTAINABLE TRANSPORT SOLUTIONS

In this preliminary research, it will be mentioned that there have been implemented sustainable solutions in cities, and it is not still obvious that whether these interventions contributed the sustainability level of those cities and car dependency has decreased or not. In further part of the research, cities of İstanbul, Ankara, Konya, Samsun, Kayseri, Gaziantep will be investigated through figure demonstrations in order to open and trigger new discussions on research issue. The critical hypothesis here is that although there have been urban rail, cycling and pedestrianization implementations in Turkish cities, the interventions inciting automobile use in the city have also been continuously increasing. Consequently, it has become questionable whether the sustainable transport interventions have worked effectively or not. The expected outcome of research will be that it has been so difficult to overcome the dominance of neo-liberal urbanization and transport policies through only sustainability impacts on transport.

1 INTRODUCTION: THE ACCESSIBILITY APPROACH

Accessibility is a well-established concept in planning research. It measures the ease of reaching destinations or activities, or the potential for interaction (Hansen, 1959). In very general terms, accessibility can be defined as the level of ability to successfully reach a certain object, place, event, or person. It is a key concept for understanding the social and economic life of cities in particular and societies in general.

The purpose of this paper is to inform the ‘accessibility approach’ to transport policy, planning, and investment by means of critically analysing its implementation barriers in professional circles and how to overcome them. We argue that it is necessary to focus less on technological issues such as what are the best instruments and decision-making tools to promote the accessibility approach. There is now sufficient knowledge about that (Papa et al. 2016). Now, the priority is to identify the institutional, organisational and cultural barriers to this approach.

Mobility and transport networks can facilitate accessibility, but only to a certain extent. Defining accessibility as what is granted by mobility is a reductionism. In our view, mobility is in many cases a necessary condition for accessibility, but rarely is a sufficient one. Traditional transport planning has in numerous instances failed to realise this important nuance. As a result, traditional transport planning has frequently equated implementing measures aimed at increasing mobility to improvements in accessibility levels. That is not necessarily a very accurate way of understanding what happens. This is fully acknowledged by the accessibility planning approach. In fact, accessibility planning recognises that the absolute opposite to that might be closer to the truth: increasing mobility might represent less accessibility (Ferreira and Batey, 2007).

Conflicts between accessibility planning and the dominant transport planning culture have been a barrier to effective implementation of accessibility planning (Bertolini et al. 2005; Bertolini, 2012). This approach of ‘mobility-first’ planning and investment has largely failed to deliver on the broader urban goals relating to economic growth, social integration, and sustainable development. Conversely, implementing accessibility-based performance measures can allow regions to pursue more coordinated objectives around economic opportunity, social equity, well-being, and health.

Several reasons should encourage the application of the accessibility planning approach., as the potential benefits of using the accessibility approach in applied planning practice are massive. Among other benefits, it facilitates understanding with much greater accuracy how different social groups are served in different ways by the transport system and by public and private services. It also facilitates identifying with higher precision what prevents people from reaching certain places and develop or maintain certain connections. This happens because it offers valuable insights on matters as diverse as mobility and

transport, time budgets and schedules, nature and quality of services, financial and economic constraints, just to mention some possibilities. For further insights see, for example, Ferreira and Batey (2007).

Another reason is that the accessibility approach has the potential of bringing diverse activity sectors (e.g. transport and land use, economics and health care, education and logistics) together to agree on shared actions. This happens because the accessibility approach makes evident the interconnections between individual preferences and characteristics, geodemographic properties, nature and quality of services available, and mobility issues such as travel time savings, travel costs, and levels of service experienced in the transport network. This is not the case with the traditional transport planning approach as its focus is narrower and essentially concerned with mobility issues.

A benefit is also that the accessibility approach has the potential to create a common language among different stakeholders for discussing community conditions and priorities. In this way this approach offers a particularly constructive framework for action on agendas shared by transport authorities, citizens, service providers, technical experts, and land owners. It is also very constructive for creating communication bridges among people with different academic and technical backgrounds. This happens because its epistemological underpinnings are strongly linked with social inclusion theory and its theoretical basis is not mathematics, economics or engineering (which tend to be quite exclusive disciplinary areas), but social science in general and planning in particular.

Finally, another advantage is that the accessibility approach is abundantly equipped with appealing visualisation tools and techniques capable of depicting information in very clear ways. It can therefore facilitate decision-making processes by means of providing powerful visual inputs that integrate and give answers to a wide range of questions and policy issues.

However, a number of barriers exist to making the use of the accessibility approach mainstream. As a result, mobility-oriented planning continues to dominate the professional world. In this paper we aim at uncovering the barriers that planners face when trying to apply the accessibility approach in planning practice and on the pathways to overcome these barriers. This research aim is relevant and timely. Indeed, in the existing literature the main focus has been on the technical properties of accessibility measures and tools, with some exceptions (Curtis & Low, 2012; Geurs & Halden, 2015; Halden, 2014). We believe that accessibility planning research needs now to move on to study in greater detail the institutional barriers that prevent the implementation of the accessibility approach. There are strong reasons to believe that stakeholders involved in planning processes are prone to perceive the accessibility planning approach as something with massive potential, but only when this is introduced in the right institution, adopting the best approach, with the appropriate strategic support, for the appropriate goals, with the correct indicators and datasets, and with the correct timing.

The paper is structured as follows. Following this introduction, section 2 provides a brief description of the methodology used. Section 3 reports the results of the expert's survey, discussing the barriers to the implementation of the accessibility approach in planning practice and discusses pathways to mainstream accessibility planning. Some concluding remarks are drawn in section 4.

2 METHODOLOGY

In this study we applied a qualitative method loosely based on the Policy Delphi protocol (Linstone & Turoff, 2011). The purpose was to obtain insights about (i) the most critical issues in implementing accessibility planning in practice, and (ii) possible pathways to mainstream the accessibility approach. The method is based on the collection of rigorous ideas interviewing highly qualified experts who have deep understanding about the subject area under study.

We conducted a round of in-depth interviews with eighteen leading figures and pioneers of the accessibility approach working in land use planning and transport planning. These experts were chosen from an original group of most cited academic authors as defined during an initial literature review, who helped to identify other non-academic experts. The final group included experts from different disciplines (urban planning, mobility planning, finance) and organisations (academia, consultancies, government and NGOs) and geographical contexts (six from North America, ten from Europe, one from Australia, and one from South America). All these experts work in the field of accessibility planning in either public or private

bodies and are very well-known figures, if not internationally, at least in their own countries and professional worlds.

It is important to highlight that we included in the group of respondents budget professionals and transport economists because those professionals are rarely involved in studies dealing with accessibility planning. This was a conclusion derived after the first round of interviews conducted. We will come back to this point.

3 RESULTS

3.1 INSTITUTIONAL BARRIERS TO THE ACCESSIBILITY APPROACH

The results from the interviews suggest that implementation barriers can be clustered into the following main categories: i) the high costs of the accessibility approach; ii) the fragmented administrative and governmental frameworks; iii) pro-mobility established powers and traditions; iv) the influence of mainstream economics on transport planning; and v) the feeble influence of higher education and research organisations. These factors are likely to mutually reinforce each other.

With regard to the first point, it emerged from the interviews that accessibility analyses need much more extensive datasets than those required in traditional mobility-based modelling processes (typically focused just on simple information about origins, destinations, travel demand, and impedances) and this has a cost. For this reason, accessibility planning is correctly perceived as a more expensive and time-consuming process than traditional transport planning. It was argued that adopting accessibility planning processes comes across as a quite unattractive choice to many public or private organisations. Availability of financial resources is therefore likely to determine which local and national authorities can adopt accessibility planning tools.

According to the interviewed experts, lack of funds for the implementation of accessibility planning is closely linked to the organisation of local and governmental authorities. These are unlikely to provide financial support for schemes that are not aligned with policy priorities shared by several stakeholders, departments and agencies (Banister, 2008). Strategic governance for achieving accessibility requires a combination of coordinated actions across urban land use planning (e.g. housing policy), transportation planning and regulation, financing of investment and operations, and pricing and cost recovery. This is difficult to achieve as it corresponds to a higher level of institutional interaction and cultural complexity.

A third point raised by our experts was the difficulty to overcome the well-established transport planning tradition, strongly based on civil and mechanical engineering and economics. Indeed metrics used by the transport approach are easy to communicate and reflect short-term impacts of political choices. The accessibility approach measures distribution of land use and transport benefits that are not always in the decision maker's agenda. Furthermore, accessibility planning measures long term effects, which are in contrast with the short terms effects needed by politics which the mobility planning approach can more easily offer.

A fourth aspect is the influence of mainstream economic science applied to transport planning. Traditional economic analyses of transport investments, such as the Cost-Benefit Analysis method (henceforth CBA), primarily use mobility indicators like travel time savings to estimate economic value. While there are still a number of significant complexities not completely solved associated with the objective measurement of accessibility in a way that fits the data needs of CBAs. In other words, as stated by one of our experts: 'the economic language used by transport planners has a universal appeal. Accessibility planning does not speak in terms of economic values or prosperity, while everyone wants to be prosperous'.

A final aspect raised from the experts we interviewed is the feeble motivations of higher education and research organizations to promote the accessibility agenda. Academic researchers are not necessarily doing much to promote a transition from mobility to accessibility thinking. According to some answers collected, this mostly happens because academics conducting research with more impact-oriented goals are not necessarily finding it very attractive to do research on accessibility.

3.2 PATHWAYS TO MAINSTREAM THE ACCESSIBILITY APPROACH

This section reports the answers to the second issue discussed in the interviews, which was focused on the possible pathways to mainstream accessibility planning. Those can be summarised in the following five points.

The first action is to clarify much better how accessibility gains and losses can be equated to financial gains and losses so that cost-benefit analyses and other econometric assessment tools can be effectively informed by the accessibility approach. To make accessibility planning mainstream it is important to make evident the financial gains resulting from the accessibility approach and who benefits from it. It seems likely that many accessibility planning experts resent the dominant econometric thinking logic that has become so deeply rooted in transport planning. As a result, they overreact to it by means of dismissing almost completely all sorts of financial and budgetary considerations. It is not acceptable that accessibility planning becomes unable to determine with at least some precision the value for money of alternatives even if this is at some stage considered a secondary policy objective. Some form of assessment of value for money of alternative solutions is therefore most needed.

The second needed action according to the group of experts is aimed at reducing the high costs of accessibility planning by supporting the development and dissemination of open access software and data. As stated in the previous section, one of the main limitations of accessibility planning is that it requires a considerable amount of data, but this action could potentially have massive implications in terms of communication between people and planners. For example, online collaboration (i.e. collaborative mapping projects), GIS, and data visualisation tools are leading to the fusion of the data collection, analysis, and representation steps of accessibility planning.

The third action consists of making accessibility part of the common sense language. The group of experts we interviewed stressed the importance of the 'public demand' of accessibility. In other words, it is crucial the role of everyday apps and tools used by the people, to make them aware of the concept and the benefits of accessibility, rather than the benefits of mobility. If there is a public demand for accessibility, then planners and decision makers would be forced to provide what citizen ask for.

The fourth action is in the hand of academics. This consist of developing a holistic understanding of accessibility. The interviewed experts agreed that a common framework to account for the diverse institutional processes that promote the accessibility agenda is a crucial conceptual point to be taken into consideration. This requires in the first place a holistic understanding of what accessibility is and what promotes or reduces it.

The fifth action is to identify and mobilise institutional, geographical, and community implementation niches. One of the experts stated that accessibility planning has much to offer to a wide variety of businesses and corporate powers and it might represent for these actors something as desirable as acquiring more clients or locating better places to invest.

The sixth action consists of increasing the accessibility appeal. Accessibility experts should be able to 'sell' accessibility when dealing with influential decision makers in the same way mobility experts 'sell' the outputs of their transport models.

4 CONCLUDING REMARKS

In cities and countries across the world, accessibility-oriented planners and practitioners are struggling to implement accessibility policies and programs. This paper started with the notion that technological barriers are not the key ones preventing the accessibility approach from becoming mainstream. The key barriers have instead an institutional nature, and those have been discussed in this paper. Transport, land use and budgets professional using the accessibility approach can bring about a new dimension in planning. In order to achieve a transition from the mobility approach to the accessibility approach a number of actions were collected All the actions presented in the section above correspond to very particular needs in terms of enhanced knowledge about how to proceed. We would like, however, to stress a specific research need in greater detail. A deeper understanding is needed about the extent to which local and national issues influence the topics addressed in this study. We limited our research to the identification of

general international and cross-institutional issues. Future research should explore the institutional barriers of accessibility planning in specific national and institutional frameworks.

A final remark to make before concluding is that the knowledge developed by the mobility approach should be seen as a step towards the accessibility approach. This is an evolutionary process. To plan accessibility necessarily requires a good level of mobility planning and so the accessibility approach includes the mobility approach and all its knowledge forms, infrastructures and technologies. The accessibility approach adds more aspects and dimensions than those exclusively concerned with mobility; it does not and it cannot exclude mobility as a concept or as a social and economic value. This point means that there is no sense in seeing these two approaches as alternatives. They are instead stages of evolution in transport planning that build upon each other and need each other to evolve.

ID 1618 | HOW CONGRUENCE BETWEEN FORMAL AND INFORMAL INSTITUTIONS EFFECTS INTEGRATED TRANSPORT AND LAND USE PLANNING: A STUDY ON DUTCH NATIONAL PLANNING PRACTICE

Marijn van Geet¹; Sander Lenferink¹; Jos Arts¹; Wim Leendertse¹

¹University of Groningen

m.t.van.geet@gmail.com

ABSTRACT: The field of transport planning is in flux, influencing the way developed countries plan, program and budget their transport infrastructure. Planning scholars and policy makers increasingly acknowledge that integrating land use and transport planning generates opportunities for synergetic benefits and helps evade unwanted consequences such as project time and cost overruns. Despite this emerging concept of integrated infrastructure planning, examples of successful employment remain scarce. For this paper the institutional context associated with infrastructure planning has been studied to identify incongruences which hamper integrated infrastructure planning practices. The explicit focus is on how horizontal (cross-sectoral and cross-border) and vertical (between scales) integration in road infrastructure planning is adversely influenced by counteracting formal and informal institutions in different phases of the policy cycle. Evidence is derived from a six-month research project on the current Dutch national infrastructure Planning, Programming and Budgeting System. This research has studied how integrated infrastructure planning is influenced in the different phases of the policy formulation, policy adoption, policy execution and monitoring and evaluation. Findings are distilled by triangulation of literature research, policy analysis, interviews with 22 experts, 2 focus groups and a workshop. In addition, multidisciplinary sounding board meetings, including both scholars and practitioners, were organized to reflect on interim findings. Results illustrate that every phase of the decision making process presents distinct formal and informal institutional incongruence which hampers integrated infrastructure planning. Furthermore, insights were generated on the different roles formal and informal institutions play in affecting integrated infrastructure planning practices. Findings of this study may be used as input for institutional design strategies which aim at enhancing the integration between infrastructure and land use planning as well as for developing further research trajectories.

1 INTRODUCTION

As scholars and practitioners increasingly acknowledge the synergies that can be obtained through transport and land use integration a change it witnessed in the way public authorities plan, program and budget transport infrastructure (Gudmundsson et al., 2015). Despite land use and transport integration is a central goal of contemporary transport policies in developed countries, successful implementation of such integration remains insufficient (UN-Habitat, 2013). As a result potential value is missed, which could have been acquired from the synergies that arise when transport and land use planning are integrated in processes of policy formulation and project delivery.

Land use transport integration has been a topic of research for a long time (e.g. Wegener and Fürst, 1999). Multiple scholars have emphasized the need for an institutional perspective in addressing the adverse influence of institutional barriers on achieving integration (e.g. Marsden and May, 2006; Hull, 2010). Curtis and Low (2012) even state that “time and time again it appears that institutions block the way” (p.13). A growing body of literature on this subject provides insight in how general barriers block the formulation and implementation of integrated transport policies. Isaksson et al. (2017) suggest there appears to be a demand for more in-depth understanding of the multifaceted and chaotic institutional conditions in which these barriers operate as transport planning still tends to exist in siloes (UN-Habitat, 2013).

This study focusses on the Dutch planning context where land use transport integration has been a policy goal for decades. Since the 1990's a converging trend between transport planning and spatial planning is witnessed (WRR, 1998). National government has undertaken multiple attempts to redesign the national transport infrastructure planning programming and budgeting (PPB) system to achieve further land use transport integration. PPBSs function as institutional vehicles structuring different phases of policy

formulation, adoption, execution and evaluation. Hatzopoulou and Miller (2008) point out that the influence of frameworks for appraisal and implementation on the delivery of integrated transport policies can also be negative.

This paper addresses the effects of institutions to integrated transport planning on national level. It aims to offer to a more detailed understanding on how congruence between institutions influence land use transport integration in different phases of infrastructure planning, programming and budgeting. Data is collected in an depth case study research taking Dutch national PPBS as unit of analysis. Through a sociologic historic institutional perspective differentiating between formal and informal institutions a more comprehensive perspective is offered on the effect of different institutions within different phases of the PPBS. The theoretical perspective adopted in this study is introduced in the next paragraph. The subsequent section elaborates on the data collection within the applied case study methodology. Thereafter research findings are presented and interpreted a discussion and conclusion section.

2 ANALYTICAL FRAMEWORK

2.1 CONCEPTUALISING LAND USE AND TRANSPORT INTEGRATION

Transportation planning is traditionally characterized by a sector-oriented, technocratic, predict and provide approach resulting in narrowly defined infrastructure projects aimed at enhancing network capacities. Driven by societal developments such as increased environmental awareness, emergence of the network society, scarcity of space and changing financial-economic contexts this approach broadened through processes of internal and external integration (Heeres et al., 2012). Ambitions for multi-modal solutions through coordination between different modes and networks to influence mobility behaviour lead to a process of internal integration. Concurrent to this development a process of external integration, emphasizing the reciprocity between transport systems and land use systems, as stressed by Wegener and Fürst (2004), lead to a strong focus on the integration of transport planning with other spatial sectors. The concept land use and transport integration captures this contemporary approach to transportation planning in developed countries. Elaborating further on this notion, a more detailed conceptualization is provided by distinguishing in dimension and types of land use and transport integration. The interpretation of land-use transport integration used in this research is summarized in table 1.

2.1.1 HORIZONTAL AND VERTICAL INTEGRATION

The distinction between the horizontal and vertical dimensions of integration are widely recognized and discussed in spatial and transportation planning literature (e.g. CDS, 1999; Stead and Meijers, 2003; Hatzopoulou and Miller, 2008). The horizontal dimension refers to inter-sectoral, intra-sectoral, and cross-territorial integration. Vertical integration occurs between different layers of government. Although transport planning is often a responsibility of national governments, Isaksson et al. (2016) see the local and regional planning scale as key arenas for implementing integrated mobility solutions. Transport systems in itself are multi-scale of nature (Arts et al., 2014); within any particular government layer there are specific conflicts and synergies between domains of transportation and between transportation and land use (Gudmundsson et al., 2015). Successful land use transport integration includes both dimensions.

2.1.2 POLICY AND PROJECT INTEGRATION

Scholars agree that land use transport integration differs at the strategic level and the operational level (e.g. Cowell and Martin, 2003; Heeres et al., 2012; Gudmundsson et al. 2015). Integration at the strategic level is here referred to as policy integration, along with Stead's et al. (2004) definition. Stead et al. (2004) present a hierarchical distinction between cooperation, coordination and integration, which produce different output and levels of interaction. Policy integration "includes dialogue and information (as in policy cooperation), transparency and avoidance of policy conflicts (as in policy coordination, policy coherence and policy consistency) but also includes collaboration, attempts to create synergies and the use of the same goals to formulate policy (Stead, 2008, p.140). Policy integration is based on shared goals, as such requiring a higher level of interaction than coordination and cooperation, creating stronger

interdependencies between horizontal and vertically dispersed actors. Integration at the operational level, defined here as project integration, focuses on the integration of land use and physical infrastructure in integrated area development projects. Multiple researchers have shown how combining transport infrastructure with other local land use goals, such as housing, energy and recreation, enables different interests to merge, enhancing the societal, economic and environmental revenue of projects (Arts et al, 2014; Elverding, 2009). This type of integration is associated with the better, faster or cheaper achievement of interests against a decreased effort and enhanced overall outcomes for an area, in form of higher quality or more sustainable results (Heeres, 2017,p.14).

	Horizontal	Vertical
Land use transport policy integration	Inter-sectoral, intra-sectoral, and cross-territorial integration between land use and transport policies.	Multi-level (between government layers) integration between land use and transport policies.
Land use transport project integration	Integrating infrastructure development with other land use development within area development projects.	Integrating transport interests and land use interests dispersed across government layers in area development projects.

Table 1 – Conceptualization of land use transport integration as a comprehensive notion which can be subdivided into four components.

2.2 AN INSTITUTIONAL PERSPECTIVE ON LAND USE TRANSPORT INTEGRATION

For this study institutions are defined as any form of human devised constraint (both formal and informal) structuring social interaction (North, 1990). It is argued that all planning and decision-making takes place within a certain institutional context (Alexander, 2005). These ‘rules of the game’, a much used appellation for institutions, influence the behaviour of actors in the process of designing, negotiating and funding policies by prescribing what is considered appropriate, adequate, right and wrong in specific situations (March and Olsen, 1989). As such institutions help explain why specific patterns of collective behaviour occur as they do. Within any process of policy formulation and implementation a variety of different ‘nested’ institutional contexts meet and interact (Alexander, 2005). This study focusses on both formal and informal institutions as defined by Hemke and Levidsky (2004,p.727). The focus on both types of institutions is crucial to capture all incentives and restrictions underlying behaviour (Helmke and Levisky, 2004).

Due to their structuring influence on social interactions institutions are considered to influence processes of land use transport integration. Marsden and May (2006) show how institutions play an important role in the development and delivery of integrated transportation policies. Institutional congruence is used here as a concept to gain a deeper understanding on the the way institutions influence land use transport integration efforts. Institutional congruence fits with historic institutionalism from a new institutional sociologists perspective, as formulated by Hall (2010). He states that a society “replete with multiple layers of institutions...that provides footholds for many courses of action” (p.22). Institutionalization can be described as a “historic accretion of culturally specific forms and practices with their origins and diffusion related to their specific contexts: sectors, societies and subcultures” (Alexander 2005, p.212). The choices made when an institution is formed, will have continuing influence on policy in the future (Peters, 1999). As such it is said that emerging institutions are inspired by existing ones (Thelen, 1999). The development of institutions is regarded as a path dependent process resulting in unintentional consequences (Taylor and Hall, 1996) Institutional congruence focusses on the mutual influence between different formal and informal institutions. Institutions can either reinforce, have no impact on, or weaken each other’s effect (De Jong, 2008). Two types of congruence can be distinguished. First, a (mis)match between old and new institutions. Institutional structures which have been appraised in the past can effect institutional structures underlying contemporary policy objectives. The second type of congruence infers a (mis)match between existing institutions which have been developed from diverging strategies (De Jong, 2008).

2.3 SYNTHESIS

The structuring influence of institutions on social interaction patterns makes institutional theory appropriate in the context of land use transport integration. Achieving land use transport integration requires interaction between a variety of actors dispersed across horizontal and vertical dimensions. These interaction patterns change in the different phases of planning, programming and budgeting of transport infrastructure. Due to the structuring influence of institution on social interaction patterns, both formal and informal institutions are important in the formulation and implementation of integrated land use and transport policies. This research aims to provide an in depth perspective on how institutions influence land use transport integration by studying the congruence between the institutions within the phases of policy formation, adoption, execution and evaluation.

3 RESEARCH DESIGN

The findings discussed in this article are derived from a six months research project on Dutch national spatial and infrastructure planning. This project studied how land use transport integration is hampered in the different phases of the policy formulation, policy adoption, policy execution and monitoring and evaluation of the Dutch infrastructure Planning, Programming and Budgeting (PPB) System. As will be discussed in section 4, the Dutch PPB System, MIRT, is undergoing a major change in which both horizontal and vertical integration are pursued. Although the findings are to some extent specific for the Dutch situation, lessons can be drawn for other countries as well, since PPB Systems are a common instrument for connecting policy and practice in transport planning, which all struggle to successfully bring integration from the strategic policy level to the project practice (UN-Habitat, 2013). In order to assess the integration and the role of formal and informal institutions, we applied methodological triangulation that included besides the literature research, policy analysis, interviews, focus groups, a workshop and sounding board meetings.

First, policy analysis was performed, which included the Dutch Spatial Planning Act (In Dutch WRO), the Dutch Infrastructure Planning Act (in Dutch Tracéwet), the series of documents of the National Spatial Strategy, the National Mobility Strategy , and the Long-range Programme for Infrastructure, Spatial Development and Transport (in Dutch MIRT), and supporting policy documents. The policy analysis provided the input for 22 interviews that were conducted. These interviews were semi-structured, allowing for a structured discussion of relevant concepts emerging from the literature study, as well as flexibility for interviewees to bring up their own experiences and conversation topics (Liamputtong and Ezzy, 2005). The interviewees were all experts working at the Ministry of Infrastructure and the Environment (in Dutch Ministerie landM) and the Directorate-General for Public Works and Water Management (in Dutch Rijkswaterstaat). All are closely involved with implementing the current spatial planning and infrastructure policies, or engaged in the revision of the PPB System.

Subsequently, 2 focus group discussions enabled the findings from the interviews and policy analysis to be discussed in a broader group of people. As such the focus groups combine interaction, obtained through participant observation, with in-depth knowledge of experiences, obtained through in-depth interviewing (Morgan and Spanish, 1984). The participants were chosen based on their organization, either from the Ministerie landM or from Rijkswaterstaat, their orientation towards policy or practice and their "articulateness": their ability to reflect on their field and form and express their opinion.. The focus group discussions were held around statements derived from the policy analysis and interviews. These statements provided the starting point for discussion, and proved to be successful in activating the participants.

Finally the workshop and multidisciplinary sounding board meetings, including both scholars and practitioners, were organized to reflect on interim findings. During these meetings the progress of the research was discussed, sources and contacts were disclosed and avenues for future research were identified.

4 RESULTS

4.1 CASE INTRODUCTION

The Dutch national government carries a legal responsibility for planning, building and maintaining national surface transport infrastructure networks. A national Infrastructure Fund secures annual budgets for executing this task. The allocation of this fund is done with national PPB system called MIRT - Long-range Infrastructure, Space and Transport Programme - which serves as an official annex to the national budget planning. The MIRT rules provide a formal administrative institutionalization structuring the procedure of policy integration, policy adoption, policy execution and monitoring and evaluation. In several distinct phases separated by formal administrative decisions, ministerial strategic transport policy goals are translated into clearly outlined projects (see figure 1). As such MIRT is an institutional instrument structuring policy implementation. Since its adoption in the early 90's the MIRT rules have been periodically revised to reflect the gradual policy shift from a sectoral transport planning to integrated land use and transport planning. A short historical perspective is offered on the context in which the PPB System was developed and evolved. For a detailed historical perspective this research refers to Arts et al. (2016).

In 1991 MIT, the precursor of MIRT (without R which stands for 'ruimte': space), was introduced, during a period of New Public Management, as a transport PPB System to operationalize controllability, transparency and output steering. MIT was designed to move away from a planning system which was at that time considered bureaucratic and received increasing social critique (Van den Brink, 2009). In line with private organizational management principles a division was made between policy making at ministerial level, and policy delivery by governmental agency Rijkswaterstaat. Alongside the incremental adoption of New Public Management principles, a shift occurred towards integrated planning (Heeres et al, 2012). Land use transport integration became a central policy goal. This goal was even captured in the Traffic and Transport Planning Act (1996) to "emphasize the need for integrated traffic and transport policy. This means intersectoral integration and integration with spatial planning, environment and economy"¹. This converging trend between transport planning and land use planning continued, uniting two disciplines with divergent rationales (Filarski and Jeekel, 2016; WRR, 1998).

Figure 1 – The current MIRT procedure and its development throughout the years

In 2008 the 'R' was adopted in MIRT. The Ministry of Transport, Public Works and Water Management and The Ministry of Housing Spatial Planning and the Environment merged into one Ministry of Infrastructure and the Environment. Also Rijkswaterstaat as executive agency underwent a reorganization as a new management framework stressing public-orientation and interactive planning (van den Brink, 2009). Despite these, and several other institutional adaptations, the implementation of land use transport integration has shown to be limited successful (Lambrigts et al., 2016). A review of the MIRT procedure, initiated in 2014, resulted in revised MIRT rules in 2016 aimed at stimulation land use transport integration along the principles broad scope, custom-fit and collaboration (Ministerie IenM, 2016). The next paragraphs describe how this goal of land use transport integration is institutionalized into the MIRT rules and how other formal and informal institutions are influencing the extent to which that goals is achieved in practice.

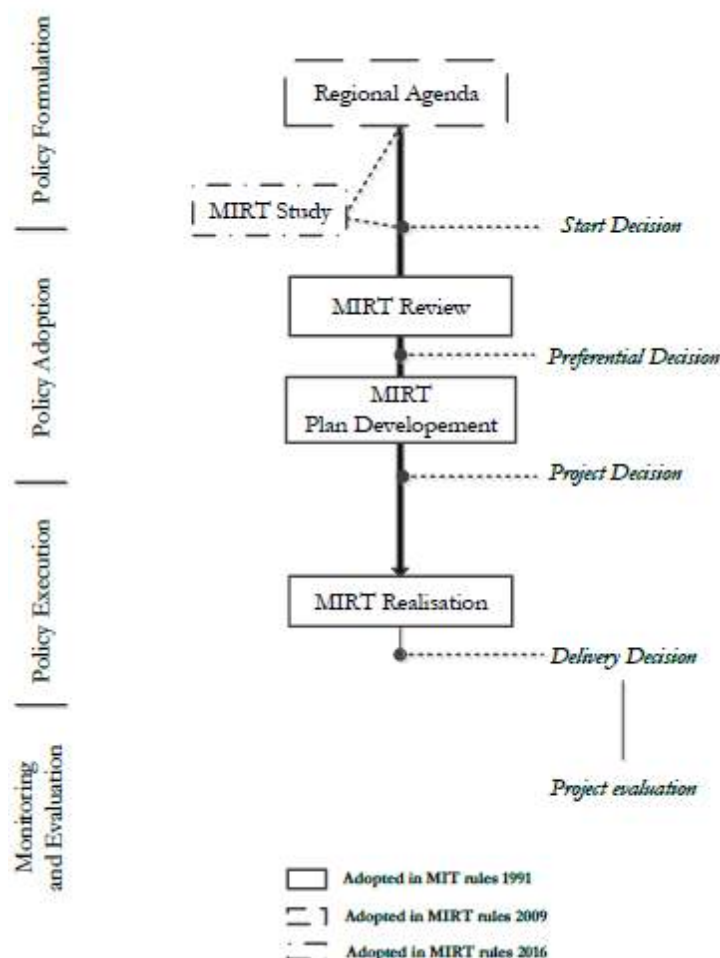

Figure 2 – The current MIRT procedure and its development throughout the years

4.2 POLICY FORMULATION IN MIRT

Traditionally MIRT aimed at efficient and transparent project delivery. Policy formulation was separately done at ministerial level. As the ambition for land use transport integration developed the front end stage of the MIRT was redesigned to facilitate policy development and policy integration. In 2009 the Regional Agenda was formally introduced in the MIRT Rules and periodical administrative consultations were adopted in the decision making process to encourage policy integration (Ministerie VandW, 2009). The Regional Agenda functions as a platform for integrated agenda setting at regional scale. Its aim is to establish collaboration and integration between different governmental bodies (vertical and horizontal) and between sectors within one of the seven defined agenda regions (Ministerie landM, 2016). These agendas provide input for formal decision making that done by national , regional directors and when relevant market an civil society actors during annual administrative consultations. The MIRT rules describe this as a strategic deliberation process in which formal decision making occurs and transport related policy issues are defined. A policy problem is formally adopted with a start decision, this marks the transition towards the next phase of the MIRT process. When more insight is required in the policy issue it is an option to start a MIRT Study. The phase of policy formulation ideally policy makers and decision makers from different governmental bodies, as well as market and civil society actors.

The traditional top down sectoral orientation of MIRT, limited employability of the Infrastructure fund and political culture are described by respondents as the institutions influencing land use transport integration in this MIRT phase.

“From a historical perspective policy making at national level has occurred in siloes, separated in different departments” (Respondent B2, 2017). “The infrastructure component is very dominant. A MIRT

administrative consultation, put very black and white, is all about public officials safeguarding projects (Respondent C8, 2017). Respondents describe a culture where collaboration between departments and ministries is obvious. This can be illustrated by the following three quotes. “The added value of taking an integrated approach in national level cannot be expressed in economic benefit, and current culture economic benefit or enhancing effectivity are the main incentives for collaboration”(Respondent B5, 2017). [On a ministerial visit of a government official responsible for the allocation of housing development sites] “he says: I want to build these houses as fast as possible so we should develop on pasture. Developing in urban areas is too much hassle” (Respondent B5, 2017). “I just notice that the collaboration and coordination between ministries is not very good. Multiple accidents are happening because we do coordinate well” (Respondent c8, 2017). Furthermore MIRT is said to be very much top down as national interests are dominant, and “the money contributed by regional partners is usually much lower” (Respondent C4, 2017).

The allocation of the Infrastructure Fund is legally confined to the construction, management, maintenance and operation of transport infrastructure for people and goods¹. Potential land use planning solutions for transport issues can therefore not be financed with the Infrastructure Fund. In line with findings of IBO Werkgroep (2016), multiple respondents have defined this as a barrier for land use transport integration. The follow quote reflects this: “as soon the topic changes to finance problems emerge. Mobility mingles with other policy issues and things get difficult” (Respondent B1, 2017)

Decision making in MIRT is strongly influenced by politics. “Members of the parliament and aldermen, they demand projects. That is how they discern themselves” (Respondent B5, 2017). It influences how the MIRT Rules are interpreted “it is a very nice model. But every now and again projects just come falling from the sky” (Respondent B4, 2017); examples are given of projects that start at the MIRT review phase (Respondent B6, 2017). Research by Mouter (2016) confirms the strong influence of political games on decision making. This political culture is also mentioned as a barrier for collaboration: “Politics and trust do not mingle well. I mean look how things go in the Tweede Kamer [Dutch Lower House of Parliament], people are constantly trying to bring each other down” (Respondent C7, 2017).

4.3 POLICY ADOPTION IN MIRT

The phase of policy adoption is institutionalized with the instruments MIRT Study, MIRT Review and MIRT Plan Development. The MIRT Study aims at providing additional insights into a, in the administrative consultation, defined transport policy issue by e.g. delineating the scope, pinpointing its relation to other policy topics or distinguishing involved actors. This instrument aims at providing an integrated perspective. The outcome of a MIRT Study can be to that no further action is required, that measures should be taken outside MIRT or a start decision is made and the policy issue proceeds to MIRT Review. The MIRT Review consists of a problem analysis and the formulation and weighing of different solutions, aiming to formulate a preferred alternative. MIRT Review is a very structured procedure starting divergently, looking for diverse solutions, and then converging working towards specific project formulation (Rijkswaterstaat, 2010). MIRT Rules stimulate a broad an inclusive perspective by requiring the consideration of at least one alternative that does not comprise infrastructure development. A preferential decision, marking the transition between MIRT Review and MIRT Plan Development, is made during administrative consultation. MIRT Plan Development translates the chosen alternative solution into executable planning along. The MIRT rules prescribe a project approach for sectoral oriented solution and a programme approach for integrated solutions comprising multiple interrelated projects. A project decision binds the involved actors legally to execute their task.

A central topic in the interviews and focus groups on the policy adoption phase is the cultural clash that occurs between policy makers and project managers. Ambitions of integration from policy makers strokes with project-management culture. “Practice shows the more things you try to combine, the more complicated a project becomes. Project managers are accounted for keeping within time and money. So then you do not want to make things complicated” (Respondent B1. 2017). The strong focus on projects in MIRT is seen as negative influence on the adoption of integrated policies. Programme management is introduced in latest MIRT rules as intermediate structure between integrated land use transport policies

¹ Parliamentary Papers II 1990-91, 21 912, nr. 3

and project execution (Ministerie IenM, 2016). Programme management is widely acknowledged by respondents as a potential approach to stimulate the delivery of integrated policies. On the current employment of programme management a respondent states “you see that programmes are very much focused on a single modality [...]we have a wonderful railway programme [...] but this programme can be considered a collection of different projects to get. This works fine, but integrated? Not really” (Respondent B6, 2017).

4.4 POLICY EXECUTION IN MIRT

During the MIRT Realisation the focus is on project or programme delivery. The scope, time planning and budgets have been translated into contractual arrangements before the start of this phase. That makes MIRT Realization a clearly delineated and straightforward process. The delivery decision provides accountability on the realisation process and marks the end of this phase.

Respondents agree that there is minimal room for integration during MIRT Realisation . “Once you entre MIRT Realisation you are dealing with ridged scope leaving no room for negotiation” (respondent B6, 2017). For project managers it is attractive to keep the scope of the project narrow as it creates. The emphasize on clear project delineation is one of the reasons why project delivery is still very much a transport planning oriented endeavor. “Creating a robust network. That is why I realize infrastructure. Not because I want the road to be beautiful” (Respondent C4, 2017).

4.5 MONITORING AND EVALUATION IN MIRT

The MIRT rules do not contain policy evaluation instruments. Evaluation delivery decision does contain a project evaluation, which is performed a year after project delivery, that monitors if the legal norms (e.g. air pollution, noise level) are met.

Outside the MIRT rules the Environmental Management Act requires an Environmental Impact Assessment for infrastructure projects which possibly have a negative environmental impact. This can be considered another type of project evaluation. Evaluation loops from project delivery to the policy from which they originate are non-existent in MIRT at the moment (Respondent B1, 2017). But this is changing as “the minister specifically asked for MIRT monitoring [referring to Regional Agenda] in two administrative consultations” (Respondent B5, 2017). Currently there are several initiatives to establish policy evaluation instruments, but these have not been formally institutionalized. “We want to specify the Regional Agendas to enable their evaluation. At the moment this is not possible [...] it requires the regional agenda’s to be more specific” (Respondent B5, 2017). Also “there is a lot of resistance for policy evaluation from the regional partners involved in MIRT” (Respondent B5, 2017).

5 CONCLUSION

Transportation planning in developed countries has shifted from a technocratic approach towards a focus on land use transport integration. Despite this shift, successful implementation of land-use transport integrating remains scarce. Multiple scholars have referred to the influence of institutions land use transport integration. Through an in-depth case study on within the Dutch national transport PPB System we have tried to gain a deeper insight in how institutional congruence influences land use transport integration. This was done by analyzing the different phases of policy formulation, adoption, execution and monitoring and evaluation and disentangling land use transport integration into four components by distinguishing between dimensions (horizontal and vertical) and integration types (policy and project). Distinguishing between phase and components of land use transport integration was valuable. This enables to show, first of all, that each of the four phases has distinct role in achieving land use and transport approach. And second that distinct institutions, both formal and informal, influence specific dimensions or a specific type of land use transport integration.

As such the institutional congruence approach deployed here has led to a more detailed understanding on how land use transport integration is achieved. Due to focus on the whole planning programming and

budgeting system our findings remain somewhat. A more in-depth analysis of each of the different phases is expected to reveal a more detailed understanding on how a complex whole of different institutional structures, informal and formal, originating from different time frames, collectively shape the process of land use transport integration.

ID 1651 | THE AMBIGUITY OF CYCLING AND URBAN DESIGN

George Liu¹; Sukanya Krishnamurthy¹; Pieter van Wesemael¹

¹Eindhoven University of Technology

y.liu.5@tue.nl ; s.krishnamurthy@tue.nl ; p.j.v.v.wesemael@tue.nl

1 INTRODUCTION: ALIGNING CYCLING AND URBAN DESIGN

The term “urban design” has been a source of ambiguity among researchers focusing on cycling for a few decades now. Although commonly alluded to, urban design often lacks a precise definition in relation to cycling, and when used to describe cycling, is often referred to in conjunction with other ideas, such as planning, transport, and land-use. For example, a Google Scholar search for the term “urban design cycling” lists a mix of various sources, including literature like “Environmental Correlates of Walking and Cycling: Findings from the transportation, urban design, and planning literatures” (Saelens et al., 2003), which provides an overview of transportation literature and little to none on urban design. This reflects the general state of cycling research, and Krizek et al. (2011) attests that that cycling has been viewed primarily in functional terms in relation to urban design, and that comparatively less research has been done on the aesthetic and experiential aspects of cycling. They also articulate the gap between the urban designer’s social and experiential focus on the pedestrian realm, such as sidewalks and plazas, and the traffic engineer’s operational focus of flow and speed in the motor vehicle realm of highways and intersections (Forsyth and Krizek, 2011; Hamilton-Baillie, 2004). However, this raises questions on the ambiguous role of urban design within the domain of cycling, and how urban design methods and processes can be used to address problems related to cycling and space. Furthermore, it must be understood why these problems fall specifically within the realm of the urban design discipline, as opposed to the expertise of urban planners, traffic engineers, or many of the other disciplines that also engage with cycling. In particular, this paper investigates the role and opportunity for urban design to expand the qualitative approach for framing the relationship between cycling, mobility, and space. Working on the assumption that the domain of cycling can benefit from a comprehensive overview of the various fields of literature it draws from, including urban planning, transport, mobilities, and public health, this paper is a critical evaluation of existing literatures and the role urban design can play here.

The first part of this paper introduces modern urban design as an interdisciplinary field, and articulates how urban design is distinct from the disciplines of urban planning and traffic engineering in how they study mobility and transport. Given the close ties of the urban design and urban planning disciplines, there is a tendency for researchers to refer to the two disciplines collectively, reflecting the ambiguous line between what is urban design and what is planning (Steino, 2004). Yet, there is value in defining each discipline separately, and Moudon (1992, p. 331) argues that the emergence of the urban discipline in the 1960s was “born out of a search for quality in urban form... focused on urban environments that have both functional and aesthetic appeal to those who inhabit them.” Hence, the urban design approach is one that prioritizes the aesthetic qualities of urban space while accommodating the functional requirements of cycling.

The second part of this paper surveys the academic literature on cycling and places the research into three frameworks: functional, social, and experiential. These frameworks have been developed from a literature review of the landscape of the literature on cycling, and these three frameworks will be used in this paper as approaches to understand cycling, mobility, and space. The importance of each approach has dominated and receded as the role of urban designers have evolved in relation to other disciplines that are also concerned with urban space and mobility, including public health (Freestone and Wheeler, 2015), traffic engineering (Dumbaugh and Rae, 2009), urban sociology (Jacobs, 1961), environmental psychology (Lynch, 1960) and mobilities studies (Sheller and Urry, 2006).

Finally, this paper concludes by outlining the relationship between urban design and the other disciplines that also study cycling. If urban planning is positioned as the more technical and quantitative of the two disciplines, then the role of urban designer may be to uncover the social, aesthetic and experiential aspects of cycling, in line with the urban designer’s particular interest of the experience of space in general. Insofar that urban design is recognized as an independent discipline and that researchers use the term “urban design” to refer to a body of ideas, it is useful to carve out space for the academic study of

cycling in relation to urban design, or, alternatively, to establish the urban designers' interdisciplinary role in facilitating the synthesis of knowledge from many disciplines.

Modern conceptions of the relationship between cycling, mobility, and space is often a combination of historical ideas, and some of these ideas have branched into their own disciplines. To understand how cycling is positioned in the context of urban design, this paper demonstrates a progression of mobility and spatial frameworks that has resulted in our current understanding of the relationship between cycling and urban design. The goal of this paper is to use these frameworks to form an interdisciplinary conceptualization of the current academic discourse on the relationship between cycling and the built environment through a literature review. By examining these ideas using the functional, social, and experiential frameworks, the contributions of various disciplines can be incorporated into urban design thinking.

2 METHODOLOGY

This paper uses cycling and urban design literatures to identify overlaps and gaps in current research about cycling, mobility, and space. The goals of this literature review is twofold: (a) to establish the nature, methodology, and central problems of the contemporary urban design discipline and the opportunities for urban design to contribute to cycling research, and (b) to provide an overview of the research on cycling from various disciplines to arrive at an appropriate framework to perform a synthesis of cycling research into the urban design discipline.

To ascertain an overview of the state of the cycling literature, a broad search for topics relating to cycling and the built environment was conducted using Google Scholar to identify the disciplines currently studying cycling and the built environment. The most important attributes for locating sources were: year of publication, number of citations, and references to urban design literature. The literature search found that urban design often lacks a precise definition in relation to cycling. When used to describe cycling, urban design is often referred to in conjunction with other disciplines, such as planning, transport, and land-use. The focus on the functional aspects of cycling in the context of urban design has also been noticed by Forsyth and Krizek (2011) in their literature reviews.

The literature review then focused on articles that explicitly focused on non-functional aspects of cycling and models about how these non-functional aspects relate to the built environment. Through this process, fifty-one articles were reviewed and the disciplinary affiliations of its authors were identified. These articles were then tagged with keywords of their main content. The frameworks and models contained within these papers were compiled and summarized, and grouped into the disciplines of urban design, urban planning, engineering, transportation, public health, and mobility studies. These frameworks provided the basis for organizing this article. The key consideration for selecting a final framework for this article was its ability to accommodate interdisciplinary processes that are used to study cycling in urban design. To arrive at the three frameworks used for this paper, the functional aspects of cycling as most commonly studied by researchers was found to be juxtaposed against the aesthetic and experiential aspects of the environment (Forsyth and Krizek, 2011; Latham and Wood, 2015). In addition, this review also adds the social framework that seeks to capture a major area of research that is missing from the functional-experiential juxtaposition. These include the how people view cycling in the context of their social environment (Daley and Rissel, 2011) and how cycling fits in with the public health goals of society (Saelens et al., 2003). Together, the review of the cycling literature across many disciplines created the functional, social, and experiential frameworks that will be used to examine cycling in relationship to urban design.

3 INTERDISCIPLINARITY AND NORMATIVITY IN URBAN DESIGN

Since the establishment of urban design in the 1960s, urban design has drawn methods and ideas from other disciplines, and is characterized by Steino (2004) as "motley body of ideas", or what Carmona (Carmona, 2014) regards as a "mongrel discipline". Within its recent past urban design has inherently been an integrative discipline that draws from other fields of study. To support the core theories of urban design, Steino argues that, "the viability of any normative theory of urban design in practice depends on its ability to relate to other rationales" (Steino, 2004). Hence, approaching cycling from the urban design

perspective requires a framework for either integrating knowledge from other disciplines into the field of urban design or for creating knowledge that is specific to the field of urban design. Carmona (2014) outlines a few options for moving the urban design discipline forward. In the paper, “The Place-shaping Continuum: A Theory of Urban Design Process”, Carmona observes that the urban design discipline can be conceived in two ways:

First, as a focused amalgam of core knowledge and practice pragmatically drawn from other fields, both professional and intellectual.

Second, as a distinct and evolving field that has added to, worked over and given new meaning to this borrowed knowledge and practice through [...] fashioning it together into a singular and tolerably coherent field of knowledge [...] the generation of new knowledge around what is unique about the subject and practices of urban design. (Carmona, 2014)

Implicit in drawing knowledge from other fields is to also integrate and make the various pockets of knowledge coherent and connected to create a whole body of knowledge that is greater than the sum of its parts. Khan et al. (2014) contrasts the relatively fragmented multi-disciplinary approach of “contracting out of services”, to the interdisciplinary and transdisciplinary integration of knowledge as envisioned by urban design:

It is in interdisciplinary work that the participants cross their ‘own’ epistemic boundaries, to co-produce new concepts and methods. [...] Alternatively,] transdisciplinarity involves the members of different scientific and practice fields working together over a long period of time, which creates the possibility of producing an overarching synthesis that goes beyond any single framework. (Khan et al., 2014, p. 399)

Currently, the urban design discipline is criticized for its absence of a positive methodology to support the normative values of the discipline. Normative theories of urban design project visions of the good city, and most urban design theories rank the importance of various aspects of the city. In contrast to the focus on aesthetics in relation to mobility, the mid-nineteenth century gave rise to a functionalist view of cities and public space. This view can be seen in the field of urban planning and transportation forecasting, starting with the four-step traffic model has been used since the 1950s and remains in use in some places today (McNally, 2008). The functionalist view of the relationship between mobility and space reduces travel as a necessary cost of moving two points in space (Sheller and Urry, 2006). However, reducing mobility to this functional problem also implicitly removes the aesthetic and social considerations that is urban designers. The effect of this functional view of mobility is to remove considerations of travel experience, and to reduce the journey to two dominant measurements: time and cost.

To counter this functional view of transport literature in general, and cycling in particular, the most important value of urban design as a discipline is its normative arguments in defining what a good city is. One insight from urban designers is to balance the needs mobility to serve the good city, rather than designing cities around the needs of transport modes (Bertolini, 2012). Urban design in particular has a rich history of normative theories that have influenced cities of the past century. Steino remarks,

Normative theories of urban design generally take a critical stance towards the status quo. Thus, the societal theories of urban design are critical towards the existing society, envisaging new concepts for society and its organization in space. (Steino, 2004)

One role of urban designers could be to prescribe the normative values and visions of cycling and mobility in cities but to leave the technical expertise of construction with the engineers. This division of labour is a viable arrangement, as long as the normative-positive division holds true. However, as the technical disciplines have dominated the academic study of cycling, the functional approach have also encroached into the normative aspects of cycling, and dominated the study of transport and mobility in general (Spinney, 2009). The distinction between the positive and normative aspects of cycling is important in itself because the idealistic visions for cycling’s role in the good city not cannot be established merely through positive methodology alone, but rather, it must be developed from a normative stance. If, for example, cycling is portrayed as a value-free domain of transport engineers, then the connection between cycling and the good city can be lost, giving way to a mechanistic focus on speed, movement, and transport efficiency.

After locating the core knowledge relating to cycling in urban design, the goal of urban design could be the creation of interdisciplinary and transdisciplinary integration of the diverse range of knowledge on cycling that exists today. This process provides new scaffolding for normative theories of urban design to be supported by positive methods from other disciplines. Hence, the lack of core knowledge and the ambiguity of the word “urban design” is an opportunity for integrative research. In relation to cycling, the task is two-fold. First, to catalogue areas of cycling knowledge that can be properly classified as within the urban design domain. The overview of various disciplines later in this paper is an attempt at constructing the “amalgam of core knowledge” (Carmona, 2014). Second, to coherently tie together bodies of multi-disciplinary cycling knowledge and to facilitate the collaboration of various disciplines.

4 THREE FRAMEWORKS FOR UNDERSTANDING CYCLING, MOBILITY, AND SPACE

Moving towards defining urban design as an interdisciplinary and normative field of cycling research requires a framework that brings together knowledge from other disciplines. So far, researchers have developed models for integrating various factors contributing to people’s decision to cycle (Saelens et al., 2003; Wang et al., 2016). However, existing models do not bring diverse disciplines and their respective methodologies together to support normative arguments about how cycling can be a field of integrative and interdisciplinary work. For example, while technical studies may be innovative in inventing safer intersections layouts and smoother bicycle paths, these individual improvements should be positioned in relation to research on social issues of culture, health, and social norms. Yet, it may be in an entirely different framework under which these two seemingly disparate fields of study may be connected. One example is to use the experiential framework to demonstrate that factors such as physical fitness and the skill level of the cyclist may affect both individual social perception of cycling (social) as well as their ability to comfortably use certain types of physical infrastructure (functional). This section identifies the functional, social, and experiential approaches of analysing cycling to provide frameworks under which various disciplines may interact.

These conceptualizations range from: 1) the engineering and planning perspectives associated with the functional framework, in measuring the speed, direction, and flow of traffic and understanding the relationship between land use, mobility, and accessibility (Botma and Papendrecht, 1991; Heinen et al., 2010); 2) the public health and urban sociology perspective associated with the social framework, in considering mobility and urban form in relation to social connection, physical exercise and active healthy lifestyles (Wang et al., 2016); and 3) the mobilities and environmental psychology perspective associated with the experiential framework, in studying the sensation and legibility of the environment from the perspective of the cyclist (Jones, 2012). Using the perspectives provided by various disciplines, this section will review the main ideas associated with the functional, social, and experiential frameworks as they relate to cycling.

4.1 THE FUNCTIONAL FRAMEWORK

From the modern urban planning perspective, a functional line of thought can be drawn between cycling and the built environment through quantitative land use and activity variables (Bertolini, 2012). The functional framework pursues the positive aspects of logistics in terms of movement, speed, and flow while seeking to minimize the negative impacts of congestion, collisions, and delays. To identify functional relationships, studies have been conducted to assess the correlation between built environment variables, such as trip distance, bike lanes, crash risk and bike parking, and people’s willingness to cycle (Heinen et al., 2010; Wang et al., 2016; Winters et al., 2011). The genesis of the functional framework can be traced back to the works of Le Corbusier, Robert Moses and the post-war idea of master planning. In this era, the goal of town planning went beyond establishing the physical location, form, and layout of land uses and buildings, and extended to the ideals of detailed master design of entire communities (N. Taylor, 1998). Although this functional conception of the city over the last decades has been ceded to engineers and urban planners through the division of public space into the traffic and design realms, the hybrid nature of cycling has challenged urban designers to integrate the needs of mobility with those of place-making (Hamilton-Baillie, 2004).

The traffic engineering discipline is most usually associated with the functional study of the bicycle in relationship to the built environment, viewing the bicycle as a physical element of traffic. Taylor and Davis (1999) summarizes the functional aspects of infrastructure design undertaken by their paper “Review of Basic Research Bicycle Traffic Science, Traffic Operations, and Facility Design”. As reviewed by this article, basic research in engineering relates to factors such as intersection control, pavement surfacing, acceleration characteristics, and cyclist reaction time, to name a few. The dominant methods for this line of research are naturalistic observational methods using traffic counts, computer simulation, and mechanical measurements such as size, speed and energy. In relation to urban design, these studies make explicit the physical parameters of the bicycle, and that the human-bicycle system has have limited capabilities. For urban designers, these limits serve to define the minimum necessary, but not sufficient, conditions for designing cycling-oriented spaces.

Travel demand is a topic that concerns both engineers and urban planners. In a mechanistic paradigm, people are assumed to travel in order to go to a destination. The total distance that people travel depend on the frequency of the trips and the destination of those trips. Relative cost and travel time are the usual measurements of behaviour in this model, but incorporating the idea of generalized travel cost without identifying its components results in a highly simplified idea of why people travel (Wee et al., 2013). The financial costs are conceived as the costs of gasoline, bus fares, road tolls and parking meters. Time costs are conceived as the missed opportunity of doing the next best thing as each minute of travel is reduced. This way of thinking implicitly values shorter time and greater speed. However, conventional models of travel demand do not explicitly consider the quality of the journey itself, even though an attractive urban environment is especially important to enticing active modes such as walking and cycling (Spinney, 2009).

A related component to travel demand is the mode choice of how people choose to travel. In order for people to choose to travel by bicycle, the bicycle must, on the whole, be advantageous compared to other methods of travel. Mode choice is related to travel demand as a percentage of total travel by bicycle. Mode choice can be influenced by trip characteristics such as trip distance (a function of land use), travel costs, cycling facilities, and other variables that are listed in detail by Hunt and Abraham (2007). However, choosing the bicycle for travel is also largely dependent of many factors are unrelated to trip characteristics, such as attitudes towards cycling and socio-demographic characteristics (Fernández-Heredia et al., 2014).

Land use factors such as density and use is recognized to have as having a large influence on cycling. However, land use is different from travel demand (when and if to travel) and mode choice (how to travel) in that the resulting land use patterns in cities is not the result of individual choice. On a trip by trip basis, a person may choose to travel down the street or to another city, or a person may choose to travel by car or by bicycle. However, living location and land use is constant over a longer period of time compared to choosing the method of travel (Wee et al., 2013). Therefore, land use is seen in combination with social measurements such as income and age as an overall factor in affecting people’s travel demand and mode choice decisions.

The functional framework ties together engineering research on the physical characteristics of cycling and the infrastructural needs of the cyclist with urban planning research on the relationship between travel choice, and land-use variables. For urban designers, the functional framework provides a wealth of quantitative studies that demonstrate a variety of ways in which cycling is related to the built environment, both as a physical object in the environment and as a transport alternative to other modes of travel such as automobiles, transit, and walking.

4.2 THE SOCIAL FRAMEWORK

The social framework is one of the earliest frameworks employed by urban designers with strong historical roots. Shaped by thinkers and designers, such as Jane Jacobs and Jan Gehl for example, the recognition of social dimensions of cycling has pushed urban planners and designers to extend their studies to the social factors that affect cycling. Gender, age, and cultural background have all been shown to affect people’s willingness to cycle (Harms et al., 2014; Pucher and Buehler, 2008). The idea that mobility is shaped by society is revealed in the history of cycling itself, having initially been viewed as a leisure activity of the wealthy and upper class with the introduction of the penny farthing. Only at the turn of the twentieth century, with the invention of the safety bicycle that was affordable to the masses, did cycling

become a common transport tool (Shove, 2012). This social concern with cycling extends to the present line of research, where cycling can be viewed as a highly politicised practice, with its own culture and subcultures (Spinney, 2009). Recently, there has been a notable increase in studies of the relationship between active mobility, physical exercise, and healthy neighbourhoods from the public health perspective (Dill, 2017).

Active modes of travel, such as walking and cycling has been the attention of public health professionals as a routine way to integrate more physical activity into everyday life. In recent decades, the academic study of public health and active transport has borrowed heavily from the methods used by traffic engineers and urban planners in creating quantitative analysis of the relationship between bicycle use and the built environment. (Saelens et al., 2003). The implications is that if land use can be demonstrated to affect cycling, then land-use policies should be able to affect public health through more travel-related physical activity. Public health studies have explicitly emphasized this relationship between policy and rates of bicycle use, both in terms of reducing death and injury from collisions and the positive health effects of increased physical activity due to cycling (Pucher and Dijkstra, 2003).

Social perceptions about the image of cyclists and peer groups associated with cycling also affect people's willingness to cycle. Is cycling a sport or a transport activity? Are cyclists viewed as law breaking? Daley and Rissel (2011) examine these questions and conclude that improving the social perception of cycling and cyclists has a large role to play in promoting cycling as a mainstream activity. Hence, the decision to cycle is not only influenced by the built environment, but also by the images of what cycling represents (Daley and Rissel, 2011). For example, in a survey of adults in a Flanders, a Dutch speaking part of Belgium, researchers found that social support played a more important role than environmental variables to encourage cycling. The results seem to suggest that given adequate cycling infrastructure, it is important for people to have friends and family who also support cycling (de Geus et al., 2008). Similar findings supporting the importance of social support in cycling was also found in study of a Portuguese population (De Bourdeaudhuij et al., 2005).

Measuring the social costs and benefits, as opposed to the individual costs and benefits of cycling, includes how users benefit from cycling as well as how cycling affects others in society. Two main approaches have been taken by researchers to understand the decision to cycle. One method analyzes the social, economic, and spatial data and relate those data points to the method of travel (Saelens et al., 2003). Another method is the use of surveys that ask people about their personal motivator and barriers to cycling (Winters et al., 2011). Some social benefits include the reduction of pollution, the creation of a more lively urban environment, an increase in general healthiness through exercise, and more equitable transportation access (McClintock, 2002). On the individual level, people choose to ride their bicycle because it is pleasurable, fun, fast, healthy, or to obtain a greener identity. However, the person choosing to travel by bicycle may not necessarily consider that their neighbours may breathe easier because of reduced air pollution, nor do people travel by bicycle consider that others may spend less time on a highway traffic jam.

The social framework ties together research on the physical activity benefits of cycling, social perceptions of cycling, and the various aspects of calculating the costs and benefits of cycling. For urban designers, the social framework brings awareness that the factors such as the image of cycling is also an aspect that can be influenced by the design language of the built environment. In addition, public health research shows that the benefits of physical activity from cycling for transportation yields health benefits in addition to improving accessibility through better transport options.

4.3 THE EXPERIENTIAL FRAMEWORK

The experiential framework focuses on the aesthetic experience in urban design. The experiences of movement has been studied by urban designers from the perspective of the person walking and through the windshield of a car, yet there the experience of movement from the perspective of the cyclist has not been extensively studied (Forsyth and Krizek, 2011). From the walking perspective, Bosselmann (2007) writes about perceptions of time through different urban environments by representing journeys through cities around the world using pictorial sequences. From a faster perspective, "A View from the Road" analyses the highway landscapes through the perspective of the driver (Appleyard et al., 1964). Only much more recently has extensive research been conducted from the cycling perspective. Stefansdottir (2014)

positions the experience of cycling in relation to a recreational and commuting purposes, drawing from theories of phenomenology of sensory perception and experience, urban design theory, and theory of environmental aesthetics. The field of mobilities studies have used mobile methods to analyse the experience of cycling, with Jones (2012) making explicit the sensory demands placed on the cyclist, and Latham and Wood (2015) viewing cycling in relation to the infrastructure that surrounds cycling.

In contrast to the land-use and transportation interaction that is studied closely by public health and urban planners, the field of urban design has its focus on the aesthetic qualities of urban space. However, much of this aesthetic study is done using stationary methodology, where the researcher observes space and other people's activities from a fixed point. Using stationary methodologies, urban designers are well versed in concepts such as mental maps, activities programming, wayfinding, and contact between people. Lynch (1960) also highlights the individual's subjective relationship to the built environment using the urban design concept of "legibility", and Koseoglu and Onder (2011) applies Lynch's ideas to spatial forms and physical landmarks. Although Lynch's ideas of scales in terms of size, time, and complexity can be studied through the perspective of the cyclist, movement through space is more commonly analysed through the perspective of the pedestrian (Ewing and Handy, 2009; White, 2007) or from that of an automobile (Appleyard et al., 1964). These urban design ideas highlight that human experience of cycling cannot be fully described by physical measurements alone.

Surveys have been used to establish the human preferences of cycling infrastructure and environments. The survey approach is important because it attempts to capture the cyclist's perspective of their interaction with the environment. Questionnaire studies asking about the preferences of current cyclists (Hunt and Abraham, 2007; Li et al., 2012), current and potential cyclists (Winters et al., 2011), and a sample of the population (Tilahun et al., 2007). However, the survey method usually asks cyclists to recall their experience, resulting in a reflective account of people's experiences

What is notably missing in the field of urban design are techniques to observing cyclists, who experience the environment from a moving perspective, in order to understand how the particular movement of cycling can create its own meaning in relationship to space (Spinney, 2009). The most comfortable environment as perceived through a bicycle must be designed at a scale that is in between the scale of pedestrians and the scale of automobiles (Forsyth and Krizek, 2011). This pattern of scenery may be boring for the pedestrian or distracting for the driver, but is perfectly enjoyable at cycling pace. Thus, Forsyth and Krizek (2011) writes, "cyclists' speed, height and skill diversity present challenges and opportunities for urban design in terms of scale, texture and change over time."

To capture cycling experiences on a moment by moment basis, the perspective of the cyclist has recently been studied through the application of mobile methods by mobilities researchers. The use of video and ride-along interviews has been especially informative in capturing the experience of cyclists in motion (Latham and Wood, 2015). Others have focused on how cyclists mediate their exposure to the environment through devices such as headphones (Jungnickel and Aldred, 2014). By using mobile methods, the field of mobilities advances tools for exploring the user perspective of cyclists in real-time, and reveals cyclists' strategies for interacting with unpleasant aspects of infrastructure. Law and Urry (2004) argues that "existing stationary methods have difficulty dealing with the sensory – that which is subject to vision, sound, taste, smell; with the emotional – time-space compressed outbursts of anger, pain, rage, pleasure, desire, or the spiritual." The mobilities scholarship offers urban designers the tools for understanding cycling through movement, as opposed to the static interpretation of the experiential and aesthetic aspects of a city. It is through mobile methods that the tangential user motives of cyclists can be understood (Spinney, 2011).

The experiential framework ties together research in the field of mobilities and environmental psychology about perceptions of movement through the city, the legibility of space, and the sensory experience of cycling. The experiential framework focuses on the aesthetic dimension of urban space that is at the core of the urban design discipline, and recent research applies uses innovative mobile methods to understand how various elements of urban design are perceived through the perspective of the cyclist.

5 CONCLUSION: INTEGRATION OF CYCLING INTO URBAN DESIGN

Thus far, this paper has explored the boundaries of the urban design discipline, presented the potential role of urban design in articulating a platform for interdisciplinary and transdisciplinary research on cycling, and provided a review of cycling research through various frameworks. The final part of this paper concludes with a few examples of how the integration of cycling into urban design could happen.

Since Moudon (1992) and later Carmona (2014) articulated the core literature of urban design as the body of theoretical literature related to Lynch, Whyte, and Appleyard, the strength of urban design can be argued to lie within the experiential domain, with an awareness of the social issues associated with space. However, the contribution of urban designers have been largely limited to what Forsyth and Krizek (2011) expressed as the functional understanding of the requirements of cycling. Perhaps part of this problem is that other disciplines fail to see how the more qualitative aspects of urban design knowledge can be integrated into the largely quantitative methodology of urban planning and traffic engineering, exacerbated by the siloed nature of cycling research. In addition, there is a failure to recognize how the normative theories of urban design can play a role in the design of future cities to complement the positive methods used by other disciplines to understand cities (Moudon, 1992).

From the traffic counts of transport engineers, to video ride-alongs of mobilities researchers, to the surveys about social attitudes, the largest contribution of other disciplines to urban design is in the realm of methodologies. It seems that on balance, the use of qualitative methods applied to the study of cycling is more a more recent venture, and remains less explored than the use of quantitative methods. This focus on quantitative data is evident within the functional framework derived from traffic engineering, and planning, as well as in the social framework that uses demographic and physical activity data to study cycling. On the street level, a striking contrast between the qualitative realm of urban designers and the quantitative realm of traffic engineers is given by the following example:

The immediate, close-up environment of almost all our cities is determined by curbs, asphalt, road markings, bollards, traffic signals, barriers, and signs. We will negotiate our journey into and through the city amidst a landscape fashioned by traffic engineering. The rules that govern this landscape have little in common with the special cultural history and values that will have shaped the architecture and the unique signature of place. (Hamilton-Baillie, 2004)

Here, a distinction is made between the foreground and the background of the city. In one domain, the functional control of the traffic engineers dominate. In the other domain, the aesthetic, social, and experiential priority of urban designers can be seen. The social perspective on cycling also contains both quantitative and qualitative approaches. On the one hand, there is the traditional quantitative methods of using demographic and physical activity data in correlation to quantitative measures of the urban environment such as street layout, residential density (Saelens et al., 2003). On the other hand, social researchers have also studied the qualitative image of cycling, as well as the role of social support and peer groups in people's decision to cycle (Daley and Rissel, 2011; de Geus et al., 2008) While research within the context of the functional and social frameworks employ positive methodologies, the normative values of what is measured, and implicitly promoted, is often unarticulated and uncriticised.

These new methods give urban designers the necessary tools for going beyond the utilities model of transportation planning used dominantly by transportation engineers and economists referred to as the "black box" conception of mobility referred to by Sheller and Urry (2006). In a study on cyclists' perceptions, Fernández-Heredia et al (2014) articulates:

The fact that the classic factors which determine transport user behaviour – such as cost and time – are not as influential regarding bicycles use as for other modes may indicate that these other kinds of factors of a psycho-social type gain importance in the correct characterization of cyclist behaviour.

This reflects the mobilities critique of assigning value solely to stationary places and the utilitarian method of conceptualizing of travel as simply a matter of derived demand, used as a means to get to from origin to destination. Sheller and Urry (2006) argue that "[t]ransport researchers [...] take the 'demand' for transport as largely given, as a black box not needing much further investigation, or as derived from the level of a society's income. They tend to examine simple categories of travel, such as commuting, leisure, or

business as if these were separate and self-contained.” By examining the experiential and qualitative aspects of cycling using mobile methods, urban designers can look inside this black box of travel to better understand the experience of travel, and to design the built environment to improve the cycling journey.

If urban designers know more about the social and experiential aspects of cycling, then is there framework to also integrate the technical expertise of engineers into the urban design process? This comes back to the question of the normative-positive divide and the position of urban design as an interdisciplinary or transdisciplinary field of study. For urban designers to set the normative agenda to move away from engineering concepts such as efficiency, speed, and traffic density, then these functional aspects of cycling must be adequately articulated in the context of greater social goals such as accessibility, aesthetics, and diversity. The functional aspects of cycling, from lane widths to intersection design to paving materials and traffic capacity serve as the building elements of enabling the physical operation of bicycles. These functional factors alone, however, only serve as necessary, but not sufficient factors of the good and pleasant cycling experience. Other elements, such as imageability, enclosure, human scale (Ewing and Handy, 2009), and perception, aesthetics, morphology (Forsyth and Krizek, 2011) are qualitative criteria, each consisting of numerous variables, yet it is precisely because these elements are not subject to direct numerical measurement that urban designers have the opportunity to apply qualitative methods of research and design. This provides the opportunity for urban design to integrate the functional, social, and experiential frameworks of cycling with research methodologies from multiple disciplines into a more complete understanding of cycling, mobility, and space.

1 INTRODUCTION

Public transport plays an important role in functioning of every large city. It facilitates the flow of people and goods, and connects strategic areas of housing, labour, commerce or entertainment. Cities cannot develop properly when relation between those areas is not satisfactory. Public transport accessibility is a key factor to a stable operation of the whole system that city creates. It is generally understood as the ease of access to the means of transport and the ease of travelling to desired destinations. Concepts of the transport availability are used in the research on the settlement network, transportation systems and spatial development at every level (Olszewski, Dybicz, Śleszyński, 2013).

Public transport accessibility evaluation may significantly support management of city components of the city and whole transit network. The analysis should precede every major construction investment. It may also help local authorities intervene when current condition of public transport services is deficient in certain areas, especially housing developments poorly connected with public service areas and workplaces. Therefore, the following paper presents an attempt to assess a public transit time accessibility on the example of a medium-sized European city - Warsaw.

1.1 PUBLIC TRANSPORT SYSTEM IN WARSAW

Public transport system in Warsaw metropolitan area operates on the area of the city and 30 adjacent communes and covers about 2500 km² (517 km² in Warsaw and 1912 km² outside the city borders). The annual number of passengers exceeds 1 billion (Urząd m.st. Warszawy, 2015). The system consists of 267 bus lines, 26 tram lines, 4 city train lines (SKM) and 2 metro lines. Moreover, passengers who have appropriate tickets are able to use train lines operated by Masovian Railways (KM) and Warsaw Commuter Railway (WKD).

Important part in the public transport system is played by rail transport (railway, metro and tram), however bus is the most accessible mean of transport to the largest group of passengers. According to the data from 2013 it is estimated that during the year buses transported over 550 mln passengers, which is twice more compared to the number of passengers transported by trams or metro (Table 1). Tram is the second mean of public transport in terms of number of passengers. The third is metro (the youngest mean of transport in the city) which gains importance because of its capacity and travel time. Metro in Warsaw it is still under construction and the next 6 stations are going to be commissioned in 2019. In the peak time metro runs every 3 minutes. (Urząd m.st. Warszawy, 2015)

Mode of transport	Number of passengers [2013]
Buses	557 974 004
Trams	264 201 709
Metro	180 187 218
Railway – Fast City Rail (SKM)	22 578 235
Warsaw Commuter Railway	4 276 420
Railway – Mazovian Railroads (Koleje Mazowieckie)	30 043 675
Sum	1 059 261 261

Table 1 - Estimated number of passengers in 2013 divided into modes of transport.
Source: Urząd Miasta Warszawa, 2015

1.1.1 MODAL SHARE

According to data obtained during the travel survey of Warsaw inhabitants in 2015 nearly half of travels are made with public transport and one third of them with private vehicles. Almost 20% of trips are made on foot. After excluding the latter from the analysis the modal share occur as follows: 56.9% public transport, 38.6% private motor vehicle, 3.8% bicycle, 0.7% other means of transport. (Kostecka, 2015b)

Every day inhabitants of Warsaw make 3.348.336 trips from which 44.1% comprise trips between home and workplace, 11.1% - trips between home and place of education, 35.1% - trips between home and other destinations and 9.7% - other trips with no connection to home. Majority of trips start and finish within the city boundaries and only 4.5% have their start or end outside it. Spatial layout of journeys shows that most of them take place on the west side of Warsaw (59.6%) and over one fifth (23.2%) requires crossing the Vistula river. (Kostecka, 2015b)

The analysis of the data from years 1980, 1993, 1998, 2005, 2015 reveals the increasing value of inhabitants' mobility index in period 2005 - 2015, after a long period of decrease 1993-2005 (Kostecka, 2015b). The cause of this increase is an ongoing process of development of rural areas in suburbs of Warsaw (urban sprawl) which is considered nowadays as one of the major problems in the city's spatial management.

Moreover, after the decrease of public transport share in 1980-1993 an inhibition of the decrease can be observed in years 1998-2005. It is the result of high expenditures to improve the public transport system and the competitiveness of it in terms of traffic congestion. On the other hand, in last 10 years public transport modal share dropped by almost 10%. Simultaneously the number of walking trips decreased from 30,1 % in 1980 to 17,9 % of all trips in 2015 (Figure 1). The cause of it is the increase of motorisation index and easier access to means of public transport (com. Figure 1).

Figure 1 - Comparison of travel structure, by travel methods for travel in general. Source: Kostelecka, 2015b

The study of traffic volume conducted in 2015 (Kostelecka, 2015b) provided the numbers of cars within the metropolitan area. It is estimated that during a working day about 1 million of cars cross Warsaw borders as well as central area of the city (in both directions); 550 thousand of cars come from metropolitan area and 450 thousand from outer area. Furthermore, a significant rise of the motorisation index can be observed, which results in an increasing modal share of individual motor vehicles starting from the end of 1980s (Kostelecka, 2015b). According to the data published by Central Statistical Office in 2012 there were 580 vehicles per 1000 inhabitants in Warsaw, whereas in the 90's there were less than 400 cars. Similarly the index of motorisation raised in counties adjacent to Warsaw. For example, in Warsaw West County there were even 612 vehicles per 1000 inhabitants in 2012 (Urząd m.st. Warszawy, 2015). Increasing motorisation index and less access to public transport in communes outside Warsaw result in 59,9% share of cars (and only 29,6% of public transport) in all trips made by inhabitants from these areas (Kostelecka, 2015). These are the reasons for high traffic congestion during peak time in Warsaw. According to TOMTOM Traffic Index list Warsaw was ranked 42nd most congested city in the world (TomTom, 2017).

Cars are one of the main causes of air pollution in the city. According to Voivodeship Environmental Protection Inspectorate (WIOŚ) linear sources in the total pollutant emission share in Warsaw is the highest for nitrogen dioxide and particulate matter - PM10. The highest concentration of pollution occurs in vicinity of the roads of high traffic density and areas with dense development, especially in the city centre. A similar problem affects the whole metropolitan area where in 2011 according to Supreme Audit Office (Najwyższa Izba Kontroli, 2014) 63% of total PM10 emission from this zone was caused by linear sources (mostly transport). Moreover, a big number of motor vehicles in the city results in noise pollution. In fact, Warsaw is claimed to be one of the most polluted cities in Poland in terms of the number of people affected by overscaled noise and the area in which acceptable noise pollution index is exceeded (Warsaw City Council, 2015).

1.2 METHODS OF PUBLIC TRANSPORT ASSESSMENT AND ITS INSERTION INTO PUBLIC SPACES

Public spaces are one of the most significant components of urban environment. Not only are they important for social reasons but also influence the functionality of public transport system. Hence, authorities responsible for creating, managing and enhancing such system (including local government, urban planners, transport engineers, etc.) should introduce proper tools and methods of assessment of public transport accessibility. Since GIS become more and more common as an aid in different public governing areas, it seems obvious that methods of assessment of public transport accessibility will also be implied through such systems.

Cities around the world use different methods to study and analyse their public transport systems. They are usually based on evaluating time of accessing the public transport or distance between the stations and locations of residence (Fransen K. et al., 2015). Nevertheless, many other substantial factors may be taken into account to receive more precise view of a particular public transport system. For instance, PTAL (Public Transport Accessibility Level), a method introduced in London and then implemented in other British cities after modifications (GMAL, Greater Manchester Accessibility Level) consists of evaluating

time to get to public transport station from a defined Point of Interest and waiting time based on time tables (Measuring Public Transport Accessibility Levels, 2010). Welch and Mishra (2013) during their research on Washington-Baltimore region multimodal transport system and its impact on the environment added the factor of importance of the stations. They analysed the public transport frequency in peak and off-peak periods. The element that significantly improves the public transport accessibility assessment is evaluation of the time or cost of the journey to the defined destinations. Research on public transport vs. private car accessibility estimation in Tel-Aviv metropolitan area (Benenson et al., 2011) included walking time from the origin to a stop, waiting time, summarised journey time (travel times and waiting times between different buses) and walking time from the final stop to the destination (employment areas and other urban functional areas). Through GIS tool Urban.Access, developed by the researchers, the BTT (Bus Travel Time) was compared with CTT (Car Travel Time). Previously mentioned Lei and Church (2010) noticed that including estimated travel time into public transport accessibility assessment may occur insufficient. The value fluctuates depending on timetables. Including this factor into public transport accessibility assessment methods demands sophisticated GIS analyses implied into a specific public transport system.

Introduction of public transport accessibility assessment methods in other cities and enhancing them in existing ones pose a significant challenge for local authorities and specialists. It may help them recognise transportation service deficient areas and reshape the system accordingly.

2 METHODOLOGY

The main aim of the study was to analyse the quality of Warsaw public transport service. The model of public transport created on the basis of the total travel time to the city centre or to the key, centre-forming destinations enables identifying areas which are insufficiently serviced yet densely populated.

In order to measure the accessibility of public transport in Warsaw, it was crucial to identify key areas within the city spatial layout which are frequently attended by inhabitants. Those areas play important role in the city structure as they ensure workplaces, trade, education, recreation and community interactions. During the study points which represent district (major) centres and local (minor) centres were selected in every district of Warsaw.

The most significant part of the city is undeniably the city centre. In Warsaw it encompasses the area of the inner district Śródmieście and parts of adjacent districts: Wola, Ochota, Praga Południe and Praga Północ (the last two located on the right side of Vistula river) (Warsaw City Council, 2006). This area concentrates main government and local authorities' offices, embassies, international institutions and nationwide agencies as well as commerce, education and cultural objects (including historic Old Town and New Town). Multiplicity of key destinations within the inner city did not allow to select one central point of Warsaw, instead several points on two hierarchical levels were chosen (Table 2).

In the urban environment, apart from the inner city, it is possible to distinguish district and local centres. The first are usually anchored by local government seats, shopping malls or education institutions, especially universities. Such places attract not only residents of particular district but also from other parts of the city. According to the local planning act (Urząd Miasta Warszawy, 2006) district centres should be located suitably in the district layout, easily accessible and well connected with the city centre and housing developments. At this point, the fact that transport hubs influence strongly the city environment and often become district centres must be highlighted.

Local centres can be defined as multifunctional areas dedicated to residents of particular districts, which provide them with various services including retail, healthcare, education, culture as well as places of recreation and community integration (Oddział Warszawski Stowarzyszenia Architektów Polskich, 2015). Such areas, usually located between housing developments and public transport stops, aim their amenities mainly at local residents. Local centres were determined on the basis of "Warsaw Local Centres" project conducted by Association of Polish Architects in which areas of natural social interactions in the city's spatial layout were selected (Oddział Warszawski Stowarzyszenia Architektów Polskich, 2015).

Table 2 presents the list of important points distinguished from the urban space of Warsaw. They are divided into two groups based on their place in hierarchy of district and local centres and sorted by districts on each side of the city. Figure 2 shows the location of selected points.

West side of Warsaw	
1) Bemowo District Centre: 1) District Council of Bemowo Local Centre: 1) Department store <i>Hala Wola</i> ; 2) Wrocławska bazaar; 3) Supermarket <i>Stokrotka</i> at Radiowa St.; 4) Bemowo shopping centre	9) Włochy District Centre: 1) Railway station Włochy; 2) Shopping centres at intersection of Popularna St. and Jerolimskie Ave.; 3) Shopping centre Okęcie Local Centre: 1) Bakalarska marketplace; 2) Community centre <i>Artystyczny Dom Animacji</i>
2) Bielany District Centre: 1) District Council of Bielany, 2) Józef Piłsudski University of Physical Education, 3) Cardinal Stefan Wyszyński University Local Centre: 1) Sales and service centre at Conrada St., 2) Department store <i>Megasam Żoliborz</i> , 3) Metro station <i>Stare Bielany</i> , 4) <i>Wolumen</i> bazaar	10) Wola District Centre: 1) District Council of Wola; 2) Daszyński Roundabout; 3) Wola Park shopping centre Local Centre: 1) Sales and service centre at Górczewska St.; 2) Bazaar at the Kolo neighbourhood; 3) Former cinema <i>Kino Femina</i>
3) Mokotów District Centre: 1) <i>Galeria Mokotów</i> shopping centre, 2) Warsaw School of Economics Local Centre: 1) Broniewski Orszka Square, 2) Jordan garden at Odyńca St., 3) KADR community centre, 4) Walszewska bazaar, 5) <i>Land</i> shopping centre	11) Żoliborz District Centre: 1) Wilson Sq. Local Centre: 1) Department store <i>Hala Marymont</i> ; 2) Grunwaldzki Sq.
4) Ochota District Centre: 1) Narutowicz Square, 2) Szczerbiński park (skiing slope), 3) <i>Reduta</i> shopping centre Local Centre: 1) Department store <i>Hala Banacha</i> , 2) <i>Moldawska</i> marketplace	East side of Warsaw
5) Śródmieście District Centre: 1) surroundings of intersection of Jerolimskie Ave. and Marszałkowska St.; 2) <i>Złote Tarasy</i> shopping centre; 3) Metro station <i>Ratusz-Arsenal</i> ; 4) Krakowskie Przedmieście St. nearby Warsaw University; 5) Plac Zamkowy in front of The Royal Castle in Warsaw; 6) National Museum in Warsaw Local Centre: 1) Department store <i>Mirowskie Halls</i> ; 2) Savior Square; 3) Union of Lublin Square; 4) <i>Arkadia</i> shopping centre; 5) Warsaw University of Technology	12) Białoleka District Centre: 1) District Council of Białoleka Local Centre: 1) Sales and service centre at Światowida st.; 2) Shopping centre at Modlińska st.
6) Ursus District Centre: 1) Railway station Ursus; 2) District Council of Ursus Local Centre: 1) Acher Park; 2) Plac Tysiąclecia; 3) Sales and service centre at Wojciechowski St. (nearby Park Hassów); 4) <i>Skorupa</i> shopping centre	13) Praga Południe District Centre: 1) Wiatraczna Roundabout; 2) PGE National Stadium; 3) District Council of Praga Południe Local Centre: 1) Sales and service passage at Francuska St.; 2) Shopping centre nearby Szembeka Sq.; 3) <i>Promenada</i> shopping centre
7) Ursynów District Centre: 1) District Council of Ursynów Local Centre: 1) Metro station Stokłosy - Ursynowski Shopping arcade; 2) Metro station Natolin - Galeria Ursynów shopping centre; 3) Metro station Kabaty - Tesco supermarket; 4) <i>Na Dołku</i> marketplace; 5) supermarket Auchan Puławska	14) Praga Północ District Centre: 1) Metro station Dworzec Wileński; 2) Plac Weteranów 1863 r. (entrance to The Warsaw Zoo) Local Centre: 1) Haller Square; 2) Różyci bazaar
8) Wilanów District Centre: 1) District Council of Wilanów; 2) The Wilanów Palace Local Centre: 1) Center of Divine Providence (Centrum Opatrzności Bożej)	15) Rembertów District Centre: 1) District Council of Rembertów; 2) Railway station Rembertów Local Centre: 1) War Studies University
	16) Targówek District Centre: 1) District Council of Targówek Local Centre: 1) <i>Renova</i> shopping centre; 2) Trocka bazaar; 3) Wiecha Square (in front of <i>Rampa</i> Theatre)
	17) Wawer District Centre: 1) District Council of Wawer (nearby railway station Międzyzłote); 2) Children's Memorial Health Institute Local Centre: 1) Local community centre Marysin; 2) <i>Falenica</i> marketplace
	18) Wesoła District Centre: 1) Railway station Warszawa-Wesoła; 2) District Council of Wesoła Local Centre: 1) Sales and service centre at intersection of Brata Alberta St. and Wspólna St.; 2) Sales and service centre at Trakt Brzeski

Table 2 - District and local centres in Warsaw Source: own study

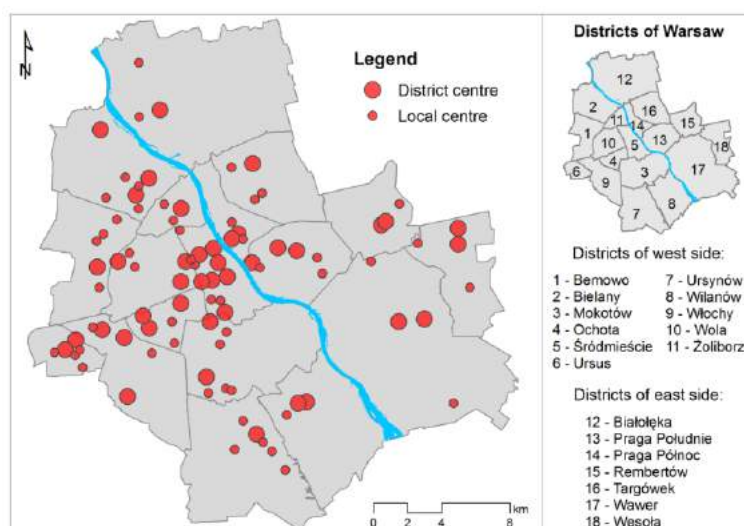

Figure 2 - District and local centres in Warsaw. Source: own study

2.1 MODEL OF WARSAW PUBLIC TRANSPORT

Model of public transit used in the study was based on data in the General Transit Feed Specification (GTFS) – a standardised data format for storing public transit routes, stops, and schedules (Morang, 2017). GTFS data is used e.g. in Google Maps transit trip planning or other planning applications. Since 2008 the number of transit agencies sharing open schedule data in common format increased from barely dozen to over a thousand agencies from almost every country around the world (Czebotar, 2017). Many major public transit systems, especially operators in US, have made up-to-date GTFS data for their systems readily available for download. Open-data movement also contributes to producing schedules in GTFS format, commonly available from a dedicated feed registry list (Transitland, 2017).

Public transit accessibility was evaluated using schedule-based transit analyses in ESRI environment. Tool “Add GTFS to a Network Dataset”, created by Melinda Morang, allows adding GTFS data to an ArcGIS network dataset and performing schedule-aware analyses using ArcGIS’s Network Analyst extension (Morang, 2017). GTFS schedule data for Warsaw was obtained from website Transitart (Inovatica, 2016). Network dataset was built using source point features (stop locations) and line features (roads obtained from Database of Topographic Objects - BDOT). Evaluation of public transit accessibility was performed using service area layer from Network Analyst extension. A network service area is a region that encompasses all accessible streets within given time breaks and is calculated on the basis of given cost - in the following study travel time with transit (ESRI, 2017). Accessibility was measured on the basis of travelled time, which is crucial for assessing public transit quality. The average travel time by public transport in Warsaw differs in years 1980 – 2015 and estimates 33 minutes in 2015, which is close to 30 min benchmark proposed in several studies (Cox, 2012; Goliszek & Połom, 2016). On the other hand, travel time between house and work destinations, the most often motivation of trip by public transport, was the highest of all motivations and estimated for 40 minutes in 2015. Moreover, the number of trips longer than 45 min, which is a limit time value of travel between city areas, was the biggest in this group (Kostecka, 2015; Warsaw City Council, 2015). The methodology of the study was based on detailed positioning of isochrones of access in 5 minute intervals. Isochrones covered 15 min, 30 min, 45 min, 60 min and 90 min travel time to the destination. Calculation model is presented in the Figure 3. The test performed within morning rush hours, 6:00 – 9:00, on a working day.

Figure 3 - Model for calculating isochrones in given intervals. Source: own study

Deviations in the operation of public transport were analysed using population data from 2011, derived from geostatical portal (<http://www.geoportal.gov.pl/>), divided into census blocks. The area of high population density was later used to select areas characterised with high population density and low public transport time accessibility. To obtain this, travel time and population data were standardised and summed, resulting in the indicator of the public transit time travel quality. Areas where average travel time was lower than 30 min were classified as satisfactory from the point of view of public transport handling. Public transit time accessibility indicator was classified using method of Natural Breaks into three classes (Figure 6).

The next question considered analysing accessibility of district and local city centres. Basing on the map of recognised areas (Figure 2), created isochrones covered travel time to the nearest destination in 10 min intervals (10 min, 20 min, 30 min, 40 min, 50 min, 60 min). The performed test included travel time towards facility, at 9:00 am, on a working day (Figure 7).

3 RESULTS

The results of service area analyses show differing public transit accessibility at following time intervals (Figure 4).

Figure 4 - Public transit time accessibility at 6:00 (a), 7:00 (b), 8:00 (c) and 9:00 (d) on working day. Source: own study.

Differences in time travel can be observed on the borders of the intervals. To obtain quantitative assessment of public transit accessibility in morning peak, the average travel time isochrones were calculated on the basis of raster isochrones in 5 min intervals in period 6:00 - 9:00 (Figure 5).

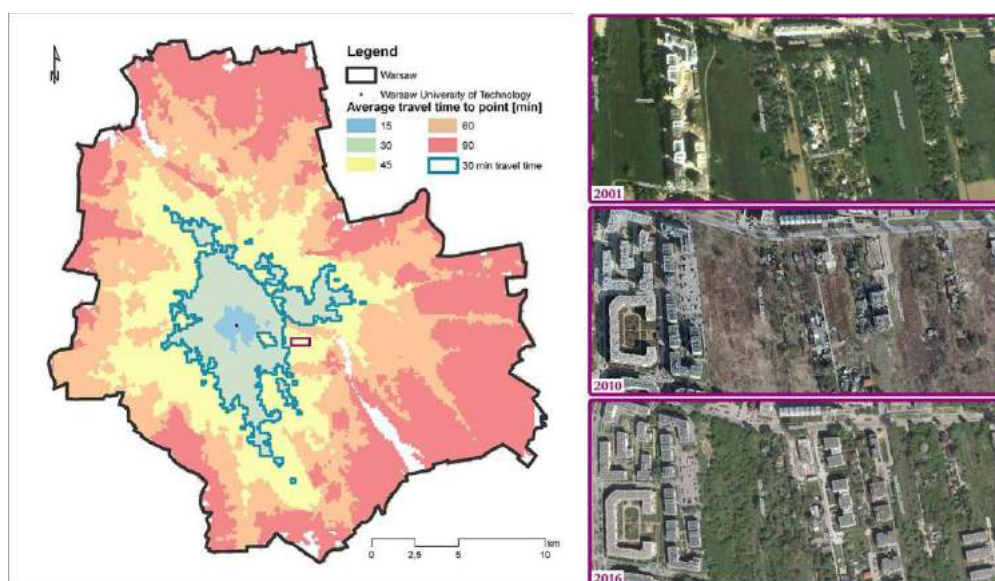

Figure 5 - Public transit average time accessibility in morning peak on working day. On the right: Czerniakow area in Mokotow district. Source: own study, <http://www.mapa.um.warszawa.pl>

Map of average travel time isochrones to city centre in the morning peak shows that the area of the lowest, 15 min travel time, is relatively small and covers area that can be also reached within 30 min walking distance. The satisfactory, 30 min travel time area covers both sides of the river. However, Vistula river is a visible barrier for public transit accessibility. In general, right side of the river has lower level of transit service to the city centre, located on the west side of the river. Strong influence of the metro lines and rail transport can be observed. Outside their service, the average travel time from the external parts of the city reach up to 90 min and higher.

Area with a lower time accessibility to the city centre, but still within a close distance, can be generally divided into two groups. First group includes areas closed for public transit, such as airports, railways, cemeteries, parks or industrial areas. The second group consists of new, rapid developments - attractive in the terms of location, nevertheless, not able to provide sufficient public transit service. Czerniaków, part of the Mokotow district (Figure 5), is exceptionally negative in the context of travel time. Located only 3 km from the city centre, but with 45 min average travel time, is intended for new, intensive housing investments.

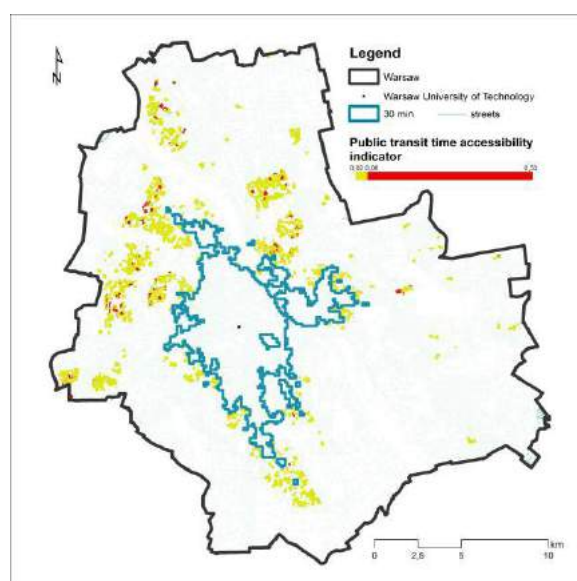

Figure 6 - Public transit time accessibility indicator. Source: own study.

Outside the area of 30 minute average time travel to the city centre live 1 283 875 residents of Warsaw, which gives 74% of total Warsaw population. Area of acceptable (30 min) time accessibility covers only 10% of city area. With the use of public transit time accessibility indicator highly populated areas, with significant travel time to city centre could be assigned. These are mostly observed in large-panel system building settlements on the north of Warsaw (Chomiczówka in Bielany district, Bemowo, Praga Północ, Białołęka). Low quality of transit service was also observed in western edge of Ursus district and in Ursynów district, despite their rail connection with the city centre (Figure 6).

Second part of the study consisted of identification and analysis of public transit accessibility of district and local centres (Figure 7).

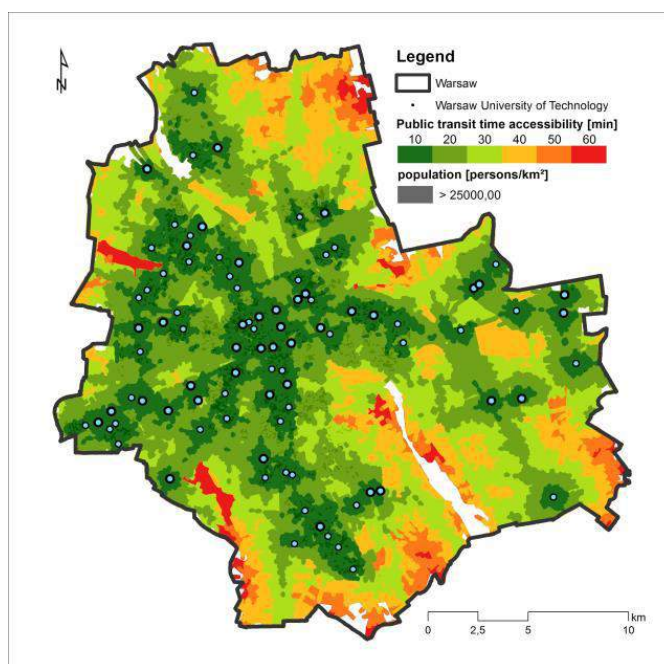

Figure 7 - Public transit time accessibility to district and local centres at 9 am on a working day. Source: own study.

The map shown in Figure 10 presents district and local centres localisation and the time of accessing them from every place in Warsaw at 9 am on a working day. It may be clearly noticed that the centres are distributed unevenly. An aggregation of them occurs in the centre of the city and along the major transit routes, where the access time approximates 10 minutes. Satisfactory results also cover more remote areas, such as Ursus and Włochy districts and areas with metro line stations. However, many service deficient areas may be also indicated. They usually cover developments placed away from major transit routes and close to Warsaw borders. Nevertheless, critical areas such as part of Mokotów district near Vistula river (e.g. Czerniaków, mentioned before) or Rembertów and Targówek localised relatively close to the city centre also have excessive access times to district and local centres. Such state is partially determined by the lack of the centres in those areas and improper public transport connection between them and the closest centres. Another peculiar phenomenon is the differentiation of the public transport time accessibility to district and local centres on both sides of Vistula river. The number of the centres on the west part of the city is far higher and the distribution of their localisations is more regular.

4 DISCUSSION

The source data processed in the study may be characterised as generalised and approximate. This is the reason for many limitations affecting the outcome. First of all, the analysis refers to a 3-hour period of time during a single day. Timetables are the input data for public transit course. Therefore, the study do not consider real time situation, traffic jams and unplanned schedule variances caused by unforeseen events. What is more, the population statistics from 2011 census do not show precisely the real distribution of inhabitancy and, even more importantly, do not fully correspond with the analysed schedule from 2016. Another important factor that has an effect on the results of the study is spatial data limitations.

Visualisation and storage of spatial data requires its proper classification, normalisation and generalisation. Localisation of local and district centres is represented by point symbols. Their spatial approximation affects the process of evaluation of their public transport accessibility. In addition, designated walking routes do not consider spatial barriers such as development fencing. Bus stop access times are affected because of this limitation. It is also important to take into notice the fact that population density distribution data processed in this study is classified into polygons that define statistical circuits. The results of the study are highly determined by the way the data are gathered and classified.

Visualising processed data on maps enables analysing many relations and phenomena. The distribution of the local and district centres in relation with the development areas or population statistics may be analysed. The spaces that are deficient in the centres may be designated. However, studying the centres localisations the observers are unable to conclude if they fulfill their role. Although the method of assessing public transport accessibility applied in the research served to evaluate the time to get to district and local centres, it does not give a full insight into real time journeys not connected with job or studying destinations and afternoon local centres traffic peak. The assessment results indicate variance in journey time in different hours, over 30-minute accessibility areas, public transport service deficient areas and potentially well communicated areas but lacking in compact development.

5 CONCLUSIONS

Historical conditions of shaping Warsaw (substantial settlements were located in the distance from the city centre) have a great impact on the present transportation problems. The connection between localisation of neighbouring developments and the course of the major transit routes is noticeable. The data concerning the size of traffic jams and the number of cars coming to Warsaw every day (Warszawskie Badanie Ruchu, 2015) shows the significance of carrying out such studies and manage metropolis transport policy properly. Traffic jams are one of the major issues in Warsaw and a significant challenge for its development. Investigating travel time with public transit might give an insight and a potential answer to understanding travel behaviour of the city inhabitants. What is more, expanded analysis of public transport accessibility in Warsaw may make for a strategic tool in creating spatial policy integrated with development of transport infrastructure. It is a significant element of sustainable development, introduction of which may determine stable growth of the city. That is why usefulness and applicability of the data on public transport level may be improved considerably by sharing the data for free. Local authorities, investors, scientific researchers and social activists may produce different types of information from the data and apply it in the realisation of their undertakings. Furthermore, such initiatives may lead to creating information bank accessible for everyone.

There is a noticeable deficiency of district and local centres in the new developments. It may be caused by poorly prepared services programme for the dwellings and the emphasis on the financial effectiveness of the investments. Secondly, the centres overlap transport nodes and well communicated areas. There is no certainty whether the centres emerged first and the transport accessibility was ensured then or inversely. Future public transport policy should be proactively managed in relation with localising new centres. Local authorities also have to take into consideration analyses of scientific researchers such as SARP (Polish Architects Association) and local community suggestions. These sources of information may enrich the knowledge of the authorities about the condition of public transport and possible solutions to its enhancement. Formation of spatial policy in such cities as Warsaw requires equipping every development unit with proper services including public transport system. When the system seems to be insufficient to connect the area with the central part of the city, local and district centres pose a crucial role there. Districts such as Włochy or Ursus confirm the thesis. Although their accessibility to city centre is poor, local and district centres are easily available for the dwellers.

The areas assessed as well serviced are those where the access time to the city centre does not exceed 30 minutes. In other ones the public transport system is characterised as insufficient. Constant occurrence of traffic congestion indicate that public transport in Warsaw may not be enough attractive to combat the problem. On the other hand, ongoing development of metro line is a hope for a change in the adverse state. The problem may lay in the fact that spatial planning in Warsaw is not properly integrated with PT development. The law favours quickly performed investments set to financial benefit of the developer. Therefore, many low serviced areas emerge on the city surface and the costs of equipping them properly become much higher.

Areas with high population density and simultaneously low public transport time accessibility were characterised as low service areas, insufficient in terms of public transit quality. These were parts of the city with great population density, therefore significant in terms of handling a municipality. It is possible to analyze new public transport investments' impact on accessibility of public transport in different city areas. Extension of the second metro line in Warsaw is considered to have a great effect on public transport accessibility in many areas, among which there are many low service areas at the moment. It is very important to extend further studies to suburban areas, since they are housing a large number of people employed in Warsaw.

In conclusion, the quality of public transport poses a significant element of the condition of the city in general. Therefore, the public transport system should be included in spatial policy and integrated with its other components. Then, new dwelling investments would be preceded by the development of transport network. Such order of completion of new dwelling projects may make the process much more effective. The areas of most critical level of public transport accessibility in Warsaw (localised close to the city centre, densely populated, with over 30 minute access time to the city centre) cover the area of the new-built metro line. It may be a partial solution to the problem in those places.

The research presented in this paper shows how crucial for proper functioning of the whole city is well organised public transport. Such studies should be implemented into spatial policy of Warsaw. The scope of the analysis, however, should be extended. Other factors, such as localisation of suburban areas, planned public transport and building investments or new traveling trends, as well as real time data should be taken into account. Enhanced research may help evaluate the condition of public transport in Warsaw more precisely and enable local authorities to implement suitable instruments to improve the whole system.

ID 1683 | RECLAIMING STREETS AS PLACES OF DIALOG: CAR-FREE SUNDAYS IN ISTANBUL AS AN EXPERIENCE OF SOCIAL DIMENSION OF TRANSPORTATION

Kevser Üstündağ¹; Arzu Erturan Topgül¹

¹Mimar Sinan Fine Arts University

kevser65@gmail.com ; arzu.erturan@msgsu.edu.tr

1 INTRODUCTION

In parallel with the economic, environmental and social problems in the world, tendency for alternative and sustainable transportation approaches have increased. As a solution to these problems, people-centred and sustainable transportation policies are developed on the bases of their successful and permanent results in long term. This study, discusses streets as spaces of dialog by focusing on social dimension of transportation. Existing trend changes in transportation, which considers human movements and accessibilities as their focus rather than vehicles are questioned in local scale. In this context, the study introduces experience of Istanbul in Turkey concerning the social dimensions of transportation in order to reclaim the streets as public spaces for dialog. The study conveys the experiences of Carfree Sundays events in Istanbul in order to discuss the reflections of people-centred transportation approach and its socio-spatial effects on streets.

Based on these ideas, "Street Belongs to Us Organisation" was founded in 2010 as a non-profit organization, which focuses on people-centred cities and streets for a livable future in Turkey. This organization was involved in different projects, campaigns, interviews, events, workshops to make citizens aware of the transportation problems and alternatives, different usages of public spaces in terms of peoplecentred and livable cities. The main project of "Street Belongs to Us Organisation Once in a Month" - Carfree Sundays organized by 'Street Belongs to Us Organisation' in Istanbul aimed to produce long-term solutions for traffic culture. In addition to this, another main objective was providing information, governance and communication networks where all the actors of the process are included. Collaboration with other organizations such as municipalities, local residents, NGOs, sponsors, and local initiatives to achieve efficient participatory urban processes was the main structure of this project. This experience indicates that change in transportation can help reclaiming street as places for dialog, interaction and communication as well as a fundamental parameter of transportation network.

2 SOCIAL DIMENSION OF TRANSPORTATION

The city has a complex and comprehensive structure, composed of various parameters. Transportation network connects the relations of all those parameters in functional, economical, environment social ways. Transportation network as a basic connector plays an important role in shaping spatial and social structure of the city. Therefore transportation should be handled not with only physical but also with its social dimension. The fundamental focus in solutions of transportation should be on human individuals and their accessibilities. Within this context, social dimension of transportation and its significance will be discussed under this topic.

Transportation is the function transferring an object, goods or human beings from one point to another. Accessibility is to reach a place, which is the target. The difference between those two terms is important in terms of approach to the transportation. Nowadays, movement of vehicles from one point to another has become an objective; hence that has caused the development of cities being depended upon vehicles. This approach, which is defined as vehicle-centred, although providing solutions in short terms, has not been able to resolve the accessibility problem of the individuals for long term. On the contrary, ignoring the potentials of walking (pedestrians), which is the most original and economical perspective hence it is finishing up the resources of the city. In this model, vehicle is being considered as the central element of movements and it prolongs the durations of trips as well as this model where human scale is underestimated, causes health problems by increasing the noise and air pollutions as environmental factors and finally causing the irreversible destructions. This car-oriented approach has been clearly accepted as unsustainable in transportation literature. This brings us to develop sustainable approaches and solutions for transportation.

The term of sustainability, as a conception, which became increasingly important in world politics and prevalent for transportation policies, represents the effort to fulfil the transforming needs and to present solutions for their complications by moderate and foresighted use of existing natural resources. The concept of sustainability consists of three primary dimensions: economy, ecology and community. Therefore, it can be argued that a sustainable transportation system has to be environmentally - sensible, economical and socially aware. But in sustainable transportation discussions, mostly the social dimension is missing or weak. In addition to this sustainability dimension, in this understanding transportation is realized only by engineering and technical approaches and not being shared by inhabitants ignoring that it is a public service.

Transportation should be handled from social point of view rather than with its physical dimension. Therefore, transportation requires not only engineering field as profession, but also collaboration of different disciplines, administrators, citizens and civic associations. It has to be focused on human being rather than vehicle in searching the solutions for improving the quality of social life, while speculating on long-term study solutions instead of providing solutions for short-term conditions. Such a situation obliges us to produce transport solutions both human oriented as well as sustainable.

In order to fill this gap, new approaches such as 'Organic Transportation', which this paper is based on, have occurred. Developed as an alternative solution for existing problems of urban transportation, the approach towards organic transportation concentrates on human mobility with a special focus on bodyoriented transportation types such as walking or cycling and with regards to tools of mass

transportation and automobile use. Instrumental for creating a sustainable society, organic transportation seeks not only physical but also social transformation in order to attain sustainability. While relying on human-oriented and sustainable approaches towards transportation, organic transportation takes principles of environmental consciousness, social multi-dimensionality and affordability of sustainable transportation into account and is also based upon the principal need for human mobility. Beyond mentioned accounts, organic transportation is influenced by the organic structure of existing network of systems, which enables it to overreach theories and conceptions by being physically present in and alongside current urban structures.

Components of urban milieu to be exact, to provide urban solutions derived from the needs of a city and transform cities into healthy living environments. In accordance to this conception, organic transportation lays its most crucial emphasis on human mobility and passenger accessibility. It promotes public health through the instrumental prevalence of body-oriented accessibility opportunities, whilst encouraging public use of urban spaces through the integration of pedestrians and bicycles into the urban transportation system.

Last but not least, the goal of organic transportation is to preserve and carry the natural, historical and cultural milieu of cities into the future. Organic transportation claims that without social transformation adequate spatial transformation cannot be archived. (Galychyn O., Üstündağ K., 2017).

Organic transportation does not only encompass physical regulations or technical and infrastructural analysis, but it also enhances aspects of management and governance, socio-cultural dimensions, institutional regulations and the enactment of tracking and educational organizations, indicating towards a multi-dimensional and multi-disciplinary process, as shown in Figure 1.

Figure 1: Multi-Disciplinary Structure of Organic Transportation

Organic Transportation approach considering human individual in central position offers equal accessibility solutions for all, which aims to sustain healthy communities and a balanced urban life. Therefore, such an approach considers the accessibility as base and supports public transport systems, as well as giving priority to pedestrians and cyclist in the city.

Considering the individuals who are inevitably join the transportation network in streets as soon as they leave from their domiciles, the importance of individual preferences becomes quite understandable. Each and every intervention in city's transport system has an impact on daily life of individuals. In order to achieve sustainability for the society in this intervention, the individual also resumes some responsibilities. Persistence of personal preference in driving a car has undesirable impact on transportation system of the city. In order to get rid of above described vicious circle, the necessity of creating a social awareness seems rather obvious.

One of the key characteristics of Organic Transportation is locating people in the centre of the solution process and strengthens governance. In this approach, the human being who is the basic subject of transportation – pedestrian in transportation system- has to be included in the process of solution. In addition to this, his/her responsibility in solving the problems becomes rather clear and visible. In order to involve individuals to solution process, street scale in a crucial starting point in this approach.

The street, which is the spatial part of a daily life, is the fundamental parameter of transportation network. Jane Jacobs claims that the streets are the living rooms of the city. In Organic Transportation approach, streets are not only the spaces where accessibility is obtained more so they are the public places where socialization initiates. In other words, streets are public spaces where people come together and create a

place for dialog. As a basic urban unit, streets are our first steps from our houses to the public life. They connect other public spaces to each other and provide a platform for social interaction. Streets are places in which we defend our rights and the key origin for bottom-up actions.

Nowadays streets are left to the vehicles eliminating the human beings hence losing their original public space qualities. In order to reclaim the streets for the use of citizens a process has commenced where by above mentioned, engineering and technical solution are considered together with social dimension. The problematic of regaining the streets by citizens is creating a model which the society is included in the process and is environmentally, economically and socially friendly, to reach the basic objectives of making the city more livable. This need triggered a movement in the world under different names such as Reclaim the Streets, Carfree Sundays, Ciclovía, Own Your Streets (Raahgiri) etc.

The picture above (Figure 2) illustrates an image from Bogota in 2013, and the picture below (Figure 3) shows Mumbai's 'Raahgiri'- Own Your Street events in 2014 organised by Equal Streets Movement. In these examples around the world, it is obvious to claim that there is a tendency for change towards livable and healthy transportation systems. For a permanent change, bottom-up based actions are needed crucially. These actions should involve different decision makers, actors, NGO's, stakeholders in the process of solution. In this context, a success story from Turkey will be given in terms of a bottom-up action for reclaiming streets as a part of an 'Organic Transportation' approach in the following topic.

Figure 2 : Carfree Sunday Events from Bogota | Figure 3: Carfree Sunday Events (Raahgiri) from Mumbai

3 RECLAIMING STREETS AS PLACES OF DIALOG

Cities in the World are shifting their agendas from vehicle-oriented transportation towards sustainable, people-centred approaches and implementations. This change focuses on human scale and starts from city streets and aims to increase the quality of life. This process of change is composed of different components such as economic, ecological, social, political and cultural dimensions. In this context, transportation is no longer just an engineering profession; it has become a socio-cultural discipline at the same time. This point of view led different disciplines to work in collaboration and create new solutions to transportation problems. Within this scope, municipalities, NGO's, inventors, universities and local residents are developing projects.

Based on these ideas, "Street Belongs to Us Organisation" was founded in 2010 as a non-profit organization, which focused on people-centred cities and streets for a livable future in Turkey. This organisation involves in different projects, campaigns, interviews, events and workshops to make citizens aware of the transportation problems and alternatives, different usages of public spaces in terms of people-centred and livable cities. The 'Street Belongs to Us' Organisation is working in collaboration with other organisations such as municipalities, local residents, NGOs, sponsors, and local initiatives to achieve efficient participatory urban processes.

The background of the NGO goes back to 2007. Myself, Kevser Üstündag, have initiated such a first example in Turkey based upon my personal studies at City and Regional Planning Department in Mimar Sinan Fine Arts University. In 2007, this idea has started as a pilot project of '7th Towards World Carfree Cities Conference', which was held in Istanbul. As the social dimension of transportation, "Street Belongs to Us Once in a Month" events were organised in order to reclaim streets for people. In 2010, my colleague Arzu Erturan and a core group enhanced this initiative in order to get a legal entity as an NGO.

The first project of the NGO was an event series named “Street Belongs to Us Once in a Month”. These events had started as the pilot projects of the 7th Carfree Conference in 2007. Events were organized to show people how to reclaim streets as public spaces for a livable neighbourhood and city. The main purpose was to reclaim streets as people-centred places and to show the alternative usages of the street in order to revitalize street culture by closing the street to vehicular traffic for one day. In this context, the main aims of the project were; achieving livable streets for livable cities, encouraging the participation of the local people in the solution process, creating a platform for dialog between different actors, emphasizing accessibility for all, discovering and experiencing alternative modes of public space, creating people-centred public spaces, and spaces specifically for people and not only for cars.

Within the scope of “Street Belongs to Us Once in a Month” events, various activities were organised in order to revitalize street life for different groups such as paintings for children, picnic with neighbours, yoga/pilates workshop for grown-ups, bicycle tours for bikers, music for everyone, street games etc. Figure 4 demonstrates the activities took place on the street. In these events, neighbours had chance to spend time together, communicate and develop or improve their dialog. And Figure 5 demonstrates the change in the street before and after the event. It can be clearly seen that carfree streets provide peoplecentred space to interact, socialize and create dialog between residents and different stakeholders.

Figure 4: Images from Street Belongs to Us Once in a Month Events

Figure 5: Before and After the Street Belongs to Us One in A Month Event in Istanbul.

“Street Belongs to Us Once in a Month” events were based on people-centred approach and aimed to build a governance and communication network that allows a co-solution process of different actors starting from local street residents. It’s a bottom-up movement involving different actors such as municipalities, local residents, NGOs, universities, public institutions, media, civil initiatives and creates a participatory process. By raising awareness of different actors about people-centred streets, these events

aimed to start the change in transportation by strengthening the social actions and active citizenship. These events were organised to inspire other transportation cases to create a bottom-up, participatory process. Main collaborators of the events are illustrated in Figure 6.

Figure 6: Collaboration with different stakeholders

During the organisation of these events, different actors contributed such as Sisli, Besiktas, Kadikoy, Beyoglu, Fatih, Sariyer, Beykoz, Uskudar Municipalities from Istanbul; the Greater Municipality of Istanbul and its Department Traffic, Department of Parks, Department of Gardens and Green Areas; Government of Istanbul. Suat Ayoç Traffic Victims Association, Turkish Traffic Safety Association, Turkey Pedestrian Association, Bicycle Association, Alternative Life Association, The Spinal Cord Paralytics Association of Turkey, Turkey Disability Association were some of the NGO's that have contributed to the events. A radio programme was run by members of the NGO at Acik Radyo (Open Radio) and various brochures were printed to support these organisations.

Figure 7: Images from activities organised at Street Belongs to Us Once in a Month Events

After Istanbul experience, in 2014, 'Street Belong to Us Once in a Month' events' effects spread to other cities and took place in Sinop, a middle-sized city in Black Sea Region of Turkey. In collaboration with Sinop Sustainable Development Association, Sinop Municipality, Sinop Association of Development of Woman's Labour and locals of Sinop, 5 different streets were reclaimed as people-centred public spaces. In 2015, during the organisation of the 6th event, training sessions were organised for the local collaborators in order to enable them and sustain the effect of the events. Local collaborators had successfully completed these trainings and had right to organise 'Street Belong to Us Once in a Month' events in Sinop. This occurred as an important step for the NGO in terms of making a lasting impact.

4 CONCLUSION

The 'Street Belong to Us Once in a Month' events set out principles of good practice for a social action based event in streets with the participation of citizens. These events raised the awareness of street culture, public space and livable streets. They were organised in 12 different streets in Istanbul in collaboration with different municipalities and NGOs. As a physical outcome, three of these streets were permanently changed into pedestrian-friendly streets by the municipalities. Local authorities permanently changed Abdi İpekçi Street, Atiye Street from Sisli Municipality and Iskele Street from Kadikoy Municipality. Abdi İpekçi Street and Iskele Street became more pedestrian friendly with a slowed traffic and widened sidewalk, while Atiye Street was closed to vehicle traffic and pedestrianized. As a result, 'Street Belong to Us Once' was declared as a successful case study by ELTIS¹.

'Street Belong to Us Once in a Month' events raised awareness of local governments and residents about people-centred streets. This can be both seen in the physical change of three streets made by local authorities in Istanbul and social change achieved in Sinop to sustain the events by local NGOs and residents. This indicates 'Street Belong to Us Once in a Month' events have not one day but long-term permanent effects. On the other hand, these events created a platform for dialog between different actors in a city in order to reclaim streets as people-centred places. In addition, it can be deduced from 'Street Belong to Us Once in a Month' that is much more likely to achieve both physical and social changes in transportation when people have opportunities to get involved into to solution processes and be part of a it. As long as city residents are a part of the solution, they will be the closest supporter and follower of urban issues.

ID 1742 | CHANGING MOBILITY BEHAVIOURS IN ACADEMIA UNDER AUSTERITY: THE CASE OF FEUP

Catarina Cadima¹; Paulo Pinho¹

¹CITTA - Research Centre for Territory, Transport and Environment,
Faculty of Engineering, University of Oporto
cadima.catarina@gmail.com

ABSTRACT: The purpose of this paper is to explore how commuting patterns of university students have changed, in face of the recent austerity that has been occurring in Portugal. Our findings based on two surveys carried out in 2006 and 2012 (before and during the austerity period) reveal that students have changed their travel patterns during economic crisis, becoming more multimodal, friendly of public transport and less dependent on private car. Interestingly, the results also indicate that this change on modal choice was particularly significant for distances longer than 8 km. Indeed, in 2012, students travelled longer distances taking advantage of the improvements in the public transport system, namely in the local Light Rail System that was not yet fully available in 2006. On the other hand, transport costs seemed to be able to explain, to a larger extent, the travel behaviour of those who did not use the individual car. In 2006, the main reason pointed out to move on foot was the time and comfort in short distances, whereas in 2012, the main reason was the overall cost of the journey. Although the overall evolution of the students' travel behaviour pointed towards greater sustainability patterns, the identified changes also reveal that the social contexts gained more importance. Keywords: University students, travel patterns, mode choice, private, public and non-motorized modes, austerity.

1 INTRODUCTION

The global financial crisis has had a strong impact, being in Europe particularly serious in peripheral countries such as Portugal, Ireland, Iceland, Greece and Spain (European Commission 2014; Frade & Coelho 2015). This crisis has exacerbated territorial differences between countries and social groups (Eurostat EU-SILC 2013, Martin 2011, Ulfarsson et al. 2015). According to Geels (2013), in political terms, it is understood as the right time to make profound changes in behaviours. It can be an opportunity to make transitions more sustainable, combined with green policies, and also, on a different perspective, the opportunity to introduce "structural" reforms with significant reductions in the welfare state and citizens' rights (Geels 2013). For this reason, one of the main issues associated with this theme is to understand why in some territories the effects of the crisis were felt more than in others (Hassink 2010).

Since mobility is part of the daily life of citizens, it is natural that it has undergone changes with the impact of the financial crisis. A financial reduction in family or personal life's budgets implies an adaptation to the new reality, which includes the need to reduce costs, including those associated to transport. It is recognized the difficulty of changing mobility habits, especially for individual transport users (Garcia-Sierra et al. 2015). One of the main differences in travel behaviour due to the financial crisis has been the reduction of travel frequency (Nielsen 2015), although the travel behaviour depends on the social groups under study (Marquet & Miralles-Guasch 2017). However, adaptations are complex and may include changing modal choice, destinations and residence, among many others. Some of these adaptations may be circumstantial, but others may lead to a change in daily mobility habits (Garcia-Sierra et al. 2015). In this sense, according to Marquet et al (2017), it is necessary to analyse with some caution their impacts not only in geographical terms but also in different social groups (Smith & Swain 2010).

Following the financial collapse in the US and shortly after the beginning of the Greek debt crisis in the first quarter of 2010, in April 2011, the government called in international institutions (the so-called troika, ECB, European Commission and IMF) to bailout Portugal¹. The long-term effects of the economic crisis and the

¹ While the European financial crisis is often presented as a contemporary product of the Eurozone and banking crises, Portugal's specific difficulties are also an outcome of recent and historical factors. According to Moury & Freire (2013) many political actors argue that both the government's right-wing coalition and the "troika" have gone beyond their mandate by imposing so-called "structural" reforms on the country, which severely reduced the welfare state and citizens' social rights.

austerity measures implemented in the recent years have had a strong impact on the economy (Cairns et al. 2014; Cairns 2011; Frade & Coelho 2015; Freire & Moury 2013), for example: growth stagnation, decrease of public and private consumption, the fall of 6.5% in Gross Domestic Product (GDP) between 2009 and 2012, a general reduction in State expenditure (in particular in health, education and social security), an increase of 8% of unemployment (17% in 2013), which most severely affected youth unemployment from 15 to 24 years of age, from 16.6% to 37.7% (Frade & Coelho 2015). As a result, families saw their incomes fall sharply (freezes and wage cuts, significant increases in taxes, rising unemployment), so they had to adjust their budgets and lifestyles and make significant cuts in spending, including the costs associated with transport and mobility habits. Besides the transport measures conducted by the Portuguese government, (e.g. introduction of tax fare on SCUT¹-motorway, introduction of new tariffs on fuel prices rising from 2005 - 1,15€/l to 2012 - 1,64€/l [DGEG]) and the rising price of oil in the world market also led to an abnormal increase in the price of public transport. Frade & Coelho (2015) report that 37.4% of the families surveyed say they have made cuts with transport and fuel (37,4% households who cut spending 2010-2014%).

The economic crisis also seems to have been the cause of the decrease of about 1/3 of the number of students enrolled in private university education in the period 2006 and 2012 (source INE 2014; Cairns et al. 2014) and the increase in the number of students in public universities. It also seems to have been felt in the emotional state of university students, who see the crisis as a disruptive factor for their future, in relation to several aspects such as the possibility of finding employment, of financial independence, of constituting a family and their sense of well being (Cairns et al. 2014, David et al. 2015). Although university students in Portugal are, still, a privileged group, it is possible that these measures had an impact on travel behaviour. Exploring university students' travel behaviour in two different times can reveal fundamental and valuable information to provide better guidance on future practice². Uncovering student's perception and travel mode choices behaviour changes may help us to make preliminary recommendations for university transport demand management in order to decrease car dependency among students.

1.1 UNIVERSITY STUDENTS COMMUTING PATTERNS AND FACTORS AFFECTING THOSE PATTERNS

In recent years, the commuting patterns of university students have garnered increasing attention. The reason for this interest is not only because the study of university students' movements represents a high number of commuting hours in the city, but mainly because they are recognized to represent an important target group in the transformation of behaviours, because they are more prone to change (this is generally the time when they build their independence and begin to make their own decisions) and because they represent the future leaders (Zhou 2012; Zhou 2014; Zhou 2016). Several studies can be found which deal with different aspects of university students' travel behaviour. These include, among other issues, housing and commuting choices (Zhou 2014), use of GIS to visualize and assess travel behaviour (Rybarczyk & Gallagher 2014; Whalen et al. 2013), or promoting a proactive and sustainable university transportation (Zhou 2016; Kaplan 2015). Other studies focused on academic mobility and university policy (Hopkins et al. 2015), and others on the introduction of travel demand measures (TDM) in academia (Bleechmore et al. 2011; Bamberg et al. 2003; Fujii & Kitamura 2003), as well as promoting active mobility patterns (Bopp et al. 2016; Whalen et al. 2013; Shannon et al. 2006). More recently, some researchers focus on the individual, the habit and attitudinal travel behaviour - psychological characteristics (Klößner & Friedrichsmeier 2011; Lavery et al. 2013; Bamberg et al. 2003). Despite the emerging literature, most studies have failed to adequately specify relations of relevant explanatory variables (Zhou 2016).

Moreover, mobility patterns can vary with culture, technologies, characteristics of places, people and other external factors (Crane & Crepeau 1998)³.

1 SCUT – abbreviation of - 'without costs for the users' in its origin

2 For the definition of strategies and political measures it is essential first of all to begin with the knowledge and understanding of the reality that one intends to change

3 For example, Danaf (2014) in their study in Beirut Area, Lebanon, found that safety concerns and context are very important factors, as women university students tend to use more car or jitney, in that sense, cost differences among or

The mobility patterns of a given population are the reflection of this population in the territory, its social and economic-political organization. In the last decades, there have been profound changes in mobility patterns due to the continuous growth of the motorization rate, number of trips, distances travelled, urban dispersion and increased dependence on private transport, which has compromised the levels of sustainability of most urban areas and to become a central theme of the political debate (Banister et al. 2015; Pinho et al. 2015). It is consensual that to influence modal choice, it is necessary to know the factors that justify it. However the literature is not consensual on their identification. Zhou (2016) argues that little has been done to quantify the marginal effects of the factors, which are central when policy-makers design and prioritize efforts to promote alternative modes. An in-depth understanding of the factors influencing travel patterns and the extent to which these measures can change these conditions is therefore a main problem to address. To categorize the main exploratory factors influencing modal choice we will adapt the Cervero's model (2002) with Zhou (2016) and Paez (2004). In this sense, we chose to organize our explanatory model around three broad groups of factors: (i) individual characteristics (ii) characteristics of the trip and (iii) characteristics of the built environment with time contextual variables. The main factors that we used in our study are summarized on Table 1.

<p>Trip characteristics (quality and availability)</p> <ul style="list-style-type: none"> Travel time; Frequency; Costs <p>Individual characteristics (Students profile = traveller socio-demographic characteristics and attitudes/ motivation)</p> <ul style="list-style-type: none"> Age (Cervero 2002) Gender (Cullinane 2002) Car ownership (Sanchez and Arruda 2002; Ewing et al. 2005) and Driver's license for car (Naess 2005) Living arrangement (Zhou 2014; Zhou 2016; Alais et al. 1996) Main transport perceptions and degree of satisfaction (Cullinane 2002; Bamberg et al. 2003) Other external reasons (e.g. safety Danaf et al. 2014) <p>Characteristics of the Built Environment (factors related with campus profile)</p> <ul style="list-style-type: none"> Distance (Shannon et al 2006; Whalen et al. 2013) Pedestrian infrastructure and cycle quality (Rodriguez and Joo 2004) Road system (Baltas 2003; Naess 2005) Network and public transport system (Naess 2005; Lavery et al. 2013) Accessibility (mixture and diversity, transport system available, road system available, information available...) <p>Factors related with Campus profile (basic campus characteristics)</p> <ul style="list-style-type: none"> Location (Mihors and Celliers, 2013; Ewing et al. 2005; Naess, 2006) Size (Ewing et al. 2005) Residence availability for students (on or off-campus) (Zhou 2016; Zhou 2016) Modal choice availability and quality (Naess 2005) Diversity on the activities (e.g. canteen, sports, leisure) (Zhou 2016) <p>Contextual variables (economic/political history and other indicator variables by country and presence of TDM)</p> <ul style="list-style-type: none"> at local level - presence of Travel Demand Measures and improvements on public transport system at national level and global level - economic crisis and important political / economic and historical measures, reforms changes 	Time constraints
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------

Table 1 - The main factors and variables explored in this study that influence mode choice Trip characteristics (quality and availability)

- Trip characteristics. The main factors usually included are time, frequency and associated costs. We also included information about multimodality. Lavery et al (2013) found that active travellers are seldom captive users of a single mode.
- Individual characteristics. The individual characteristics of travellers that are used in the models are gender, age, income and car ownership (Zhou 2016; Zhan 2016; Cullinane 2002), the number of existing vehicles in the household (Danaf 2014) and socio-economic factors such as educational level and annual household income (Naess 2006), being the last two more common in European studies (Klöckner & Friedrichsmeier 2011). Other individual variables explain heterogeneities among university students' transportation behaviour, higher socioeconomic or academic status is linked to a preference towards private transportation, whereas the use of public transport is more common among undergraduates of lower disposable income (Tezcan & Tanış 2011), mostly because of direct cost Barata et al. 2011). Younger students are also more

network grow on public transport may not have impact on mode choice. Although very scarce, data on the evolution of mobility of university students in two or more moments, seem to show a tendency of reduction of the use of the automobile and of the increase of the use of the public transports and the modes (French and Giles-Corti, 2010; Miralles-Guasch, Melo and Sarda, 2009; Marquet and Miralles-Guasch, 2017).

predisposed to alternative modes of transportation (Zhou 2012). Gender divides preferences and concerns, women tend to walk or share transportation (Zhou 2012) while men prefer their own car or bicycle (Delmelle & Delmelle 2012).

- iii. Characteristics of the built environment. The last three decades were rich in empirical studies focusing on the relationship between local physical environment and individual travel mode choice (Pinho et al. 2015). We chose to include in our study the DD of Ewing & Cervero (2010), which are the Population Density (number of inhabitants per km²); Diversity (mix of land uses); Design (connections and interconnectivity of the infrastructure and quality of the pedestrian environment - house vs. college). Distance and Accessibility (distance to destination, available transport system, diversity in route) (Ewing & Cervero 2010). The literature conclude that urban development can significantly influence the ways that people choose to travel (Cervero 2002; Zhou 2016) and the amount of travel by car is significantly higher in suburbs than in city centres (Naess 2005).

Within the characteristics of the built environment we can find in the literature some of the specific characteristics of university campuses. Most studies in the area concluded that the basic campus characteristics that influence students mobility patterns are, without a specific order, campus size, residence availability (on or off-campus), location (rural, suburban, urban), and diversity of activities. At local level we can also find other explanatory contextual factors such as presence of travel demand management (TDM) plans, strategies and programs, class schedules and telecommuting availability (Tomlinson 2014; Zhan et al. 2016; Zhou 2016).

The travel demand management (TDM) can include vehicular restrictions in some streets or parking cost (Shannon et al. 2006), introducing reserved bus lanes and signal priority at intersections, reducing public transport costs (subsidized fares, transit pass, others) operating an express bus service between campus and off-campus areas, and increasing student housing on or near the campus among others (Shannon et al. 2006).

Many of these exploratory factors influencing modal choice can be found in cross-sectional studies. However, in a study over time, there is still a need to include macro social contextual factors (economical/political and historical factors). For example, a war or a natural disaster will naturally generate different mobility patterns, in our study the crisis and the introduction of austerity measures had a great impact on the life of the Portuguese population and should be analyzed. These contextual factors - local, national and global factors, can be very important because cross-sectional data means that the analysis is essentially static, however, a study along time requires space-time changes should be considered (Paez 2004).

This article explores the main changes of commuting patterns of university students from before the financial crisis in 2006 to some years afterwards during the financial downturn and implementation of austerity policies in Portugal (2012). The purpose of this paper is to analyse the main factors that influence those patterns and ascertain their interrelations, as well as the main barriers and motivations affecting transport decision, focusing on the case of students from the Faculty of Engineering of the University of Porto (FEUP).

2 FEUP IN SPACE AND TIME

The Faculty of Engineering at University of Porto (FEUP) is part of the Asprela Campus (AC) and is located at the limits of Porto consolidated city, in the frontier line of three major municipalities of the Metropolitan Area of Porto, Porto, Maia and Gondomar and between three major motorways. This large university with 30,000 students is an important transport activity generator in Oporto Metropolitan Region¹. This university campus is relatively recent, conceived as a 'university city', after the relocation of the old university buildings spread from the urban centre of Porto to this area. The AC enrolls a large number of

¹ This Faculty have no transport policies or other travel management measures like parking costs, students until 23 years old have some subsidies to public transport costs from the Portuguese government.

public and private Institutions, lacking, however, diversity on commerce and housing. AC is one of the largest traffic generators in the Northern region, facing daily high levels of traffic congestion.

In Portugal, as in other southern European countries and some parts of the USA, most university students have no income and rely on their parents to pay for education fees, housing, travel and living costs (Cairns 2011; Cairns et al. 2014). Most students live off-campus¹. In Portugal there is no university accommodation policy and is common for students to live with their parents², which makes the problem of their mobility even more complex. Understand the commuting behaviour of FEUP students means to consider a larger region. The metropolitan area of Porto, the second largest in Portugal, contains a population of approximately 1.6 million people, with 1574 km² area, and a population density around 1016 (hab./km²), and has a polycentric urban structure (Pinho et al 2010:5). Like other metropolitan areas faces an increase in car use (INE, 2011). According to the 2011 Census, in a 10-year period, from 2001 to 2011, car journeys to work or school raised from 44,2% to 62,2% (INE 2011:35).

Big changes happened in the last years, in Porto. Several transport improvements and other planning measures were conducted: (a) at the local level, around FEUP's campus, new residential areas were built as well as new cycling paths, walking paths and a new road with sidewalks connecting with the eastern part of Porto; (b) at the metropolitan level, there were important changes on the public transport system (e.g. metro network improvements with more new lines, a unified ticket to public transport, Wi-Fi real time information at bus stops). We expected that both these measures and the Portuguese crisis would have an impact on student perception and mode travel choices.

3 METHODS

This article explores changes on modal choice, perceptions and barriers in a specific group. Our aim is to understand the explanatory factors that influence the modal choice along time. According to Anable (2005) if we want to built policy measures with effective results these should be designed in relation to specific target groups, which advises for the need of segmentation taking into account different attitudes and travel behaviours. In this way, policies should be oriented to those segments of the population that are more motivated to change and reduce the frequency of car use, thus justifying university students as an object of study.

The target population consisted of 5177 students in 2006 and of 4901 in 2012. Participants were 370 in 2006 and 352 in 2006 attending a University degree at Faculty of Engineering, University of Porto. Participants were randomly selected in order to set a representative sample. To determine sample size, we followed Krejci and Morgan proposal (1970, in Almeida & Freire 2007), that for an error probability less than 5% (with a confidence interval of 95%), for the population (N = 5000) the sample should include at least 360 subjects³ (Almeida & Freire 2007).

A personal survey was designed to provide information about commuting patterns, motivation and barriers for the university students. We designed an anonymous multiple-choice survey focusing on students' mobility mode choices and the reasons behind them, in reference to the day's trip to campus (Cervero 2002; Ewing and Cervero 2010). The survey was formulated considering the three groups of factors addressed⁴. In our study, it was necessary to introduce different contextual scales. It was included

¹ In this sense, it is expected to be verified that the economic crisis had an impact on the mobility patterns of Portuguese university students (Cairns et al. 2014).

² For example, the University of Porto (UP) has 9 University Residences with availability for 1192 individuals, equivalent to approximately 3.8% of the total UP students

³ Selected criteria were students attending the first to fourth years. After proper tuning with a pilot-survey, surveys were stratified among classes in various departments and colleges to get a heterogeneous distribution of degree and course in May of 2006 and after in May and June 2012. We used a sample size and the random process of selection of students for classes, year and course.

⁴ The first section asked about the main transportation mode used on the journey residence-university, if they used more than one, with their used on first, second and third place, identifying how they combined this modes of transport; also were asked time and cost associated with these commuting (modal factors). In the second section, we analyzed accessibility in the residency area (e.g. modes of transportation available, quality of sidewalks, direct bus, main obstacles and other residential amenities), main barriers that students face up on their commuting to campus, and main reasons to choose that transport used. Students were also asked about their degree of satisfaction with the public

important contextual data about changes on the transport system and accessibility¹. In addition to the local context we had to include macro-social data, a more myopic view of reality allows us to consider relevant issues, which in this study is related to the economic crisis and the impacts of measures of austerity in the modal choice of students.

Data was collected and analysed using the Statistical Package for Social Sciences (SPSS). Frequencies and other descriptive statistics were used to describe the sample and identify the main differences between the groups. Thus, this paper uses a Bi-variate and a Multi-variate Analyses in order to examine the relationship between variables. In order to determine differences between stages, numeric variables were analysed using a T-test or ANOVA and categorical variables using X2-test. Estimates could then be calculated separately for 2006 and 2012. A non-parametric test Mann-Whitney was used to verify the degree of satisfaction with public transport, answers were rated by respondents on a scale of 1-5. Only variables that were significantly correlated ($p < .05$) were included in the models.

4 RESULTS AND DISCUSSION

4.1 CHARACTERISTICS OF FEUP STUDENTS CHANGES

The samples from 2006 and 2012 included similar respondents' profiles as shown in Table 2. The respondents are on average 21 years old, ranging from 18 to over 40, and have a gender ratio of 2:1. The majority of the respondents have driving license, (given that 18 is the Portuguese legal age to obtain it), and 40% owns a car, although in 2012 there is a reduction in this percentage. The tendency for owners of personal vehicle to use it is statistically significant ($\chi^2(2) = 80.612, p = .000$). The type of residence is not only important as the social context of the students' mobility patterns, but also because of distance to campus and network availability (Table 3). Regarding students' residence, approximately 2/3 live with family and 1/5 rented a house¹¹. The type of residence is associated with the travel distance – on average, students living with family travel 11 km to campus. The number of students living in a 4km radii is almost the same between 2006 and 2012 (137, 40% to 141, 41%),

However one of the main differences is the number of students living nearer, less than 1km, from university, which did double in 2012².

	2006	2012
age mean	21	21
range	18 - 46	18 - 51
male	67 %	69 %
female	33 %	31 %
with license to drive	79 %	78 %
who own a car	42 %	40 %

Table 2 - respondents' profiles (valid responses)

transport, as prior research provides evidence that attitudinal variables may influence the perception of different modes and, therefore, affect the level of utility that individuals derive from certain aspects of travel (Whalen). Finally, in the third section, respondents were asked questions related to individual characteristics such as: age, gender, car access, driving license, type of residence, residence address and code (GIS)

¹ This is directly related to the characteristics of the local physical environment, and to the thesis that support the premise that a good public transport system brings users. ¹¹ In 2012 there was a slight increase of students living with their families and who rent, partly because the number of students that bought a house dropped (from 13% to 7%). This in part was expected during austerity period, when there were law changes, including in credit approval (Law N°58 and Law N°59/2012) being very difficult to get access to credit housing benefits.

² This can be explained in part because this campus is relatively recent and there is an adaptation period for housing construction and getting into the market rent (private investment) in and around the campus.

Location		2006	2012
< 1km		8%	16%
1 – 4 km		32%	25%
4 – 8 km		32%	25%
> 8 km		28%	35%

Bus station (direct route)	35 %	24 %	
Motorway	39 %	37 %	

a Bird distance, calculated from respondents' postal code of weekday residence.

Table 3 – Demographic profile of respondents

4.2 MODAL BREAKDOWN OF ACCESS TO FEUP

Multimodality doubled from 2006 to 2012, as we can see in Figure 3. When it comes to Public Transportation, metro has gained popularity in 2012 doubling the number of students (16% to 33%), depositing bus (26%)¹. Train is also increasing popularity (10%), despite the fact that there is no train station in the vicinity.

Lavery and Paez (2013) found that people who use active commuting are seldom unimodal. In our study this is aided by the fact that the nearest metro station and the bus hub are at 7 to 10 minutes away from campus (900m from FEUP's main entrance). Thus, these results also confirm as it has been observed in other studies, that university students tend to have a unique travel behaviour, different from the general population and use more alternative modes (Whalen et al., 2013). In Portugal, from 2001 to 2011, car journeys raised from 44,2% to 62,2% (INE 2011:35).

Figure 3 - Frequency of Mode choices when travelling to campus, in mono- and multi-modal trips (percentage of responses).

4.2.1 SHIFTING TIME AND MONTHLY COST

In 2006 home - college travel time was 30 minutes on average, but the high standard deviation (sd. 21,061) suggests a large dispersion around this reference value. In 2012 there was a slight increase in this value to 33 minutes (sd. 23.41). In 2006, students traveling by car were those who claimed to spend the most money on commuting, averaging 60€ per month (s. 50.62, 0-350€), the average travel time was around 23 minutes (sd. 14:27, 1-120 minutes), while in 2012 there is a decrease in the average value spent in the car 50€ (0-150€ N = 101) and travel time for students traveling by car 2012 varied from 2-60 minutes, with an average of 20 minutes (sd.10,43). Students traveling on public transport in 2006 spent an average of 40€ a month (29-150€), and took between 5-125 minutes (sd. 23.51), taking an average of 44 minutes. There was also an increase in the average amount spent on public transport 43€. Meanwhile, the average travel time for public transportation increased to 48 minutes (sd. 23.35, 10-120 minutes).

¹ For this, we present two possible factors – there was an adaptation period after the introduction of metro in the area, after which PT users shifted from bus to metro, and metro has a more regular and dependable service than bus.

4.2.2 GENDER, AGE, DRIVING LICENSE AND CAR OWNERSHIP

Our results revealed that female students tend to share a drive and use public transport more often than male students. This finding is consistent with Zhou (20012) and Delmelle and Delmelle (2012). However, data showing statistically significant differences found in 2006 are becoming only slight differences in 2012, mainly due to male student's behavioural changes. The overwhelming majority of the surveyed students (80% of 370 and 78% of 350) have a driving license. Younger students tend to use more public transportation and older students tend to use more the private car. The tendency is similar in both years, in 2012 out of the 50% students who use public transport, 73% students have a license, as well as 75% students of the 19% students who usually travel on foot or by bicycle have driving license, which means that the vast majority of students who do not regularly use private transport has a driving license. Finally, in relation to possession of the vehicle itself, 42% and 40% responded positively. Access to car leads to its use (Limanond et al. 2011; Klöckner & Friedrichsmeier 2011). The tendency for owners of a personal vehicle to use it is statistically significant ($\chi^2(2) = 80.612, p = .000$).

4.2.3 RESIDENTIAL AREA AMENITIES

To analyse factors of physical environment of place of residence that may influence the mobility patterns of FEUP's students, we asked students about some specific characteristics of their context, given that we had already some data on the destination. Indeed, the access to a metro station has increased, in 2006 23.9% of the students lived in a place with a Metro station less than 400 meters away and in 2012 29%¹. In fact, the number of students using the metro is now much higher, from 16% of respondents in 2006 to 33% in 2012 and from the students using metro only 30% use it as a first mode of transport, 27% go by car (17.4% solo, 15.7% carpooling), 17% catch a bus. From these 17% shifts himself to walk to get to the station and 10% use the train later combined with metro. If we think that sidewalks are one of the ways to get to a bus stop or underground station, we understand that most students have poor conditions either to move on foot or drive to a bus stop, which, as we have seen, were fundamental to the incentive of these two modes of transportation (Zhou 2012). Only 36% of respondents stated that they could use wide and comfortable sidewalks, however, of the respondents in 2012, 49% claimed to have access to these. On the other hand, a similar percentage of the studied population claims to have fast roads nearby. As high levels of accessibility, derived from highways, promote the use of private transportation (Cervero 2002), there is a greater incentive to use motor vehicles.

4.3 STUDENTS COMMUTING CHANGES AND MAIN FACTORS

The dominant modal choice is different from 2006 to 2012. In 2012 the preferred main mode choice was public transport (50%) but in 2006 it was the private transport (44%). Non-motorized modes maintained approximately the same average. The results indicate a statistically significant increase of public transport users and statistically significant reduction in car drivers (Chi-squared tests or Z-test - Montgonery). These results show a tendency of FEUP's students modal choice to become more similar with other research results (Marquet & Miralles-Guasch 2017) and far away from others (e.g. Zhou 2016).

Dependent variables	2006 n=370		2012 n=352		X ²
	n	sample %	n	sample %	
Walk or Bicycle	73	20%	67	19%	
Public Transport*	142	38%	177	50%	*
Private transport	162	44%	108	31%	*

Table 4. Students commuting patterns

¹ The extension of the metro network reflected in the general population has increased the use of this transport. As we referred there were improvements on metro with more lines covering a larger area of influence (from 45 to 69 metro stations). Literature defends that improvements on network public service will increase their use (Shanon 2006). Pinho and Vilares (2009) point out that the introduction of metro helped to reshape the regression process of public transport, although metro also got some bus users.

TRAVEL DISTANCE BETWEEN HOME-FACULTY

The distance is one of the determinants of the choice of transport mode. For students who live at ranges less than 4 km from faculty walking is the preferred mode choice (Table 5). This result is similar to the majority of studies, which indicate that for distances less than 1 mile (1.6km) the preferred way is to walk, however our data show that this distance may be higher depending on other conditions. Distance is an explanatory factor in active commuting (Delmelle & Delmelle 2012). Closer locations (less than 10/20 min.) lead to trips made by foot or bike (Bopp et al. 2011). However, Whalen et al. (2013) found that distance may vary importance depending on distance travelled (Whalen et al., 2013). For distances between 4km and 8 km modal choice possibility is variable, it is distributed between public and private transport. These results, in conjunction with the maps illustrating the spatial distribution of residence, indicate that more than 50% of car use can be shifted by non-motorized or public transport modes, as argued in literature until 5 mile or 8 km is a biking zone (Shannon et al. 2006). In that sense, they are a feasible option for students, however the availability in and near campus free parking gives students comfort and time. In our study, we also observed that for trips over 8km there was a significant change in behaviours, from car use to the use of combined collective transportation. Our data also indicate statistically significant differences for distances over 8km. In 2006 the preferred mode of transport was car but in 2012 the number of students who failed to take the car went down to half, from the public transport clearly being the preferred way.

		travel distance			
		< 1 km	1 - 4 km	4 - 8 km	> 8 km
<i>Walk or Bicycle</i>	2006	76,4%	25,6%	0,0%	,0%
	2012	67,9%	37,6%	6,0%	1,0%
<i>Public Transport*</i>	2006	7,3%	45,3%	59,1%	66,4%
	2012	14,3%	31,2%	45,7%	45,5%
<i>Private transport</i>	2006	16,4%	29,1%	40,9%	32,8%
	2012	17,9%	31,2%	48,3%	53,5%
χ^2				*	*

Table 5 – commute distance and modal choice

Our study also reveals that the average distances from students who walk are different between 2006 and 2012¹. Type of residence is related to distance of travel. Students living in rented housing live near campus and prefer non-motorized. The preferred transport mode for those who rent housing system is still walk, probably because there is more freedom among location choice and modal choice. This finding is consistent with the findings of Shannon et al. (2006) and Lavery et al. (2013). However, Lanzendorf (2002) found that living arrangements and household type were not significant.

MAIN REASONS TO CHOOSE ONE MODE OF TRANSPORT AMONG OTHERS

Cost was statistically the most significant factor between 2006 and 2012 (statistically significant increase), which somehow seems to be associated with the economic crisis (Table 6). Like the research of Delmelle and Delmelle (2012) our results also reveal that male students are more cost sensitive than female students. Public transport is known as cheaper than car, although cost may not be a key factor for changing to public transport and other factors may have greater impact, such as time and comfort. In accordance with literature our results revealed that time is an important reason for mode choice. In both samples time is the most perceived reason to car users. In 2006 for non-motorized was the most important reason too. Journey time by car is perceived to be much less than it may actually be (Beirao & Cabral 2007). Driving is also associated with a sense of control, freedom and accomplishment, is a necessity to maintain the accessibility sprawling urban areas (Lavery et al. 2013; Whalen et al. 2013). Cost and health are usually associated with active modes (Bopp et al. 2011; Shannon et al. 2006), time and comfort with car use (Beirao & Cabral 2007). Conversely, concerns with safety, time and comfort act as barriers to

¹ Naturally, for walking, the percentage decreases sharply with the increase of travel distance, for distances greater than 4km the use of this transportation is virtually nil. The number of students living in a 4km radii is almost the same between 2006 and 2012 (137, 40% to 141, 41%), however one of the main differences is the number of students living near, less than 1km, from university, doubled in 2012. This can be explained in part because this campus is relatively recent and there is an adaptation period for housing construction and getting into the market rent (private investment) in and around the campus.

active modes (Shannon et al. 2006), time and comfort are usually incompatible with public transport and, finally, cost is the main complaint among car users (Tezcan & Tanış, 2011).

We found out in our study that people who do not use public transport seem to have a worse opinion of them than those who use them. In order to verify if the degree of satisfaction differed in both groups (users of public transport and non-users), we used the non-parametric Mann-Whitney test, at a level of statistical significance 5 given that the scale used was ordinal. We found that the differences between the two groups were statistically significant, with the group that did not often use public transportation having a worse opinion ($z = -2,2006$, $p = 0.03$).

	2006			2012			SD
	Walk or Bicycle %	Public Transport* %	Private transport %	Walk or Bicycle %	Public Transport* %	Private transport %	
<i>there is no other option</i>	13,7%	28,9%	7,1%	10,4%	28,8%	13,0%	
<i>cost</i>	28,8%	26,1%	7,1%	56,7%	38,4%	25,0%	*
<i>comfort</i>	12,3%	23,2%	39,0%	32,8%	24,9%	48,1%

(Students could respond more than one reason)

Table 6. Main reasons to choose one mode among others

5 FINDINGS AND CONCLUSIONS

In this paper, we have explored how commuting patterns of university students have changed in face of the recent austerity period in Portugal. We aimed to gain some understanding about the explanatory factors that influence those patterns for that specific group. The crisis may explain changes on mobility needs and created a strong incentive to cut some spending costs on most expensive modes of transport, in particular for longer distances. However, socioeconomic changes alone are not sufficient to explain differences in travel behaviour. Despite the presence of other explanatory factors, the trends seem to indicate a better use of the transportation system available, students are more multimodal and the results give us significant differences among car users. The differences of modal choice have repercussions upon several aspects of mobility, such as cost, travel time and distance to/from residence. This study compares two points in time and cannot support an effective analysis of the financial crisis. However, our results seem to reflect that even if not all groups of students were affected by the financial crisis in Portugal, our research identifies a group of students that have changed their behaviours. This group is characterized by male students living with their families at distances greater than 8km. Cost is pointed out as the main reason for this option.

In summary, our results highlight some relevant findings: we verified that for trips over 8km there was a significant change in behaviour, from car use to the use of combined public transportation. In 2006 students who lived farther than 8km travelled mostly by car with monthly expenses that reached 350 euros. In 2012 these values decreased substantially. Taking into account the large number of Portuguese families who suffered from the impacts of the crisis, forced to make adaptations and changes in their daily behaviour, including mobility, it was expected that some of these impacts would be reflected in part by university students. In our study, a change in the attitudes of male students living with their families at distances greater than 8km is evident. Effectively, there is an increase in the number of students living with their family farther than 8km away from FEUP, which seems to explain a family management option. Other plausible interpretation is that, after the improvement of the metropolitan light rail, students tend to use it (> 8 km: 8% in 2006 had access to metro and in 2012 increase to 15%).

For trips that are not very long between 4km and 8km, car continues to be widely used, which suggests that at these distances the associated cost variation did not justify a change in behaviour. Thus the collective transportation system seems to benefit users on long journeys, but not for shorter journeys. This should allow us to question how we can increase the cost difference between car use and the use of public transport within urban centres, following the general trend in Europe. In our study, we can verify that within the urban zone, the car tends to be faster, and to have similar costs for those who use public transport,

since (at that time) there were no paid parking policies near the Faculty nor other type of 'penalties' for car users, nor, on the other hand, effective networks of BUS lanes¹.

We therefore reaffirm the urgency of implementing such measures. It should be noted that the economic crisis does not affect all users in the same way, the distance for those who live close remains as a consistent explanatory factor, those who live near the Faculty tend to move on foot. However, when questioned about why they are moving on foot, the response changes from reasons of 'speed' in 2006, to 'cost' in 2012, which demonstrates a change in attitude and priorities. Our study also shows that those who opt for a house renting scheme, seek to make it closer to the Faculty, substantially reducing transport costs, not only financial but also time related. However, there is no relevant difference in the size of the group between the two samples. In Portugal, there are no policies regarding the accommodation of university students, so we believe it would be imperative to introduce policies to encourage university students to a leasing system close to universities. Students who normally use public transport on their commuting most of the times combine it with other modes. Furthermore, our study also reveals that people who use active commuting (walking or biking) are more sensitive to the local physical environment. In this way, we should give special emphasis to the attributes of the local physical environment.

Synthesizing, the commuting patterns of FEUP's student are different. Our results revealed (i) Individual characteristics – gender differences have faded, mainly due to male student's behavioural changes, age is still an explanatory factor as well as car ownership². (ii) Trip characteristics - in general students are spending less money on transport, mainly because for longer and more expensive trips students changed from car use to public transport use, although this change was territorial, differences between social contexts gained importance. (iii) Characteristics of the built environment - our results reveal that an improvement on transport system can lead to an increase in its use and distance is an important factor to non-motorized modes of transport. Explanatory factors may vary depending on the mode of transport. Car users seem to favour time and comfort to cost, but our results suggest this may be not true for longer distances when cost became significant. This finding may open a window to introduce some new measures at shorter distances.

We have verified that the factors that justify the use of a mode of transport in a certain period may be different in another period. This variation of explanatory factors over time is important as policy makers must take into account their dynamics in the construction of analysis and decision models. Our study also reveals the importance of taking into account fundamental contextual macro social factors - political-economic, historic and socio cultural. In practical terms this could mean raising awareness of time and different scales of context for policy design, taking into account not only local contextual data but also macro-social ones. Lastly, the crucial question is to know, whether these changes towards more sustainable modes of transport are intrinsic and natural, accompanied by a change of mentalities that incorporates associated advantages such as savings, health, time and quality of life, or whether it is only a direct reflection of the economic situation of the country. In this sense, we consider it particularly pertinent to carry out a new study to investigate, in the current context, if there is a deflection on the use of public transport and a gain in private transportation, or if a more sustainable trend is maintained, embracing the thesis that it is important to test the transport system and improve its image in the public opinion.

¹ In general, the students improved their accessibility conditions to the metro system. Although the proximity to a metro station has increased, this improvement alone is not enough to explain the great adherence to the metro in 2012, especially for distances of more than 8km. It should be noted that the financial crisis had several impacts on the transport system. If buses were penalized by price increases and the reduction of some access lines and schedules, which may partly explain the decline in their use, so did private transport with the introduction of tolls and fuel prices. As a result, they may have contributed to the change to public transport, justifying the change in behavior and benefiting the use of the metro in particular.

² Public Transportation is relatively more used by women, but the differences between sexes are fading. Between 2006 and 2012, female student's mode shares were virtually unchanged and the mode shift is explained entirely by male behaviour.

ID 1743 | POLICIES AND MEASURES TO PROMOTE BICYCLE USAGE IN STARTER CYCLING CITIES: THE CASE OF LISBON

João Marrana¹; Francisco Serdoura¹

¹CIAUD - Centro de Investigação em Arquitetura, Urbanismo e Design
jcdmarrana@fa-ulisboa.pt ; fs@fa.ulisboa.pt

ABSTRACT: The role of policies and strategies in the promotion of bicycle usage in urban transportation is a key subject regarding the future of sustainable mobility in developed cities. This paper's intent is to contribute with a critical review on the meanings and particularities of cycling policies and measures, focusing on their nature, implementation procedure and levels of operability, while exploring their role in the 'future' of urban mobility in cycling starter cities. Hence, a general review of published studies on existent procedures, which directly and indirectly influence bicycle usage, is presented recurring to contemporary peer-reviewed and 'grey' literature. To illustrate the paper's findings and argument, a case study is also presented, focusing on Lisbon's cycling network. Preliminary findings suggest that cycling policies can be described as a set of programs developed with the intent of establishing direct and indirect rules and actions, envisioning the increase of cycling. They vary in both nature (physical, soft, complementary and knowledge measures) and implementation (short-run and long-run procedures), and are particularly effective when developed and executed at a local level. Thus, it can be argued that cycling policies and strategies can play a key role in the promotion of cycling as urban transportation and that the importance of such measures and actions differ per city's cycling development stage. This paper also supports that the success of bicycle usage in cities is strongly dependent on both political will and resolve and on a comprehensive approach, one that provides a coordinated and integrated package of cross-cutting multi-level policies and measures.

KEYWORDS: Cycling, Policy, Measure, Mobility, Urban, Lisbon.

1 INTRODUCTION

The role of policies and strategies in the promotion of bicycle usage in urban transportation systems is a key subject regarding the future of sustainable mobility in developed cities. This paper's intent is to contribute with a critical review on the meanings and particularities of cycling policies and strategies, focusing on both their nature, implementation procedure and levels of operability, while exploring their role in the 'future' of urban transportation, particularly in starter cycling cities. A systematic review of contemporary peer-reviewed and 'grey' literature regarding bicycle usage is presented. To illustrate the paper's findings and argument a case study is also presented focusing on Lisbon's cycling network. Considering the PRESTO Project, which establishes different stages of cycling development per effort and achievement considering existent cycling conditions and rate, Lisbon is presently at its starting point. In result of its car-oriented design and insufficient and disconnected cycling infrastructure the city's daily trips are currently well under a 5% share. To reverse this scenario, the Municipality has been implementing several policies and measures, focusing mostly on 'physical' efforts, overlooking important soft and complementary programs and actions. Our findings suggest that 'cycling policies' can be defined as a package of programmes and measures, used both by public authorities and private stakeholder's, establishing direct and indirect strategies, actions and rules of procedure to increase and encourage cycling as a secure, comfortable and attractive mobility solution, regardless of its purpose. Results also suggest that cycling policies and strategies diversify in nature (physical, soft, complementary and knowledge measures) and implementation (short-run and long-run procedures) being particularly effective when executed at local levels, especially if spatial dimension and territorial dispersion of urban areas is not overlooked in the process. According to Rietveld & Daniel (2004), there is a positive correlation between the development and implementation of cycling measures by local authorities and the increase of bicycle usage. At higher levels, such measures focus mostly on establishing general goals, providing dedicated funding and continued cooperation with lower levels of government. Thus, it can be argued that cycling policies and strategies play a key role in the promotion of cycling as urban transportation and that although there are many ways to increase cycling each city's situation is unique and requires a tailored mix of

policies and measures. This paper also supports that the success of bicycle usage is dependent on both political will and resolve and on a comprehensive, integrated and long range approach where the involvement and commitment of people, public and private actors is of extreme importance.

2 LITERATURE REVIEW: CYCLING POLICIES AND MEASURES

According to Healy (2006), the term ‘policies’ can be understood as an explicit governmental statement, mostly used as guidelines, with the intent of describing the vision and goals that authorities intend to implement. For Portas, et al (2003) such planning instruments should be sufficiently revealing and adaptive in order to provide signs of fresh dynamics, investment opportunities and new dimension requirements, while also establishing coherence at different spatial dimensions and with different authorities and stakeholders.

These should also be consistent with the established rights and responsibilities of both citizens and administrative authorities. Such policies are often designed to respond to a particular purpose or need, during a particular period of time (CROW, 2016). The chapter intends to clarify the role and importance that policies and measures have in the development of bicycle networks, by providing a clear description or their significance by studying their adequate levels of governmental and spatial intervention, and by characterizing both their nature and implementation procedure. In addition, a description of key policies and actions influencing bicycle provision in starter cities is also presented. Discussion will make a critical review on the accuracies and meanings of such policies and actions, as well as a reflection regarding their importance in the development of bicycle infrastructure and promotional programmes. Therefore, a systematic review of contemporary¹ peer-reviewed literature was conducted, regarding policies, strategies and measures influencing bicycle provision in cities which are presently at a starting point of their cycling network development. An analysis of non-peer-reviewed ‘grey’ literature was also conducted, focusing on data published by independent agencies and multi-level government authorities in Europe. To access such information, in addition to public libraries, on-line scientific libraries, such as Science Direct, Web of Science, Google Scholar and Transport Research International Documentation (TRID), were consulted. Website analysis of organisations such as European Cyclist’s Federation (ECF), European Commission (EC) and European Travel Safety council (ETSC) was also conducted. Searches included the following terms combined with bicycle, cycling, bicycling and/or bike: policies, strategies, planning, measures, actions, infrastructures, programmes, communication and training.

2.1 DEFINITION

Although several definitions are provided by experts and academics, they all possess as common feature the fact that ‘cycling policies’ represent a package of strategies and actions which are specifically devised to increase bicycle commuting (Buehler & Dill, 2016; Heinen et al, 2010; Noland & Kunreuther, 1995). For Pucher, et al (2011, 2010) such definition should also highlight the importance of safety conditions when commuting. Additional variations were also verified, focusing either on travel distances (shorter trips), cycling uses (utilitarian and / or recreational), provision of cycling facilities (bikeways and parking), and car restrictive measures (Tsenkova & Mahalek, 2014; Tin Tin et al, 2010; Santos et al, 2010). Furthermore, in order to provide a deeper analysis, both words naming the concept of ‘cycling policies’, were studied separately by accessing respected online dictionaries. The Merriam-Webster dictionary provides several descriptions for the word ‘policy’, namely: “prudence or wisdom in the management of affairs; and a high-level overall plan embracing the general goals and acceptable procedures, especially of a governmental body”. Oxford dictionary defines the same word as “a course or principle of action adopted or proposed by an organization or individual”. Cambridge dictionary refers that ‘policy’ means a set of ideas or a plan of what to do in particular situations officially agreed to by a group of people, a business organization, a government, or a political party. The Encyclopaedia Britannica defines ‘policy’ as “a set of measures or actions (plans, regulations and behaviours) used by a government, a corporation or other organizations, both public and private”. Regarding ‘cycling’ (cycle/bicycling), the Merriam-Webster dictionary describes it as the act of ‘riding a bicycle’ and the Oxford dictionary as “the sport or activity of riding a bicycle”.

¹ Published between 2000 and 2016.

Cambridge dictionary considers it to be the act of “riding a bicycle or related to riding bicycles”, while Encyclopaedia Britannica, defines ‘cycling’ as the “use of a bicycle for sport, recreation or transportation”. Cross referencing all prior descriptions one verifies that although different in content they are in fact relatively similar in concept.

2.2 LEVELS OF INTERVENTION

According to Graham & Marvin (2001), the majority of cities across the world display spaces that are interconnected to other areas within the urban landscape and across national and international distances, forcing us to consider that space and scale are being refashioned in ways that change the configuration of existent infrastructure networks, thus reshaping physical and social environments of cities. Different scales of intervention, jurisdiction and representation hold a key part in the debate concerning the role that public authorities have, or should have, in spatial planning, particularly regarding bicycle network development. For the European Commission (2011) there is considerable potential for increasing the number of travellers using bicycles instead of motorized vehicles in their daily commutes within urban areas. But to achieve such intent, planning practice will necessarily have to consider integrated multi-level policies, strategies, rules and measures, which should preferably be provided by different policy sectors and levels of government (Stead, 2010). There are several concepts regarding spatial or territorial ‘levels or scales’. For Johnston, et al (cited in Marston, 2000, p. 220) ‘scale’ can be defined simply as a ‘level of representation’. Castells (cited in Brenner, 2000, p. 363) believes that ‘scales’ are representative of the different spatial unit’s¹ that constitute the capitalist system, in an attempt to define territorial levels as spatial expressions of social functions. Howitt (cited in Marston, 2000, p. 220), considers that the concept of ‘scale’ holds other distinct aspects namely size, level and relation, claiming that scale should be assumed not as dimension (urban, metropolitan, continental) or level (local, regional, national), but as a relational element, one that is part of a complex mix that also includes the notions of space and place. Such multiplicity of accumulated and enclosed spaces, actively and interactively produce the territories which we inhabit, which we observe and, one may add, which we (re)shape. Therefore, it is intended to comprehend which ‘dimensions’ and ‘levels’ are most suitable considering the development of cycling networks. The concept of ‘level or scale’ was addressed from a governmental and organizational perspective (public and private), considering the following levels of political power: Community²; Central; Regional; and Municipal. The concept of ‘dimension or size’ was analysed from a territorial perspective, considering the following dimensions: European, National, Metropolitan and Urban³. For the past years, several policies and guidelines have been developed at a Community level, with the intent of actively and positively contribute to territorial cohesion and sustainable mobility of member states. In the European Union, there are particular examples such as the Territorial Agenda 2020 (2011), which revises the Leipzig Charter (2007) on sustainable European Cities; the European Transport Safety Council Report (2012) regarding security policies and strategies for bicycle commuting within the European Union; the European Commission Report (2013) regarding the development of sustainable urban mobility plans; and the Declaration of Paris “City in motion: People first” (2015), which defines strategic priorities for future projects regarding transport, health and the environment, underlining the importance of promoting people-centred policies with the intent of facilitating access to inclusive, sustainable and healthy mobility systems. The European Commission is also supportive of the concept that cycling actively contributes to the improvement of urban quality of life and has been increasingly supporting the development of cycling projects (European Commission, 2013, 2011; Van den Noort, 2007). Overall, the European Union has been setting the general framework, providing funding and establishing standards regarding good cycling practices and continued cooperation with member state regions and municipalities (Mircea, 2012; Dufour & Ligtermoet, 2010; Banister et al, 2007). Central governments influence cycling through national policies intended to increase bicycle usage and safety, dedicated funding to regional and municipal governments, traffic regulations, roadway and bikeway design standards, in addition to mass dissemination of cycling knowledge and benefits. However, most policies that increase cycling and make it safer are developed at regional and, in particular, municipal levels, since in addition to having the ultimate responsibility for adopting and implementing specific bicycle infrastructures and programs, they frequently reveal courageous political will and leadership to support and finance cycling for transportation, by pursuing challenging and difficult measures, since, in most cases, people still favour commuting by car (Buehler &

¹ Neighbourhoods, urban cores, metropolitan regions, national urban systems.

² Community’ level refers to supranational organizations, in reflexion to the present European system.

³ European’ dimension refers explicitly to the European Union, while ‘Urban’ represents the city dimension.

Pucher, 2012; Urbanczyk & Laubenheimer, 2011; Blackledge et al, 2007; Rietveld et al, 2004). Despite its relevance and importance, the association between the urban dimension and the municipal level may not produce effective legislation, since regulations that identify and specify the necessary standards may already exist at higher levels (regional or central). Therefore, when necessary, bicycle projects can be developed with the intent of enabling and implementing particular policies by recurring to urban projects which otherwise could not be considered since they had no apparent legal framework (Portas et al, 2003). Moreover, beside these spatial dimensions and governmental levels, the spatial size of cities should also be considered when developing cycling plans. According to Pucher and Buehler (2012), promoting bicycle commuting in large cities¹ is considerably more challenging than in small cities², since in addition to their greater land area, longer trip distances, more extensive transportation systems, heavier traffic, and more noise and pollution, larger cities often comprise more local governmental jurisdictions and thus, additional bureaucratic layers. On the other hand, cycling development in small cities is less challenging for all the opposite reasons. Spatial variation in bicycle use within cities is also an important subject. Cycling rates tend to be significantly higher near centre and historic urban areas, since they are in close distance of important amenities (transport interfaces, university centres and cultural facilities) and social, commercial and service areas, in opposing to outer neighbourhoods (Buehler & Pucher, 2012).

2.3 NATURE AND IMPLEMENTATION

Sadik-Khan & Solomonow (2016) consider that "(...) streets are the social, political and commercial arteries of cities (...)" (p. 3). However, current levels of motorized traffic commuting in such 'arteries' are as undesirable as they are unsustainable (Van den Noort, 2007). Public policies and measures on sustainable transport that until recently had been mostly directed at motorized vehicles are now being 'redirected' to other modes of transportation, namely bicycle commuting. The importance of policies and measures to promote cycling has been steadily rising and is now well recognised by the European Union in addition to local, regional and national authorities. Therefore, the following subchapter will address physical, soft, complementary and knowledge cycling policies and measures, focusing on their nature (push and pull) and implementation procedure (short and long-run). A general framework of programs and actions that positively influence bicycle usage, particularly in starter cycling cities³ will also be presented. According to Santos, et al (2010) physical policies focus on measures of infrastructural nature, and are an indispensable first step in encouraging cycling in starter cities by providing cycle friendly facilities and developing cycle routes and networks (Riley, 2001). In addition to increasing travel safety and comfort, such physical measures signal commitment from local authorities and also send the message that cycling is a respectable and 'usual' way to commute within cities (Dufour & Ligtermoet, 2010). However, no single measure suffices and it is now clear that focusing on cycling infrastructure provision, although important, will not by itself lead to an increase in bicycle mode share (Pucher & Buehler, 2012; Urbanczyk & Laubenheimer, 2011; Van den Noort, 2007). Getting people to commute by bicycle requires a sustained campaign that makes people aware of new choices in result of new infrastructure developments. Coordinated with physical policies, soft policies (Santos et al, 2010; Riley, 2001) have proven effective in stimulating people to commute by bicycle (Pucher & Buehler, 2012; Urbanczyk & Laubenheimer, 2011; Pucher, Dill & Handy, 2010). These are intangible measures intended to bring about behavioural change by publicizing infrastructure improvements and availability, promoting travel awareness, information, special events, training and education programmes. Communication should start as soon as there is a clear commitment to cycling improvement programs, thus providing the opportunity to put cycling on the map, focusing on particular groups, such as students, millennials, recreational users and eco-friendly clusters, among others (Urbanczyk & Laubenheimer, 2011). Furthermore, complementary policies and measures should also be considered, namely those intended to restrict or hamper car use and circulation, discourage car purchase, adopt cycle friendly regulations, design mixed-use communities and transit oriented projects that facilitate the proximity of residential areas to transport hubs, local amenities, commercial and service centres (Pucher & Buehler, 2012; Pucher, Dill & Handy, 2010). Also, the adoption of bicycle use by certain visible professions, such as postal carriers and the police, may contribute to increase cycling visibility and credibility (Urbanczyk & Laubenheimer, 2011). Knowledge policies which emphasize the role of investment in research and development towards sustainable mobility should also

¹ According to Buehler & Pucher (2012), large cities have over 500.000 residents in their metropolitan area.

² According to Handy, et al (2012), small cities are defined as having fewer than 300.000 residents.

³ Cities with insufficient users (mode share under 5%), scarce cycling infrastructure, car oriented road design and absent cycling culture (Urbanczyk & Laubenheimer, 2011; Dufour & Ligtermoet, 2010).

be considered (Santos et al, 2010). Considering the diversity of policies and actions designed to increase bicycle usage, a general framework is presented including some important measures, particularly used in starter cycling cities with the intent to make cycling possible, safe and respectable (see table 1). Regarding the nature of cycling policies and measures, one can consider two distinct yet complementary solutions to achieve a modal shift from commuting by car to bicycle usage (Riley, 2001). Push measures¹, or 'sticks', developed with the intent to persuade people away from car usage by making driving less attractive (allowing to improve cycling competitiveness regarding car travel), and pull measures², or 'carrots', aimed at improving and creating alternative mobility solutions, such as bicycle commuting, enhancing safety, convenience and comfort of bicycle users (Eriksson et al cited in Santos et al, 2010; Kalter, 2007; Riley, 2001). According to Rietveld & Daniel (2004), such policies, commonly used in transportation research, appear to adequately apply to bicycle usage as well. Push and pull measures need to be combined in a mutually supportive package of policies restricting car commuting while improving and promoting the availability and attractiveness of alternatives, focusing on public transport, car sharing, cycling and walking (Buehler & Pucher, 2012; Banister, 2008). Policy combination theory considers that the effects of policies increasingly reinforce each other, so that the total effect of a policy package is larger than the sum of their effects if applied separately (Lautso & Wegener, 2007). Nonetheless, push measures appear to also have stronger impacts than pull measures in bicycle development (Blackledge et al, 2007; Kalter, 2007). The implementation of policies and measures affecting the provision of bicycle commuting and its integration with public transit is a complex process that is being increasingly established (Tsenkova & Mahalek, 2014). For any starter city to adequately promote cycling policies, key factors have to be secured, namely: garner necessary public and political support, commitment and encouragement; determine an appropriate package of policies and actions; ensure a good policy development process³; and devise a tailored mix of short-run and long-run implementation procedures (Pucher & Buehler, 2012; CROW, 2009). For Noland and Kunreuther (1995), long-run procedures are frequently used when employing 'push' policies and measures. Given their sensitive and challenging nature they require careful planning and promotion resulting in a more time-consuming development. On the other hand, short-run procedures, which are usually associated to the implementation of pro-bicycle actions (pull measures), provide a swifter process due to their more direct and less challenging character (Noland & Kunreuther, 1995). The successful implementation of such policies and measures often depends on strong leadership and adequate capability of authorities to integrate the necessary elements for overcoming existent 'traditional barriers' and 'cultural attitudes' on cycling (Pucher, Buehler & Seinen, 2011; Blackledge et al, 2007; Van den Noort, 2007; Rietveld & Daniel, 2004). Implementation also requires complementary efforts from other individuals and interest groups, such as cycling advocacy organizations⁴, in addition to local authorities (Pucher, Buehler & Seinen, 2011).

Table 1 – General framework of programs and measures¹

The integrated and coordinated implementation of incentive and restrictive measures, in association with comprehensive bicycle plans, is crucial in increasing bicycle commuting, and has been associated to the on-going expansion of cycling share, especially in European Countries (Buehler & Pucher, 2012; Pucher & Buehler cited in Tin Tin et al, 2010, p. 61; Noland & Kunreuther, 1995).

2.4 DISCUSSION

The importance of a right set of policies and adequate development and implementation process in cycling promotion is now well recognised, particularly in cities that intend to increase their bicycle share (Pucher & Buehler, 2012; Van Den Noort, 2007). Our findings suggest that such 'cycling policies' can be defined as a package of programmes and measures, used both by public authorities and private stakeholder's, establishing direct and indirect strategies, actions and rules of procedure to increase and encourage cycling as a secure, comfortable and attractive mobility solution, regardless of its purpose (utilitarian or recreational). Such policies are most effective when developed and executed at a local level, particularly if spatial dimension and territorial dispersion of urban areas is not overlooked in the process. At higher levels, such measures focus mostly on establishing general goals, providing dedicated funding and continued cooperation with lower levels of government. The development of policies and measures should be cross-referenced with different government levels and spatial dimensions by ensuring that considered planning systems achieve both vertical and horizontal integration, namely, governmental cooperation and spatial consistency and coherence (Buehler & Pucher, 2012; Banister et al, 2007). In addition, results also suggest that cycling policies and measures may possess distinct, yet complementary, forms and natures, devised with the intent to implement 'encouraging and discouraging actions' to promote bicycle commuting, during a particular period of time, preferably including a tailored mix of short and long-run

¹ This table is based on the European Commission Presto Project - Promoting cycling for everyone as daily transport mode, and work developed by Pucher and Buehler (2012) and Pucher, Dill & Handy (2010).

procedures. Such an effective and integrated implementation requires interactive and participatory processes, where the involvement and commitment of people, public and private actors is of great importance in raising society's awareness regarding sustainable urban mobility, namely bicycle commuting.

3 CASE STUDY: THE CASE OF LISBON

Lisbon has a land area with nearly 100 km² and is home to approximately 547.773 citizens. Such extensive territory is characterized by a large plateau and 15 km of riverfront as well as numerous routes along valleys and ridges (CML, 2013). The City is currently expanding and improving its bicycle network, with the intent of making cycling possible, safe and more respectable. The main goal of such investment is the improvement of both security and comfort conditions during circulation in addition to the reduction of energy consumption, pollutant emissions and noise level. Also, the promotion of cycling as a valid alternative in urban mobility will contribute to elevate the city's quality of life and improve its accessibility, making it more attractive and inclusive. This chapter describes and explains Lisbon's cycling network focusing on its evolution and considered policies and measures. The research method focused on qualitative data, namely literature review of policies, strategies and measures influencing bicycle provision in starter cities and content analysis of reports, public presentations, infrastructural solutions and promotional programs concerning bicycle commuting development in Lisbon, including the city's bicycle network layout. Also, exploratory interviews were conducted with Municipality's advisor and technical staff, responsible for the network development and overseeing. Most used information was provided directly by the Municipality of Lisbon, although additional data was also retrieved from specific websites (Municipality and bicycle friendly association's)¹.

The authenticity of such information as well as the credibility of its source was determinant criterion regarding its assortment and use. Regarding techniques and tools, in addition to observation of documental information, a spatial analysis of the city's cycling network allowed to understand its evolution, hierarchy and bicycle route types. Such analysis provided a better understanding of the intent and level of commitment the Municipality has regarding bicycle commuting. It also allowed to group and study the incidence of the network's bicycle routes typology, thus enabling to understand the level of effort regarding the construction of safe and comfortable routes. These analyses were developed recurring to CAD and GIS software, in addition to Google earth satellite images².

3.1 NETWORK DESCRIPTION AND EVOLUTION

The development of the city's cycling network was analysed considering two distinct moments. The first moment, which began during the year 2000, was a lengthy and complex process. In seven years merely 14 km of routes were built, namely in Monsanto Park, to the west of the city, in the Campo Grande urban park, located in Lisbon's central area, in Telheiras located to the north, and in the Parque das Nações area, located northeast of the city. In 2007, Lisbon was a city without cyclists despite all created paths, making it difficult to justify a continued commitment in this type of infrastructure (CML, 2013). Nonetheless, the municipality resiliently continued to focus on its network continuity and evolution, reinforcing its development dynamic. Between 2008 and 2009 Lisbon expanded the network in approximately 24 km, an increase of approximately 170% regarding the first seven years. Between 2010 and 2014, 26,2 km of new routes were added to the city, namely the river link between the area of Parque das Nações and the downtown historical area. Also, a cycling route was implemented in Avenida Duque de Ávila and Avenida da Liberdade, one of Lisbon's most emblematic and important boulevards. Overall, in the course of 14 years, little over 63 km of cycling network were developed. During this first phase, the focus was in establishing connections between existing green areas and important amenities and infrastructures such as public transport interfaces and university areas (CML, 2013). Of the developed network, implemented between 2000 and 2012, merely 28% were deployed in road areas (roads and parking spaces), with the remaining 72% constructed in green spaces and pedestrian areas (sidewalks). Although not being the

² Images captured between July 2001 and February 2016.

most convenient solution such option was considered valid since during this first phase, which according to the Municipality can be considered as an experimenting phase, the network was developed using a more conservative approach focused on users unaccustomed to travel by bicycle, especially in a system dominated by motorized vehicles. However, in 2013 a different approach began to be introduced (second phase)¹. In addition to the devise of the city's cycling network, the development of bicycle routes gained a fresh momentum and started displaying a different concept, with 63% of all new bicycle routes sharing the road with motorized vehicles, 24% in parks and green areas and merely 13% in sidewalks. Whenever possible, segregated routes were created, particularly in areas with higher traffic volume, intensity and speed (CML 2013). Despite the absence of quantitative data, by 2014, particularly during spring and summer, it was noticeable that more people were already commuting by bicycle (CML 2013). During this second phase, the Municipality intends to create approximately 90 km of new bicycle routes across 142 streets, and approximately 70% of such routes will be completed until 2019 (CML, 2017). Considering this new strategic framework, one that envisions the bicycle as a mobility solution supportive of the public transportation system and focused on utilitarian cycling, a new network layout was designed with the clear intent of increasing bicycle share in Lisbon. This moment, which one could say corresponds to an assertion and expansion phase, is also characterized by an enhanced focus in user's requirements, regardless of their age, gender or experience, and a new hierarchical organisation system. Three levels were considered: Fundamental; Complementary; and Local. The fundamental network intent is to enable daily commutes between the city's different 'core areas' and neighbouring municipalities such as Amadora, Odivelas, Oeiras, Loures and Almada. Considering such agenda, the bicycle routes need to ensure safe, comfortable and functional travels to its users so that they can commute quickly and efficiently. The complementary network has the key purpose of establishing connections between the fundamental and the local network and to important amenities (public transport interfaces, university centres and cultural facilities, among others.) in addition to social, commercial and service areas. The local network intent is to ensure home to work connections, while also enabling easier access to local commercial and service activities. This hierarchical system has a key role since it contributes to the creation of safe, fast and comfortable commutes throughout the city. In addition, the existent network will also be rehabilitated, 250 new bicycle parking areas will be constructed, and a shared bicycle system will be implemented with an estimated offer of 1.410 bicycles, most of them electric, distributed by 140 stations.

3.2 CONSIDERED POLICIES AND MEASURES

The information included in the following subchapter was provided by the Municipality, namely reports and public presentations, but most importantly, it was retrieved from interviews conducted with Municipality's advisor and technical staff responsible for the development, implementation and management of Lisbon's cycling network. Focusing on programs and actions associated with the network's current development phase, these interviews were structured in order to understand the following: Intended agenda (political and technical), allowing to verify if it addresses societal needs and requirements; Policy preparation, focusing on steps taken during the plan's development; Policy decision, namely what type of support and agreements were necessary and secured; Policies implementation process, considering the network's current focus and its envisioned evolution; Compliance tools and procedures to enforce the selected policies and measures; and Evaluation of achieved results, allowing to understand if the considered goals were accomplished². According to the Municipality, Lisbon's cycling network was developed considering a medium to long term political agenda, sustained by both its governmental and technical staff, with the intent of promoting bicycle commuting as a 'new' solution in urban mobility, one that needs to be carefully integrated with the city's present and future transport system, as part of its sustainable mobility and environmental strategies. Its main goal is to increase cycling³, and provide users, regardless of age, gender, travel purpose and experience, with a secure, direct and comprehensive bicycle system. In order to develop its network, in addition to information gathering, different spatial and social analysis were developed by the Municipality⁴, in addition to the development and assessment of different solutions prior to the conclusion of the 'final' network layout. However, during the design phase of considered bicycle

¹ The local authority's government programme regarding sustainable mobility clearly stated the intent to include cycling in its agenda (2013-2017).

² Based on Hoogerwerf & Herweijer policies development and implementation stages (CROW, 2016).

³ The current share is under 1% according to provided information. Regarding intended cycling share objectives, a specific value was not established by the Municipality.

⁴ Traffic network; Land use and constraints; Amenities, commercial and service areas; Public transportation system; Urban morphology; Public space; Terrain model; Master plan and regulations, among others.

routes it became clear that necessary adjustments to the network layout were needed¹. Also, a formal strategic report of the cycling network was not developed, although a draft version was completed by the Municipality's technical staff, a fact that some of the interviewed were unaware. This was a complex process, made of forward and backward movements, which involved substantial negotiation, mostly at a governmental and political level (between deputy mayors offices and local parishes), regarding the concept, route typology and implementation procedures. Regarding the network layout, quorum was definitely achieved, namely regarding the fundamental and complementary network levels. Nonetheless, not all urban projects currently being developed seem to be aligned with the envisioned strategy, presenting questionable solutions regarding cycling routes and intersection design, possibly affecting users safety, directness and comfort, and in the long run, the increase in bicycle usage. Presently the network's development focus is almost exclusively in physical measures overlooking soft measures in particular. Considering both political and technical conditions and momentum, it is conceivable that by 2018/2019 the additional 90 km's of cycling routes will be added to the current cycling network, focusing on its fundamental and complementary levels. In order to ensure the compliance and enforcement of the network's designated objectives, programs and actions, in addition to Lisbon's Master plan, the Municipality possesses as additional tools local regulations and design recommendations and guidelines included in the city's public space design manual. However, additional tools such as communication and information events are not being considered, making it more challenging to campaign for cycling. It is expected that the launch of Lisbon's bike share system may reverse such scenario. Nevertheless, the key question centres on the extent to which the envisioned goals are being fulfilled, and in that regard the results do not disappoint. Although obtained by direct observation analysis, it remains clear even to cycling sceptics that more and more people are now commuting by bicycle. Such finding is also supported by results presented by Lisbon's existent bicycle counter located in one of the city's centres. Data analysis allows us to conclude that regarding a three-month period², this year's values reveal a 60% increase in cycling journeys when compared to those retrieved in 2016. Regarding developed policies and measures, they focus frequently on physical policies (infrastructure), namely: Routes and links design, including several elevated connections; Intersection design, focusing on safety and reducing stop periods for users; Parking solutions, although additional focus is needed regarding the creation of sheltered and guarded parking solutions; and Public transportation, such as allowing users to travel with their bicycles on trains, subways and buses in addition to creating parking facilities at stops and interchanges. Concerning complementary measures, present attention is clearly in the implementation of the city's bike share system. Additional actions such as traffic calming, mixed streets, improving public transportation frequency, and creating parking areas near city's entrances are also being considered. The creation of management policies and measures regarding urban logistics and tourism shuttle transportation is also being assessed. Knowledge policies, namely installation of additional bicycle counters throughout the city, focusing on its centre areas, and the creation of partnerships with local universities with the intent of analysing cycling's evolution and performance are also being deployed. However, as previously stated, soft measures development and implementation is considered to be overlooked, either regarding the number or frequency of promotion, information and education actions and events. Nevertheless, soft actions have already been executed, namely learning and safety programs, events and festivals, safe routes to school, bike to work days, mostly driven by private cycling advocacy organizations working in collaboration or with the endorsement of the Municipality, corroborating the important and active role that such groups have in campaigning for cycling.

4 CONCLUSION

The importance of Policies and measures in promoting bicycle usage in cities is widely recognised by providing positive impacts in cities environment, road safety, health issues, social equity, improved mobility and accessibility, among others. According to Van den Noort (2007), such programs and actions are targeted to correct misperceptions that people may have about cycling and to highlight its positive aspects and benefits in order to increase usage. Lessons learned also suggest that in addition to being most effective at a Municipal level, such policies and measures should be developed and implemented considering a comprehensive and integrated approach, cross-referenced to higher governmental levels and different spatial dimensions, ensuring the involvement and commitment of people, public and private stakeholders. However, no two cities are alike. Although distant from realities of other cycling cities such

¹ Such network layout inconsistencies are in fact a natural part of the spatial planning process (systemic theory).

² From February to April.

as Amsterdam or Copenhagen, Lisbon may shortly increase its current share to values close to cycling cities such as London, Seville and even Paris. Upon its completion, Lisbon's cycling network will have approximately 160 km of routes, representing an increase of nearly 140% in a short period of time. This is a clear demonstration of the Municipality's intent and determination in promoting bicycle usage as a valid and viable solution considering the city's intended mobility system and environmental sustainable agenda. According to the PRESTO Project¹, starter cities such as Lisbon, should have as main goal making cycling possible, safe and respectable, and focus on infrastructure efforts (physical policies) with the intent of developing safe, direct, and coherent routes. Promotional efforts, namely soft, policies, should also be considered, focusing on measures and programs that encourage, convince and reward cycling, in addition to publicizing infrastructure improvements thus providing the opportunity to put cycling on the map and hopefully stimulating people to start riding. Regarding implementation procedures, these should focus on a neighbourhood scale progressing to a city wide network as cycling increases. By cross referencing Lisbon's deployed policies and measures with the PRESTO project guidelines, it becomes clear that in overall the city's network is being developed and implemented in accordance with such recommendations. However, the network's infrastructural efforts started being developed at a city-wide dimension instead of focusing on local neighbourhoods. In addition, important features are being overlooked, namely soft policies and measures focused on promotion, education and information efforts. It is important to increase the understanding of both the public, politicians and the media regarding planning concepts and issues to provide a more clear and tangible knowledge regarding the Municipality's intentions and objectives for its cycle network (Banister et al, 2007). Also, additional and more specific objectives should have been presented instead of a single general goal such as 'increase cycling'. Establishing a bicycle share value to be achieved during a timeframe would allow to more accurately assessing if the intended objectives were being met and why. The inexistence of a strategic report that sets overall goals, details policies and actions to be achieved during a specific timeframe and provides for a comprehensive, coordinated and integrated approach, in addition to the identified inconsistencies in the network layout, makes it difficult to recognize Lisbon's cycling network as an effective planning and compliance tool. Preliminary results regarding the increase in cycling usage are encouraging and future expectations are high. To continue with its cycling progress, Lisbon will have to achieve an adequate balance between physical, soft, complementary and knowledge based policies and measures, set out a vision and a clear strategy and monitor results along the way. It can be argued that real change can only be attained by changing priorities and actions of individuals and by promoting debates regarding what type of cities people want to live in (Banister, 2008). Therefore, two fundamental questions must be placed by Lisbon's public authorities: Are we serious about promoting cycling as urban transportation and what are we willing to continue changing to get there?

ACKNOWLEDGEMENTS

The authors are thankful to the Municipality of Lisbon, explicitly to the Deputy Mayor's offices responsible for Green Structure and Energy and Urban Planning and Public Space, for providing and allowing the use of information regarding Lisbon's cycling network.

ID 1751 | SOCIO-SPATIAL DIMENSIONS OF HOW TO MAKE A CITY BICYCLE-FRIENDLY: THE CASE OF KAYSERI, TURKEY

Muhammed Ziya Paköz¹; Asım Mustafa Ayten¹; Özlem Kevseroğlu Durmuş¹

¹Abdullah Gül University

muhammedziya@hotmail.com ; muhammed.pakoz@agu.edu.tr

1 INTRODUCTION

Traditional transport policies based on automobile usage are regarded as no longer sustainable all over the world and governments are seeking new methods to encourage other modes of transportation such as walking, cycling and public transport. In Turkey, there is a big increase in the awareness of importance of the sustainable and integrated urban transport in the last ten years. Cycling in Turkish cities has also increasing importance both in national and local level. Parallel to this interest, the Ministry of Environment and Urbanism released a new regulation about the design and construction of bicycle paths, bike stations and tracks within the city in 2015. In addition to this, governmental bodies have been carried out a number of projects that aimed to encourage bicycle usage. This willpower has also influenced local authorities to make cities more bicycle-friendly.

Kayseri is a middle-sized Central Anatolian city with approximately one million population. The city has been doubled its population in the last 20 years and it is still growing rapidly. The local government has been built 34 km tramlines and 35 bike-sharing stations within the city and tried to integrate bike stations with tram stops. However, the overall development of the city is still automobile-oriented and the modal share of bicycles in daily commuting is almost zero. There are also safety problems for cyclists in the city.

Within this study, we aimed to examine the bicycle experience of the city from socio-spatial perspective and evaluate it according to the Copenhagenize Index criteria. Within this scope we will firstly reveal the existing condition in terms of bicycle infrastructure and bicycle usage in Kayseri. Secondly we will evaluate the experiences of cyclists in the city. For this, we conducted a survey with 125 active cyclists that cycle in daily base. We asked them both the physical conditions in the city and their experiences of cycling. Finally, we will propose a framework to be able to become bicycle friendly city.

2 BACKGROUND

Cycling transportation in cities is very common today. Bicycle sharing schemes offer a valid alternative cycling mobility in urban areas combined with public transport for longer distances. A lot of research (Pucher, et al., 1999; Pucher & Buehler, 2008; Forward, 2003; McClintock, 2003; Jacobsen, 2003; Pikora, et al., 2003) has extensively examined the role of cycling for transport. These researchers have listed the advantages and disadvantages of biking, and found how it influences the transportation pattern in cities.

There are also benefits for cycling such as ensuring public health in cities, reduced traffic congestion, improved accessibility, better air quality, less noise, lower carbon foot print, costs reduction, education-it helps children improve their physical health and fitness, land use-ten bicycles can be parked in the space taken up by one car. Additionally, Cycling is the most green house gas efficient transport mode. It has created new and huge transportation sector in economically. For example, 21 million bicycles were sold in the EU, in 2014 year.

The use of public bicycles has quickly expanded, although as a newly-developing mode of transportation its related theory and research is still in the early stages and largely focuses on site planning and scheduling, changes to and influence of transportation mode, analysis of the operation model, evaluating user satisfaction, and the characteristics of public bicycle users. (Yang R, Long R, 2016:2)

Meanwhile, There are following policies and programmes concerning with the cycling in Europe. Especially, It is important that The European Union policies on transportation and bicycle programmes in cities. European Union has taken care of the priorities and action plan on bicycle within the public transportation. In 2011 dated White paper, It is called as In this report, It is declared that Individual transport is preferably used for the fiscal miles of the journey and performed with clean vehicles (White paper report:2011:5) Clean urban transport and commuting, public transport choices are more widely available as well as the option of walking and cycling.

On the other hand, EU action plan supported that road safety, air quality, use alternative fuels that best fit their local strategies, EU standards for new infrastructure, continuing the ambition for a model shift towards more sustainable modes. Additionally, EU supports to cycling in cities. (According to Eurobarometer, %7.4 of European citizen used the bicycle as their primary means of transportation in 2010, By 2020 We want to see the level of cycling at %5 of the modal split. (www.eurocities.eu.sustainable, 2015)

The EU has taken an active role in promoting cycling trying to make the best use of this mode of transport by involving it in its efforts to achieve the European 2020 strategy targets. When EU Ministers of transport declared their commitment to promoting cycling as a climate friendly and efficient transport mode. In recent years, two particular features of our society have come to be recognized as serious problems that require urgent action climate change and sedentary life style. (Pape M, 2016:5)

Eurocities network suggested that more funding for public transport, cycling and walking strategies should be available. European commission supports the transition towards cleaner and more performing cities through sustainable urban mobility plans. Meanwhile, European Cyclist Federation announced ECF manifesto interesting with the title ECF manifesto for a call for ACTION 10 key measurement to get more people cycling more of ten in Europe. There are a lot of benefits of cycling as consist of environmental, economical and social. The other legal document as declaration on cycling as a climate friendly, transport mode (European Council, 2015) For cities the visible promotion of cycling through measures such as bicycle share scheme feeds into wider branding strategy. For cities, visible promotion.

There must be increased that strengthen international, national, regional cycling networks. So, It should be integrated cycling to the multi modal transport policy for realising to smart mobility because of improving the urban mobility action plan. For example, EU action plan consists of many items: air quality, use alternative fuels, standards for new infrastructure, strengthening city involvement. Cycle plans should be designed to create networks for destination oriented daily cycling and to encourage cycling demand. For instance, There are still using cycle superhighways, cycle route network, cycle tourism routes in England. On the other hand, This process also should integrated sustainable urban transportation system as well comprehensively. It will lead that minimize energy cost in transportation in economically, ensure healthy living in daily life for every city dwellings, enforcement to social entity and ties in urban social structure. For this reason, Cycle-friendly cities have been planned mostly. Those cities attract investment, encourage neighbourhood revitalisation and can improve citizens quality of life.

It has been observed that bicycle and uses of it in sustainable and integrated transportation systems has increased all over the World. As We know that urban transportation and traffic safety and passes with different transportation modes by urban dwellings. It has existed Which has consist of walking and bicycle transportation integrated with public transportation in cities for urban mobility. Netherland and Denmark cities have top of the cities for cycling. Those cases are suitable cities for efficient use of bycycling. For instance, in The capital city of Denmark as Copenhagen, According to the EPOMM Modal Split tool results in 2012, It has been identified that Daily total trips by users has made %28 by using bycle and has made

%20 walking. According to another research in 2014, (Special EuroBarometer, Quality of Transport 2014) The users mostly prefer the transportation modes that bicycle use has an %8 in totally. And walking as %14. At the same time, different indicators as examined that bicycle use, traffic safety, bicycle tourism, market size, make an advocacy of bicycle riding for European Cycling Federation Additionally, The results of a research in 2014 by ECF (European Cycling Federation) as following as emphasized.

Content	Ranking	Countries
Bicycle use	1 rank	Denmark
Traffic security	1 Rank	Luxembourg, Malta
Bicycle Tourism	1 Rank	Finland
Market Size	1 Rank	Slovenia
Advocacy	1 Rank	Denmark

Table 1: The ranking distribution of cycling parameter for countries
Source: European Cycling Federation publish, 2014

In our metropolitan cities, There are dependent upon car oriented transportation system versus on public transportation system included walking and bicycle transportation. This case has lead to many problems environmentally, economically and socially. In the Ninth Development Plan for the term 2007-2013 the plan, "pedestrian and bicycle transportation would accompany public transport services in a way to allow the establishment of a sustainable intercity transportation system and these modes of transport would be prioritized and encouraged." The Environment and Urbanism Ministry declared a legal document as law that bicycle routes in inner urban roads, bicycle stations and design and construction of bicycle park spaces in 2015. This act only consists of main issues about the bicycle routes stations and design and construction of it. Whereas, What It should be role of walking and bicycle transportation integrated with sustainable urban mobility plans. This kind of plans have realized on measure mobility in cities that priority to pedestrian, not automobile and other mobile vehicles based on. Moreover, Bicycle roads infrastructure are inefficient that commonly no longer and safer for users in big metropolitan cities in Turkey. But, The municipalities have deal with the bicycle transportation integrate to the other modes of transportation.

3 CYCLING IN KAYSERİ: BICYCLE-FRIENDLY CITY?

3.1 EXISTING SITUATION

Kayseri is a rapidly growing industrial city in the middle of Anatolia, Turkey. While the population of the city center was 536.392 in 2000, it has surpassed 1.000.000 people by the end of 2016. The number of university students, academics and tourists has also increased at this period. Today the city is more dynamic and cosmopolitan city, and it necessitates meeting a wide spectrum of needs and expectations of new inhabitants.

More than half of bicycles are available to use in this station
 More than half of bicycles are not available to use in this station

The local government has been built 34 km tramlines and 35 bike-sharing stations within the city and tried to integrate bike stations with tram stops.

KAYBİS bicycle sharing system, which started to operate with 25 stations and 300 bikes in 2010, serves with 35 stations and 600 bikes by 2017 and uses the system 453 people per day (URL-4). The locations of the bicycle sharing stations in the city are seen in the map. As it is seen in the map, if there is available bike in a station, it looks green in the interactive map.

Figure 1: KAYBİS bike share stations (2017)

However, the overall development of the city is still automobile-oriented and the modal share of bicycles in daily commuting is almost zero. There are also safety problems for cyclists in the city.

The bicycle infrastructure of the city is insufficient in terms of bicycle paths and bicycle facilities. There are totally 17,2 km bike lanes and 20,2 km shared paths (bike boulevards) in the city. The government planned to built just 2 more km bike lanes in the near future. The existing bikeways can be seen in the figure 2.

Figure 2: Existing and Planned Bikeways in Kayseri (2017)

3.2 BICYCLE EXPERIENCES: SURVEY RESULTS

We conducted an online survey with 125 active cyclists in the city between the dates of 22.04.2016 and 02.05.2016. With this survey, we aimed to understand their profiles and cycling experiences in the city.

PROFILE: AGE, GENDER, EDUCATION LEVEL, INCOME LEVEL, AND CAR OWNERSHIP

The demographic profiles of respondents also show what kind of people is cycling in a daily base. According to survey results, although there are active cyclists at all age groups, the people who are between 15 and 39 years old are mostly cycling in the city. The gender split reveals an unbalanced situation. Only 14,4% of total respondents are women. It can be easily seen in the city that most of cyclists are men because of socio-cultural background and safety issues.

Education level is another determinant to understand what degree the bicycle usage turned into a 'bicycle culture' in the city. While 36% of respondents are university students, 39,2% of respondents is graduated from a university (undergraduate or graduate level). So there is a tendency to cycle after graduation. Because a big percent of cyclists are students, the income level of 47,2% is seem a bit low. However there are a considerable number of cyclist in middle and high income levels. 39,5% of active cyclists has their own private cars. It also shows that cycling isn't regarded in the city as only a job of poor people who can't afford private or public transport.

BICYCLE USAGE: FREQUENCY, PERIOD, PURPOSE, DURATION, AND PREFERENCE

According to survey results, while half of respondents cycles every day, 32,8% of them cycles at least twice or three times in a week. 56% of them cycles throughout the year both in winter times and summer times. 72,8% of cyclists uses their bicycle as a means of transport in addition to sports and recreational

purposes, and half of respondents cycles each time more than one hour. Cyclists think that cycling is healthy, safe, environmentalist, practical and economic transport mode respectively.

These results demonstrates that despite the fact that the modal share of cycling in daily commuting is almost zero in the city, there is an increasing awareness that bicycle is not only a sports vehicle but also a mode of urban transportation, and it should be facilitated to use them in daily base and in winter times.

BICYCLE USAGE: SAFETY ISSUES

Safety is the most important factor that affects bicycle usage. There should be both individual safety requirements and administrative measurements to protects cyclists. 32,8% of active cyclists says that they had an accident while they are cycling, and 44,8% of them says that they are almost to have an accident while cycling. The first reason is other motor vehicles (57,4%) in the city traffic. The other reasons that the respondents remarked are related with another cyclists, pedestrians, physical problems (sidewalks, walls, city furnitures..etc) and so on.

Especially drivers in the city traffic are the nightmare for the ciyclists because there aren't enough bicycle facilities in the city and cyclists have to use motorways in their trip. So drivers and cyclists come across many times throughout the day.

BICYCLE USAGE: BIKE SHARING PROGRAM (KAYBİS)

Only 18.4% of active cyclists reported that they used the KAYBİS bicycle sharing system. Those who do not use the KAYBİS system firstly say that they don't really need it because they have their own bicycle, when asked why. In addition to this, the other reasons why they don't use the system are the charge system, the long duration of the acquisition of the KAYBİS use card, the location of the KAYBİS stations and the feeling of that the shared bicycles are bulkier and less comfortable than their bicycles.

Respondents basically suggest that the KAYBİS system would be more efficient if there are some arrangements as follows:

- Facilitating KAYBİS card purchases or allowing to rent bicycles with credit cards only
- Increasing the number of bike stations
- Building separated and continuous bicycle paths between stations
- Preferring faster and more comfortable bikes.

MAIN PROBLEMS AND SOLUTION RECOMMENDATIONS

According to the survey results, the most important problem that cyclists encounter in Kayseri is the insensitivity of drivers and the lack of respect for cyclists. The second major problem is the inadequacy of bicycle paths. Apart from these two basic problems, the other issues mentioned are as follows:

- Bicycle roads intersect with motorways/ no separated bicycle path
- Existing bicycle paths occupied by vehicles
- Intense vehicle traffic
- Bus drivers
- Road safety
- Pedestrians and drivers do not respect cyclists
- Car-oriented planning of the city / arrangement of traffic lights according to cars
- Inadequate warning signs
- Bicycle thieves
- No suitable environment for ladies with bicycles
- Bicycle parking problem
- Selection of materials used on bicycle paths.

However, in order to increase the use of bicycles in Kayseri, the following must be done according to respondents:

- Providing adequate physical infrastructure (separated bicycle paths; safe bike stops in city center, in front of health and education institutions, at tram stops, at stations and terminals, in parks; facilitating bicycle transport on trams and buses; signalization...etc)
- Legal and administrative arrangements (regulations to protect bicycle drivers, heavier penalties and sanctions for possible violations of drivers, strict controls)
- Training, promotion and awareness raising (training of bus drivers; hanging posters to raise awareness on billboards at certain intervals; sending SMS to all vehicle drivers, emphasizing that the bicycle is a vehicle and has the right to use the motorway, cycling and awareness trainings in primary, secondary and high schools; festivals and activities)
- Cooperation (Collaboration and cooperation with bicycle associations, NGOs, local and central government units, bicycle shopkeepers)
- Incentives (Providing bicycle users with discounts on municipal cafes and restaurants, allocation of certain streets for bicycle use only one day a week).

BICYCLE USAGE: MOSTLY USED ROUTES

Those who participated in the survey were asked about the routes they used most frequently in cycling in Kayseri and these routes were processed on the map (See Figure 3). As seen in the figure, while the city center and Talas stand out as the most frequent used destinations, Erciyes University and Anayurt are marked as other important destinations. However, it is seen that there are routes used by cyclists both east- west and north-south directions. When this map is evaluated together with existing bicycle routes, the inadequacy of existing roads is once again seen.

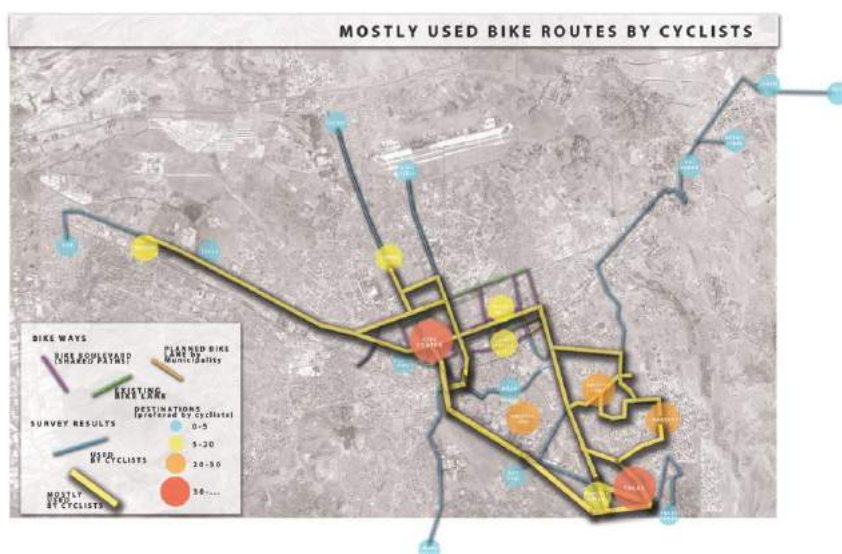

Figure 3: Mostly used bike routes by cyclists

3.3 HOW TO MAKE KAYSERI BICYCLE-FRIENDLY: CHALLENGES AND OPPURTUNITIES

The Copenhagenize index is a system of scoring cities that have strived to adopt bicycles and make them a practical transportation form. The scoring system was developed in 2011 along with James Schwartz, inspired by Monocle's Liveable Cities Index and Economist's rankings.

In this system, cities are scored between 0 and 4 in 13 different categories. In some cases, in addition to these points, 12 additional points can be given to appreciate the extra efforts of the cities. After all, the city with the highest score is selected as the most bicycle-friendly city.

The 13 categories used in the Copenhagen index are as follows: Advocacy (NGO's), bicycle culture, bicycle facilities, bicycle infrastructure, bike share programme, gender split, modal share for bicycles, modal share increase since 2006, perception of safety, politics, social acceptance, urban planning, traffic calming (URL-1)

In this section, the potentials of Kayseri to become a bike-friendly city and the factors that make it difficult will be evaluated according to the above-mentioned 'Copenhagen Index' criteria.

Advocacy: It can be said that the decisive influence of civil society on public policies in Kayseri is weaker than in other cities in Turkey. Nevertheless, it is observed that there has been an increase in awareness on this subject in recent years. Currently there are 10 different associations or groups in Kayseri that are involved in cycling (URL-2). Among them, 'Thursday Evening Cyclists' (PABs) are actively engaged and are working to increase awareness of safe cycling and the spread of bicycle use in the city. However, the impact of these groups on local government is quite negligible.

Bicycle culture: Kayseri offers a very convenient environment for cyclists thanks to its flat topography and wide roads. Nevertheless, due to increased vehicle ownership and car-centric transportation planning, the city is becoming less and less bicycle friendly and the importance of bicycle as a mode of transportation is reducing day by day. As can be seen from the above survey results, the fact that drivers and pedestrians do not respect bicycles and that existing cycling roads are constantly occupied by car owners shows that cycling culture has not developed enough in the city.

Bicycle facilities: It can be easily stated that Kayseri has a long way to go in terms of bicycle facilities such as accessible bike racks, ramps on stairs, space allocated on trains and buses and well-designed wayfinding.

The number of bike racks in the city is very inadequate, there is no safe parking lot to be tried. Although the vast majority of bicycle tracks in the city are now invisible, they have not been renovated. In addition, it is not possible to ride a bicycle on the buses. However, they can carry their bike on the tram, except during peak hours (07: 00-10: 00 and 16: 00-20: 00) and with a one-pass payment for the bicycle (URL-3).

Bicycle infrastructure: As mentioned above, the total length of bicycle routes in Kayseri (including shared roads marked with signs) is 38 km. These roads, which are located only on certain streets in the city center and on a section of the Talas road, show that the infrastructure of the bicycle in the city is very inadequate. When we examine the most common routes used by cyclists according to the survey results, the inadequacy of bicycle routes is better understood.

Bike share program: KAYBİS bicycle sharing system, which started operation with 25 bicycle stations in 2010, is the first urban bicycle sharing system in Turkey. Within 7 years the number of stations has increased from 25 to 35 and the number of users has increased. However, the lack of bicycle routes between some bicycle stations and the problems listed above make it difficult to use bicycles safely. Bicycles can only be rented in April-November period, and they are not in use in winter period.

Gender Split: According to the survey results, only 14.4% of the active cyclists are women. This rate shows that the city needs to provide adequate infrastructure and safe environment for women to use bicycles.

Modal Share: Since there is no available data about modal split in the city, it seems difficult to determine the changes in modal share of cycling over time. However, it is observable that bicycle use has declined in recent years as a mode of transport in the city.

Perception of Safety: Although there is no binding regulation for bicycle safety and helmet use, it is observed that there has been an increase in the use of helmets recently as a result of the work of NGOs.

Social acceptance: Traveling on a bicycle in Kayseri is the most difficult and dangerous type of travel. The reason for this is that both car owners and pedestrians do not care about bicycles and do not give right-of-way. This is the main complaint of the survey respondents.

Urban policy and planning issues: In Kayseri, car-centered planning has been adopted since the 1950s. Especially in recent years, the number of bridges that are increasing rapidly, accelerates the car traffic in the city and makes crossing of cyclists difficult. Cycling-oriented applications such as the signaling system

for bicycles, bicycle bridges have not yet been passed on. Unfortunately, bicycle routes are not designed on newly opened roads, and new routes are planned only as roads and pedestrian walkways. As a result, the car-based planning approach makes the city more difficult and dangerous for bicycles every day. Although there is a willingness to build a bicycle route in the central government, it seems that local authorities' willpower is in the direction of car-centered planning.

4 CONCLUSION

Kayseri, with its flat topography and medium size, is a city with initial advantages for being bicycle friendly. Kayseri, an industrial city, has been designed as a car-centered spatial organization since the 1950s, with the influence of socio-spatial relations originating from the nature of the industry. This process has improved the sprawl patterns of the city against the bicycle, and the bridged junctions built in the city made it difficult to use the bicycle.

The fact that the industrial city's logistics-labor-market relations have put the wheeled vehicles in the forefront has caused that the city's economic power has put pressure on local governments to keep car-centered planning. Eventually, the city is very far from becoming a bicycle-friendly city today.

In this paper, both the existing bicycle infrastructure of the city as well as the results of the survey, which reflects the city experiences of the active cyclists, have been evaluated together with the above-mentioned Copenhagen index criteria. It is very clear that the city does not come to an adequate level in bicycle infrastructure, bicycle use, bicycle culture, planning approach, social acceptance, modal split, and gender split. On the other hand, trends in the world, as well as the interest of the central government, are compulsory for all cities to reconsider the bicycle issue. Kayseri's efforts to get away at least partly from industrial city identity and to become a tourism city require a new spatial organization. It is expected that this new trend will lighten the industrial pressure on the city and open up the investments that will make the city bicycle friendly.

T14 | POLICIES FOR SMART AND CO-CREATIVE CITIES

CO-CHAIRS: FRANCESCO PILLA; PAULO MORGADO

As the world is becoming more urbanized, cities act as magnetic forces, attracting talent, knowledge, creativity and businesses. More than countries, cities will have a leadership role shaping the future and facing relevant challenges.

Besides being spaces of growth, innovation and knowledge, many cities presents a legacy of inadequate infrastructures (transport, sewers, electricity and water supply) and under-investments on social policies to face social exclusion, poverty, gender inequality, ageing, and a lack of public participation, public health and education). Besides traditional problems, new problems are emerging related to global greenhouse gas emissions, climate change, sea level rise and coastal pressure, recycling, domestic garbage, food supply, renewal energy, energy-inefficient buildings). Those are just some of the challenges that cities across the globe are facing today in a context of economical and financial crisis.

Technology plays an increasingly role in our lives. From the ubiquity of smartphones to the world of wearables, nowadays almost everything and everyone is connected. It's a wired world where every single actor, from global companies to a person, are a main data source, observatories in real time of our lives, our houses, our cities, our economy, our quality of live (Towsend, 2013).

Smart cities are data driven; the foundation of any Smart city project (1spatial, 2016, in <http://1spatial.com/campaign/smartcities>) depends on geospatial data, not only for knowing and monitor the needs of the citizens, but also to foresee alternative futures, prepared to face future challenges. Today, cities suddenly have access to big data, but the challenge is to transform this big data in useful data (eg. Intelligence), highlighting the role of advanced geographical models to understand cities in a context of system of networks and flows (Batty, 2013).

For many cities, smart cities model (Smart cities final report, 2007 In http://www.smart-cities.eu/download/smart_cities_final_report.pdf) has been the answer. This means to build a city through a combination of smart economy, smart mobility, smart environment, smart people, smart living and smart governance, being technology, cooperation and competition the driving forces of a better future. City administrations, utility companies along with ITC firms are partnering to explore ways for cities to grow smarter. Along with this technological revolution we are also witnessing a shift in how we should be planning and manage a city.

How to overcome the referred issues, be attractive and still manage inclusion and sustainable growth, but with less resources? In particular, this session seeks papers that engage with the planning and lived realities of Smart Cities, Big Data, IoT, M2M, VGI and PPGIS in Europe.

ID 1645 | A THEORY OF TECHNOLOGICAL CITIES

Milan Martinović¹

¹Faculty of Geography University of Belgrade
milan.martinovic05@gmail.com

1 INTRODUCTION

When two forces unite, their efficiency double.

Sir Isaac Newton, 1687- Approximately

Spatial planners must adapt to the modern way of planning cities. In today's modern world planners play a key role in the development of cities, but on the other hand have equal opponents in the form of policy, regulation, technology, where each individual has a certain role in development. The planner is the one who needs to adapt all the obstacles, to rise above all and successfully directed the planning of the city.

Cities in Europe are the main driving force of the economy and any change of the urban environment can leave severe consequences, both good and bad. It is very important that the planner should be careful and wise with the withdrawal of drastic moves to improve the city. Cities were created with a great goal to provide the best possible life for the population. The modern city for its population should provide good health care, good jobs, education, fast and reliable transportation, a healthy environment, a variety of cultural events, a place for rest and relaxation. Humanity over the next 100 years are expected the era of technology and energy, and we, as planners we have to be ready to prepare our cities through technological and energy development. Late implementation of modern technology can leave major implications on the functioning of cities, such as non-use of renewable energy, which directly leads to uncontrolled consume non-renewable natural resources. The current and future reality of space must be understood as a system in an uncertain environment, the development of which influence tendencies and "breaks" their subsystems and the interactions between them (Dabović, 2008).

Currently, in the world, about 50% of the population lives in cities, and the UN forecasts that by 2050 will reach 70%, and by 2100, 86% of world population will live in cities. Total population by 2100 will be between 11 and 12 billion, and just in cities is expected to live about 10 billion people, so it is important that cities adapt to the future. Our understanding of cities is being transformed by new approaches to the complexity of Sciences (Batty, 2005). One of the main goals of this paper is to activate the cities through technological development, especially cities that are in various indexes are not in the top 50 in the world, who do not have a very high income. Cities such as Belgrade, the capital of Serbia, with its 1.6 million inhabitants strategy must be oriented to the planning of the city with the great help of technological innovation. The energy that surrounds us and which is accessible must successfully collected. Precisely this kind of technological developments in cities such as Belgrade will quickly make progress in the future, and the current position as a medium-developed city can be ranked even better and more powerful in the world's top developed cities.

2 METHODOLOGY

In this paper, for the first time was presented a theory of technological cities. The paper introduces the concept, characteristics, and definitions of the technological city. Also explained the solution to the city to overcome the problem of lack of space for living, through a new vision of urban planning of cities, where a circular belt from the center to the periphery are alternately residential zones and green zones. While heavy and polluting industries ejected from the central and changed with the new modern high residential - business buildings. Regarding the latest technological achievements are represented by the superior technology in the field of transport - trains Hyperloop. The paper analyzed the long-term trend of global warming, for these purposes, data were collected from NASA and is based on an analysis of existing data collected in recent decades, and recent data from 2017. A comparative method was used in comparing Lisbon, Madrid, and Belgrade for daily solar radiation, data were collected from the archives of NASA. The method of analysis and evaluation was applied during the collection of relevant data from the scientific literature, statistical registers. In this paper, one of the prime objectives is to present the sustainable

development of cities in the near and distant future and to answer questions on how cities should be developed in the future with the help of technology.

3 TECHNOLOGICAL CITY: T-CITY

Definition of a technological city:

The technological city represents the sustainable functioning of the population and the nature, which are connected by modern technology into one entity.

Figure 1 - T-city, Residential - business area, Green area, Hyperloop route.

As shown in (Figure 1) the combined system of residential and business areas, green areas and tracks of Hyperloop trains. The current way of building a residential zone that was based on the outskirts of the city buildings lower number of floors, and in the city center we have a very high building. Such an approach leads to the constant expansion of the city due to the increasing population in cities as a result of the lack of places in the city center for the population. An express development of cities and their remarkable functional significance requires a large number of the population lives and works in the city center, a technological cities must be planned to meet the needs of future life and work.

The three lines of Hyperloop trains that will connect the outskirts of the city with the city center. The trains that reach speeds of up to 1200 km/h, will be transporting passengers in the future in an incredibly short time. A combined system of residential and commercial areas, green areas and tracks Hyperloop trains.

T-city (short) as a modern technologically innovative system consists of three zones that circle from the center distributed in the form of residential - business complex with extremely high buildings in each of the three rings (Figure 2, red). This approach construction for the period from 2020 to 2100, provides enough capacity for all residents of the periphery to the center.

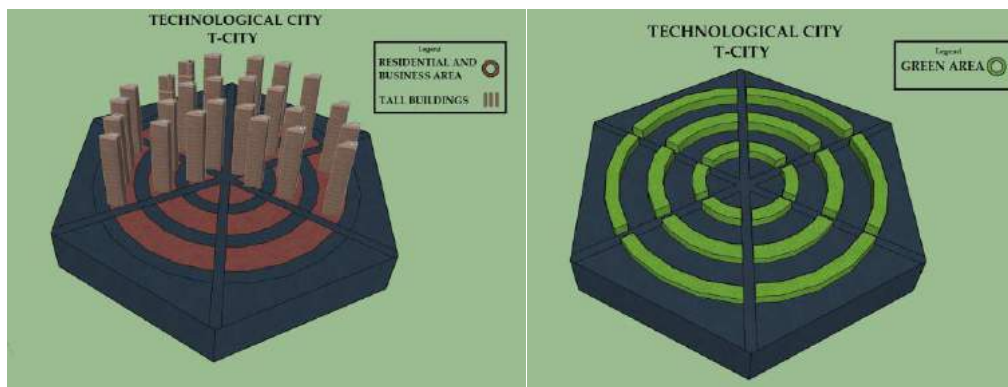

Figure 2 - T-city, Residential and business area. | Figure 3 - T-city, Green area.

Three rings of green belt that would be located near residential and commercial buildings, which would enable the population fast and easy access to nature. This kind of planning green spaces are innovative, and provides all residential - commercial buildings to be between green areas. In doing so, the planning of cities, attention should not be focused only on the construction but must devote a lot of attention to the protection of nature. The spatial planner in the city has two masters, one is population and the second is the nature. Nowadays nature is the one who calls out loudly for help, and we as planners we must not fail to respond to this call.

4 CHARACTERISTICS OF TECHNOLOGICAL CITY

To become a sustainable technological city, it is very important that each segment of the technological development of the city is at a high level.

The technological city is characterized by:

1. A large number of technological innovations.
2. Modern infrastructure.
3. Metro or a light rail system with high throughput capacity, with the remaining synchronized traffic, that is extremely fast and practicable (present). In the future, technology city will adorn Hyperloop trains that reach speeds up to 1200 km/h.
4. The high population density. The high modern building will allow the amortization of a large number of people.
5. Special places on the outskirts of the city that will serve to collect energy from renewable energy sources: solar farms, windmills, solar collectors: MEC (Milan Energy Collector) This ambitious project is expected in 2026-2030 etc.
6. Extremely high modern buildings that are energy efficient, which will in future be covered all over the windows, which will have solar panels installed, all windows will collect solar energy into a single solar system in one building.
7. Digital systems for monitoring all types of changes in the demographic changes, social changes, pollution of air, water and land, economic changes, etc..
8. A large percentage of investments from the budget of the City in the development of new technologies.
9. Transparency between the city, experts and the population, a high percentage of citizen involvement in solving problems. Group and individual involvement in the adoption and implementation of innovative technological solutions that can improve the functioning of the city, as well as public access to all types of information.
10. Flawless land use planning, land that will be a valuable resource in the future.

5 TRAFFIC - CURRENT STATUS AND FUTURE - HYPERLOOP TRAINS

5.1 CURRENT SITUATION

Cities that have not developed their own Metro systems and light rail systems remains largely limited to the requirements of the modern city. High density and a large number of employees in the central zone requires Metro, and the city that does not have built Metro is slowly but surely becoming not sustainable. In the absence of Metro, traffic jams occur, primarily because of a large number of cars, buses, and trams in the city center. On the other hand, cities that have recognized the demands of the modern city and started with the construction of the metro system, 70's, 80's, 90's, have the ability to implement new technology in existing infrastructure (underground roads beneath the city that are dug decades ago). The problem occurs in cities that do not have formed full Metro systems (such as Belgrade), which already has a traffic system unsustainable. Also, investors do not want to invest money in something that can be realized through several decades, and the idea of giving up is on both sides, by investors, and by the management board. Construction of Metro puts the city on the world map, strengthens the business area, contributing to the economic and social sphere, as well as environmental protection. Cities without subway can have a certain development, but lose every race with a serious city in which a metro system in the center of one of the basic components of good functioning.

5.2 THE FUTURE

Hyperloop concept including traffic vehicles like the current speed trains, but in this case transported the goods or population inside the tube, and moving at a speed up to 1200km/h. High speed is the result of the lack of air resistance in the tube and magnetic levitation which eliminates friction from the wheels.

Figure 4 - Hyperloop trains, Source: <https://hyperloop-one.com/>

Hyperloop will probably initially be granted for freight traffic, which will allow the company to demonstrate the safety of such an advanced system. If the system proves reliable then it will go to the transport of passengers. This project represents an exceptional engineering challenge, and one of the biggest problems is the construction of huge vacuum tubes, which must be perfectly sealed, the length of several hundred kilometers. Instead of complete vacuum in the tube, it will only lower the air pressure that can be achieved with standard industrial pumps. The initial budget for Hyperloop is "only" \$ 6 billion, and it is expected that this figure rapidly increased by ten times.

5.2.1 AUTOPILOT 2.0

Self-driving vehicles could reinvent how people live and travel around cities. They could also prompt cities to reconsider whether they even need parking spots. In the development of cars that have automatic control leading company is Tesla, which has the most innovative solutions when it comes to the development of this technology. Tesla vehicles have the hardware needed for full self-driving capability at a safety level substantially greater than that of a human driver. According to the Tesla Company „Eight surround cameras provide 360 degrees of visibility around the car at up to 250 meters of range. Twelve updated ultrasonic sensors complement this vision, allowing for detection of both hard and soft objects at nearly twice the distance of the prior system. A forward-facing radar with enhanced processing provides additional data about the world on a redundant wavelength that is able to see through heavy rain, fog, dust and even the car ahead“.

5.3 SOLAR ROADS

By 2050, energy demand in the world will increase twice. It is because of these problems that await us in the future, we as a society should discuss further how we can take advantage our cities, but not to jeopardize nature, in order to collect the greatest possible amount of energy. The exploitation of the roads as a collector of energy is one of the newer ideas. Roads is everywhere in the world, but they occupy only 10% of the time. According Wattway (2015) to a house fed electricity is enough Wattway 20 m² of solar panels, which are embedded directly in the road.

This pilot solar road is located in a small community in Normandie Turuvr, which has about 3,500 residents. France has started building the first 1km of solar road, with a donation of 5 million euros and thus encourage other countries to invest in modern technology that can lead to positive effects, and that in addition to the environment remains intact. The Wattway company plans by 2020 could lower the price at

the approximate price of ordinary solar panels, noting that the price of solar energy production in just 6 years from 2009 to 2015. reduced by 60%. It is obvious that this is a remarkable technological advance, but it is not currently viable. It is questionable how will road behave during the rain, and how to expect the tire contact under different weather conditions? The original plan of the project is to set up 1,000 kilometers of road, which would cost a lot, even \$ 5 billion. A price per installed watt solar maximum capacities of the road is 17 euros, by comparison, the solar rooftops achieved 1.3 euros and 1 euro on the ground. Simply at this point, the solar road in this way is not sustainable, but it is a great incentive for the installation of new innovative technologies for the common good.

6 SUSTAINABLE DEVELOPMENT OF TECHNOLOGICAL CITIES

Cities in the coming decades have to implement innovative technology to achieve constant sustainable development. During the Climate Convention held in Paris in late 2015, representatives from 194 countries agreed to continue activities to reduce emissions of gasses that cause the effects of "greenhouse gasses". The meeting was held in order to avoid further and greater damage ecosystems around the world due to climate change. They discussed a number of strategy for overcoming this problem, one of them is the transition to renewable sources of energy (COP 21, 2015). The state of the environment in cities is not in a state where it should be. Change of purpose of land in cities is a major problem, the largely agricultural land is converted into construction, green area is almost gone, except for a few small parks in the city center. It is therefore of great importance that cities of the future plan good environmental protection, which would preserve the natural resources that adorn cities in the world. In recent decades, the combination of technology and the development of cities is inevitable, a technological innovation can greatly contribute to improving the current state of the environment. It is very important that good technological innovation systems implemented in cities and have a good think about what type of technology used to exploit the maximum potential of a particular city. The technology is developing rapidly, and if certain city invests a large amount of money, such as solar farms, it is important that the funds invested payments over a certain period, not only the pure economic profits but also "eco-profit" where minimizing adverse environmental impact. Solar energy is clean and renewable energy or green energy, also called clean energy, because its use does not pollute the environment (Stevović, 2016). In addition, if the city decides to solar energy, care must be taken to purchase solar systems tested according to the latest standards, which from day to day have a better result in the collection of solar energy. The progress of science in modern society has contributed to the man mastered various technologies but is pushing the same society as a "risk society" (Jovanović, 2015). In coming period, cities have to adapt to technological innovations to every segment of the city could be further improved, where each denial or deviation from the technology in the development of the city leaves a big lagging behind the other European cities.

6.1 CLIMATE OF CITIES

The combustion of large amounts of fossil fuels in cities leads to the formation of high concentrations of carbon dioxide and the formation of greenhouse gasses, wherein the sunlight is retained in the earth's atmosphere. Increasing the concentration of carbon dioxide in the atmosphere has reached the highest level in the past 800,000 years, which has led to a global average temperature increase of one degree Celsius from the period 1880 to the present. According to NASA, the surface temperature in 2016 was the warmest since modern record-keeping in 1880 (Figure 5).

Figure 5 - Long-standing trend of global warming, Source: NASA

Cities must more decisively to apply all available technologies to adequately reduce unnecessary energy consumption. Some of the ways in which cities can provide sustainability are the following:

1. The use of renewable energy sources – use of solar panels is of great importance for the incredible energy savings, and also for the preservation of natural resources that cities have and more rational use. The solar farm needs to be built on the edges of cities, where land prices is lower.
2. It is important that each city starts with the reduction of electricity consumption, one of the solutions is the introduction of LED lighting as street lighting, which can greatly reduce power consumption.
3. Replacement of old cars that run on gasoline, with new electric cars. Replacement of old buses with new eco-buses, replacing the old dilapidated trains with new Hyperloop trains that reach speeds of up to 1200 km/h, which is expected for 5-10 years.
4. Green roofs on the tops of buildings in cities have a direct impact on cleaner air and a healthier environment.

It is expected that the supply of fossil fuels, as well as non-renewable sources of energy, are consumed in the next hundred years (Šešlak, 2015).

7 DAILY SOLAR RADIATION

For the purposes of this study, an analysis is made to the potentials of the following cities: Lisbon, Madrid, and Belgrade, with the aim to show that Belgrade does not lag behind too much for the cities that largely use solar panels and take advantage of solar energy. When mentioned solar energy in Serbia, it is immediately thought of South Serbia as a great potential, but from a given graph can be concluded that Belgrade has enough energy that could be collected, and that the lack of solar panels is just an excuse. In order to compare the potential (Figure 6) of cities to collect solar energy, studied the data received by NASA (the National Aeronautics and Space Administration). Calculating the amount of electromagnetic energy (solar radiation) on the surface of the Earth.

Figure 6 - Daily solar radiation - Lisbon, Madrid, Belgrade, comparative overview Source: NASA, Chart – author.

From presented three cities, Lisbon has the highest potential daily solar radiation, which is the highest level in the period from May to August, with a maximum in June of 7.26 kWh/m²/d. Madrid in every month of the year has a slightly lower that are approximate to Lisbon. While Belgrade expected in the third place, the maximum in July of 5.97 kWh/m²/d, but still have sufficient amount of solar energy that can be collected.

8 GLOBAL ENERGY POTENTIAL OF RENEWABLE ENERGY SOURCES

It is very important to know the accurate and reliable data on how much each state has a capacity of renewable energy. In the following charts (Figure 7,8,9) is displayed the 15 leading countries that have the greatest potential of renewable energy in the world. The paper analyzes solar energy, wind energy, and bioenergy.

Figure 7 – Solar - Renewable Energy Capacity top 15 Country, Source: <http://resourceirena.irena.org>, Chart – author.

China is the leading country when it comes to solar energy with exceptional 77.433 MW, Japan with 41,609 MW and Germany with 40,987 MW almost equal second and third position.

Figure 8 – Wind - Renewable Energy Capacity top 15 Country, Source: <http://resourceirena.irena.org>, Chart – author.

As wind energy is concerned, China is also in the first position with 148.641 MW, United State of America is second with 81,311 MW, while the best ranked European Country is Germany, which has a capacity of 49,747 MW.

Figure 9 – Bioenergy - Renewable Energy Capacity top 15 Country, Source: <http://resourceirena.irena.org>, Chart – author.

The top five countries stand out when it comes to the capacity of bioenergy, the first is Brasil with 14,179 MW, followed by the USA 12,458 MW, China 12,143 MW, Germany 9,336 MW, and India with 9,185 MW.

These data clearly show an extremely large amount of energy available. Some countries that are ranked lower, can boost the particular country to advance in the segment in which lags behind competing countries in the region. The cities are epicenters of the economy and such resources must be used in the best possible way to get more energy from renewable energy sources, and thus save natural resources.

9 T-CITY

Each technological innovation can contribute to a better, healthier, and more beautiful life for the residents in the technological city. Further in the paper are described briefly my two original technological innovation, which can contribute to improving life in the city. First innovation is large and the second is small scale, precisely this difference in size tells how both small and large technological innovations can contribute to the development of the city in the future.

9.1 MILAN ENERGY COLLECTOR – MEC

The first one is a big and ambitious project called the Milan Energy Collector, a collector that collects solar energy through the multiplication of sunlight through the latest innovative lenses. The resulting overall energy is many times greater than a conventional energy collected by ordinary solar panels.

Figure 10 – Milan Energy Collector - MEC | Figure 11 – Milan Energy Collector - MEC

The collector consists of a large number of special lenses that are lined one above the other and in the end, solar energy is collected into a special generator.

The generator has a moveable front part, there is installed a sensor that monitors the intensity of the sun's rays and rotates to exploit the maximum potential of the sun's rays.

9.2 KEEP WALKING

Second technological innovation is very little, approximately is the size of a credit card. This is a sensor that detects movement of cars in the open building entrance, and an audible signal informs the population that passing along the street to avoid traffic accidents with cars coming out from a buildings output.

Figure 12 – Keep walking sensor

This is a technological innovation that can save people from injury. In my street, which is a few hundred meters long, there are more than 5 of these open passages through which the cars coming out from building. Both technological innovations are in the process of developed, which should be protected by a patent.

10 CONCLUSION

In recent decades, modern period brings with it a large number of technologically advanced systems that are being implemented in developing cities to become a more functional city. If in the city center, we have one good thing - a large number of technological buildings, and many negative things - a lot of traffic congestion and a lack of energy, whether we can then only after a one positive parameter classify a particular city as a technological city? Of course not, it is necessary that each segment of the technological city works seamlessly with to the modern technology used for energy, environmental monitoring, use of the latest technology in order to improve and modernize transport, all cars should switch to electric drive, to contribute to the reduction of air pollution in cities. Can Belgrade become a technological city?

Daydreaming or potential feasibility in the future? Belgrade has the potential to be in the next few decades (2030-40) closer to the technological cities. To achieve such an ambitious goal, it is a lot of investment in all aspects of development. Beginning in the infrastructure, transport, environment, quality of land planning, making better laws and regulations, construction technology modern buildings that are more energy efficient, the implementation of digital systems and monitoring of all segments of development, pollution, large investments in technology systems. The impact on the movement of climate change in cities to a large extent has a society, and that anything could change in the future, it is necessary to include more technological innovation that can have a positive impact on improving the current situation. The sudden use of energy in the world has raised concerns about supply and exhaustion of energy and resources, as well as a heavy impact on the environment: ozone depletion, global warming, climate change. Transport in urban areas is one of the leading polluters, a strategic city should direct a change in the automotive industry to eradicate polluting fuels and to move on cars driven by electric power. Eko buses that do not cost a lot more than just old buses can also contribute less to air pollution. Hyperloop trains that should work in the coming period, can greatly change the way population movement and transport of a large population in a short time and certainly brings benefits in the economic and the ecological sphere. Now is the time to plan the future.

This paper is dedicated to my professors.

ID 1673 | A CLOSER LOOK INTO HOW LAND-USE, SOCIAL NETWORKS AND ICT INFLUENCE LOCATION CHOICE OF SOCIAL ACTIVITIES

Vishnu Baburajan¹; João António de Abreu e Silva¹

¹Instituto Superior Técnico

vishnu.baburajan@tecnico.ulisboa.pt ; jabreu@tecnico.ulisboa.pt

ABSTRACT : Technology now enables individuals to travel more flexibly, thanks to ICT and the numerous social networks. The choice of location for social activities has become very flexible, sometimes allowing changes to a previous decision on the move. In addition to this, the characteristics of the residential and

university location also play a vital role in the choice of location for social activities. It would be quite exciting to uncover the behavioral patterns associated with these decisions. Hence, this study pursues the following objectives: 1. to analyze the influence of ICT, social networks and land-use characteristics of the residence and university in choice of location for social travel. 2. To analyze the similarities and dissimilarities in the choice of activities pursued during weekdays and weekends. Students from the two different campuses of Instituto Superior Técnico were presented with an online questionnaire, intended to collect information about the use of ICT and social networks, in addition to the travel characteristics and socio-demographics. Emphasis was made in capturing the characteristics of social networks and ICT usage. Information on the land-use characteristics was later obtained from secondary sources. Factor analysis was initially carried out to extract factors related to use of ICT and social networks, which were to be later used in the model for choice of location. The alternatives considered for location choice include: location within 800 m from the residence, location within 800 m from the university, locations away from home and university and evenly spread locations. The analysis was performed separately for travel during weekdays and weekends, to understand the differences and similarities in behavior during these different time periods. A multinomial logit model was estimated to model this choice. This adds to the literature, the understanding of influence of use of ICT, social networks and land-use characteristics, in the context of social travel.

1 INTRODUCTION

Advancements in technology has made travel more flexibly. This can largely be attributed to the growing popularity of Information and Communication Technology (ICT), smartphone penetration and social networking sites. The use of these can have different effects in travel, such as substitution effects, complementary effects and peer pressure in travel decisions. For example, the use of smartphones might help do away with some of the shopping trips, but might as well induce socializing activities. Social trips are increasingly being scheduled using social network applications (WhatsApp, Viber) and websites such as Facebook. This makes it important to analyze the impact of these in travel decisions. Compared to the past, individuals are now presented with a wide variety of choices. This will have significant effects in the travel patterns of students, especially university students for whom, these provides a conducive environment for a more flexible travel. University students are also important considering the widespread penetration of these gadgets and the ease with which university students get acquainted with these emerging technologies and gadgets, compared to other age groups.

This has changed the way people travel. With the increasing use of smartphones and internet, individuals can now request taxi online through services such as Uber, Cabify, Lyft, etc. With most of the public transportation systems across the globe developing mobile applications and websites that provide information to make travel convenient, individuals can now use public transportation better. In yet another instance, the widespread popularity of social networking sites, now enable individuals to plan social trips easier and in groups. The location choice is now being increasingly made using these mobile applications. Individuals make decisions en-route making it difficult to understand location choice and specifically that of social activities. This is because, the location of workplace or university is usually predefined and thus, the importance of social travel. This paper, focusses on the influence of ICT, social networks and land-use on the location choice for social activities.

The objectives of the study are, 1. to analyze the influence of ICT, social networks and land-use characteristics of residence and university in choice of location for social travel, 2. to analyze the similarities and dissimilarities in the choice of activities pursued during weekdays and weekends. The analysis is carried out using data from around 500 students from two different campuses of Instituto Superior Técnico. Data was then processed and the location choice had the following four levels, viz., located within 800m from the residence, location within 800m from the university, locations away from the residence and university and evenly spread locations. Factor analysis was initially carried out to extract factors related to the use of ICT and social networks. These factors were later used in the specification for the location choice model. Considering the nominal nature of the variable, a multinomial logit model was estimated separately for choice during weekdays and weekends.

Exploratory analysis indicated difference in choice between weekdays and weekends. To understand this further, models were estimated and the factors influencing the choice were identified. It can be seen that socio-demographics (age, gender, etc.), land-use characteristics (road capitation), social networks

3 DATA DESCRIPTION

For the study, data corresponding to use of ICT, social networks, travel data and socio-demographics of students from two campuses of Instituto Superior Técnico (Alameda and Tagus Park) was collected using an online survey. Though data was collected from around 700 students, after accounting for incomplete records, data from only around 500 students could be used for the analysis. Land-use data from secondary sources were later linked to this data.

The common practice is to evaluate the destination choice using a single day activity diary. This could sometimes lead to underestimating of recreational trips. Individuals seldom undertake recreational trips on a regular basis and hence by collecting a single day activity diary and estimating models using this data could lead to potential underestimation of recreational trips. To overcome this, in this study, individuals were asked about destinations to which social trips were made in the past week, separately during weekdays and weekends. We believe, this will help address this potential underestimation to a great extent.

Figure 1 Shares of Destination Choice

The above figure illustrates the location choice shares in Lisbon, among students. Unlike the conventional approach, we have adopted a different definition for location choice. The main rationale for the following definition is that most of the activities by university students are anchored around the university and school, during weekdays. It can be observed that, most of the activities are pursued around the university (school) during the weekdays, whereas during weekends, most of the activities are undertaken at locations other than residence or university.

4 METHODOLOGY

The first objective of the study is to identify the influence of land-use, ICT and social networks on the location choice of university students from the two campuses of Lisbon. To achieve this, variables depicting land-use characteristics, use of ICT and social network were collected. Some of these variables were later reduced to factors using factor analysis to ensure parsimony and ease of use and in the estimation of models for location choice and to make behavioral insights. As has been mentioned previously, an alternative definition has been adopted for location choice variable. Considering the nominal nature of the variable, multinomial logit model has been used.

The second objective relates to the identification of similarities and dissimilarities in location choice, between weekday and weekend. As can be observed from the exploratory analysis in Figure 1, there is a significant difference in the choice of destination, between weekdays and weekends. This analysis will try to understand the factors contributing to this difference. This could be due to some socio-demographic factors, land-use, use of ICT, social networks or simply due to the difference in availability of time. This can be identified by estimating separate models for weekdays and weekends.

Multinomial logit model has been widely used in travel demand models, in modelling choice of mode, route, destination, to name a few. The models are based on the principles of utility maximization. The simplicity in use, estimation and interpretation have resulted in widespread use of MNL. Interested readers

are advised to refer to the following { (Ben-Akiva & Lerman, 1985) and (Koppelman & Bhat, 2006)} for more information related to MNL.

5 MODEL ESTIMATION AND DISCUSSION OF RESULTS

As has been mentioned in the third sections, four levels are considered in the analysis for location choice, which includes within 800 meters from residence, within 800 meters from university, elsewhere and even distribution of locations. Location within 800 m from the residence has been considered as the base alternative. Considering the need to analyze the factors contributing to the difference in choice preferences between weekends and weekdays, separate models for location choice has been estimated.

Table 1, given below presents the estimation results of the analysis. The coefficients and the statistical significance of the estimated variables have been presented. As a convention, symbolic representation of the statistical significance has been used. Further, some of the variables have been included, even when not statistically significant, to avoid instances of false negativity.

The goodness-of-fit measures have been summarized below the coefficients. In this particular analysis, it can be observed that the rho-squared values are 0.17 and 0.16 for Week Day and Week End respectively. Alternative specific coefficients have been estimated for the models.

5.1 WEEK DAY

Gender has a negative effect, indicating that men are less likely to prefer locations close to the university, in comparison to areas around the residence. This is the same for students of age between 30 and 40. Considering the need to pursue work after studies, students who are employed full time have lesser priority for choosing locations close to university. When close friends reside nearby, the location for social activities is more likely to be around the residence, as social activities are usually dependent on close friends.

In an effort to probably reduce the inconvenience associated with travel, students belonging to large families are more likely to pursue activities near the residence. This could possibly be because the activities are could also be family events. When close friends stay in the neighborhood, the preference is similar to that of pursuing activities near university. As expected, with increase in road capitation, the likelihood of pursuing activities in other localities decreases.

Again, gender has a negative effect on consider locations evenly distributed. This could be because women are less likely to travel during weekdays considering their responsibilities at home. The same is the case with students who are full time employees. And this could possibly be because of their inability to pursue social activities during week days at locations away from their residence. The residual time available after mandatory activities (university and work) will be limited.

5.2 WEEKEND

It is worth mentioning that, close friends living in the neighborhood has an effect in the choice of location of for social activities during weekends. The choice of a location near the university has a negative preference. This is probably because, with more close friends within the locality, it might be convenient to pursue social activities within the neighborhood. In this case, the role of use of instant messenger is interesting. The variable indicates decreasing levels of instant messenger use during weekdays and weekend. Decreasing use of instant messenger use during weekdays has a positive influence in social activities near university during the weekend thus indicating the role of instant messenger as a substitute for social activities during weekend or as scheduling mechanism for social activities (scheduling for activities during weekend, during weekdays). And, with decreasing use of messenger during weekend, there are fewer social activities during weekend near university, which probably indicates the use of instant messengers in scheduling. With more number of acquaintances, there will be fewer social trips during weekends. With increasing access to vehicles, there will be more social trips in areas near university.

With close friends staying in the locality, there is lesser probability of students pursuing social trips at any other place, other than near university and residence. This could probably be because, social activities undertaken by individuals are dependent on close friends. With them in your locality, the need for pursuing the same away from residence is not necessary. However, if the friends are within the same municipality, away from the locality, it can be seen that, individuals are more likely to pursue these activities elsewhere.

For students aged between 20 and 30, any location is equally preferable. This can be associated with the greater flexibility associated with this particular age group. They also may not have family to take care and hence can plan travel easily. With more close friends in the close vicinity, there could be fewer social trips in other locations. And with more close friends within municipality, social trips are more likely to be pursued in other locations. With decreasing use of social media during weekdays, lesser social trips are pursued in areas away from residence during weekends. This could be because individuals might resort to use of social media during weekends.

	Variable	Week Day	WeekEnd
Near University	Constant	4.48***	-.33
	Age is between 30 and 40	-1.31640***	
	Gender	-.69***	
	Full Time Employee	-3.07***

6 SALIENT FINDINGS AND CONCLUSION

This study analyzed the location choices of students from Lisbon. As has been mentioned previously, the destination choice of the individuals have been defined based on the distance from the residence and the university. This is considering the fact that the location of these mandatory activity locations play a crucial role in deciding the locations of social activities.

It can be inferred from the analysis that the factors influencing the location choice of students during weekdays and weekends are different. This is both, in terms of the variables that influence and also based on the coefficients of these variables, when present in both cases. In terms of socio-demographic variables influencing these decisions, it can be observed that age, gender, employment status and household size plays a critical role in location choice. Further, the access to vehicles are important in the case of social activities during weekends. For trips during weekdays, presence of close friends in close neighborhood is a contributing factor. Whereas for trips during weekends, presence of close friends within the municipality

and use of social media and instant messengers also influence the location choice. Only the land use characteristics such as road capitation, emerged to be significant in this study.

It would be important to understand this behavior further, with the use of variables that can capture the land-use characteristics in more detail. This could possibly be the reason for the comparatively poor performance of the proposed models and hence needs to be explored. It would also be important to use other discrete choice models.

1 SPACE AND GENDER

The finding, on the one hand, that the future of cities will have important social and economic consequences due to an urban design implemented by information and communication technologies and, on the other hand, the gender perspective as the principle chosen to support social and economic progress based on equality in Europe (Horizon 2020, article 15), prompts us to propose a study that integrates a gender analysis and research around parameters and variables of the innovative design of the city's public space.

The question about the ways in which the genre of the subject modifies the conceptions and representations of (public) space is an indispensable question. In a previous publication we made reference to the more performative and interactive feminine behaviour in comparison with the typical ontological metaphysics of the masculine "fact" and the authorship (Trachana, 2012: 121-122) The current work of the woman is diluted in the family, in the group. Its essential condition is that of an off-centered

subject, of an extended body, of "being" in front of the central myths, of "the action that resists acts" (Agamben, 1998). The performative behavior is closer to manual craft than to scientific attitude, and is imbued in the action-reaction time, in everyday life within a given context where implication and commitment acquire an important dimension. The ways to interpret space and to create relationships in space are, consequently, a subjective and critical positioning. Their way to act, we maintain, is through an instinctive knowledge. This implies an awareness of the environment in which sensations and reflections, images and concepts can be correlated. It is a kind of biological and anthropological knowledge, which involves the senses, desires and physical limitations. This type of experience of the reality constitutes a cognitive state much more complex than rationalism, than the dominant capitalist and masculine thought.

Another classic theme -supported by feminisms- is that of the relations between the public and the private (space). The dual configuration of polis and oikós, from the Aristotelian politics constitutes the starting point of a genealogy of the feminine confinement in the domestic space. For this reason, the struggle for emancipation had to be, first and foremost, an appropriation of what was denied to women or a vindication of the deficiencies that women were supposed to have so that they could be considered as subjects worthy of a forbidden space.

Contemporary literature has dealt extensively with the relationship between space and gender and particularly with the theme of public space on the subject of biopolitics and the categorization of the public and the private¹. Women crossing the threshold from private to public space, the "unique" route of women in contemporary public spaces, the oppression and representation of the feminine, the patterns that followed the associationism and political activism of women, the changes in the structures of domination and their particular conceptual verdicts have all been helpful themes not only to redefine the notion of gender but to regulate a social body and, at the same time, to eradicate a harmful construct of what gender is. That is a way of breaking with the illegitimate tie between biological sex and gender, which, in fact, does not guarantee the achievement of the desires for individual emancipation. The study of rich and powerful women, transgressors and rebels, slaves and prostitutes ... who differently crossed the threshold of the domestic sphere to circulate in public spaces with different vehicles, with different speeds, with different companions, leads us to consider "the idea that the private space had functions that went beyond what was simply domestic"(Huguet and González Ed., 2008).

The first International Congress on Gender and Space organized by the UNAM (April 14-17, 2015) revealed the different expressions of gender inequality that persist in the use and appropriation of spaces, especially in Latin America; also the persistent inequalities regarding the visibility of women in the public space and the gender violence; the conditions of working women, but also the transgressions and resistances, the expressions of appropriation of the public space; the trespassing as well of social spaces, the effective capacity that the female subjects have to transform the meaning, the conventional uses and the heteronormative and gender logics of certain social spaces. The investigation and presentation of all these categories have once again supposed a vindication of non-hegemonic subjectivities whose experience of different spaces is articulated in a different way. In so doing subjective positions different from the dominant one were made patent, as well as different possibilities of living and inhabiting the space-time continuum.

According to Foucault (2009), social space is not a "kind of emptiness", it is rather a framework of social relations that define orders, emplacements, attitudes and displacements. That space, in which "the erosion of our life, our time and our history" develops, only acquires sense and meaning from social assumptions and relationships. It is place for games of power and domination, for a symbolic and imaginary framework that incessantly turns it into a lived, imagined and regulated space. The complex relationship between gender and space can only be explained by the incessant intersection between both categories; by the constant intersection in which such variables get mutually constituted and form a social reality with palpable effects on social interactions, emotions, affections, displacements, daily activities, identities, resistances, transgressions, confinements and locations, stays, sojourns and rhythms.

To decipher tensions, gaps and beaches, to detect the emergency of changes and creativity and to give way to a conception of physical space with characteristics linked to the contemporary modes of production of space, it is necessary to endow the term with meanings that combine symbolism, intersubjectivity ,

¹ The Journal *Astrágalo*. Cultura de la Arquitectura y la Ciudad, v.5 published in 1996 the monograph , Space and Gender ("Espacio y Género").

variability and corporeality. Today we speak of an “augmented space” because of information, of a multisensorial confluence of the spatial and temporal dimension that produces favourable hubs for the study of different meanings, and that can reflect both, daily and ritual complexity. Undoubtedly, in the last decades urban social life has become incomparably more complex than anything known so far: social exchanges, use of time, forms of mobility and communication have been modified. Among these transformations, perhaps the most notable and emblematic, according to Remedi (2000), is the substantial modification of social space, the spatial organization of inequalities, social isolation, the context as a breeding ground of tensions between extreme forms of tradition that bind to the past, and a modernization that is expressed in a leap of scale in multiple aspects of urban life, leap that has to do many times with the use of communication and information technology.

2 CARTOGRAPHIES OF THE NEW URBAN COMPLEXITY

2.1 AS A RESULT OF WOMEN'S REVOLUTION

The need for the existence of a public space where to meet and be present to contribute to the development of healthy communities is a key dimension to promote an innovation of the traditional and institutionalized methods of how to make city and overcome the model of globalized urbanism. What does globalized urbanism consist of? The model of globalized urbanism holds the fear of the others and the refuge in private life (Borja, 2005). The concept and belief that it is possible to contain the world in the house and in the neighborhood, as well as in its complements - the motorway and the automobile - are simultaneously the result and cause of a new way of organizing the urban space and of relating in this space.

It is, therefore, a question of making new approaches to the built environment, augmented as a result of information and communications policy, without falling into the concept of 'smart cities' as mere business and political marketing in the hands of companies dedicated to technological products. In this technological realm, in fact, the differences are accentuated and the fear of the others is manifested by giving priority to surveillance and security. It is also manifested by means of technological endowments in areas of high economic and consumer level in contrast with what happens in popular neighborhoods, and also what happens in urban centres in contrast with the periphery. Technological devices are used by those who have the means to acquire them, what gives them access to specific formation. But the key question with regards to the implementation of smart cities is how to improve the standard of living and the coexistence by optimizing the collaboration of technological means and investigating inclusive and non-exclusive modes and applications. Before that it is necessary to study the attitude of men and women towards technological changes and the perception and use of ICTS by ones and the others.

In a former publication we studied the consequences of the revolution of women in the second half of the twentieth century (Amann, Trachana a.o., 2013). The traditionally accepted dichotomy between public space and private space has been demolished while the house has progressively got emptied of contents as the city has become more complex. Whoever kept the house and cared for the family has slowly entered the public sphere of the social so that the 'family', with its traditional meaning, is no longer the only reference for the organization of the space as, nowadays, issues of the private and the public get intertwined with identity issues till forming a new indivisible theoretical-empirical construct.

In the Arendtian social sphere activities related to pure survival appear in public (Arendt, 2005, p.65). There is a philosophical tension that is aimed at emptying the philosophical separation between public and private (...), which aims to displace the hierarchical construction of binary logics (Scott, 1990, 42). The maintenance of the public and private dualism not only hinders the historical understanding of sexual roles and their stereotypes, through categories attached to separate compartments in which the cultural abstractions mask both, their identities and their relationships. They also despise the possibility of instability and change throughout life. And if the boundaries between the public and the private are now dissolved, the city must be analyzed as a multidimensional system and face the urban space from the same conditions of complexity and diversity observed by Jane Jacobs in the 60's. "The main responsibility of urban design and planning should be to develop cities that are ideal places for the flowering of wide ranges of plans, ideas and opportunities ... to generate diversity and to attain its maximum potentialities" (Jacobs, 1961).

It is, therefore, essential to update cartographies of urban life so that alternative proposals can be proposed for the design of the city. The urban demand is now as complex to determine and satisfy as the existence of a great diversity of users. It requires a comprehensive multidisciplinary analysis that addresses both the socioeconomic, sociocultural and geographical aspects as well as consumer behaviors and value systems and preferences associated to lifestyles and the capabilities of each one. It is no longer a matter of solving spatial functionalities that divide the city into zones, as we were taught by modern urbanism. It is a matter of superimposing layers of information and generating new atlases of urban habitability.

Women's revolution and their incorporation into the labor market has not only had obvious sociodemographic consequences such as the delay of the maternity age and the decrease of the birth rate. There has been a fundamental change with regard to care: the abandonment by women of activities related to the care of the domestic space, the inhabitants of the house and especially the dependent groups formed by children, the sick and the elderly, which has seen its number increased in an aging population. At the same time there has been a growth of single households and other forms of coexistence and communities have emerged: from the emergence of Airbnb and elderly people communities, to the cohabitation of university students and the elderly, and other innumerable formulas. There have been profound changes in the labour structure due to unemployment, precarious work, reduced working hours or moonlighting. Immigration from countries in developing economies, the growth of female immigrant caretakers who have been introduced into homes or the migration of young south European people to the north are just a few brushstrokes to add to the new map of the city. All this represents new space-time relationships and trajectories of life and coexistence in cities.

From the sociocultural point of view, a renewed assessment of the leisure time, with a greater diversified consumption of entertainment joined, in many cases, to a body culture, have generated different space-time relationships that are incorporated into the daily schedule of the citizens. All those who can, within all segments of the population, dedicate some free time to go to the gym in the case of adults, attend extracurricular activities in the case of the youngest, and walk urban distances and do physical exercise in equipped parks, in the case of the elderly. This concern for healthy life and exercise also influences a change in eating habits which, in turn, have consequences both, on the preferences of consumption as well as on the supply of the different consumer centres.

These are just some obvious references that point to a paradigm shift and that need both quantification and also relative evaluation. From the paradigm of the functionalist city of the Athens charter - organized on the basis of standard functions, standard families and a society of certain homogeneity and certain gender roles - to a city with very diversified functions and uses and that is experienced from a subjective point of view. The incorporation of ICT in everyday life is, undoubtedly, a factor that contributes substantially to the space-time perception. This has implications in everyday life, family, relationship between genders...in learning, the self-assessment of personal and social life in relation to a specific habitat and the degree of spatial identification with the public space. The representation of a world that can be controlled by technology constitutes an imaginary and, in this sense, we need to explore how, in fact, artificial intelligence can affect urban life. With this technological revolution the fundamental question around new patterns of planning and city management is posed. How can we overcome globalized urbanism, create pleasant spaces for urban life, manage inclusion and citizen participation in a project in which quality public space for the citizens coexistence and principles of urban ecology, sustainability and resources saving are taken into account? Indeed we need to explore ways in which cities can develop more intelligently.

There is an obvious need to study the paradigm shift in the forms of artificial environment production based on a real and diversified demand versus the market offer; to study the demands in the urban space as a complex system of capacities, activities, means and requirements and to generate cartographies of the daily life that allow to elaborate a programmatic sheet for the urban project; to respond with the new enabling technologies to the challenge of building an augmented environment by defining the requirements for the design of systems that address the diversity and complexity of the new patterns of habitation; to research around the smart applications and the modalities of affection of the subjectivity; the experience of the smart city and its implications in everyday life.

The fundamental key of the pending research is to locate the constraints and perspectives of building places, territories and relationships for greater inclusiveness and equity, what means fostering a new

imaginery of everyday community life where confidence and identification with the place are promoted. And that compromises a gender perspective in the reflection. How can technological implementation contribute to reinforce integrating social dynamics, propose a multi-functional urbanism that favors diversity and social mix and an urban design that reinforces the collective life as already argued the legendary Jane Jacobs in 1961? To design from a gender perspective means to design for the diversity of people and collective situations, for solitude and for meeting for intimacy and for the community.

2.2 AS A RESULT OF THE TECHNOLOGICAL REVOLUTION

Nowadays the space where we develop our lives is, indeed, an augmented environment, a technologically implemented space that produces profound effects on multiple areas of communications, knowledge and life experience. The perception of the body-space-time-language, the understanding of what constitutes the conception of the ways of being in the world, the others, relationships, education, socialization, work, health ... are mediated by the digital technology (such as presence or absence). This is an important moment to re-examine the situation of women in a restructured environment through the relationship between science and technology "(Haraway, 1991, 165).

ICTs bring with them a change in the line of thought according to which relationships are conceived in the city. Its networking pattern logic implies a de-hierarchization and a potential horizontality of the processes and, at the same time, a much more nourished information exchange. This feature, coupled with other conditions of our time that include a series of questionings in the foundations of social disciplines, makes of ICTs an interesting element, object of monitoring within the framework of the current city. From the point of view of the information and communication technology it would fulfill the dream of democracy and freedom, access to information to which all citizens are entitled and the possibility to promote interactive receptors. And from the concerns of ecourbanism it would imply a total reformulation and the search for a new paradigm that could cross the discipline of urbanism to world-wide level. The design of the city would no longer be only a formal matter but a question of management and exchange between different layers of information, knowledge and disciplines involved.

The recognition of the influence that the so-called information society has had in the realm of urban life is decisive in order to move towards any new model. Its scope, still greater than the changes produced on the television and the telephone in the last century, implies changes even more profound than any advance in the field of building and infrastructures in the transformation of the urban space. The effects of ICTs on urban life, the daily activities of citizens and, as a consequence, the space that these activities engender is more than evident. The technological innovations in the areas of computers and telecommunications that we are witnessing today are generating profound transformations in social and individual behavior that are ultimately redefining the public space and its limits. This is an immense field of research aimed at developing the necessary cartographies to create reliable specifications for a renewed urban design, informed by the many existing channels.

The importance of ICTs when thinking and designing the cities of the future is related to an increase of intelligence that is translated into efficiency in existing environments. It is a trend that is presented as a necessity in the world today. Information and Communication Technologies undoubtedly play a fundamental role in the evolution of spaces towards more sustainable, comfortable, interactive and intercommunicated environments to improve the quality of life of the people who live there. Much of the ICT applicable to these environments can be included in what has been known in recent years as the Internet of Things, that implies that all elements in nature are able to communicate with everything that surrounds them, and to transmit information of their state, position, etc. so that decisions can be made based on it.

These environments can be either a room, a complete dwelling, a neighborhood, a vehicle, a subway car, an airplane, a boat, a park, a hospital, a hotel, or a complete city. A permeability is established between the boundaries of these environments and a continuous space-time whose experience is and will be very different in a future that is almost present. To reflect all the technologies that will be present in our day-to-day life in the city of the future and all the initiatives that currently exist in the development and implementation of these technologies, the ITI (Technologic Institute of Informatics) has produced a "Brief Report of Trends 'Smart Environments: ICTs in Smart Cities'". This fundamentally focuses the concept of "Smart City! on three spheres: natural resources, health and urban mobility.

But usually they are business initiatives that investigate and promote the technologies applied in smart cities and the research developed by universities with external financing are aligned to business interest. Leading companies such as IBM work implementing equally with their projects and products urban environments in Spain, Portugal, Greece and Israel. Technological companies are advancing at a staggering speed in recent years to establish themselves and compete in this market by offering various installations, devices and applications that are overlapping with the settings inherited from the last century. In most cases, they can be considered implementations that affect specific aspects demanded within the broad spectrum of urban life's needs. Smart cities do rely on data. But what kind of data? With what intention and by whom are these data collected? how data are associated and become useful is the important question.

It is true that a wide variety of institutions - both private and public - currently work, experiment and develop research projects in this sector of the intelligent city. Among them there are large multinationals such as INTRA and in terms of universities, in Spain, for example, UC3M publishes about 68 research groups working on projects related to smart city and UPC has around 120 projects that make reference to the field of administration and public safety, education, human capital and culture, energy efficiency and environment, traffic and urban mobility, health, transport and railways, elderly people. In this respect the Technical University of Madrid (UPM) coined the term 'city sciences' which encompasses interdisciplinary postgraduate training and research projects.

Once the cybernetic world is already incorporated into everyday life and the demand for fiber optic infrastructure has recently joined the usual facilities, the possibility to simulate a smart city through sensors and devices, increases. The goal of "intelligent environments" is to bring the user processed information that is integrated into their daily activities through mobile devices and interaction. The technology that is applied to the urban space addresses very different aspects: from security for any undesirable or risky situation and surveillance (concepts associated with the vulnerability of the feminine gender and its safety), to public lighting, surveillance cameras, etc. To the security and control that become priority themes in smart city designs, we must add themes that have to do with time and efficiency. Efficiency and speed are values of our time. Energy efficiency linked to sustainable consumption, fuels and mobility, public lighting, etc. are added. There are also criteria of comfort, attendance to people, accessibility and "design for all" that are part of a large repertoire of smart applications. On a design level, they could be categorized according to the functionality or comfort with many nuances related to consumption, transport, leisure, etc. focusing on time saving and other resources. Undoubtedly, this tendency has its pragmatic references in the architectural view of "the machine city", perfect in its parts and reasonably analyzed in each element separately.

Technology is able to control facilities, adjust costs, optimize consumption, offer comfort, safety and most importantly, help the user save time. Lighting systems, pollution, information about public services and means of transport are controlled through programming systems. Within a wide range of fields of action, applications specialize in determined functions and adapt to existing structures and systems. Everything seems possible. The interaction of these systems with the person or the environment is established through the smartphone and touch screen. Its use seems to be easy (user friendly) and there are even special devices for people suffering from functional, visual, auditory, mobility or even cognitive diversity. Most of the applications that exist in the market implement a space designed by architects and conform to some regulations.

The criticism of this technology that generally implements the urban project is that it is normally generated from the supply side and not from the reliable knowledge of the needs and the diverse desires of the great diversity of users that configure the real demand. The architects who design the living space with geometry as much as the engineers who design devices and applications ignore the experiences and real concerns of users and the needs of specific places. The approach proposed here for the contemporary city has to emerge from the radicalized coexistence of both situations: is it appropriate to propose an urban space as a space endowed with urbanity when an intelligent system allows citizens to develop urban activities in the best possible way?

The purpose is to address the new forms of social construction of space and relationships in a connected world. On the bases of the characteristics of the network culture that, in our opinion, define the forms of subjectivity and online collectivity, the erosion of the public and private spheres is favored. The materiality of a connected life transforms our relationships with the space, the body and others. In contrast with the

protection of privacy that our connected room offers- that space that anthropologically allows us to construct identity and intimacy, now permanently connected - to the interactive public space, the augmented environment by ICT becomes a place for the production of the public. Today all those that are connected to internet become visible, we want to be seen.

The spheres traditionally differentiated and linked to the production and reproduction of the world, with the masculinisation and feminisation of different spaces and practices of culture, have definitely been eroded. This erosion shows some scenarios and roles hidden as well as those who lived among its walls and that are now connected. Women these days emerge from the connected private spaces to get immersed in the public realm seduced by the inexhaustible entertainment of the screens, learning to manage time and to build their subjectivity (Zafra, 2010).

The confluence in the network of production, reception and distribution spaces and, as a consequence, the apparent horizontality of these practices backed by the celerity and the excess as signs of this confluence. generate an illusion of choice and emancipation. Taking into account that the logic that manages this excess in large, huge numbers cannot be but statistical, it is not strange to notice the rapid equivalence of connectivity with service. As a counterpart to this hyperconnectivity, the excess of time and dedication spent by women in particular, seems to us a new form of saturation and vulnerability.

The swift from "I" to "we" in the community space, the technologically implemented and connected city, becomes an illusion. Technological immersion mutates into individualities that, in a first impression, move from old strong bonds to light bonds marked more by affinity than by identity, more by presence than by belonging, and both by the biopolitics of spaces and the technological materiality as well as by the constraining virtual network. The community seems to be articulated today as a multitude of people alone and interfaced by the machine, a multitude of people that are always connected (Zafra, 2010).

However, from the abovementioned characteristics, the emergence of new scenarios of creative possibility and of entrepreneurship that counteract the adversities inherited from precariousness in so many areas of the working and social life of women, particularly, can be detected.

Political philosophy and feminist political analysis can be productively applied to the new conditions that ICTs have created for women, although much more research is needed on the specific impact of ICTs on different populations of women whose lives are being profoundly altered by the new technologies, often in ways that are leading to serious physical and mental health problems. This holds true for professional women with a high level of education in academia, sciences and industry, doctors and computer engineers, as it is for administrative and factory workers or rural and urban workers. Given that most women are already doing "double shift" (production and reproduction), the demands and pressures of the just-in-time economy (JIT, a method originated in Japan to organize production in factories) and the high speed are affecting women more than most men. The high levels of chronic fatigue syndrome, depression and stress, even among professional women - which is the best documented group - demonstrate the high human costs of our economic and cultural productivity systems. According to Fernández and Wilding (2006), to achieve strategies of action, we must analyze the impact of new technologies on sexuality and the subjectivities of women; the conditions of production and reproduction – already linked in the case of women; gender roles, social relations, and public and private space; and it is necessary to challenge the naturalised value attributed to speed and efficiency, when these do not take into account the limits and needs of the organic body.

3 FOR AN INFORMED DESIGN OF CITIES

From this shallow analysis it follows the necessity to combine the efforts of the academia and the responsible institutions to investigate the real and specific demands of the different settings; conduct studies that address the complexity of urban conditions in order to design policies and carry out specific urban projects and not simply indiscriminately implement technological products in all spaces. This would serve to bridge a large gap existing between today's operational strategies - built on the basis of homogeneous demands and bureaucratically and rigidly managed - and the current real demands, increasingly heterogeneous, fragmented, and variable over time.

To this effect, the visions of citizens, an incredible amount of subjective data that are generated in the networks, could complement and enrich objective geospatial information. The “collective intelligence”, the potential of the presence and participation of citizens in common things and the self-organization capacity of identities through the network that promote actions transforming the urban space has to be placed somehow at the service of the city.

It is true that in the field of disciplines that work on any aspect of the urban space, important methodological changes have been produced as we referred elsewhere (Trachana, 2012), so that Sociology approximates its methods to Ethnology and Anthropology abandoning theoretical models and trying to appropriate the urban through the direct sensory experience and the description of the particular (Delgado, 2007). Lévi-Strauss (1987) already warned us about the impossibility to access the real through the schematization of the action or the conceptualization of experience. The author also warned us about the abyss existing between what is thought and what is experienced. Everything that is present, and susceptible of being seen, observed and narrated matters much more than what is known. What is observable, intuited, the haptic, acoustic, luminous, thermal sensations which immediately affect the life of individuals, which constitute the sensitive space and not merely the formal-material city, is the most important (Trachana, 2013).

The question that arises is how to capture sensations, descriptions, formulations and proposals, which are difficult to classify, compare and analyze, in order to translate them. Blumer (1969) suggests “interactionism” as a set of honest descriptions of the area studied that would be an alternative to the protocolized information formats. This type of research is conceptually opposed to formalist research, so that problems, criteria procedures, techniques, concepts and theories fit the empirical world, a world that seems to have ceased to interest us.

In this context, recording techniques of what happens outside, of what depends on perceptual and sensitive value, such as drawing, photography, video, sound recording and voice, play a key role. Dialogue remains the most effective way to access the meanings that the actors attribute to the elements of the assessed environment. Therefore, the methodological questions concerning the way of detecting, recording, categorizing, and interpreting urban events call for a certain restoration of the much reviled confidence in the direct observation of the flow of urban life. The attention given to bodies and their languages, the role attributed to oral information, the capture of social activity in public spaces, could never be replaced by an established mechanic, by the established statistical values and meanings or simply by the application of regulations and legal prescriptions.

The assumption of this naturalistic perspective, at least regarding a readiness or openness towards the things and facts that are there and seem to be eager to be understood in their composition, requires the humble work of data compilation and inventory. The best we can do is the transcription and classification that properly corresponds to the observations. The detailed description to give an account in cartographic terms and record minutes of the observed, is considered as urgent and indispensable. The intensive and methodical use of the human capacity to receive sensory impressions whose variants are then destined to be organized in a significant way is the previous work to determine the real demands in order to give answers in terms of design and technological implementation of the urban space.

But the exhaustive immersion in the physical-tangible then raises the question of how to combine life with cartography, a map, a plane, a project, which is already the most philosophical theme of the same truth. The digital paradigm provides us with network construction and superposition of layers as a possible way of recording direct observation, the description of the given and its alterations. The digital tools allow to superpose and to read multiple registries, different types of observation, to capture movement, time and evolution, continuities and discontinuities, events, everything exposed to the senses apart from any preconceived idea and the abstract. All that can be converted into project data are no longer exclusively provided by public administrations - which, in fact, are currently undergoing a great effort to openly make them available to the public.

There are several individual and collective initiatives that investigate in this sense to create and transmit descriptions of the urban condition with new types of data that allow to complete the geospatial information and enrich the experience of the city. In this research it is possible to observe the ways in which smart applications affect subjectivities, their implications in daily and family life, the relationship between

genders, the emerging changes and the differences between men and women when dealing with technology.

Our purpose here is to account for the changes and resistances of today's urban life, the role of women contemplated with all the complexity and diversity that the contemporary social fabric presents, together with a technological background that demands a prevailing need to investigate in order to detect, determine and evaluate its effects. During the last decades, in the field of architecture where we are and also in related engineerings in an exacerbated way, action has prevailed over reflection (Lleó, 2006). The technology of products and tools has deeply affected the ways to design, the ways to act, collaborate, participate and produce the architectural space.

But what remains as the main issue is how optimized is the contribution of the media tools arsenal we have and the amount of data and information accessible to provide us with this global and totalizing vision that encompasses real, physical, corporal, intellectual and cultural demands to incorporate to the urban project and city planning. How can we derive from the analysis and interpretation of real and reliable data towards a project specification? Without any doubt, the field of research that opens in front of us is multidisciplinary. It is time to abandon the usual complacent solitude in which projects are developed both in architectural studios and research groups at the university.

To deal with the world of authentic specialization, we are asked to assume the need to interconnect specialized worlds, getting trained as authentic generalists in an institution such as the School of Architecture which, from a complex knowledge has to connect and relate the multiplicity of expertise. We have, in this sense, as teachers and mediators to promote substantial changes in the discipline by training agents as mediators, negotiators and communicators.

Advancing a little more in our thesis, we could say that the city and not the building, is the scale, the augmented framework of architectural intervention. The expanded architecture is the city, the city that becomes home. And our mission is to endow the city with this condition of use. What we need to change is its use value versus its value as a product that characterizes the current city. The new paradigm integrates elements of the virtual and the material world. Being already a "mixed environment" where the advancement of technology allows the juxtaposition of virtual information and the material environment where citizenship activities take place - giving rise to what is known as augmented reality (RA) – that is a new way of being in the world and related to it, between the body of the user and a generally mobile device.

The path taken towards a stage of complete digital and face-to-face integration effectively responds to the bipolar condition of the individual and by projecting it into the realm that inhabits get, on the one hand, an introverted position that explores the house and the city as a shelter of the self, and on the other, it considers them as the structure that enables and organizes all what is circumstantial.

The words that allow us to describe the city as a real and contemporary alternative, after having mapped the diversity and complexity of the variables analyzed above and many others, is hybrid (Trachana, 2014), liquid (Bauman, 2007), movable (Delgado, 2007), invisible (Innenarity, 2004). We are able to approach the project understanding it not as the quasi-mathematical consequence of a linear process with the hermetism of the finished product. Against the permanent materiality of the architectural orthodoxy and the project rigidity there is the heterodoxy that promotes change, the assimilation to a fluid environment, the aesthetic dematerialization of construction in favor of facilities, the consideration of flexible and adaptable strategies in any field, and the convergence of a digital immaterial environment that extends and increases the traditional architectural space.

4 SMART CITY AND WOMEN: THE CHALLENGE OF TIME MANAGEMENT

Today's society is changing its habits due, firstly, to the continuous variation of the vital situations that allow us to identify ourselves as nomads due to globalization, labour circumstances and the elimination of borders as well as the acceptance of the destabilization in everyday life, which is identified with the concept of "performativity" posed by Judith Butler (2007), and that makes reference to the existence of many forms of behavior as identities. What affects us fundamentally is time much more than space. The interaction with space and objects takes place in time, a time that is not neutral but specifically dedicated

to our body, our mind and our relationships. Relationships for a physically and emotionally developed life in an ecological and sustainable space designed with responsibility and, as it cannot be otherwise, pierced by large amounts of bytes. We continuously transform, either consciously or unconsciously, this space through its use, manipulating matter and transforming energy with our bodies. We alter the environments through the information we receive and transmit leaving traces that are changing the social environment. We generate affections and phobias, desires, ties and works, and generate waste, much more waste than an evacuation network can withstand with the hope that an intelligent system will transform it into new consumption possibilities and release the overload of a deteriorated world.

If the woman, with her imperceptible daily task through daily domestic work guaranteed that in the face of the threats of an unstable, changeable and hostile world, the house would remain unchanged and became the home to which we all arrived sooner or later, who will be able to guarantee now this immutable condition of the home linked to the maintenance of space and its inhabitants?

Now the permeability between the body, the house and the world through ICT is a fact. It is not a question of avoiding a conflict or an alleged deficit of domesticity, but of taking care of all the unsustainable aspects derived from the management of the augmented habitable environment.

Undoubtedly, time is the variable that appears as a priority for the development of a truly intelligent city proposal. A time intelligently managed after an experience accumulated by women over the centuries and undervalued and ignored by the rest of humanity. An administration of time that guarantees the fulfillment of all needs so that each one of the activities of the human being can be developed in this scope. A time that systematically analyzed through cartographies of daily life allows to visualize each of its derivations and implications with the body, the city and the rest of the planet. A time to meet demands that, once detected, can be introduced into a complex system of interrelationships and implications and be assumed by a set of design specifications, management, maintenance and control of a responsible urbanity.

We are not very sure of what we have in our hands, perhaps because of sheer ignorance of the technological potential still in development, but we can bet that between a variable, diverse and indefinite body and a global city, complex and plural, we need to find the solution together with the fellow engineers, psychologists, anthropologists, sociologists, and housekeepers of any sex, race, and condition as we are irremediably connected.

T15 | LAW AND PLANNING UNDER SOCIETAL CHALLENGES

CO-CHAIRS: RACHELLE ALTERMAN; LEONIE JANSSEN-JANSEN; BEATRIZ CONDESSA

Almost all countries have laws, regulations and government institutions related to planning and building controls. Planning laws often also enable intervention in property rights – such as expropriation and land sharing – and may entail fiscal aspects (levies, fees, negotiated value sharing).

These issues range from procedural matters - processes that affect quality of governance, to substantive policies and instruments that may enable the creation of spaces and shape land use (for better or worse). In times of increasing uncertainty, European (dis)integration, neo-liberal economic approaches, and social and demographic changes, a new focus on innovative processes and practices applied to planning of territories, regions and cities is needed. These are all very critical questions regarding the interplay between Law, spatial planning and property rights.

Can the law and planning institutions meet the challenges posed by inclusiveness and multiculturalism, promoting flexible planning approaches and collective engagement? How do they affect planning laws geared to handle distributive justice issues within cities, countries, and across borders? This track invites research proposal on any topic that relates to planning laws and land policy, whether directly or indirectly. An indication of the scope of the track can be seen from the following list of areas: Statutory (regulatory) planning systems and instruments: How well can they accommodate emerging economic, socio-demographic and environmental realities? Regulatory land use instruments: local statutory plans, zoning, building permits, agreements with developers, “exactions” or “planning gain”, regulation of open space and natural resources, regulations of already-built environments and other; Public property rights / private property rights / private property responsibilities: tensions between them, land for public services, customary collective / private rights, expropriation, compensation, land readjustment, taxation of land values, transfer or development rights;

Governance structures and procedures: How does planning law structure the relationships between central governmental control, local government, markets, and non-governmental organizations? How does the law frame public participation and involvement, conflict management and dispute resolution? Contribution of planning law to an efficient and equitable management of land and ecological resources; Non-compliance with planning laws: issues of illegal, “informal” “irregular” development – processes and enforcement. Innovations, methodologies and advances in planning legislation in its various territorial, regional, metropolitan and urban scales. Systematization of processes and practices applied to the planning of territories, regions and cities.

Questioning and analyzing experiences and processes and innovative management practices in territorial planning at different scales. Analysis and proposal of territorial, regional, urban, fiscal and tax, policy instruments applied to the planning, management and public administration at various federal levels. Contributions may focus on theory or investigate particular issues, focusing either on a particular country or cross-nationally. Since legal and planning systems vary greatly from country to country, authors should make the legal structures and procedures as transparent as possible. To be considered for this track, the author needs to point out some relationship with the underlying legal framework.

Contributions may focus on theory or investigate particular issues, focusing either on a particular country or cross-nationally. ID 1404 | EVALUATION OF THE INSTITUTIONAL FRAMEWORK AND POLICIES OF SPATIAL PLANNING IN GREECE

Vasiliki Charalampidou¹

¹National Technical University of Athens
vacharala1992@gmail.com

1 INTRODUCTION

The study, examination and classification issues relating to the planning process are imperative for today's society, which often faces significant territorial problems. As a field of expression of the various public policies, the actual space is regulated with certain tools that are activated and promoted by the planning legislation. In particular, regional planning as a strategic level may provide the necessary guidance, incentives and solutions to any kind of problem. Thus, the interdependence of the individual parameters constituting the planning process (policy - legislation – plans – spatial structure) and the circular route followed can be perceived.

2 THE ROLE OF LEGISLATION IN PLANNING

Urban planning is the subject matter of various sciences, namely, philosophy, sociology, political science, demography and law, resulting in issues of an interdisciplinary and complex nature. The implementation of urban planning comes as the result of two individual components, those of politics and legislation. Spatial planning, therefore, as a conscious attempt to modify the real world through implementing scientific methods or other means of making decisions, is a complex act including elements of scientific thought and political practice. (Kafkalas, 2015).

The latter involves, in the first place, policymaking and law regulations and secondly, the implementation of the urban planning policy. These two components are inextricable and interdependent. The legislation and in general the institutional framework aims at determining the operation of the authorities responsible for the urban planning policy, regulating the relations between the implementation tools – means (plans, projects) and providing guidelines and the basic orientation of any horizontal or sectoral policy to be followed. The term institutional framework entails all the legislative measures that define the rules followed by a human activity within the operational framework of a certain social group (Papapetropoulos, 2008). Urban planning is an activity regulated by the law as well (Papapetropoulos, 2004), and as the basic method of implementing state activity, it falls under a legal – institutional framework of state organisation none other than the Constitution itself (Melissas, 2002). Today, urban planning is not only a means but also the guiding tool of an active state policy. Urban planning is admittedly not a linear procedure, as it involves the setting of goals and the means to realise them.

In Greece, generally, the institutions, in the strict sense of the term, are the text of any kind of regulation (Laws, Decrees and other acts) also known as tools of the corresponding policy. Essentially though, the institutions reflect quite a few elements of a policy, on the one hand containing its goals and objectives and on the other hand specifying the majority of measures and the means of its implementation. The legislation provides the urban planning tools (plans) through which the goals and intended results are illustrated. When speaking of the Greek reality in particular, an abundance of plans yet a shortage of planning as a social and political procedure are mentioned (Beriatos, 2015). For this reason, the study, consideration and critique of the institutions is, at the same time, a study of the corresponding political and historical framework that they reflect (Beriatos and Papageorgiou, 2013).

3 BASIC ISSUES OF SPATIAL ORGANISATION IN GREECE

The uniqueness of the Greek space in terms of organisation and integrated approach is given, as, albeit being an inherently heterogeneous environment, its acquired characteristics and the anthropogenic intervention in it have intensified the problems and created several difficulties. It is, therefore, necessary that these spatial organisation issues which have arisen over time be analysed. The consideration of these

issues is essential as they are the ones taken into account and tried to be resolved by the latest spatial laws. The aforementioned issues are classified into six categories ranging from the most significant to the secondary ones according to the direct spatial imprint.

3.1 NETWORK OF SETTLEMENTS

The first and foremost category is that of the network of settlements. It is characterised per se by the spatial dimension and features the most crucial issues. This group differentiates itself from the next one as it mainly focuses on the role and functions of the settlements.

A recently observed phenomenon is that the competitiveness of the settlements has strengthened, instead of their complementarity, which partly depends upon urbanisation. This competitiveness, created at the expense of many settlements and cities, has not allowed satisfying exploitation of their potential. It is clarified that the competitiveness is not deemed unacceptable. It is, in fact, a beneficial course for every city or settlement, especially at a national level where all of them should be competitive towards foreign cities or settlements so as to be the first choice when it comes to investments, tourism, etc. In the case of the country itself it is important that there is complementarity so that the growth dynamics and comparative advantages of each settlement are exploited to the fullest. As a consequence, the country's growth will be balanced without considerable differences between metropolitan areas and rural settlements.

3.2 RESIDENTIAL RECEPTACLES AND AREAS OUTSIDE URBAN PLANNING ZONE

The second category focuses on issues of residential receptacles as well as issues of the areas that are outside the urban planning zone. Urbanisation, which has been observed worldwide but also nationwide over the last 50 years, has created several problems, as the tendency of the population to gather at urban centres is intensifying the pressure on the natural and built environment at a rapid pace. This has created great spatial needs not just for accommodation and infrastructure, but generally for establishing an integrated policy with specific measures and guidelines.

The first crucial issue worth mentioning is the phenomenon of building outside urban planning zones which has been taking place for years within the Greek space. Meanwhile, in the last few years the logic adopted is the one suggesting the expansion of cities, in other words converting rural areas to residential ones. This is also related to urban sprawl, which denotes the dispersion of urban functions in extra-urban space, making the purely extensive residential growth clear. The unequal relation between the city and the province stems from the above and also from their fragmentary and not integrated attitude.

Within the urban environment, different problems arise such as either individual abandoned shells, or whole regions particularly in cities and metropolitan areas. The reasons behind them are more complex and closely linked to economic as well as social constituents. Finally, high building densities in cities do not operate in the framework of the compact cities' philosophy, while, along with the shortage of open space within the urban fabric, a fragile environment and poor quality of life are created.

3.3 INFRASTRUCTURE & ARTIFICIAL NETWORKS

Infrastructure is divided into two subcategories; the first is concerned with its existence and connectivity whereas the second is concerned with the state or lack of the infrastructure itself within a specific space. The spatial planning issue of infrastructure in Greece is related to the strengthening of the role systems and networks play in the national integration and interregional cohesion (Skayannis, 1994). The association of Greece with the rest of the Balkan countries over the last few years is deteriorating, as phenomena of introversion are currently being observed. Even though insularity is among the main characteristics of the country, it has not been exploited to the fullest. The island space has been the recipient of significant ramifications due to a delay in uniting different kinds of planning, in adapting the growth procedure and the planning as regards to the characteristic of insularity (Gianniris, 2012).

Except for everything mentioned above, the immense requirements in various forms of energy aiming at covering needs have caused serious problems. In Greece, the exhaustible forms of energy, namely the oil

and natural gas, are facing problems regarding their transportation, distribution as well as safety. On the other hand, even though the renewable ones require a lengthy period of time to be taken advantage of, they compensate by producing secondary sources of energy.

3.4 NATURAL ENVIRONMENT

The fourth – and last – category directly related to space, concerns the natural environment. The environmental stress in Greece derives both from extrinsic factors, else known as global phenomena, such as the acid rain or the greenhouse effect, and from intrinsic factors which are the most important and are examined here. Quite frequent is the destruction of biotopes and ecologically sensitive areas and forests, important for the flora and fauna of these areas and for the conservation of the ecosystems just because they were outside the urban planning zones or even because of unauthorised roadside construction. The environment was almost always considered a receptacle for residential growth or a base for greenery growth and recreation identifying it, to a great extent, with nature issues in cities (Coccossis, 2012).

Lastly, a supranational phenomenon worth mentioning and which has a direct effect on spatial planning is climate change. It is an issue in need of total and integrated dealing as its outcomes are bound to affect the global community significantly. Among the effects to be produced, the rise of sea levels is noteworthy because it is altering and transforming the borders between countries, or even worse, may eradicate whole states.

3.5 GROWTH ISSUES

This category of growth issues includes highly diverse issues, though it also has both a direct and indirect impact as regards to spatial planning. The productive structure, either of a smaller area or a whole country, is one of the most important constituents affecting its growth prospects.

Undoubtedly, the sectoral and structural policies are the ones determining the framework of action and development of the productive sectors and more generally of the economic activity. The long-term dependence of the productive base on the two main constituents of the primary and tertiary sectors, agriculture and tourism respectively, has spurred an inward-looking tendency in production and economy. More specifically, tourism is an ever-developing industry and simultaneously has diffuse geographical impacts (Getimis and Economou, 1992). The basic problem which has emerged in the Greek space is the inability to develop a polycentric system with considerably high and sustainable population and production figures in rural areas (Petrakos and Psycharis, 2004). In this direction, each city and the respective region as a whole, has to balance the intra-regional differentiation and extend its comparative advantage against the others.

3.6 ADMINISTRATIVE ISSUES

The following constitute an overview of the general aspects of administration and, secondarily, of specific points regarding the process of urban planning. First of all, centralisation and the difficulties in decentralisation affect the urban planning issues because at lower scales, where local authorities should naturally make the decisions about most of these issues, the decisions are actually made by the central authority. Even though the majority of the local authorities are able to take responsibility and be active, the lack of personnel and the inadequacy in specialised political institutions and bodies does not allow that.

Moving on to particular details, overregulation concerning spatial planning is a prevalent characteristic of the Greek reality. It definitely is a serious problem as the large number of laws is the reason behind inconsistencies, ambiguity and sometimes conflicting views. For this reason, a lack of legal certainty has emerged (Economou, 2015). In addition, the lack of monitoring in the process of urban planning is becoming noticeable because the regional as well as local bodies do not participate at all in monitoring and evaluation. They are the results of a deficit in integrated policy, which is evident in some cases, such as the late and gradual completion of the national land registry and the lack of coordination between sectoral policies and authority.

4 COMPARISON OF INSTITUTIONAL FRAMEWORK AND POLICIES

Although the general philosophy of urban planning is the same among the European countries, there are, indeed, some significant differences which, in the case of Greece, may serve as an example. After studying the current trends in urban planning in Greece, it is felt that over the last few years the concepts of spatial planning and space regulation have been redefined, while particularly focusing on spatial organisation and issue “resolution”, both subjects of the two principal spatial planning laws, namely Law 2742/1999 ‘Regional planning and sustainable development and other provisions’ and Law 4269/2014 ‘Regional and urban reform - Sustainable development’, which shall directly respond to these. Through close examination and comparison of these Laws, it becomes apparent whether and how each of them addresses the above analysed spatial planning issues.

The difference between the two Laws is evident even by just examining their structure (Table 1). L. 2742/1999 is structured in six chapters, whereas L. 4269/2014 expands in only two chapters, of which the first has five subchapters. It is also noted that L. 2742/1999 applies exclusively to spatial planning, in contrast with L. 4269/2014, which refers as a whole to the reform of the urban planning system, while at the same time, the categories as well as the land use content are described in detail in its second part.

Law 2742/1999	Law 4269/2014
Chapter A	Chapter A
Objectives and Guiding Principles of Spatial Planning	Urban and Regional Planning
Chapter B	Part A1
Spatial planning tools	Basic concepts and structure of the spatial planning system
Chapter C	Part A2
Means of spatial planning	Strategic spatial planning
Chapter D	Part A3
Mechanisms for implementation, control and support of spatial planning	Regulatory spatial planning
Chapter E	Part A4
Administration and management of protected areas	Digitisation and electronic recording of institutional geospatial data - Codification of spatial and urban planning legislation
Chapter F	Part A5

	Categories and Content of Land Uses

Table 1 - The structure of the two laws.
Source: Law 2742/1999, Law 4269/2014, Own elaboration.

The whole structure of L. 2742/1999 seems more mature when it comes to the urban planning process and reveals the integrated approach in that sector. The framework Law is the one that set the implementation mechanisms of spatial planning (Gourgiotis and Tsilimigkas, 2016). L. 4269/2014, though, is mostly aimed at reforming as a process, instead of preventing and then resolving accumulated problems. Chapter A is the core of the present law, as it points out the new integrated urban planning system of the country, which meets the modern needs, is responsible for remedying issues and conflicts between laws upon implementation of previous frameworks and aims at conserving the man-made, natural, residential and cultural environment, by avoiding further conflicts and overlapping of the different levels of planning. Chapter B attempts to update land uses mentioned in the P. D. of 23.02.1987, due to significant changes in modern lifestyles and new socioeconomic data.

It is useful that reference be made to the urban planning systems promoted by the two laws so that the reform and the changes made can be understood, emphasising though on a higher and strategic level. The lack of spatial planning over the years has led to a convoluted and unclear institutional framework. Whilst the smallest, in terms of land area, countries tend not to have many plans, Greece does, and in addition to that, the system reflexes are not of any help. L. 2742/1999 adopts a two-way harmonisation between spatial planning and developmental planning. It is characterised by a clearly more intense orientation in strategic planning, which is manifested in two ways; firstly, it covers issues such as the

international role that are of a horizontal nature, and secondly, it adopts a guiding attitude regarding sectoral issues (Economou, 2009).

In 2014 an attempt was made, through L. 4269/2014, to cover such weak spots by reducing the number of planning tools at every level. Strategic spatial planning features plans of an executive and guiding nature while master planning features plans of regulatory terms. At the same time, L. 4269/2014 relates spatial and urban planning both to the developmental planning of the country and to the guidelines and directives of the European Union, promoting three geographical levels and five planning categories. The comparison of the two Laws, regarding not only their structure but also their content, revealed some very important evidence referred to below.

4.1 STRENGTHS AND WEAKNESSES – SHORTCOMINGS

Assessing the basic spatial planning legislation (L. 2742/1999 and L. 4269/2014) and composing any policies that stem from it leads to useful observations concerning the shortcomings and weaknesses in spatial planning techniques and in the country's priorities.

Comparing, therefore, the two Laws, both positive and negative conclusions can be drawn. L. 2742/1999 has a time frame of fifteen years, while L. 4269/2014 includes both medium-term and long-term goals. Furthermore, an observation worth mentioning is that the former Law entails a spatial assessment of the present spatial planning state, which at least from a legal – technical viewpoint, has to be referred to only in its Explanatory Report. In contrast, L. 4269/2014 justifiably does not include this spatial assessment in its final version. The Law's strengths include the reduction of urban planning levels, their distinction into strategic and regulatory levels and the inclusion of specialised plans within the integrated spatial planning system as well as the quick amendments in certain plans. On the other hand, some significant deficiencies of the most recent Law are detected mostly in the area of the coordination and harmonisation between different leveled plans (vertical harmonisation) and same leveled ones (horizontal harmonisation) (Giannakourou, 2015). In general, the central mechanism used essentially to monitor the process of urban planning and the harmonisation of individual levels is absent here.

4.2 CRITICAL EVALUATION

4.2.1 GENERAL OBSERVATIONS

Overall, the question of whether and to what extent the new system has tackled the weaknesses of the previous one has not been adequately answered. The fact that it reduces the number of plans from seven to four in relation to the previous system is an advantage, time, however, is absolutely necessary for such reforms. Fortunately, quick amendments are provided for in certain plans. The flexibility in real estate development gives room for private investments that may act as a driving force of economic recovery. A proper attempt is being made to associate spatial planning with developmental planning, a fact that was missing from the already existing institutional texts on urban planning.

On the contrary, though, the essential and properly drawn up specifications were not issued in a timely manner. The ones issued until that time had several inconsistencies and deficiencies in terms of policy. Moreover, there is no content in the spatial planning levels and the relations between them are practically absent, as is the role played by the specific spatial and urban plans. In addition, there is a universal need to clarify the role and responsibilities of all those engaged in the spatial planning system, apart from the responsibilities to launch and approve plans. In any case, such deficiencies in conjunction with the financial crisis imply the risk of non-implementation.

The new legislation introduces a concept in urban planning based on the top-down approach, something that could potentially cause serious problems to the spatial planning process and its effectiveness (Portokalidis & Zigoriri, 2015). The Regional and Urban Reform is in need of a plan and system with specific objectives, axes and actions, mechanisms to monitor and evaluate findings, as well as the establishment of appropriate alliances at an institutional and socioeconomic level.

4.2.2 MORE SPECIFIC OBSERVATIONS

Regarding issues at a national level, the 'General Framework of Spatial Planning and Sustainable Development' is the one giving the priorities and strategies required for the integrated spatial development and sustainable planning of the national space, however, it is so general a plan that it lacks flexibility and speed. The new Law is estimated to set as a prerequisite the quantification of the National Spatial Policy's objectives and axes, while at the same time, the coordinating role that regional planning plays will have to be determined in relation to the national policies which have spatial impact. In other words, it will have to be predicted that this specific policy and the National Development Strategy should be mutually supportive and coordinated. At a regional level, a holistic approach to spatial planning is observed as the interactions from municipal developments are taken into account, thus simplifying the planning of said level.

5 URBAN PLANNING AMID CRISIS

Despite the lack of financial resources, the inaction, conservatism, the wait and see approach and the embarrassment in front of new challenges that the Greek reality faces, the recently adopted L. 4447/2016 'Spatial planning - Sustainable development' is expected to cope with them and make up for the weaknesses of the previous one. With a slightly different scope regarding the plans, it includes a forecast of the new sectoral policies concerning the conservation of the cultural landscape, the natural environment and the land policy. At the same time, the financial and national growth strategy and the community policies that influence the structure and growth of the national space are taken into account along with those about the environment and territorial cohesion. In addition, digital technologies for land use are exploited (Network Natura 2000, Forest maps, National Cadastre, Archaeological Cadastre) and a new geospatial database with an integrated reference to institutional texts and monitoring by the competent bodies, in order for projects and investments that are in progress or delayed due to possible conflicts and incompatibilities to disentangle. Generally, the new Law's urban planning system is characterised by an attempt to be more flexible in planning.

However, during the economic crisis, spatial planning is losing its executive nature in the name of growth. The question as for whom and depending on which goals the planning takes place remains, while another thing worth noticing is the large number of spatial regulations and provisions with a direct or indirect spatial impact in accordance with the managing of the financial crisis the Greek society is experiencing (Klabatsea, 2017). A shift, therefore, from the spatial expression of the crisis to its management through spatial planning has occurred. This is because overcoming the socioeconomic crisis was attempted with financial terms. Finally, there are fewer attempts towards safeguarding the public interest and an incompatibility between incentives in legislation and the results of regulations exists as well.

6 CONCLUSIONS

The challenges that the field is facing are immense. Owing to the various short-term as well as long-term prospects that are provided by spatial planning, the already existing natural and anthropogenic environment is very likely to become sustainable. It should be made clear that the challenges – changes mentioned above essentially relate to the structures and procedures of spatial planning. The short-term prospects involve the urban planning tools and more specifically the monitoring of Regional Plans, as this scale makes it easier for any changes and transformations to be perceived, so as to use feedback for this particular planning process through feedback itself. Collecting data from every Region may serve as input for determining criteria, based on which, the guidelines of the respective plans can be evaluated. The fact that urban planning is static could not be further from the truth. In fact, it has to have an immediate response to current needs. For instance, the fact that the new Partnership Agreement 2014 - 2020 contains several specific references that consider urban planning a prerequisite, means that every Ministry has to participate in a joint "spatial discussion" (Gourgiotis, 2015).

The long-term prospects, on the other hand, are mainly concerned with the more general structures of the urban planning system. The criteria to be established and the evaluation of the plans' guidelines may contribute to the production of certain monitoring indicators. These indicators will concern not only the quantitative characteristics of every spatial unit, such as employment figures or the per capita GDP, but also the qualitative ones, such as the state of the road network, always related to the spatial dimension.

Besides, there are also other policies, mainly European, such as the growth strategy called 'EUROPE 2020', which includes mandatory indicators. The construction of a database, which is essential to be renewed and updated on a regular basis, is a planning infrastructure that together with the completion of the national land registry will eliminate any rigidities of the system and accelerate the procedures. It is a sufficient and necessary condition, of course, in the long term that the institutional framework of spatial planning be, now, single and coded without any inconsistencies and deficiencies. Only under this condition can the system be considered modernised and integrated.

ID 1416 | MULTI-LEVEL CLIMATE GOVERNANCE IN GERMANY – THE OPPORTUNITIES AND CONSTRAINTS IN FORMAL AND INFORMAL INSTRUMENTS FROM A LEGAL PERSPECTIVE

Martin Wickel¹; Cathrin Zengerling¹

¹HafenCity University Hamburg

martin.wickel@hcu-hamburg.de ; cathrin.zengerling@hcu-hamburg.de

1 SETTING THE SCENE

Climate change is one of the most pressing societal challenges of our times. International climate governance is currently shifting from top-down and monocentric to bottom-up and polycentric governance structures with, inter alia, cities and local governments becoming increasingly visible and engaged actors. The research explores, from a legal perspective, multi-level and polycentric climate governance in Germany with a focus on formal and informal instruments of federal state ("Bundesland") and local level ("Städte und Gemeinden") climate action planning.

The paper, first, briefly depicts recent developments in the international climate change regime to show the current shift from mono- to polycentric climate governance structures (2). It then looks at the German system of climate governance and explores the key formal and informal instruments at national and federal state level for steering multi-level climate mitigation efforts (3). At the heart of the research, three local case studies highlight the manifold ways in which German cities are currently interlinked into polycentric climate governance, depending on how they mandatorily or voluntarily interact with vertical or horizontal climate governance axes (4). Building on these case studies, the formal and informal instruments developed at the different levels of the climate governance regime, their interrelationship, potential benefits and constraints are critically discussed with a view to effective climate mitigation action (5). Finally, conclusions are drawn and recommendations developed (6).

2 FROM MONO- TO POLYCENTRIC CLIMATE GOVERNANCE

The international climate change regime established with the 1992 United Nations Framework Convention on Climate Change (UNFCCC) and the 1998 Kyoto Protocol with its first and second commitment period has the typical top-down and state-centric structure of a multilateral environmental agreement (MEA). The agreements are addressed only to states. The Kyoto Protocol defined clear emission reduction goals that were to be reached by states within a certain time period. State actors below the national level or non-state actors did not play any direct role in the legal and institutional framework set up by the original system. They only came into play indirectly via the state level and the use of certain instruments such as emissions trading or the Clean Development Mechanism fleshed out in national legislation.

This changed with the entry into force of the Paris Agreement (PA). In order to enable global commitments, the Paris Agreement turns the top-down approach of the Kyoto Protocol into a bottom-up approach. Under the Paris Agreement, parties agreed to the overall 2°C and 1.5°C goal (Art. 2 para. 1(a) PA)¹ and the general obligation to undertake and communicate "nationally determined contributions" (NDCs) (Art. 3 PA). They did not agree to state-specific emission reduction contributions in the form of quantified emission limitation or reduction commitments expressed in percentage terms in relation to the base year 1990 for the respective commitment periods. In general, the Paris Agreement leaves it up to the parties how they compose their NDCs without predefining a certain form, other than the requirement to provide the information necessary for clarity, transparency and understanding in accordance with decision 1/CP.21 (Art. 4 para. 8 PA). Thus, NDCs submitted under the Paris Agreement differ quite significantly from one another. While some countries, for example Germany, "only" submitted a brief but clear emission

¹ According to Art. 2 para. 1(a) PA states agree to hold the "increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels".

reduction target for a certain time period, others, for example China, explicitly referred to state actors below the national level and addressed their contributions¹.

Another indicator of the opening of the former monocentric international climate regime to sub-national levels of government and non-state actors is the wording of the preamble of the Paris Agreement. Here, states explicitly recognize “the importance of the engagements of all levels of government and various actors, in accordance with respective national legislations of Parties, in addressing climate change”. While the legally binding text of the Paris Agreement does not assign rights and obligations to these actors, the Marrakech Partnership for Global Climate Action (MP) adopted by Parties to the Paris Agreement at COP 22 held in October 2016 further develops the institutional framework to include non-Party actors. With this step, the international climate regime arguably enters a new era in international law. The aim of this innovative step is twofold. On the one hand the Marrakech Partnership wants to catalyse and support climate action by Parties and non-Party stakeholders in the period from 2017-2020 (MP, p. 1). On the other hand, it aims to integrate the climate change mitigation and adaptation of a wide range of non-Party actors, including cities and other subnational authorities, and local communities (MP, p. 4), into a comprehensive and transparent management framework. For example, non-Party stakeholders participating in the Marrakech Partnership agree that their commitments are recorded on the UNFCCC Non-State Actor Zone for Climate Action (NAZCA) platform and that they regularly report on the implementation and progress towards those commitments (MP, p. 4).

Apart from the international climate regime, states also recognized the crucial role of cities in action on climate change mitigation in key documents of the global governance agenda such as the Sustainable Development Goals (SDGs) adopted in September 2015 and the New Urban Agenda adopted in October 2016 at the UN Habitat III Conference in Quito, Ecuador. For example, in SDG 11.b governments committed to “substantially increase the number of cities and human settlements adopting and implementing integrated policies and plans towards (...) mitigation and adaptation to climate change, (...)”. In the New Urban Agenda, governments committed “to promoting international, national, subnational, and local climate action including climate change adaptation and mitigation, and to supporting the efforts of cities and human settlements, their inhabitants and all local stakeholders as important implementers.” (New Urban Agenda, para 79).

Furthermore, in addition to the opening of the international climate regime and the international political mandates adopted by states in the SDGs and the New Urban Agenda, cities themselves are increasingly engaging in international networks such as ICLEI – Local Governments for Sustainability, C40 Cities Climate Leadership Group or the Global Covenant of Mayors for Climate and Energy and voluntarily pledging to reduce their local greenhouse gas emissions.

These recent developments indicate an incremental shift from a top-down state-centric to a more bottom-up and polycentric international system of climate governance (Jordan et. al 2015). In line with Ostrom’s assumption that complex societal problems with unknown solutions are best addressed by a variety of actors and overlapping policies at local, national and international levels (Ostrom 2012), this integration of non-Party stakeholders into a comprehensive management framework could turn out to be crucial for reaching the 2°C or even 1.5°C goal of the Paris Agreement. This paper focuses on German cities and municipalities as important actors in climate mitigation efforts and explores how they are embedded into the federal- and state-level legal and political framework of Germany.

3 CLIMATE GOVERNANCE IN GERMANY

Germany did not submit an individual NDC under the Paris Agreement but is bound via the NDC submitted by the European Union. This NDC states that the “EU and its Member States are committed to a binding target of at least a 40% domestic reduction in greenhouse gas emissions by 2030 compared to 1990, to be fulfilled jointly [...]”. In Germany, the national government as well as sixteen federal states, including three city-states (Berlin, Bremen and Hamburg), are endowed with formal legislative power and develop laws and policies aiming at climate change mitigation.

¹ NDCs can be downloaded at <http://www4.unfccc.int/submissions/indc/Submission%20Pages/submissions.aspx>.

3.1 NATIONAL LEVEL

The key instrument currently steering national climate governance is the Climate Action Plan 2050, an informal policy instrument, adopted by the German cabinet on November 16, 2016 (CAP 2050). According to the CAP 2050, Germany aims to become basically greenhouse gas-neutral by 2050 (CAP 2050 at 2.4). In order to reach this goal, the federal government does not impose any specific emission reduction obligations on lower-level entities such as federal states (“Bundesländer”) or municipalities. The CAP only refers to the importance of enhanced mitigation action at all levels, including the local level, in general (CAP at 4.3). It follows a sectoral and non-binding approach by setting out emission reduction targets for different sectors of industry to be reached by 2030 (CAP at 5). In line with this political guidance, regulation is also sectoral with, for example, laws on renewable energy production, emissions trading and energy efficiency. Although it has been the subject of some political and scientific debate about it (Rodi/Sina 2011), there is no climate protection law at the national level as an overall legally binding and thus formal instrument directing German climate mitigation efforts.

To date, national climate policies have only addressed German municipalities and cities via financial incentive programmes such as the National Climate Initiative (Nationale Klimaschutzinitiative). Municipalities can participate either in the funding programme of the “Municipality Guideline” (Kommunalrichtlinie) or the “Master Plan Guideline” (Masterplan-Richtlinie). The former – inter alia – provides funding for municipalities to establish integrated climate action plans; the latter supports more ambitious municipalities who commit themselves to two reduction goals: (1) reduction of their GHG emissions by 95% by 2050 and (2) reduction of their final energy by 50% compared to 1990 levels. The “Masterplan municipalities” (Masterplan-Kommunen) are financially supported in reaching these goals. So far, 41 German municipalities have voluntarily become “Masterplan municipalities”, Frankfurt am Main and Stuttgart being those with the largest populations.

Thus, under the national legal and political framework, only those municipalities which have voluntarily chosen to become a member of one of the national government funding programmes have to fulfil the requirements of the respective programmes. All other German municipalities are free to plan or not plan, implement or not implement actions on climate change mitigation within the scope of local self-governance as provided for by article 28 (2) of the German constitution.

3.2 STATE LEVEL

In recent years, seven of Germany’s federal states have enacted climate protection laws: Hamburg, North Rhine Westphalia, Baden-Württemberg, Rheinland-Pfalz, Bremen, Berlin and Schleswig-Holstein. These laws may be very broadly classified into three “generations”, bearing in mind that also those that belong to one “generation” differ significantly in terms of specific regulations (Wickel 2015 and 2013). The climate protection law and the climate protection ordinance issued by Hamburg as early as 1997 and 2007 respectively may be referred to as “first generation” climate protection laws. They are not of a strategic nature but mainly concerned with specific energy saving and energy efficiency measures for buildings and installations (Schröer and Kullick 2012; Wickel 2015 and 2013). Neither the law nor the ordinance contains any state-wide emission reduction goals nor do they require the Hamburg government to enact a climate protection plan or regulate respective minimum content or procedural requirements. The “second generation” climate protection acts of North Rhine Westphalia (2013), Baden-Württemberg (2013) and Rheinland-Pfalz (2014) set an institutional and instrumental framework for strategic climate mitigation action at state-level. All three climate protection acts set emission reduction goals for the years 2020 and 2050, require the state government to enact a climate protection plan, provide guidance on its content, responsibilities and regular monitoring, establish an advisory committee to monitor and support the climate action plan and refer to the role model function of public authorities with, inter alia, specific goals and measures regarding state-owned buildings (Wickel 2013 and 2015).

The most recent climate protection acts have been issued in Bremen (“Bremisches Klimaschutz- und Energiegesetz” 2015), Berlin (“Berliner Energiewendegesetz” 2016) and Schleswig-Holstein (“Energiewende- und Klimaschutzgesetz Schleswig-Holstein” 2017). They contain all the elements of the strategic steering of climate mitigation and adaptation efforts of their “second generation” precedents (goal setting, climate protection plan, monitoring etc.), but go beyond this strategic level in providing for more specific instruments, for example, regarding local electricity and heat consumption and supply. Thus, they

might – broadly speaking – be referred to as “third generation” state-level climate protection acts. For the purpose of the analysis of multi-level relations in the German hierarchy of climate governance, the four state laws that explicitly address the level of municipalities or districts are examined below.

3.2.1 NORTH RHINE WESTPHALIA

The climate protection law of North Rhine Westphalia (CPL NRW) is the first and so far the only climate protection law not issued by a city-state that establishes a legally binding responsibility for climate mitigation action at municipal level. It requires all public authorities, including municipalities, to enact climate protection plans (§ 5 (1) CPL NRW). However, the actual obligation to do so, the time limit and more specific content requirements are dependent on a statutory instrument that the state government is empowered to issue. Municipalities have to provide for climate protection plans two years after the entry into force of such a statutory instrument (§ 5 (3) CPL NRW). Bearing in mind the outcome of the recent state elections in North Rhine Westphalia, it remains somewhat questionable whether this statutory instrument will be issued in the near future under the new conservative state government.

In addition to this specific procedural requirement, the climate protection law underlines the role model function of the public authorities in terms of climate protection and, more specifically, the lowering of local GHG emissions, expansion of renewable energy and adaptation efforts.

3.2.2 BREMEN

The city-state of Bremen consists of two municipalities (Bremen and Bremerhaven). Their climate mitigation activities are, in addition to a general reference to the role model function of municipalities (§ 7 CPL Bremen), addressed in four main ways via the Bremen climate protection law (CPL Bremen). Firstly, there is a general duty for the municipalities to take into account the goals and explicitly outlined strategies for action in their local decision-making (§ 2 (2) CPL Bremen). Secondly, the municipalities are required to issue and apply limitations on the energy consumption of newly built, renovated or newly rented public buildings within one year of the entry into force of the CPL Bremen. The law came into force 27 March 2015. Thirdly, both municipalities have to issue specific requirements for public procurement, e.g. cars, lighting, electrical equipment (§ 9 (1) CPL Bremen) and institute controls on the energy consumption of public buildings (§ 9 (3) CPL Bremen). Fourthly, the municipalities need to develop local urban planning concepts (“städtebauliche Konzepte”) with local goals and strategies for action on climate mitigation and adaptation. Such concepts are to be publicly available, reviewed every five years and contain information on specific measures in land use planning (“Bauleitplanung”) and urban development contracts (“städtebauliche Verträge”) (§ 13 (1) CPL Bremen). The local climate concepts shall specifically examine the scope for action with respect to the energy supply of new urban developments, the design and orientation of plots and rooftops for the production of renewable energies, construction of renewable energy plants, reduction in the energy consumption of buildings and adaptation measures (§ 13 (2) CPL Bremen).

3.2.3 BERLIN

The Berlin climate protection law (CPL Berlin) highlights the role model function of public authorities (§ 6 CPL Berlin) but contains several more specific requirements on the local level. It is important to note that the city-state of Berlin, unlike Bremen, is not divided further into municipalities. As in the city-state of Hamburg, the next level down is the administrative level of districts (“Bezirke”). The districts are explicitly addressed in § 9 of the Berlin climate protection law. It states that in general districts are free to fulfil their role model function under their own discretionary scope for action. However, they are required to produce their own energy balances and carbon emission inventories, enact goals for carbon emission reductions and provide for statements regarding energy savings in district-owned buildings (§ 9 (1) CPL Berlin). Upon request, districts need to report to the senate administration on the accomplishment of the reduction goals set (§ 9 (2) CPL Berlin). The only other specific obligation on the district level is regulated in § 16 CPL Berlin. According to this, district administrations need to examine their buildings with a view to the use of renewable energies, revamp roofs of suitable buildings in cases of renovation to enable the use of solar energy for electricity and heating, and actually use such rooftops of public buildings for the production of

solar power and heat (§ 16 (2), (3), (4) CPL Berlin). Furthermore, at state-level renovation strategies and energy management for buildings are to be established to include buildings belonging to the district administration (§ 8 CPL Berlin).

3.2.4 COMPARISON

The following table summarizes the responsibilities of municipalities and districts established via state-level regulation. The overview shows that state-level regulation has two main foci: one is to require and broadly guide the strategic planning of climate mitigation efforts at the local level and the other one is to oblige municipalities and districts to establish certain standards or management procedures in areas within their remit, such as public buildings and procurement. None of the state laws requires the local level to reach certain carbon emission reduction goals. Requirements in strategic planning are limited to procedural and thematic substantive guidance. In Nordrhein-Westfalen much will depend on the content of the statutory instrument that still needs to be enacted.

	NRW	Bremen	Berlin
Strategic Planning Instrument	CAP	Urban planning concepts	-
Content of strategic planning instrument	To be specified in statutory instrument	Local goals and strategies Specific measures in land use planning and urban development contracts Examine specific scopes for action (RE plants, energy supply of new developments, etc.)	-
Process	tbd	Reviewed every 5 years	-
Transparency	tbd	Publicly available	-
Target setting	in CAP	In urban planning concepts	Goals for carbon emission reduction
Monitoring	tbd	5-year review	Energy balances Carbon emission inventories
Reporting	tbd	Review publicly available	To senate administration upon request on progress towards goals
State – local relationship	tbd	Take higher level goals and strategies into account in local decision-making	-
Role model function	yes	yes	yes
Public buildings	tbd	Limit energy demand of public buildings Institute controls on energy consumption of public buildings	Statements regarding energy savings Examine and eventually use roofs of public buildings for solar energy production (Renovation strategies)

			and energy management at state level)
Public procurement	tribd	Issue specific requirements, e.g. re cars, lighting, electrical equipment	-

Table 1 – Synopsis of the responsibilities of municipalities and districts established via state regulation

4 LOCAL CASE STUDIES

This section of the paper discusses case studies from the city-state of Hamburg, the city of Frankfurt – located in the federal state of Hessen without a climate protection law but voluntarily participating in the ambitious “Master Plan Guideline” programme – and the city of Cologne – situated within the jurisdiction of North Rhine Westphalia in order to provide examples of the different forms in which German cities can be interlinked into the multi-level web of climate governance. The case studies serve as a basis for the next chapter’s more in-depth discussion of the strengths and weaknesses of different forms in terms of the design of multi-level climate governance.

Before outlining the specific instruments developed to steer climate mitigation action down to or up from the local level, it is important to note the immense relevance of local, especially city-level, action. In 2005, approximately 75% of global energy flows were consumed in cities (Swilling et al. 2013). About half of the world’s population already lives in cities and this number is expected to rise to about two thirds by 2050 (UN DESA 2015). The share of energy consumption in cities and thus cities’ relevance for climate change mitigation action will continue to rise. Consequently, it becomes more and more important to include cities in reliable, strategic climate mitigation action and equip them with instruments, institutions and ideally also financial support that enable them to effectively contribute to GHG emission reductions.

In general, cities and other municipalities in Germany have a constitutionally enshrined right to local self-government (“Recht der kommunalen Selbstverwaltung”, article 28 (2) of the German constitution). Based on this right they can regulate and manage local affairs under their own responsibility within the limits of the law, for example via municipal ordinances and the spending of locally raised taxes. Within this scope for action many German municipalities have voluntarily enacted local climate action plans to strategically steer their climate mitigation efforts (Kahl/Schmidtchen 2013: 342). However, German and European-wide studies show a lack of mechanisms that ensure that targets are met (Sippel 2011, Bulkeley et al. 2011).

4.1 HAMBURG

With 1.7 million inhabitants Hamburg is the second largest city in Germany and the eighth largest city in the European Union. Per capita carbon emissions currently amount to 10.2 tonnes CO₂/year (Hamburg Climate Plan 2015, p. 7). The city-state of Hamburg is free to voluntarily steer its climate mitigation efforts. It is not bound by any substantive or procedural international or national regulations, for example, to meet specific reduction targets, apply certain methodologies in its GHG inventory, report to anyone setbacks or progress in its mitigation efforts, or include citizens or public authorities in its climate action planning.

Voluntarily, Hamburg has been a member of two city networks, the European Climate Alliance since 1993 and the Covenant of Mayors for Climate and Energy since 2008. It reports its carbon emission data and reduction targets to the CDP (formerly Carbon Disclosure Project) and NAZCA (Non-State Actor Zone for Climate Action) established under the Paris Agreement.

The State Parliament of Hamburg adopted its most recent Hamburg Climate Plan (Hamburger Klimaplan, Drs. 21/2521) in December 2015. The key overall targets of the Hamburg Climate Plan are to halve CO₂ emissions by 2030, reach a CO₂ emission reduction of at least 80% by 2050 compared to 1990 levels, and – maintaining a quantitative target – reduce CO₂ emissions by almost 2 million tonnes by 2020. Per capita carbon emission reduction targets are 9 t CO₂ per capita by 2020, 6 t by 2030 and 2 t by 2050 (ibid. p. 7). The Hamburg Climate Plan puts in place a transformative process divided into so-called adaptive management cycles (ibid. p. 10) and thematically focused on the following four aggregated strategic

clusters with cluster-specific goals: the transformation of urban spaces, the green economy, the city as a role model and climate communication (ibid. p. 11). For example, a sub-goal of the cluster “the city as a role model” is that the Hamburg state administration becomes climate neutral by 2030 (ibid. p. 15).

To coordinate and steer action on climate change mitigation and adaptation, the city created the Hamburg Coordination Centre for Climate Issues (Leitstelle Klimaschutz) (ibid. p. 8). This body is also responsible for the control of measures and financial flows, as well as CO₂ monitoring. Control and monitoring is a major element of the Hamburg Climate Action Plan and builds on a project-focused “bottom-up” method (ibid. p. 73 f.). Annexes 1 and 2 of the plan list 175 specific measures, the associated annual financial expenditure, measure-specific reduction targets for the year 2020 and the annual reductions achieved in 2013 and 2014.

The interim results of the monitoring process show for the year 2013 an overall CO₂ emission reduction of 14.3% compared to the base year 1990, per capita CO₂ emission reduction of 13.5% compared to the base year 2003, as well as a CO₂-intensity reduction per unit of GDP of 28.4% compared to the 2003 level (ibid. p. 78).

4.2 FRANKFURT AM MAIN

With 730,000 inhabitants Frankfurt am Main is the fifth biggest city in Germany. Per capita carbon emissions in 2010 were 9.65 tonnes CO₂ (Frankfurt Green City). Frankfurt voluntarily joined the national funding programme of the “Master Plan Guideline” (Masterplan-Richtlinie) and since 2013 has developed its “Masterplan 100% Climate Protection” issued in 2016. As a “Masterplan Municipality” the city committed to (1) reducing its GHG emissions by 95% by 2050 and (2) reducing its final energy consumption by 50% compared to 1990 levels. Participating in this funding scheme also involves putting in place a strategic planning instrument such as the “Masterplan 100% Climate Protection” to reliably steer the process required in order to reach the reduction targets and specific requirements regarding, inter alia, control and monitoring, participation and external review by an advisory board.

Frankfurt is member of the city networks German Climate Alliance and the Covenant of Mayors for Climate and Energy and it reports its carbon emission data and reduction targets to NAZCA established under the Paris Agreement.

The Frankfurt Masterplan 100% Climate Protection starts with a status quo description of final energy consumption in Frankfurt for the different sectors of electricity, heating and transport and respective subcategories (Chapter 2). In the following chapters it discusses the reduction potential in these different sectors and subcategories via energy saving measures and the use of renewable energies (Chapters 3-5). Chapter 6 highlights opportunities in the redirection of financial expenditure in the energy sector. Chapter 7 develops sector-specific scenarios (reference scenarios and measure scenarios) for electricity, heating and transport and concludes with scenarios and recommendations for covering 100% of the energy demand in 2050 by means of renewable energies. All in all, the feasibility study shows that it is possible to reach the ambitious goals for 2050.

The main coordinating body for action on climate change mitigation in the City of Frankfurt is the department of energy. A detailed table available on the department’s website lists all resolutions adopted by the city council since 2006 in the field of energy and climate policies.

4.3 COLOGNE

The city of Cologne is located in the federal state of North Rhine Westphalia and with about 1 million inhabitants is the fourth biggest city in Germany. Cologne has been a voluntary member of the European Climate Alliance since 1992 and a member of the Covenant of Mayors for Climate and Energy since 2008. The city derives its carbon emission reduction targets from the goals involved in membership of these city networks. Members of the Climate Alliance work, inter alia, towards reducing their CO₂ emissions by 50% by 2030 compared to the base year 1990. Key commitments for members of the Covenant of Mayors at the time Cologne joined were an increase in energy efficiency by 20%, an increase in renewable energies in the energy mix by 20% and a 20% reduction in carbon emissions by 2020 compared to 1990 levels (City

of Cologne). Members of the Covenant of Mayors also committed to establishing a carbon or GHG emission inventory, instruments for strategic steering towards reaching the above targets and reporting (Covenant of Mayors for Climate and Energy). Cologne reports its carbon emission data and reduction targets to NAZCA established under the Paris Agreement.

As a municipality of North Rhine Westphalia, the city of Cologne is bound by the regulations issued under the Climate Protection Law of the state. Thus, according to article 5 CPL NRW the city will be obliged to enact a climate protection plan with the specific content requirements as soon as the state has issued the relevant statutory instrument. Currently, the key strategic planning instruments in the field of climate mitigation action are the 2012 Integrated Climate Protection Concept (Integriertes Klimaschutzkonzept) with its two main parts related to energy and transport and the 2014 Program of Climate Protection Measures (Klimaschutzmaßnahmenprogramm). The Integrated Climate Protection Concept focused on energy begins with a stocktake of the energy and carbon balance for the year 2008 (chapter 2), discusses the potential of energy saving measures (chapter 3), develops energy and carbon scenarios for 2020, addresses participation in the development of specific measures to reach the targets (chapter 5), develops a programme of measures (chapter 6), tracing of its effects (chapter 7) and its embedding in networking and public relations concepts (chapter 8). The Integrated Climate Protection Concept focused on transport builds on a stocktake for the year 2006 (chapter 5), develops a reference and a climate protection scenario (chapters 6 and 7), depicts specific climate protection measures in the transport sector including guidance for their implementation (chapters 8 – 15). Chapter 16 is dedicated to controlling and monitoring the effectiveness of the proposed measures in the transport sector. Building on the findings in both parts of the Integrated Climate Protection Concept (energy and transport), the city council adopted a resolution with 13 priority measures in 2014.

5 DISCUSSION OF INSTRUMENTS

The three local case studies highlight the manifold ways in which German cities are currently interlinked into polycentric climate governance depending on how they mandatorily or voluntarily interact with vertical or horizontal climate governance axes. All three cities voluntarily participate in the European city network Climate Alliance and in the international city network Covenant of Mayors for Climate and Energy. These voluntary memberships involve certain requirements for GHG or carbon emission reduction targets and strategic planning towards reaching such targets. Via the Covenant of Mayors for Climate and Energy, all three cities report to the Non-State Actor Zone for Climate Action (NAZCA) established under the Paris Agreement and strengthened through the 2016 Marrakech Partnership. Thus, with respect to the international level it is evident that voluntary mitigation efforts by cities organized in city networks are increasingly visible and start to be integrated into the formal international climate regime established under the Paris Agreement.

In the absence of any obligatory national regulation of municipal climate mitigation action, Hamburg and Cologne, just as the vast majority of German municipalities, freely decide upon their mitigation efforts and steering of these under their right to local self-government enshrined in the German constitution. Frankfurt am Main voluntarily participates in the funding program of the Masterplan-Guideline and is thus subject to the ambitious 2050 reduction targets and strategic planning requirements set by the funding programme. The German national legal framework thus refrains from setting any obligatory minimum requirements regarding municipal climate action planning and – more specifically, inter alia – targets, process, content, instruments, methodologies, participation and transparency. So far it focuses on financial and procedural support for the highly ambitious targets of the 41 German municipalities.

At state level only Nordrhein-Westfalen and the city-state of Bremen require their municipalities to enact climate action plans via their climate protection laws. However, with respect to Nordrhein-Westfalen deadlines and content depend on a statutory instrument that still needs to be issued. Bremen has the most detailed requirements for strategic climate mitigation action in its two municipalities including target setting, minimum content requirements and a publicly accessible five-year review. In the city-state of Berlin, districts have to set emission reduction targets, put in place energy balances and carbon emission inventories and upon request report to the senate administration on progress. Hamburg was the first German state with a climate protection law but it is focused on specific energy saving and efficiency measures for buildings and installations and does not require any strategic planning. It can be observed

that at state level there is a tendency in the newer climate protection laws to include regulation on strategic steering of climate mitigation action at the municipal level.

Thus, climate action planning at city level derives its framework from different axes. In Hamburg the process is internally steered, goals and content have been decided upon politically, administratively and with public participation bearing in mind the requirements of the city networks. Special efforts have been made with regard to monitoring and control. With the support of the Wuppertal Institute, the city developed a bottom-up process to trace in a measure-specific way which goals could be reached at what cost. The process of climate mitigation efforts in Frankfurt builds on an ambitious history and is in its recent form framed via the requirements of the national funding programme of the Masterplan-Guideline. With the scientific support of, among others, the Fraunhofer Institutes IBP and ISE, the city developed sector-specific strategies to reach the 2050 emission reduction goals set by the funding programme. The city of Cologne derives its carbon emission reduction targets via membership of the Climate Alliance and the Covenant of Mayors for Climate and Energy. The current 2012 Integrated Climate Protection Concept encompasses measures tailored to the energy and transport sectors. In the future, as soon as the relevant statutory instrument is in force, this strategic planning instrument will have to fulfil the requirements set by state regulation based on article 5 of the NRW CPL. Other formal requirements of strategic climate mitigation planning only exist for the municipalities of Bremen and for districts in Berlin. The city-level climate action plans as such are in all cases informal planning instruments with no legally binding effect and no formal requirements regarding procedure, participation and transparency.

6 CONCLUSIONS AND OUTLOOK

The research has shown a growing web of polycentric climate governance structures, with cities becoming increasingly engaged and visible actors. Currently, cities and other German municipalities interact with the climate governance regime mainly via informal steering instruments. However, recent developments such as the Marrakech Partnership and the state-level climate protection laws of three German states show a tendency towards increasing formalization. It is too early to assess whether or in how far a formalization of local level climate mitigation efforts is beneficial to support cities in their climate action planning and turn them into reliable partners for international polycentric climate governance, with a view to reaching the overall 1.5 or 2.0 degree goal of the Paris Agreement. The state and city-level laboratories of strategic planning show a rich variety of target setting, development of sector specific strategies, assessment, monitoring, participation and transparency and much potential for the exchange of experiences, more in-depth scientific review and incremental strengthening of reliable bottom-up climate mitigation efforts.

1 PLANNING TRANSFORMATION TOWARD REGENERATION PLANNING AND SUSTAINABLE DEVELOPMENT IN CHINA

China's 30 years' urbanization progress and economic growth is complicatedly interweaved with land developing policy changes featured by distinctive state-led governance (Tian, Ma, 2009). Land is not only a simple container of production for growth, but also one of the most effective financing approaches for the governments with monopolistic power to get money and fund urban development (Fan et al., 2016; He et al., 2014; Figure 1). Accompanied by the worldwide greatest population mobility from rural to cities (247 million in 2015) and the rapidest urbanization growth from 26.9% to 52.7% (Figure 2), the years from 1991 to 2012 has witnessed increasingly land expansion from 2.08×10^4 km² to 4.57×10^4 km², which is criticized as "expanding land urbanization ignoring quality". (Wang et al., 2014; Yang et al., 2016; Ong, 2014; China's floating population report 2016).

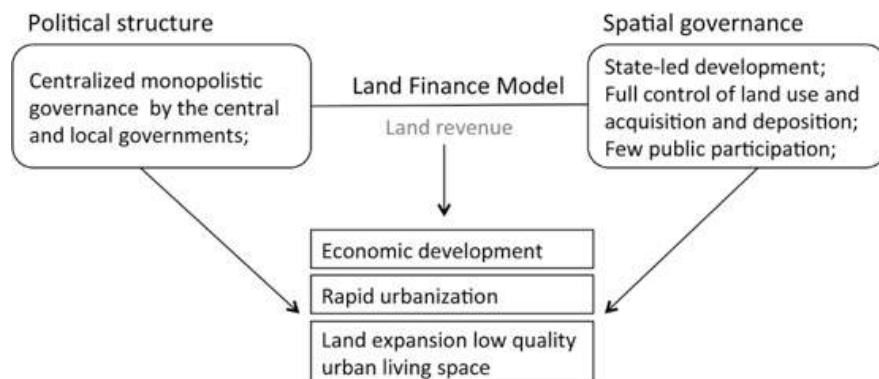

Figure 1 Logic of governance, land developing and economic development during China's reform stage

Figure 2 Urbanization and its changing rate Data source: Chinese Year Statistic Book calculated by author

This economic miracle based on land developing is exciting, quite similar to European reconstruction booming up after WWII and the urbanization marvels in other East Asian countries (World bank, 2014). However, many studies have criticized it for “draining the pond to catch the fish”, consuming too much land and creating widely distributed ghost cities. From a more profound perspective, it undermined problems such as vast public finance debt and barriers for economic shift from industry to services; the entire national economy seems “kidnapped” by the real estate market (Cai, 2017; Zhu, 2013). In response to this situation, China has been forced to revise its spatial strategies, veering towards a quality-oriented urban regeneration featured by lower growth rate, high emphasis on sustainability and formalization of institutional arrangements. In this new phase featured by the “new normal” economy, urban planning embodies a focus on structural change from expansion planning to regeneration planning by limiting horizontal urban sprawl and improving environment sustainability.

2 GENERAL DILEMMAS IN CHINESE URBAN REGENERATION

However, the space-time compression of rural-to-urban migration, industrial upgrading and urban sprawl makes Chinese urban regeneration suffer from various dilemmas like complicated property rights, lack of legal approaches for regulatory plan adjustment, and long-term informal land transactions (Hao et al., 2011; Zou, 2014; Feng, Tang, 2013), in addition to the endogenous difficulties in finance balance and consensus reaching related to multiple stakeholders (Roberts et al., 2016; Gomez, 1998; Thomson et al., 2006).

1. Complicated Land ownerships. Normally, for a developed land that is waiting for regeneration, private, collective (legal and illegal) and state-owned property ownerships formed in different historical periods always overlapped together, especially in the fringe of sprawling metropolitan area, which makes any redevelopment action very hard to put into practice. Moreover, since there are plenty of illegal settlements in urban and rural areas resulting from the contradiction between social housing shortage and massive labor migration (Ding, 2003; Liu, Zhang, 2015), urban regeneration is even a harder issue to deal with.
2. Restrictions in Land subdivision and land-use change. In term of dividing or merging developed lands for better reuse, as legislation for regeneration didn't receive serious consideration until the first decade in 21st century, the formal approach is explored for a long period, while some gratuitous lands have been transacted illegally under table. Due to the lease term constraint, no stakeholders could sell or divide the original property for better use, not to say upgrade and change the land use flexibly. The positive evolvement and upgrading of lands is obviously hampered.

Faced with these institutional deficiencies (Figure 3), a wave of institutional innovations ranging from governance, legislation, to planning has been set up in recent years, which implies great shifting of regeneration institutionalization. The paper tries to systemically underline these formalized institutional arrangements in three leading Chinese cities of Shanghai, Shenzhen and Guangzhou that have initiated a pioneering and influential institutional innovation of urban regeneration in recent years. It analyzes their institutional reform from the governance and planning-making aspects, so as to the performance

evaluations to explore whether the policies are of high problem-solving capacity in vivid public sphere rather than expressions on paper (Nicholls, 2005; Zimmermann, 2015; Buser, 2013; Smith, 2013). It can provides a broad view on Chinese urban generation to help us enhance the our understanding of decision mechanism and power balancing mechanism in current China.

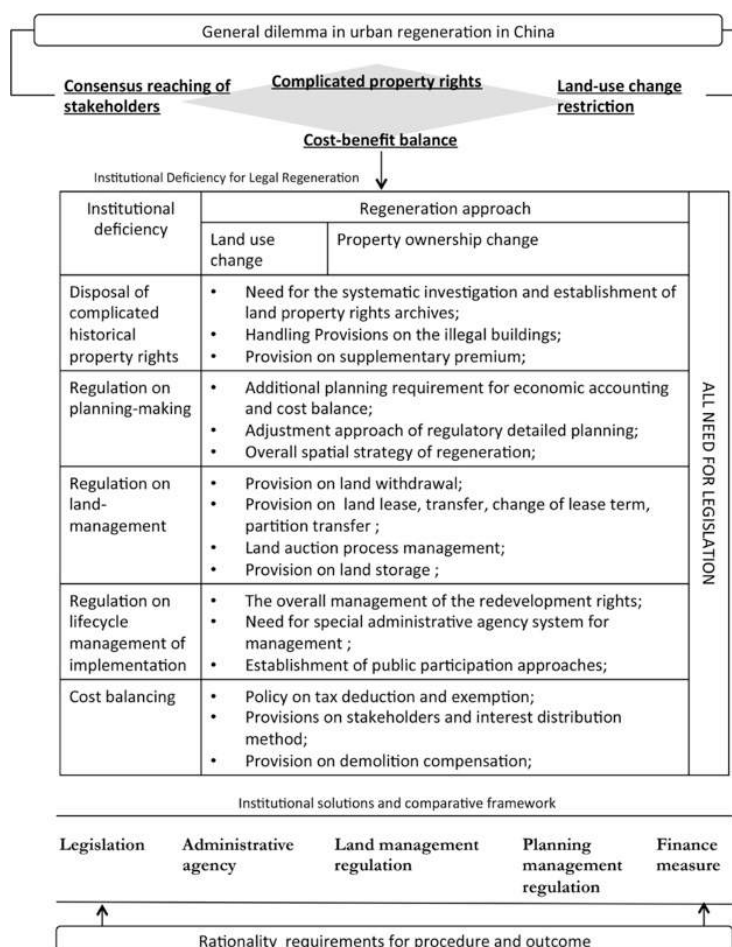

Figure 3 Dilemma, institutional deficiencies and solutions

The research is based on comprehensive understanding of the policy documents and field investigations. In the following chapters, it will firstly build a comparative analysis framework, and then goes into the deep analysis of the regenerations in Guangzhou, Shenzhen, and Shanghai. Different institutional arrangements are concluded afterward. The last section proposes some concluding remarks and suggestions for further regeneration in China.

3 INSTITUTIONAL INNOVATION OF URBAN REGENERATION IN THREE CHINESE METROPOLISES OF GUANGZHOU SHENZHEN AND SHANGHAI

3.1 COMPARATIVE FRAMEWORK

The characters of regeneration institutional arrangement is reflected from two folds, governance and planning management. In aspect of governance, administrative agency structure and legislation system sever as the foundation for performance, while other detailed management measures during the whole process also make difference to the outcome. And in the vein of planning management, new regulations involved in land use management and plan adjustment, are created by the government to deal with emerging problems in redevelopment, which is distinguished from previous new town plan. In consideration of its complexity, an analysis framework is built up as Figure 4. After direct analysis on

institutional innovation, the evaluation from aspects of legitimacy, outcome effectiveness and sustainability is also carried out.

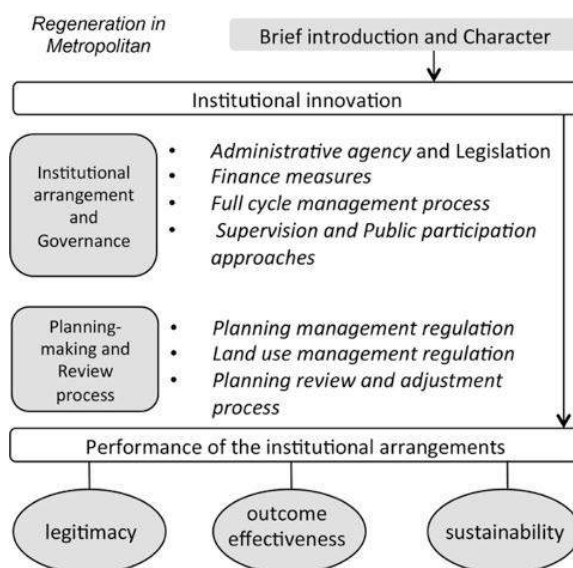

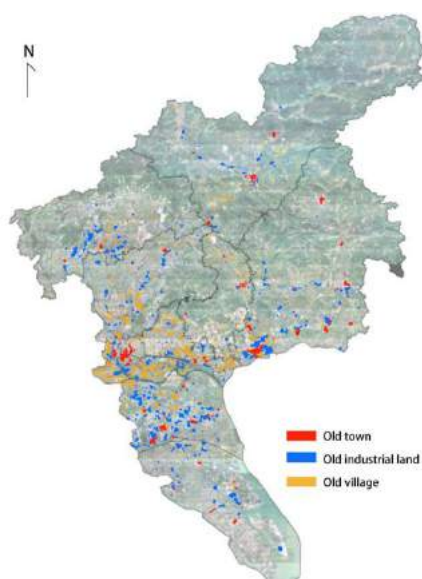

Figure 4 Analysis framework for regeneration in Metropolis

3.2 URBAN REGENERATION IN GUANGZHOU: GOVERNMENT ORIENTED

In Guangzhou, regeneration is called as “Three Olds” redevelopment¹ formulated since 2008, comprising three categories of old town, old village, and old industry area (Altrock, Schoon, 2013; Figure 5).

There are generally two modes of regenerations, the comprehensive approach (demolition-reconstruction) applied for the areas in need of overall upgrading and improvement, and small-plot generation (wei gaizao) which improves the public infrastructure and spatial quality in a small area. The total area for regeneration is up to 358.66 km², 11,182 parcels (according to the statistics of Guangzhou renewal Bureau). By July 2016, the overall completion rate is up to 10.9% (old village 14.6%; old industry land 9.6%). Regeneration in Guangzhou starts from market-oriented but transfers to government-oriented gradually by policy revision.

Figure 5 Distribution of Three Olds lands for regeneration in Guangzhou

Source: Map database for Three Olds until December 2014, Guangzhou Urban Renewal Bureau

3.2.1 INSTITUTIONAL ARRANGEMENT AND GOVERNANCE

(1) ADMINISTRATIVE AGENCY STRUCTURE AND LEGISLATION SYSTEM

In order to effectively manage the urban regeneration projects, Guangzhou established the Guangzhou Urban Renewal Bureau in 2015, which is the first urban regeneration bureau across national wide.

¹ In Dec 2008, Chinese Ministry of Land and Resources together with Guangdong Provincial Government list Guangdong Province as the trial districts of intensive land development, and endowed cities in Guangdong with legislative, policymaking power for “Three Olds”.

Urban Renewal Bureau serves as the core institution, led by the political leading group, in conjunction with other sub-district governments, systematically responsible for the regeneration management, including project declaration, regulation and policy making, and provision release, so as to coordination of involved departments. It's completely independent from Urban-rural Planning and Land Resource Bureau.

Until now, Guangzhou has released more than 20 regeneration-related policies and regulations, but no legislation yet. Among these documents, three core regulations are known simply as No.56, No.20, and "1+3" policy¹, which stipulates the specific requirements about stakeholders, planning, land auction and storage, cost-balancing measures. They settle the foundation for the institutional framework. No.56 documents was released in the first place, it gave great freedom to the developers to lead the regeneration projects, while the government served as a supervisor. During this period, the process of regeneration was very fast, because the construction need of public facilities had not been emphasized, reducing the cost of redevelopment. What's more, when the land owners realized that regeneration would create huge value-added benefits, they began to add rooftop extensions to obtain more compensations. Spatial management of regeneration became even more difficult with no strict monitoring. Considering these phenomenon, government decided to take back the leading power of regeneration by No.20, emphasizing more on public interests, facilities construction and land storage. While the 1+3 policy is more refined, obtaining experiences and lessons from the previous regeneration management, but for developers, it also more rigorous. Detailed variations from No.56 to the current policy indicates governance trend to a more strengthen state-led control with fine measurements, strictly restricting the market behaviours (Figure 6).

No.56	No.20	1+3 policy for regeneration
<p>1.Principle: Market participation with state-led.</p> <p>2.Take the land auction markets as a tangible platform to attract overall market investment, and the stakeholders could cooperate with market to renovate in a joint venture model.</p> <p>3. Market is relatively of high degree freedom, low cost, and less restrictions.</p>	<p>1. Strengthen the principle of state-led: emphasis on planning and guidance, supplement of the public service facilities, infrastructure construction, and urban public interest.</p> <p>2 Increasingly tighten Land Policy : Land parcels should be stored firstly by the government and then release for auction. Government regulates the primary area for renewal.</p> <p>3 The premium for old industry land increases, while the compensation is lower.</p> <p>4 In order to control the total compensation costs for old village, it should be regenerated in form of cluster under the lead of state and collective group.</p>	<p>1Principle: State led, market participation.</p> <p>2.Updated provisions on various aspects with fine and clear requirement.</p> <p>3. Add "Micro regeneration" to previous "comprehensive regeneration" for the convenience of small parcels</p> <p>4.Improve data survey, expert argumentation, public consultation, illegal investigation ,land withdrawal mechanism.</p> <p>4 Re-determine the distribution of benefits to protect public and government's interest.</p>

Figure 6 Outline and variation in between No.56, No.20, and 1+3 policy

(2) FINANCE MEASURES

Measurements on cost balancing reflect governance tendentious of government-market cooperation. In Guangzhou, public facility improvement, old town refurbishing, and historical area regeneration is financed by the local public finance. The land leasing incomes are used to cover the cost of land expropriation, acquisition and storage, as well as the subsidies for the encouraged industry and hard-to-balanced projects. By contrast, for old industry land and collective old villages, with value-added potential and strong regeneration initiative, are financed by the market investments and involved self-regenerated stakeholders. Following to the principle of "state-led, market operation, public participation and win-win", governments encourages innovative financing methods by market mechanism, they try to drive more enterprises and social force to participate in urban regeneration, solving financial bottleneck by a cooperative Public-Private Partnership, for example, creative mortgage loan, innovative credit financial products.

¹ No.56: Opinions on accelerating the transformation of the 'Three Olds' (Guangzhou government (2009) No. 56); No.20: Supplement for opinions on accelerating the transformation of the 'Three Olds' (Guangzhou government (2012) No. 20); 1+3 policy: Guangzhou urban regeneration policy: overall requirement, requirement for old village, requirement for old industrial land and requirement for old town (2015.11)

(3) FULL CYCLE MANAGEMENT PROCESS

Urban Renewal Bureau will lead the boundary delineation of regeneration priority areas, like historical area, land for public space and service facility, industrial upgrading area. The lower-level district governments could also investigate the need for improvement in its jurisdiction and submit proposal for priority areas in advance. After collecting suggestions from other departments and approved by the top leading group, Urban Renewal Bureau formulates an annual regeneration plan, as well as implementation and financing plan. This plan should go through expert evaluation, public consultation, and then be released to the sub-district governments for implementation. It should be underlined that the public consultation requires a stakeholder-agreement ratio higher than 80% (Old town 90%), otherwise, the parcel cannot be listed in priority regeneration area. Annual regeneration plan serves as an outline, while the local governments then make a detailed planning for the parcels. After a successful second round consultation process among the involved stakeholders (more than 80% or 2/3), the detailed planning will be again submitted and reviewed to check whether it comply with the overall urban development strategies by Urban Renewal Bureau and the leading group. The government also propose a prior data supervision process, if the submitted plan is deviated from the prior data more than 5%; the related subjects have to explain for the reasons. While public consultation committee, villagers' consultation committee and expert consultation is applied accordingly.

3.2.2 PLAN-MAKING AND REVIEW PROCESS

(1) PLANNING MANAGEMENT REGULATION

Guangzhou government creates a "1+3+N plan system" for overall planning management. The main purpose is to determine the principles and goals of "Three Olds" regeneration, besides, detailed spatial guideline, for example, regeneration types, methods, function upgrading direction, development intensity control, facility needs, key areas for historical and cultural protection, are all included. In general, it tries to lead a Transit Oriented Development, optimizing the land use structure through the redevelopment process.

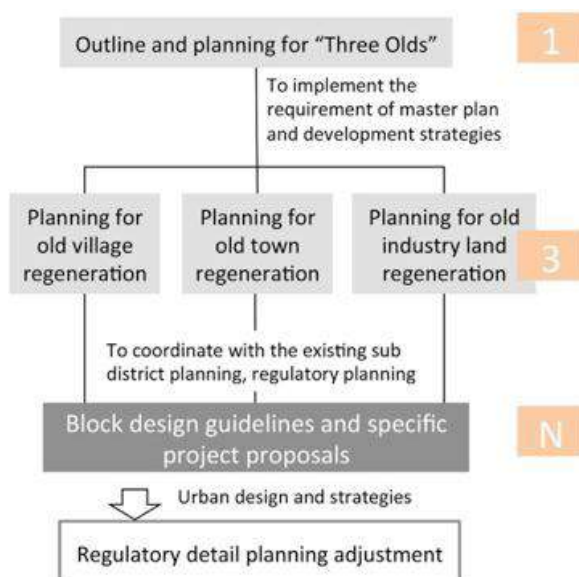

Figure 7 1+3+N planning framework

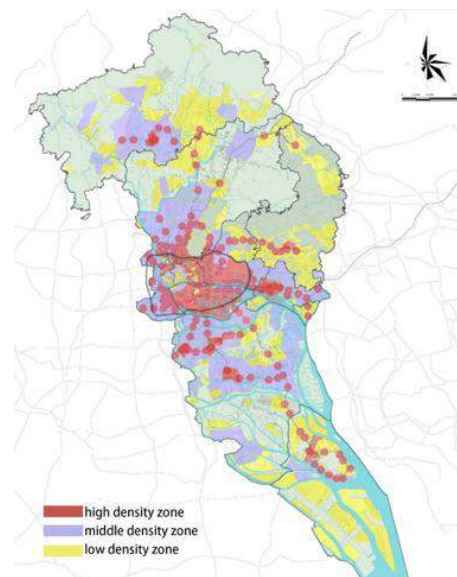

Figure 8 Density zoning according to the distance to subway and business zone
Source: planning for "Three Old" regeneration in Guangzhou (2010-2020)

(2) LAND USE MANAGEMENT REGULATION

Land use and property is the most troublesome issue. The set up of regulations on land use management is a slow but progressive process since 2008. The first issue is defining and confirming the fuzzy properties. Urban Renewal Bureau organized the sub district government to carry out detailed investigation of regeneration lands, such as household, population, historical architecture, property ownership, thus building a completed and clear status quo database of lands. For the old village, the collective economic organization or its successor should take the responsibility of clearing the land ownership and demolition of illegal buildings. If the old village is supposed to be transferred into industry or commercial land, it can hand over part of collective lands to the government, to be free from land property clean up. For the industry lands under illegal transaction, current owners could not propose regeneration until they achieve legal property right and pay for the fine.

While land supply has undergone a shift change after No.20 policy. Before No.20, the markets could transact lands directly with the stakeholders by negotiation, but afterward all the state-owned lands should be firstly stored by the government, and then bid in a unique land market. Collective-owned lands may choose to keep the ownership or transfer to state-owned lands, the latter one could sell tenure to markets, or be redeveloped cooperatively by village collective economic organization and developers. If one parcel land involves with multiple property ownership, it should be summarized as one subject representing for all, realized by signing a group legal contract or share value evaluation. In addition, lands inside and outside the regeneration boundary are equally displaced in the principle of voluntary.

3.2.3 PERFORMANCE OF THE INSTITUTIONAL ARRANGEMENTS

By the above flexible and comprehensive arrangements, formal and legal approach for regeneration is realized in Guangzhou. Its regulation system is based on the clarity of original fuzzy property rights, providing possibilities for different kinds of transaction approaches comply with the existing planning framework. However, in the exploration stage, the policy changes very quickly and it still cannot be confirmed as a rigid legislation. In response to the changing policy, outcome effectiveness shows different features taking No.20 document as a turning point. The first stage before No.20 is featured by rapid redevelopment with high market participation enthusiasm, and lots of invests entered into regeneration. Developers firstly choose the lands with clear property right which are easy access to redevelopment, moreover, the government still didn't realize the importance of public facilities, which led to inadequate infrastructure and public good supply, fragmented regeneration without consideration of the overall spatial structure. After adjusting the requirements on facility construction, rigid storage policy of land and an overall regeneration planning, the prophase approval procedures become complex. In addition, regulatory detail plan adjustment, consensus of multi-stakeholders is hard to achieve, which at last end by extension of the project period and the interests is partially shared with the state, so markets get fewer added value and gradually loses initiatives. Regeneration in Guangzhou experiences a turning from market-oriented to state-led implementation. The outcome effectiveness is not so satisfied in the second stage due to a rigid control by government. Current land storage policy is like a deformed land finance mode with less sustainability. With difficulty in carrying out projects, Guangzhou is now trying to explore policy reforms to promote market participation.

3.3 URBAN REGENERATION IN SHENZHEN : MARKET-ORIENTED

Urban regeneration in Shenzhen is classified as three types of comprehensive renovation, functional change, demolition and reconstruction. The process is obviously market-oriented, encouraging the property owner or other subjects to conduct self-regeneration. Since 2009, more than 330 villages are regenerated. In 6 years, the number of regeneration units announced in draft plan has reached to 379 parcels.

Only in 2014, the total lands for redevelopment accumulated to 210.59 hm², accounting for 36% of the annual land supply, with an investment of more than 40 billion (RMB). From 2011 to 2014, urban regeneration has provided 129,300 units affordable housing for the city (Table 1).

Year	Supply plan/10 thousand	Completion rate	Implementation of the previous year/10 thousand	Completion rate
2015	1.8 (Plan)	--	2.7 (Plan)	--
2014	3.11	110.7%	5.81	116.20%
2013	2.76	110.40%	4.27	141.40%
2012	2.39	120%	1.8	180%
2011	--	--	1.05	105%
Total	8.26		12.93	

Table 1 Shenzhen affordable housing supply (2011-2014)
Source: Shenzhen affordable housing supply plan and the implementation of the previous year

3.3.1 INSTITUTIONAL ARRANGEMENT AND GOVERNANCE

(1)Administrative agency structure and Legislation system Shenzhen urban regeneration department is under the lead of Shenzhen municipal planning and Land Resources Committee (Municipal Oceanic Administration), responsible for organization, coordination and supervision of regeneration projects (Figure 9). Such subordination relationship avoids the approval lag by division in-between departments, making it easy to carry out.

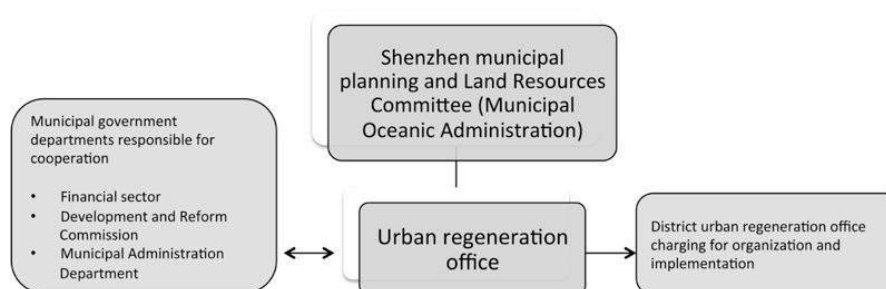

Figure 9 Urban regeneration agency structure in Shenzhen

Urban regeneration unit (chengshi gengxin danyuan) is regarded as an innovative and successful tool for project management. All regenerated parcels will be listed as a unit, and after the declaration and approval, it could replace the previous statutory plan under the protection of law. Similar to Guangzhou, Shenzhen also created a regulation system instead of legislation, ranging from detailed technical standards to regulations (Table 2), these documents regulate the rules for regeneration, methods for property clean up, premium sharing ration, so as to related affordable housing supply ratio, preferential policies on innovative industry, the latters are first creative attempts at a nationwide scale. Among these regulations, Shenzhen urban regeneration measurement regulation and detailed rules for implementation are two core documents integrating the others as a whole, illustrating for distribution of interests and operation process.

Regulations	Legislation of Shenzhen urban regeneration (in process)
Management Rules	Shenzhen urban regeneration measurement regulation
Operational guidelines	Detailed rules for implementation of the Shenzhen urban regeneration
Technical standards	Rules for urban regeneration unit planning approval
Related policies	Guidelines for demolition property clean up
	Guidelines for the reconstruction of urban regeneration land ownership
	Guidelines for the planning of Shenzhen urban regeneration unit planning
	Technical standards for premium sharing ratio in urban regeneration
	Technical standards for Shenzhen urban regeneration unit planning
	Technical standards for the implementation of low carbon ecological objectives in urban regeneration unit planning
	Policy on improving the innovative industry land supply
	Policy on management of housing for innovative industry

Table 2 Regulation system for urban regeneration in Shenzhen by author

(2) FINANCE MEASURES

Compared to other metropolises in China, the available land resource is relatively limited in Shenzhen (976km², 1772 km² in Guangzhou), so the revenue from innovative industries rather than the land premium income is the primary source for public finance. Now faced with the difficulties for regeneration financing, Shenzhen chooses to mainly dependent on the market and the property owners themselves. It's actually the best solution for historical reason. Due to great shortage of affordable housing supply during the rapid development, a large number of informal residencies, also called urban villages, distributed widely in the city, 70% of which are illegal buildings. With the extremely heavy burden of these unclear-property clearances, the government has no choice but resort to market-oriented approach to fill the long existing loophole. From the other vein, market investments with initiative for potential regeneration interests, could also provide enough public service facilities, public space and social housing for this growing young city.

(3) FULL CYCLE MANAGEMENT PROCESS

Full cycle management process in Shenzhen urban regeneration is similar to Guangzhou. The procedures could be divided into five main processes, boundary delineation of urban regeneration unit, detail planning for regeneration unit and its approval, implementation plan-making, contract signing, plan permission approval and implementation (Figure 10). Among the three types regeneration, demolition and reconstruction takes the largest ratio, of which the coordination time is longer, but the land value-added profit is larger. There are still some defects in the current arrangement, like no mandatory demolition law, lack of detailed requirement for the coordination process, such as no standard transaction price, no forced sale requirement for the original property owners. Accompanied by the soaring housing price, the formulation of one unique subject for one unique regeneration unit becomes quite difficult. The original property owners could ask for a super high compensation or unacceptable real estate replacement requirements, thus delaying the coordination time and forcing developers to trade higher than the market price. The other property right owners who have signed the transfer contract may at last break the contract. In practice, a lot of urban regeneration are delayed or even canceled because of the last few households that don't agree with the relocation compensation and resettlement agreement.

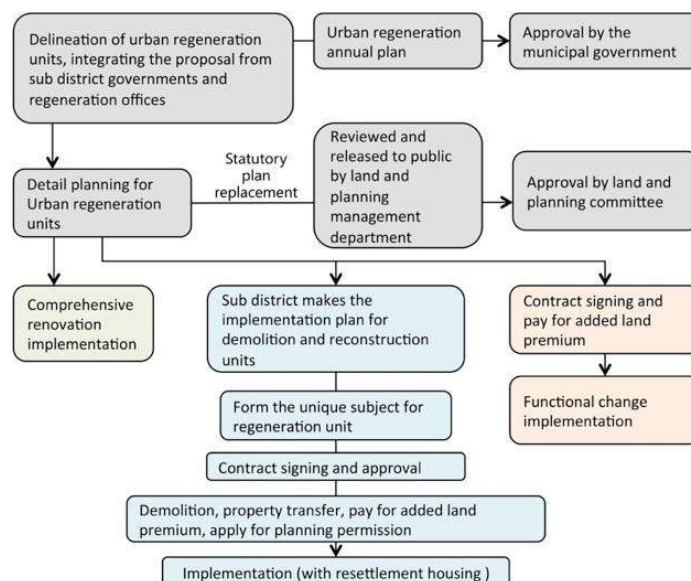

Figure 10 Planning and implementation process for urban regeneration units in Shenzhen

3.3.2 PLAN-MAKING AND REVIEW PROCESS

(1) PLANNING MANAGEMENT REGULATION

Planning management for urban regeneration is successfully connected with the existing planning system by urban regeneration unit (Figure 11), which could replace the statutory plan and break the constraint of illegalization. The special planning for urban regeneration is based on comprehensive research about the environmental condition development, the overall spatial structure and existing functional clusters' distribution. It could be divided into three kinds of regions, namely comprehensive service zone, environmental sensitive zone and industrial agglomeration zone (Figure 12). According to the distance to subway station and existing centers location, a density zoning and priority classification are created for development intensify management, in order to improve land use efficiency, public facilities and protect the environmental resource with clear sequence.

Figure 11 Urban regeneration framework in Shenzhen

Figure 12 overall spatial structure for urban regeneration Source: research on Shenzhen urban regeneration strategy

Shenzhen is a city with high-density population, so the government also tries to lead a Transit Oriented Development mode to create a livable and efficient city. The areas within 500m to subway station or to the existing urban centers are taken as the key areas to provide public facilities and affordable housing through regeneration, within which the three olds are all required to renovate. In addition, density zoning also reflects the idea of TOD model, the closer to subway station, the permitted density is higher. Besides, Shenzhen tries to become a global city by upgrading its industry, encouraging innovation industry and attracting high-skill people from the world. It tries to enhance the control of ecological boundary taking this good regeneration opportunity, therefore, old industry land and villages, are planned to clean for a better open space (Figure 11, Figure 12, Figure 13; Table 3).

Figure 13 Industrial land within 500m of the central area and the transit station source: as above

Figure 14 Industrial land within the ecological land boundary source: as above

Categories	Aim	Target land type and location (km ²)	Area (km ²)
Demolition and reconstruction or Functional change	Construction of public facilities	Industrial land within 500m of the central area and the transit station, 15 km ²	> 60
	Commercial, residential real estate redevelopment	Old villages within 500m of the central area and the transit station, 14 km ²	
		Industrial land within 500m of the central area and the transit station, 15 km ²	
		Mix use area, 6 km ²	
Comprehensive renovation	Industrial building, lands redevelopment	Industrial building in Industrial Park, 10 km ²	> 130
	Improve the public service facilities; environmental remediation	Old residential, 8 km ²	
		Old village 36 km ²	
Ecological restoration		Industrial land 86 km ²	> 19
	Restoration of ecological green space	Old villages within the ecological land boundary, 6 km ²	
		Industrial land within the ecological land boundary, 13~29 km ²	

Level	Zoning	Basic FAR	Limit
1	I\II	3.2	≤6.0
2	III	2.8	≤5.0
3	IV	2.2	≤4.0
4	V	1.5	≤2.5
Location	Distance to subway station	Subway categories	Normal station
	(m)		
	0-200	+0.60	+0.40
	200-500	+0.40	+0.20

Table 3 Regeneration strategy and target lands for improvement Source: as above

Figure 15 Density zoning for Shenzhen urban regeneration

(2) LAND USE MANAGEMENT REGULATION

For land use management, the key problem is the 70% illegal lands. While creative policies and regulations are generated as effective tools for the government to re-define the land development right and make the difficult illegal land regeneration possible with the help of developers (Figure 16). The government makes a platform for all the stakeholders. Collective village organization owning lands with illegal property less than 40% (before 2014, 30%) could hand over 20% land to the government, and then transfer the 80% lands to the developers, obtaining compensation and legal housings. While the developer could conduct regeneration after handing over 15% lands for public use with government's approval, thus through the game of redevelopment right, everyone gets the benefits they want. However, it also causes some problems like interest group, irrational game from information asymmetry and super high house price for citizens. The government set up a disguised way for the legalization of illegally lands, expanding collective land rights to non-collective and non-indigenous villagers through policy, but the legitimacy is worthy of reflection. In general, under the condition of clear property rights, the market can better transact interests, achieving balance of interests and promoting social equity. But in Shenzhen, although it seems protect the collective interests, but it actually causes great spillover of land added value and possible injustice.

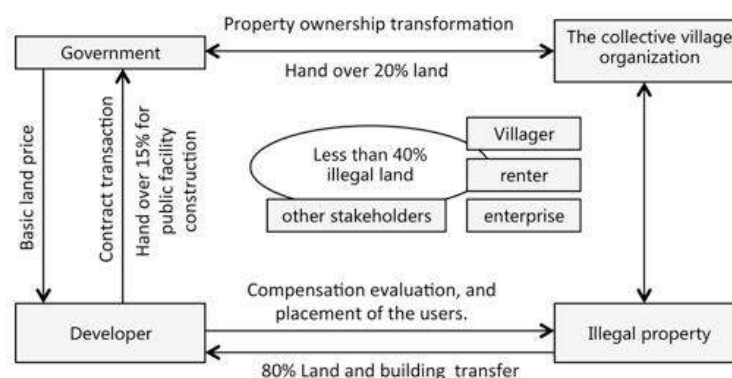

Figure 16 "15+20" property clearance and regeneration approach for old villages with less than 40% illegal land and multiple stakeholders in Shenzhen by author Refer to: Liu, Zhang, 2015.

3.3.3 PERFORMANCE OF THE INSTITUTIONAL ARRANGEMENTS

Regeneration in Shenzhen is relatively fast, following the rules of legalization and marketorientation. Rather than focusing on profits from regeneration, it pays more attention to facility supply and affordable housing construction, to provide attractive environments for high-end labors to settle down. Based on the statistic of regeneration unit drafts, the redevelopment process is growing steadily. Markets could positively involve in the process, with less intervention from the government. Agreements could be achieved between stakeholders and market directly, reducing the transaction costs. The government serves as a night watcher relay on market's initiative, underlining the important indicators for spatial governance, like FAR, proportion of affordable housing, and the land ratio for public use. Compared to

Guangzhou, the government is weak but efficient, with enough finance provided by developers and more possibility for society participation. Not only the local state, but also the stakeholders themselves, could carry out urban regeneration according to their needs. Thus, the financial burden is divided among all the stakeholders. Public finance will not have too much pressure to resort for land premium compared to state-led Guangzhou (Figure 17). However, in the long term, this full market-oriented regeneration may eventually lead to heavy burdens for the citizens due to the increasing living cost generated. And for illegal property, the policies permit fully market-oriented compensation, acquiescing the legalization process of illegal. But this defect may cause inequality and leave hidden dangers to the further. Too large developing volumes create heavy burden to infrastructure construction, and the space gentrification is less inclusive for the society gradually, especially the renters or migrants who have no rights, are totally forgotten by the policies (Tian et al., 2015). What's more, the touchiest question for the next generation is, who is able to afford another round urban regeneration cost much higher than the current one?

Figure 17 The proportion of the land premium income to the total state fiscal income in Guangzhou and Shenzhen

3.4 URBAN REGENERATION IN SHANGHAI: ECLECTIC APPROCH

Shanghai used to have a glorious history of industrial development, leaving not only amounts of heritages, but also plenty of outdated lands for regeneration, the output value of which is declining with the upgrading process of innovative industry (4.9 billion/km² in 2011). In addition, a large number of industrial lands are distributed scattered in suburban¹ (Zheng, Lu, 2015). The overall spatial structure towards a livable global city is waiting for adjustment. Faced with the bottleneck mentioned in section 2, industrial land regeneration could only be realized very slowly in an informal way. Meanwhile, the last two decades also witness large-scale demolition and reconstruction of the old residential buildings (about 112 million m² are demolished, while 747 million m² are reconstructed² with high FAR). Gradually, the limited lands are subject to high development intensity, while livelihood is kidnapped by real estate. We are pity for the disappearance of historical features at this stage. After a lasting reflection, Shanghai start to explore institutionalized urban regeneration respect for land transfer legalization, historical protection, vitality simulation and facility optimization.

3.4.1 INSTITUTIONAL ARRANGEMENT AND GOVERNANCE

(1)ADMINISTRATIVE AGENCY STRUCTURE AND LEGISLATION SYSTEM

Urban regeneration in Shanghai is charged by regeneration office under the Municipal Planning and Land Resource Management Department, similar to Shenzhen. Shanghai also take the concept of "urban regeneration unit" to connect with the original regulatory detailed planning. Until now, the set up of regulation system is still on the march. Measures for the implementation of urban regeneration in Shanghai (short as Measures in Shanghai in the following) sheds light on principles and a general framework for regeneration. It is supported by detailed rules for implementation and relevant industrial land use transfer measurements. Measures in Shanghai put great emphasis on public interests in this stage of spatial improvement, requiring for regional public facility supply and need assessment report following the overall

¹ accounted for 36.4% of the total suburban lands

² Source: Statistics Yearbook of Shanghai, from 1995 to 2014

planning; all the public elements, including public facilities, open space, infrastructure, cultural facilities, linkages, should be concluded into a implementation list as mandatory for regeneration.

(2) FINANCE MEASURES

In this process, FAR award is used as a primary bargaining tool for the government to solve finance obstacle. The FAR of historical area is strictly controlled, while increase for other areas must base on the increase of public facility and open space (Table 4). All the spontaneous regeneration subjects have the obligation of public facility construction inside his property. Therefore, regeneration costs are mostly covered by the market investment. Mix use transformation is encouraged except for non-residential to residential land.

Conversely, residence is permitted into public facilities or affordable housing usage. Because Shanghai didn't have the special rights given by the Ministry of Land and Resources, it could not balance industrial regeneration costs by property owners' self operation. Therefore, the bottleneck is still in the position. One creative approach is to get added land values by substitution from collective to state-owned land (Tian et al., 2015), but this's just a drop in the ocean for the total number.

Condition	Provide public space			Provide public facility	
	Provide independent public space and transfer the property to government	Provide independent public space and open to public use, but cannot transfer the property to government	Open public space to public use for 24 hours, but cannot provide independent public facility and transfer the property to government, for example, public corridor, ground floor	Provide public facility and transfer the property to government	Provide public facility but cannot transfer the property to government
FAR Award	2 times as the original FAR	1 time as the original FAR	0.8 time as the original FAR	1 time as the original FAR	0.5 time as the original FAR

Table 4 additional floor areas Award for commercial land

Note: the above award is for space within the outer ring, for space outside the outer ring, the reduction coefficient is 0.8.
To provide underground public facilities, the reduction coefficient is 0.8. To provide both public facility and space, there's another reduction and award ratio.

(3) FULL CYCLE MANAGEMENT PROCESS

As mentioned in above, Shanghai didn't get the "privilege" for experimental innovation of land system, so the current so called "regeneration" could be regarded as an integration of the previous work. The policy seems to have an intention but no strong strength in all aspect regulation. For example, full cycle management process in Shanghai is relatively simplified compared to Guangzhou and Shenzhen. The procedures could be divided into three main processes, regional assessment, urban regeneration implementation plan, planning permission approval and implementation (Figure 18), in which the current policy document could only highlight the regional assessment process, while the detailed provisions on management is less included (following the previous policy instead). Regional assessment report emphasis on public interest, requiring on detail investigation, demand and needs list of public elements.

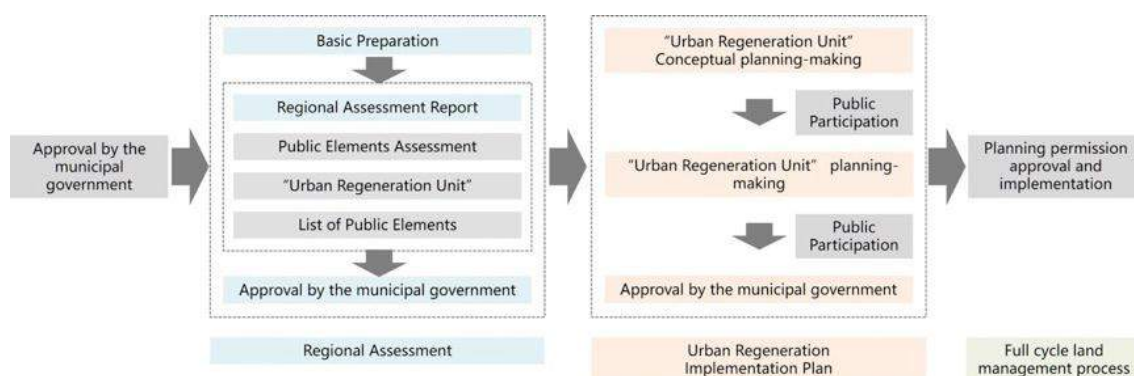

Figure 18 Planning and implementation process for urban regeneration units in Shanghai

3.4.2 PLAN-MAKING AND REVIEW PROCESS

(1) PLANNING AND LAND USE MANAGEMENT REGULATION

At present, the plan of Shanghai urban regeneration has not yet been published officially. There is only a regeneration vision towards four directions, which includes Sharing community, Innovation industrial park, Charming cityscape, and Leisure network. Reflecting the coordination of the regeneration plan and the master plan is still in progress, that urban regeneration unit is the only connection for currently. So the regeneration process is actually going under the table instead of being led by an overall planning. The units' conceptual planning-making, implementation planning-making, approval is controlled by planning department, quite similar to other non-regeneration projects. For land use management, the legalization process blocks the path of informal regeneration, Land transfer period of the urban renewal project may be re-agreed according to the specific circumstances of the project progress. Among them, The use term should deduct the used period from its original use nature and cannot exceed the longest use term regulated by government; the land use term shall be consistent with the original contract if the change of land-use is not involved; The re-agreement use term shall not exceed the corresponding maximum use term regulated by government. While the benefits maybe that it provide an exit approach for historical land.

3.4.3 PERFORMANCE OF THE INSTITUTIONAL ARRANGEMENTS

Although regeneration institutionalization in Shanghai is still in process, it still shows more rationality after 20 years' experience and lessons. The concept and principle are inclined to public services and interests, instead of economic one. However, from the perspective of legal system construction, it is lack of a specialist bureau for management. In addition, due to heavy construction load, regeneration subjects feel inactive for upgrading, and the process will slow down. Cost-balancing dilemma remain as a trouble. Besides, organic community regeneration is not reflected in these physical improvements. In current semi-mature stage, Shanghai is facing a longer period challenge in general. More innovative policies and more freedom for bottom-up efforts are needed for a more livable and creative international metropolis.

4 DISCUSSIONS AND CONCLUSION

These three metropolitan governments form their own strategies to cope with the complexities of dilemmas, taking into account the characteristics of development, historical property rights, and industrial updating needs. The institutional innovation and differentiation indicate the different modes of the state as controller (Guangzhou), supervisor (Shanghai), and promoter (Shenzhen), thereby resulting in different trajectories featured in efficiency and effectiveness. From Table 5, we could have a brief understanding of these three different modes. In Guangzhou, the government withdraws the land by storage gradually, sharing most added values with by property owners, while this path-dependent approach has a negative impact on the initiate of market. Shenzhen gives full freedom to the market by legalization of illegal land, land property transfer and intensify development; by this way, it provides enough public facilities to the city. While Shanghai could only realize this aim by FAR award due to no special land policy permitted by the central government. The common ground is the public participation under the control of the government,

requirement for market to provide public goods, which finally realize the optimization of urban image, public facilities optimization, but also widely space gentrification. Besides, in Guangzhou and Shenzhen, the real estate market has become the biggest beneficiaries, achieving great amounts of economic benefits and profit in quite a short time, which is similar to the housing boom from 1970 to 1980 in Europe. Once the government loses control in the coming years, this will finally damage the real economy and social stability. It's not wise to repeat the history again. With the increasing land value and compensation cost for urban regeneration, we need a more careful and accurate institutional arrangements to eliminate the loopholes and think over the profound influence on our cities.

	Guangzhou	Shenzhen	Shanghai
Financing mode	Land storage for finance; mostly dependent on Market investment;	Dependent on Market investment;	Market investment and public finance;
Governance mode	State-led and market operation;	Market-oriented;	State-led and market operation;
Legitimacy	Independent agency; relatively completed regulation systems but no legislation;	Relatively completed regulation systems but no legislation;	Regulation systems is set up gradually;
Authentic participation by stakeholders	Process participation in form is high, but controlled by the government;		
Public interest	Emphasis on historical protection;	Emphasis on ecological area, affordable housing;	Strongly emphasis on facility, historical protection and ecological area;
Effect on Industry	Require the market to provide according to the supply need;		
Accountability	Land prize increase;	Relatively high and free, but Controlled by the government;	openness to interest intermediation;
Outcome effectiveness	Relatively slow with property clearance, TOD development;	Fast with affordable housing and ecological land optimization, property clean up, TOD development, and increased urban density and pressure for public facilities;	Slow with historical area protection, green space, public facilities, linkage optimization, and Suburban land control;
Common effectiveness	Historical area protection; City image optimization; land price rise; public service facilities optimization;		
Sustainability	The mode of finance is a alienation of previous land finance	Better finance mode but resulting in high living pressure for citizen due to historical property;	Sustainable bout faced with the difficulties to execute
	High space gentrification, not inclusive for low-income group		

Table 5 Comparison of regeneration of the three metropolises

Due to the rapid expansion in previous stage, metropolises have been immersed in problems such as traffic congestion, environmental pollutions, inadequate facilities and irrational industrial structure. These complex "disease" forced the governments to carry out innovative urban regeneration as "medicine" for optimization. Institutional arrangements are taken to deal with the contradiction between long-term benefits and short-term high costs, to weigh the pros and cons and avoid straitened circumstances. The content description and practice comparison of market-oriented, government-oriented, and eclectic modes of governance together reflect some core principles and unhealthy hints in metropolises' regeneration governance in China.

4.1 GOALS AND PRINCIPLES: OPTIMIZATION AND IMPROVEMENT OF URBAN ENVIRONMENT RATHER THAN MAKING A BIGGER CAKE

Regeneration is originally meant to optimize the land use structure, improve sustainability, and provide space for industrial updating. However, the results sometimes turn out to be an interesting phenomenon featured by vertical growth in the post-Land Finance era, that governments get benefits from high intensive redevelopment instead of monopoly of land premium, misleading regenerations to make a even bigger cake for stakeholders who focus on interests rather than real needs of the city. It's important to jump out of the circle of expansion and land finance, taking full consideration of social inclusive, green development, spatial justice and resource sustainability. Regeneration should be a new phase of giving rather than deprivation and vertical urban sprawl. Therefore, to achieve a diversified, high-quality regeneration, principle and goals should be clarified and followed.

4.2 BOTTOM LINE: SUPPLY OF PUBLIC FACILITIES AND FAIR ALLOCATION OF INTERESTS AMONG GROUPS

The government is supposed to responsible for public facility supply and coordinating multiple interests no matter it's a dominator or not. Public interest is the bottom line, involved in public service, infrastructure, and social justice. Policy allowing for deprivation will lead to social segregation, gentrification, so as to polarization between the rich and poor, that the gain cannot make up for losses for the entire city's balanced development. Rules for implementation by the three cities Guangzhou, Shenzhen and Shanghai, all underline the importance of public realm, so as to the historical areas. Guangzhou and Shanghai also emphasize on the control of developers, land market, and actors' behaviors to reduce speculation; While Shenzhen even formulates specific provision to regulate the assorted affordable housing construction. In the previous rapid expansion tide of the cities, it is difficult to rationally forecast the demand of infrastructure and public service facilities, leaving a center-periphery structure featured by intensive facility agglomeration in the center, while the periphery is quite insufficient. Therefore, institutional arrangements should put public facility optimization and supplementation in first, finding elastic approaches flexible for the resilient needs of city.

4.3 CORE ISSUE: COST AND BENEFITS

The core issue to influence actors' participation is cost and benefits. The institutional arrangements should match against the requirements of urban regeneration. Policymaking could directly regulate the allocation of profits among developers, city-state, and individuals. Subsidies policy can promote the initiative by actors, while policy with excessive deprivation will slow down the process. The governments have an option to increase long-term industrial tax income by providing affordable lands for companies, or obtain short-term land incomes for public finance, which is not sustainable in the long run. In other words, policies are valve to control the participators and speed of urban regeneration. In addition, institutional arrangements should also play a restricted role to limits the markets' hitchhiking, speculation and other behaviors damaging the public interests. Though less intervention and weak control of real estate by policies in Shenzhen, a significant rise in housing prices inevitably occurred, leading to a high living cost for all the citizens. Therefore, effective supervision and penalty is necessary for unreasonable speculation (Chen, 2012).

4.4 ENDOGENOUS BARRIERS: THE GOVERNMENT'S ROLE AS RATIONAL ECONOMIC MAN

In the game of interests balance, the government itself also has the attribute of rational economic man, as an endogeneity. In order to accumulate for public finance, the government is inclined to domain the allocation of interests and gets benefits from selling storage land. The balance of interest between governments and markets will raise the threshold for market investment and increase the costs. For example, the government-oriented mode in Guangzhou emphasizing on land storage, has limits the speed

of regeneration process. In this case, the government doesn't not maintain neutrality but involve too much, focusing on short-term profits rather than long-term return.

4.5 DEMOCRACY AND PUBLIC PARTICIPATION: TRADE-OFFS AND RISKS

Democracy and public participation are challenges we will face in the near future. In the process of regeneration, coalition of stakeholders, market and society coalition, government and market coalition, could theoretically reduce the transaction costs, accumulate positive social benefits, and achieve a win-win goal (Yuan, 2015). The establishment of trust among stakeholders could be realized by both formal and informal institutional arrangements. However, there still are risks for failure due to the internal inequality and power imbalance. Therefore, the adoption of public participation requires deep understanding of the local situation, culture and historical background. In addition, the democracy quality of regeneration should be considered in the decision-making process of facility construction, willingness evaluation, and allocations of profits. The approach to keep accountability should be unfolded from the black box. Current public involvements are passive and LESS-effective, resulting in less consideration of local needs and social feedbacks.

Institutional arrangements for regeneration in Chinese metropolises are still in its infancy, many featured problems vary from place to place have not been recognized and excavated, requiring for constantly experiment and exploration to deepen the understanding. In order to develop more effective governance, we need to further strengthen the legalization and distinguish the advantage and disadvantage of marketorientation principles, paying attention to democratic process. The power structure is seeking for approaches to activate all possible resources, and promot the process of institutional reform and democratization in China.

ID 1442 | COMPARISON OF TWO URBAN DEVELOPMENT'S MODELS AND REDEFINITION OF URBAN PLANNERS' ROLE-- A CASE OF YUZHONG DISTRICT, CHONGQING, CHINA

Zhao Chunyu¹; Wang Zhihan¹

¹College of Architecture and Urban Planning, Tongji University
1194093493@qq.com ; wanghonri@outlook.com

ABSTRACT: Urban planning's aim is to seek social equity, to achieve social goals through the development of spatial manipulation and management system in the face of market economy and government ideology. In the face of the complex urban planning, planners should be targeted to the big city and small town planning, which should be strictly controlled at the macro level, planners and government should be the leading force and actively advocate all fields of the city to cooperate together. When it comes to the community and village level, residents can be encouraged to participate in the community's planning to their initiative, and the planners and government can formulate a series of rules and regulations to guide them appropriately, in order to create more local characteristics of the environment. Planners should have the basic quality of the space aesthetics , also need to consider the principle of market economy and social operation's mechanism behind the space, finding an association between market rules and social relations and spatial structure, to make planning policy and management regulations to achieve a better tomorrow through the improvement and adjustment of city spatial entity.

KEYWORDS: urban development's model, urban planning, market economy

1 THE SIGNIFICANCE OF THE EXISTENCE OF URBAN PLANNING

Cities and urban planning appeared very early in the history of the development of human civilization, however, since the emergence of urban planning, it has been plagued by criticism. To achieve a better living environment, planners should define their own role and figure out how to cooperate with the government, the market and the public, which is a problem worth exploring. For a long time, planners have been misunderstood that they only plan "the ultimate blueprint", emphasizing the material determinism without the comprehensive rational attitude towards social and economic factors (Zhang Bing, 1997). For example, Jan Jacobs criticized the urban planning in the "The death and life of great American cities" that the economic and social and no city like this is to be controlled, planners only focus on the appearance of city, but neglect the social and economic operation's mechanism behind it (Jane Jacob, 2006). But Jacobs was looking forward to another kind of Utopia. She did not find out that Le Corbusier, who had already died, have the planning ideas on human care, the public space and the value of the sun. In the city is not a tree, Alexander Christoph believes that the tree structure, which is commonly used in the urban planning, can not reflect the complex network system behind the city (Christopher Alexande, 2004). Planners are criticized that don't consider the operation mechanism of criticism and complexity behind the city, but in fact the modern urban planning has planned the space environment and elaborated the policy and laws in various towns in face of out of control market economy's problems, such as metropolitan diseases and rural decline etc. As Lewis Mumford mentioned in the "The history of urban development: origin, evolution and Prospect", the capitalism destroys the structure of city life, put it in the impersonal basis of money and profit (Mumford Lewis, 2008). Thus in the process of development, money is more than anything, the government and developers prefer to the land intensive development, leading to the demolition of the high historical value buildings may be removed at any time, ordinary people also learned to speculative reselling, land is regarded as commodity it is very difficult to implement effective supervision and control. In market forces dominating today, planners and urban and rural planning is of significance, planners are not only skilled technicians, but also social workers. If science and technology are accustomed to the evaluation of efficiency, social science's evaluation is fair (Zhang Tingwei, 1993). But the planners' aim isn't struggling with the market economy, planners should pursue the aesthetics form of space environment and take the economic and social harmony and stability into account at the same time.

Now the globalization era has come, the city and the country which are developed by the residents purely almost disappear, residents can use local materials according to local conditions and custom's characteristics and create a vivid and friendly environment. But when it comes to large public infrastructures and public utilities etc., cities need to have a overall planning and financial support. It's very hard to realize its deployment for the local residents without professional planners' planning and government's finance. For example, in 2010 Qiongkushitai village of Tex town in Xinjiang province was listed in "national historic and cultural village", which has been kept original ecological a long time because of the traffic inconvenience. is influenced by the modern economy is small, It keeps the original ecological life style and vernacular architecture, but until now the village still has not been powered and the villagers have to use small hydroelectric generators, life is very inconvenient (Figure 1, Figure 2).

Figure1 and ,Figure2-Qiongkushitai Village of Tex Town in Xinjiang Province(Photoed by Writer)

At the same time, if we only rely on the planners and the power of the government from top to bottom, set high rate of urbanization blindly and build the new districts without control, and ignore the actual life's demand of the residents and market rules, it could result in ghost towns, which many Chinese cities have,

a new district of skyscrapers and wide streets likes the new towns of Erlanhot, Alaer, Beitun, Aletai, Zhangye,etc. It can be seen, whether in the city or the countryside, planning requires multilateral collaboration and participation, planners' role is indispensable, but differs in the extent and managed means of different conditions and different means of planning and management .

2 THE TRANSFORMATION OF THE PLANNERS' ROLE

Planning as a prospective discipline, planners must predict and estimate the possibility of the problems and propose the solution in advance, this uncertainty may lead to the imperfect after plan's completion. At the same time, urban planning is also a comprehensive discipline, Government's departments of planning and academic institutions are lack of the solid theoretical foundation which can guide the research, because this foundation contains subjects more and more, such as economics, sociology, geography, political science and so on. Boundaries of the urban planning profession has become increasingly blurred, with each course penetrating into each other (JMcloughlin J B, 1969). It can be said that this confusion comes from the origin of city planning is the material source, but with the development of the city, there are dislocation between the needs of clients and the actual material basis of professional planners, leading to planners' own rejection. So the modern planning education and social needs hope that planners can have comprehensive academic background and accurate judgment for the future, while taking into account the different needs of government and ordinary citizens, paying more attention to the combination of two working modes (top-down and bottom-up). Planners can guide the development of the city and the whole society correctly through learning social and economic geography of a certain extent, and considering these factors when plan the space environment and formulate policies and regulations of management. Although some planning concepts considered the social, economic factors, The construction of the so-called "good" city practice is far more difficult and complex than the expected actual implementation, the garden city, neighborhood units and the new metros under the planning and construction were not more attractive than the city without planning , and even less (Zhu Jieming, 2012). Because the formation of a good city is complex and diverse, it is not enough only with the efforts of the planners, we can create good city with the cooperation by the government, planners, developers, and the public participation, then clarify and adjust the economic and social relations behind the space environment.

In order to show the differences between the top-down and bottom-up city development modes, the comparison of the Jiefangbei CBD and Shibati historical areas will be shown next, then reflect and imagine the future development paths of the two area. And planners should figure out what the role they play and what kind of positions they stand.

3 THE FORMATION AND DEVELOPMENT OF JIEFANGBEI AND SHIBATI, YUZHONG DISTRICT, CHONGQING -TWO DIFFERENT MODES OF URBAN CONSTRUCTION

The mountain city of Chongqing originated from the Yuzhong Peninsula, overlooking from the air, Chongqing city is surrounded by two rivers, likes the floating leaf, the ancient saying said that "Ba country likes a leaf floats up and down, two rivers like straps go by the Fotu barrier". Because of the special terrain and history, the old city of Chongqing is known as the upper and lower cities, upper city is the central business district, the core of which is Jiefangbei, while lower city mainly is cultural historic district such as Shibati , a slum of Bayu dwellings' characteristics (Fig. 3)

Figure3-The Upper and Lower City's Satellite Map(Drawn by Writer)

3.1 INTRODUCTION OF JIEFANGBEI OF THE UPPER HALF OF THE CITY

According to the overall planning of Chongqing, Jiefangbei CBD (central business district) is an important part of the "central business district (CBD) of chongqing". In the history the "hard core" part was the area surrounding "Dashizi", "cross street of gold", including east to the Xiaoshizi, north to Jiangbai road, Linjiang door and Minsheng road, west to Jintang street, south to the Heping and Xinhua road etc, covering an area of about 0.92 square kilometers. (Baidu Encyclopedia of Jiefangbei). The contrast with 18 ladder for

discussion of jiangbei district mainly refers to the hardcore part of the central business district (CBD) of chongqing. Before the founding of the People's Republic of of the temporary capital (Fig. 4) in 1946, which was the first comparatively consummate and systematic urban general plan in the history of Chongqing City.

Figure4-Draft plan for construction of capital for ten years
(<http://roll.sohu.com/20130704/n380680675.shtml>)

During the War of Resistance Against Japan, Chongqing, as the strategic command post of the Asia-Pacific region, experienced a rapid increase in population, and various public facilities, especially transport facilities, were extremely unsound. The planning drew extensively on the Western planning thinking, and fully considered the unique topography of Yuzhong Peninsula, which basically decided the road network structure of Yuzhong Peninsula, laying the foundation for the prosperity and development of the peninsula in the future, especially the urban core districts established at that time --Jiefangbei and Cross Street, which are also the symbols of Chongqing's CBD today. However, since this plan, the center of Chongqing has developed from the lower half of the city, flourished with the terminal culture, to the upper half, where the motor traffic was more convenient. The lower half of the city was planned to be the ordinary residential area, and the construction of a host of private houses appeared at Shibati, which turned a high-density urban area during this period. Thus the lower and the upper halves of the city gradually formed completely different styles, separated by the Xinhua Road.

After the liberation, Jiefangbei gradually became the business and financial center of Yuzhong. Later in 1997, Chongqing turned to be the municipality directly under the Central Government in 1997, and the governments of the city and the district transformed the original Jiefangbei cross (2.24 million square meters) into China's first commercial pedestrian street, which is the so-called Jiefangbei Center shopping plaza. Since then, Yuzhong District Government expanded the square to the middle section of Bayi Road,

and the extension of Minzu road, while the area increased to about 36,000 square meters, respectively in 2000 and 2001. In 2003, Chongqing made the "Chongqing Central Business District Plan", in accordance with the "Chongqing City General Plan (1996-2020)" afterwards (Qiao Hong and Yang Qingyuan, 2013). It can be said that Jiefangbei Area, as the core area of the city, has been subject to the relatively more stringent government management and planning control, which leads to buildings and the environment in better quality. The present Jiefangbei Area, gathers all kinds of large commercial complex and business office buildings, including over 60 CBD key buildings, mostly located along the Zhonghua Road, Jiaochang Road and Zourong Road--Minzu Road area. The 60 key buildings has on average 30 layers above the ground level, and 3 to 4 underground layers [9]. 45.8% of them are office buildings, 36.4% are commercial ones, and the remaining 17.8% are hotels and apartments, whose capacity rates ranges from 3.71 to 44.96 (Qiao Hong and Yang Qingyuan, 2013). While the average capacity rate is 3.6, way higher than Shanghai Lujiazui's 1.3 and Shenzhen Futian's 2.0 (Fig.5).

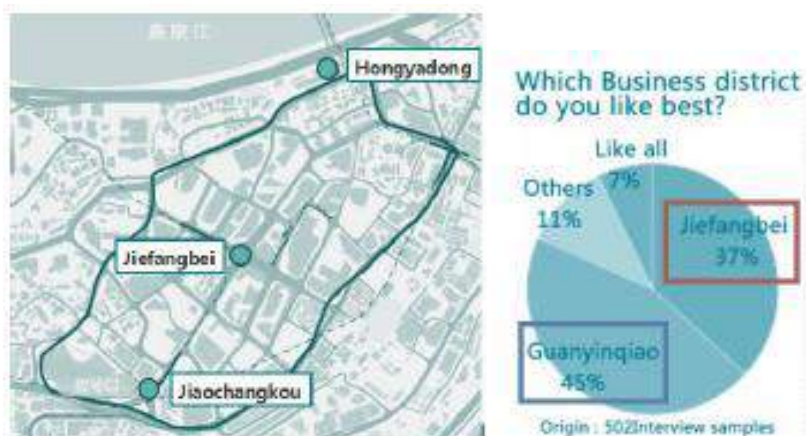

Figure5-Jiefangbei CBD Texture Map (Drawn by Writer)
Figure6-A Survey on the Preference of Chongqing's Business District
(Huirong Website of Chongqing Business Newspaper 2013-05-09)

In recent years, due to lack of space and regional industrial competition, Jiefangbei has also faced further transformation and upgrading challenges. In the past, Jiefangbei was the product by the cooperation of the powerful government and planners in the face of strong capital-driven, which was the typical type of top-down planning. In this process, in order to pursue market efficiency, certain amount of public space was given up and the ecological benefits were ignored, hence compared with the rising Guanyinqiao shopping area in Jiangbei District during recent years, Jiefangbei, as the core of the old region, is short of public space and landscape, and the popularity has been lost (Fig.6).

In addition to Jiefangbei and Cathay Pacific Museum of Art, the spatial layout and architectural style of the region are both lack of certain geographical features, affecting the further development and upgrading, which also proves the lack and necessity of public participation in its planning and development process. Taking Singapore for example, where the top-down plans are strictly enforced. In order to ensure the democratic and impartial nature of the planning as a government function, the planning law clarifies the legal procedures for public participation and planning appeals. Both the strategic conceptual planning and the implementational of the guidance planning for development need the link of public comments, which are reported to the Minister of State Development later, and properly handled (Tang Zilai, 2000). Top-down urban development model can meet the basic needs of the city, but there are also problems such as insufficient public participation, similar faces of thousands of cities and so on.

3.2 INTRODUCTION OF SHIBATI OF THE LOWER HALF OF THE CITY

The lower half of the city, especially the Shibati area, is the symbol of the spontaneously formation from bottom to top. The history of Shibati area is far longer than Jiefangbei. As early as the Ming Dynasty, Shibati got its name after the 18 ladders from the houses of the inhabitants to a well here. Before the demolition, Shibati represented the lifestyle of this old mountain city, where the tortuous mountain streets were filled with all kinds of snack shops, fruit stands, hair salons, carpenters, tailors and the so-called Bang Bang playing cards on both sides, which contributed to the living atmosphere. The majority of the

residents living at Shibati were indigenous, and Shibati is just one part of the old Chongqing. In recent years, with the rapid development of Chongqing, there came some foreign population. But the ordinary people living at Shibati has never stopped for a moment, being eager to leave this place as soon as possible, because the Shibati's infrastructure is just a mess. Residents in better economic conditions have been gradually removed. It can be said that Shibati is an inclusive and ample settled city (Fig.7, Fig.8), and its richness of life and the diversity of space is invisible in the upper half of the city. Despite the road system and fire protection facilities which are met the planning norms, the demolition of the population density up to 1700 people / square kilometers, the low and ruined buildings inside the blocks whose building density is up to 79%, the floor area ratio comes to 2.5, and the land use efficiency is low. While Shibati is still the card of the Old Chongqing. In recent years, Chongqing, whose cultural industry is relatively backward, has also had several films taken, such as "Hero of Hot Pot", "Passing Your World". And the main viewfinders are located at Shibati, Baixiang Street in the lower half of the city, indicating that the lower half is actually very characteristic and representative of the old Chongqing. At the same time, the cultural and creative industries in Shanghai are mostly gathered around the historical neighborhoods, also showing the significance of the preservation of the old city, especially the historical and cultural blocks.

Figure7-Historical images of Shibati Figure8-Shibati Main Street' Section and Plan
(Tencent Dayu Network) (Drawn by Writer)

However it is a pity that Shibati does not possess the ability to update autonomously like Tianzifang, while Chongqing, compared with Shanghai, has relatively limited needs for the development of the cultural and creative industries and tourism. Besides that, because of the location close to Jiefangbei, the economic value of the land is enormous. It has been a long time since the latest improvement of the environmental facilities done by the authorities, leading to too much debt, which caused the government to give up the update work due to the high cost, and decided to retain only part of the relatively new high-rise buildings and cultural relic protection units such as the Consulate General of France, and the rest would all face the demolition and redevelopment. Even the core protecting areas in the historic district have been removed, and the official program has been announced. Some blocks imitating the original texture, composed of pseudo-classic buildings, around with the construction of high-rise commercial offices replace instead, whose volume rate rises up to 2.5 from the original 4.1 (Fig.9, Fig.10).

Figure9 and Figure10-The Form Plan and The Rendering, From The Comprehensive Plan of Shibati
(East China Architectural Design Institute Co. Ltd)

It can be said that this is a so-called "compromise" measure taken, confusing the "historical blocks" and "style blocks", leading to the demolition of most of the blocks, leaving only the graded heritage buildings. The original historical and cultural elements will lose the authenticity of the historic district itself through a deductive way to rebuild (Li Heping and Wu Qian, 2015). Meanwhile, city officials have forgotten the origins

of the city, the Shibati is the mother town of Chongqing, and its existence means the right given to people by Chongqing, to take root here.

Research has shown that the exact contradiction of Shibati is that the local residents can not stand the bad living environment, but their employment and survival still depend on the area. Most of the demolished residents are resettled in other more remote areas, such as Nanan District, Shapingba District, etc. (Fig.10), but there are still some people who come back every day for small commodity retailing, old goods reselling, fortune telling and other business activities. There are a total of 24 letters in the Chongqing Municipal People's Government open mailbox, whose titles contain "Shibati". Among them, there are 4 proposals for the renovation proposal, 17 for relocation and resettlement problems such as compensation standard and resettlement house allocation, and 3 for rebuilding process problems such as slow transformation and construction impact. After researching "Shibati demolition" in Baidu, the messages on the first research page basically revolves around the problems the masses complain about including the low efficiency of the government, the slow speed of demolition, the too low resettlement compensation and the shame for the disappearing Shibati. From the situations above, there are 3 core issues on the demolition of Shibati: 1. The lack of progress causes the various contradictions occurred in the negotiations between the demolition office and the masses; 2. The government and the residents are difficult to reach an agreement on the demolition compensation standard. The residents measure their property value according to the market price of Yuzhong District (9,300 yuan / square meter in 2010), while the government only meets the purchase of resettlement housing standards through the assessment of institutions for compensation(4,300 yuan / square meter in 2010) , which just reaches half of the amount raised by the masses. Some businesses are losing their stores for surviving, thus their livelihood is worrying the standard for Shibati relocation compensation is too low(government website mayor mailbox,2014). Ordinary people, tourists and scholars are full of regret on the disappearance of Shibati, and appeal the new construction to restore the style and lifestyle of the old mountain city(government website mayor mailbox,2014). Wang Yuanling's "Goodbye-Shibati" photographic notes also mentioned the blind massage parlors, herbal shops, Mengshaqier Cheongsam garment factory, Roundhouse hotel, etc. at Shibati, which are the business whose customers' loss is unsustainable because of the demolition, or moving to other places to continue the meager income(lu Feifei and Wang Yuanling,2011). I believe that these are the stores with certain history and local reputation at Shibati, maintaining the local social network and playing the "street eye" role of the carrier of the street spirit, which have the possibility to operate after the transformation. The future of Shibati would only become the continuation of Jiefangbei CBD, and the antique-style Bayu residential buildings are difficult to reminiscent of the original appearance of the old Chongqing. This is the helplessness of the government in the face of market forces, but also the dereliction of the planners' duty.

3.3 TWO MODELS OF URBAN DEVELOPMENT: COMPARISON OF JIEFANGBEI AND SHIBATI

Jiefangbei CBD core area is formed under the mode of top-down city development, and gradually brings the strong popularity and high economic output, but due to the lack of public participation, there are not enough geographical features and public space. While the Shibati historic district is formed by the down-top city development pattern, and full of historical and distinctive features. But due to the lack of planning control and government management, the poor living environment and incomplete infrastructure construction finally bring about not only the demolition and reconstruction with high cost, but also the loss of city memory. It shows that the down-top mode inspires people's creativity, and creates the formation of certain geographical features, but there is such a disadvantage of the disability to continue the healthy development. Both the top-down and the down-top mode have its own advantages and disadvantages. (Tab.1)

	Jiefangbei CBD	Shibati
Formation mode	Top-down, led by the government, planners and the market	Down-top, led by the public and the market
Area	92.4 hectares	18.9 hectares
Patchment		
Spatial characteristic	Modern commercial and office buildings, mainly of high-rise and super high-rise	Bayu traditional houses, mainly low layer and middle layer
Activity and population type	Consumer groups, business people, mainly high income, highly educated	Migrant workers, mainly low income, low educated
Function	Business office, leisure and entertainment	Living, low-end business
Resident population density	55,000 people / square kilometers	73,000 people / square kilometers
Capacity rate	3.6	2.5
Building density	63%	79% (Before the demolition)

and the government, so that the folk wisdom can be fully inspired to create the space environment with more local characteristics.

ID 1461 | GOVERNING URBAN REGENERATION: PLANNING AND REGULATORY TOOLS IN THE UK

Rob Atkinson¹; Andrew Tallon¹; David Willians¹
¹University of the West of England, Bristol
rob.atkinson@uwe.ac.uk

1 INTRODUCTION

The PARCOUR (Public Accountability to Residents in Contractual Urban Redevelopment)¹ project involves a comparative analysis of urban development (of previously used land) led by public-private partnerships

¹ PARCOUR is a three-year international Research Project (2015-2018) funded jointly by the ESRC (UK), FAPESP (Brazil) and NWO (Netherlands). The participating universities are UWE (UK), Sao Paulo (Brazil) and Amsterdam (Netherlands). The focus is on 'the reuse of previously developed land' or what are usually termed Brownfield sites. This paper draws on the initial research on the UK case studies, no reference is made to the case studies in Brazil or the Netherlands, or to the comparative dimension.

and includes nine case studies (three per country) of regeneration projects in Brazil, the Netherlands and the United Kingdom (UK). This paper draws on the initial work of the project and investigates the forms of governance arrangements that have developed in the UK case studies (Bristol, Gloucester and Taunton). The paper discusses the planning and regulatory instruments that are used as part of the public-private urban development partnerships. The research is designed to explore the form(s) of governance that exist, the associated 'planning instruments' developed and whether these arrangements are able to deliver outcomes that are in the 'public interest'. In particular we focus on how the governance forms created when contractual arrangements are made between the public and private sector parties structure/influence the aims and delivery of urban regeneration. This relates to what van der Veen and Korthals Altes (2011) have termed as 'government by contract' and Raco (2012 and 2013) has described as 'planning by contract' and 'governance through detail'.

As part of the wider PACOUR project we seek to assess the extent to which planning and regulatory tools were able to provide some form of accountability to residents and other interested parties as well as to deliver outcomes that were in the 'public interest'. Indeed it is part of the project's aims to determine how the notion of the 'public interest' was constructed/understood and operationalised by the various parties involved in the development process in each case study.

Part of what we hope to do is to understand how contractual relationships, particularly between the public and private sectors, affected/influenced public accountability (in terms of transparency of decision-making) and the delivery of outcomes that were, at least in part, in the 'public interest'. The risk we perceive is that contractual relationships are shrouded in 'secrecy' under the guise of commercial confidentiality that obscures the 'public gaze' and runs the risk of effectively undermining both accountability and the 'public interest'. Thereby creating a form of 'subterranean governance' that structures the way in which these partnerships operate without being subject to any rigorous public scrutiny and accountability.

The following paper is therefore set out in six sections. Section two provides a summary of each to the three UK case study sites and the public/private partnership arrangement that exists on the site. Section 3 provides a summary of the UK national planning policy through the last 20 years. Section 4 outlines the research methodology and Section 5 presents the findings from the research to date. Section 6 discusses what the findings mean in the context of urban regeneration and includes the initial conclusions of the study.

2 UK CASE STUDIES

The three case studies sites were selected as each has developed a different type of public-private partnership approach to delivering an urban regeneration. The case studies of Gloucester and Taunton provide an assessment of regeneration of previously developed land in small to medium towns and cities in the UK, an area that is currently under researched. Each case study provides insight into the challenges faced by all parties in ensuring that public-private partnerships deliver schemes that are profitable and provide benefits to the location.

2.1 BRISTOL HARBOURSIDE

The redevelopment of Bristol Harbourside was a long and complex redevelopment history, dating back to the 1960s with the planned closure of the docks (Priest and Cobb, 1980). The local planners wanted to fill in Bristol's docks and use the land for offices and an urban motorway (*Ibid*, 1980). Following a significant level of public objection and the conversion of existing warehouses into arts and cultural centres this plan was eventually scrapped. This left Bristol with a large area of derelict land to the west of the city centre that was used primarily for city centre parking. In 1993 the local authority, and one of the area's land owners, Bristol City Council formed the Harbourside Sponsors Group with the area's other land owners (Bristol City Council, 1998; Clement, 2010). This body, along with funding from the National Lottery created a separate company called Bristol 2000 who delivered @Bristol science museum, a cinema (now an aquarium) and a public space called Millennium Square (Bristol 2000, 1996).

This left the area to the west of the site open for redevelopment. In February 2003 land owners Bristol City Council, Transco (Gas), Secondsite Properties (now National Grid) and Lloyds Bank signed an agreement

with Crest Nicholson PLC to redevelop this area, following Crest successfully being awarded planning permission on 17 October 2001. This was Crest's third attempt to secure planning permission after the first two were rejected due to fierce public opposition. The development formed a public-private agreement that Crest Nicholson, their subsidiaries and contractors would deliver the regeneration of this site before handing the roads, pavements and open spaces back into the control of the City Council (see Heurkens, 2012, pp262-290 and Heurkens & Hobma, 2014 for discussions of the Harbourside development). The final development, although slowed down by the financial crash of 2008, was completed in 2014 and at present Crest Nicholson are in negotiations to return their remaining land holdings into the control of Bristol City Council.

2.2 GLOUCESTER QUAYS

The redevelopment of Gloucester Quays differs from Bristol in that Gloucester City Council was not the land owners of the site that was due for redevelopment. The now defunct government quango British Waterways entered into a public private partnership with Peel Developments in 2002 to redevelop the area of Gloucester Docks known as Bakers Quay. Peel Developments wanted to open a new shopping centre on the site. In addition to this Gloucester College relocated to the site and a new Sainsbury's supermarket opened on the western side of the docks.

This redevelopment was aided by the creation of the Gloucester Heritage Urban Regeneration Company (for a brief description of what a URC is see McCarthy, 2007, pp40-41) by Gloucester City Council in 2004 as a means of regenerating the city. This was a registered company with a formal status and was wound up at the end of 2014. This partnership, included Gloucestershire County Council, English Partnerships and the South West Regional Development Agency (SWRDA). English Partnerships and SWRDA were government organisations who provided funding and expertise to enable the supporting access infrastructure to be delivered, enabling the shopping centre to open in 2008. Due to the financial crisis of 2008 the regeneration of the housing element of the site has yet to take place, although negotiations are ongoing.

2.3 TAUNTON FIREPOOL

Taunton Firepool is the least developed of the three case study sites and as yet much of the proposed redevelopment has yet to be realised. The development is a public private partnership between Taunton Deane Borough Council and developers St Modwen and the initial application for planning permission was rejected in August 2016. The primary reasons for rejecting this development were related to the design of the scheme and potential flood risk to the site. Like Bristol and Gloucester the development was delayed by the 2008 financial crisis, which forced a change Taunton Deane Borough Council's plans for the site to be used for office development to a retail led development.

Taunton Deane Borough Council, like Gloucester City Council created an alternative planning body to enhance the regeneration process and Project Taunton was set-up to operate as an arms-length organisation between 2004 and 2011. This was a partnership between the Borough Council, SWRDA and Environment Agency and delivered several infrastructure and flood alleviation schemes prior to being wound up.

2.4 SUMMARY

All three of our cases studies were engaged in redeveloping previously used land and all three developed public-private partnerships to carry out the redevelopment process. However, as can be seen from the brief descriptions above each developed a rather different form of partnership, which reflects past experiences (or lack of) with such activities and decisions taken by the relevant council in response to local conditions as they perceived them. What this highlights is that the term public-private regeneration partnership can cover a range of different organisational forms.

3 UK PLANNING POLICY 1990-PRESENT

UK planning policy can be broken into three distinctive levels: national, regional and local. The following section provides a summary of the regulatory instruments that exist at each level.

3.1 NATIONAL LEGISLATION AND GUIDANCE

The Town and Country Planning Act 1947 provides the basis for the post-1945 planning system in the UK. This document has been supplemented and amended by a range of subsequent pieces of legislation, circulars and other pieces of guidance. The most relevant piece of planning legislation for our case studies is the Town and Country Planning Act, 1990. This act provides an overarching list of regulations to all areas of planning and is supplemented by legislation related to specific areas such as heritage and the environment. In addition to acts of parliament there has been several “*guidance*” documents issued from central government. These include general strategic guidance documents relating to planning to the more detailed technical guidance such as Planning Policy Statements (PPS). PPSs formed a comprehensive set of guidance designed to cover all areas of planning to ensure that things such as the local heritage and environment were protected.

Guidance documents are not legally binding but are designed to assist local planning authorities and this means that due to their prescriptive nature the authorities can choose to disregard the guidance if they believe it is not in their best interests to implement it. The Planning and Compulsory Purchase Act 2004 did however state that PPSs should be considered before planning would be granted. PPSs formed an important part of the regulatory framework during the early construction phases of the case study sites, however in 2012 the UK Government introduced the National Planning Policy Framework (NPPF), a 65 page document that replaced all existing PPSs (CLG, 2012).

3.2 REGIONAL GOVERNANCE AND GUIDANCE

Regional Development Agencies (RDAs) played an important role in the regeneration of all three case study sites from their inception in 1999 and their abolition in 2012. In relation to our case studies the relevant RDA was the South West of England Regional Development Agency (SWRDA). Their work was supported by a Regional Assembly (SWRA) and the Government Office of the South West (GOSW). The most relevant document produced by SWRDA during this period was the Regional Economic Strategy, which outlined how SWRDA planned to deliver growth to the whole of the south west of England over the next 30 years. SWRA produced the Regional Spatial Strategy for the South West and although neither document was legally binding, local authorities were required to take them into account when producing their Local Development Frameworks/Plans. This was the case until 2012 when SWRDA was abolished.

Following the abolition of the RDAs the UK Government created another regional organisation, called Local Enterprise Partnerships (LEPs). The LEPs lack the spatial range, scope, funding and land holdings of the RDAs and are formed of voluntary partnerships between local authorities and businesses at a sub-regional level. As such they form a different type of public-private partnership. Through our research they have been described by an interviewee as “bidding vehicles” for central government funding, rather than a facilitator of urban regeneration in a similar way to SWRDA.

3.3 LOCAL DOCUMENTS AND LAWS

Local Authorities were required to create Local Development Frameworks or Plans that set out where planning and development would be supported in the local region. These have been replaced with Core Strategies since 2012 that set out planning expectations to 2028. Local Authorities can also create supplementary planning guidance, specific to their locale that outlines what is likely to be permitted for development in the area. In the case of Gloucester this includes details specific to the protection of historic buildings within the city. Other key documents that need to be considered include conservation plans and local by-laws that outline what activities and development are permitted within the site and surround area.

National Planning legislation allows local authorities, as part of any planning agreement, to request financial contributions by the developer to pay for infrastructure works that enable the development to go ahead. This is called Section 106 (S106) funding. Section 106 refers to the Town and Country Planning Act 1990. This S106 payment is designed to offset the impact of the development and in the three case studies has been used to fund highway infrastructure improvements, public transport infrastructure and flood alleviation works. The S106 payment was replaced by the Community Infrastructure Levy (CIL) in 2011, which was to provide funding that was not specific to the development site, but could be spent anywhere within the local authority's area. In all three of our case studies such agreements were entered into, although it should be noted that private developers often sought to renegotiate these agreements after contracts had been signed (for an overview see Burgess, Monk and Whitehead, 2011).

4 METHODOLOGY

The PARCOUR project explores the contextual and historic basis of each of the three case studies identified above to analyse the elements of the regeneration process that are similar and those that are different within the regulatory framework of the United Kingdom. While the project has developed an overarching theoretical and methodological approach to structure the research, particularly the comparative dimension, (see Atkinson et al, 2015), in relation to the case studies the research uses an inductive grounded theory approach to generate data from interviews with the key people involved in the regeneration process. At present there have been eight interviews conducted in Bristol and Gloucester and six in Taunton. Utilising a 'snowballing approach' each interview has led to the identification of both key people and documentation related to the development. This has led to contact with the key people and requests for access to the documentation, where it is publically available.

The data gathered has been analysed using NVIVO software to identify the key themes and issues that have arisen in each case study. The data has been coded into four primary categories:

- Partnership;
- Governance;
- Planning; and
- Public.

The data in each of these codes has been broken down into further sub-codes to highlight how each development unfolded.

All 22 interviews to date have taken place face-to-face, as this has allowed the interviewer to interpret both the verbal and non-verbal language used within the interview (Denzin, 2009). Each interview was semi-structured to allow the interviewer to retain control of the discussion. This approach also allows the interviewee to bring forward new information that had not been found in the desktop study or in prior interviews, providing new information for the research.

A second phase of interviews will be conducted at a future date to identify the 'missing pieces' within each case study. This stage will include interviews with some of the original interviewees, as well as other people that have been identified through the research.

5 FINDINGS

For all three case studies the interpretation of national legislation and guidance, regional guidance and local documents sit with the planning authority. How this is interpreted and developed varies depending on each site. This section will discuss how this system worked and the issues this created in terms of governance and delivery of schemes that were seen to be in the public interest.

5.1 BRISTOL HARBOURSIDE

As discussed in Section 2.1 it took Crest Nicholson three attempts before they were eventually granted planning permission to redevelop the Harbourside site. This was because the first two applications,

submitted in 1999 and 2000 were rejected due to issues over the quality of the outline planning applications. Objections came from both the public and the Church of England, due to the proximity of the development, in particular a multiplex cinema, to Bristol Cathedral (Combe, 1999). In March 1999 Crest Nicholson were asked by the Council to withdraw their application and find a 'different solution' (Onions, 1999). The second application was rejected in January 2000, with the City's Planning, Transport and Development Committee stating:

"The development would fail to provide sufficiently a coherent network of well-defined streets and spaces 'appropriate to Bristol city centre and this prominent historic urban context'" (BCC, 2000).

As part of our interviews, one interviewee who was part of the planning committee in 2000 said that the scheme was rejected as: *"there was no imagination, nor thought or any detail of urban design"*. In this case the planning committee were making their decision based on the Planning Policy Guidance 15 (Planning and the Historic Environment), by stating that the development did not fit within the historic context of Bristol. This also links back to Bristol City Council's own 1998 Planning Brief for the site, which the proposal by Crest Nicholson did not adhere to. In this case the public interest was served by the local planning authority by ensuring a development did not go ahead that did not match the type of development that was expected, both by residents, interest groups and the planning department in Bristol.

5.1.1 HARBOURSIDE SPONSORS GROUP

The Harbourside site had been difficult to redevelop due to the mix of landowners based on the site. In addition the land owned by British Gas (Transco) would need decontaminating to enable the development to take place. Bristol City Council therefore set up a formal agreement with the other land owners in 1993 to promote and facilitate the regeneration of the site (CABE, 2001; Clement, 2010; Huerkens et al., 2015). Each member of the Sponsors Group signed a non-legally binding agreement called the Harbourside Accord, where each party agreed to work together and take their profits out of the scheme at the end of the redevelopment process. The Harbourside Sponsors Group provides an example of an important governance arrangement that enabled the redevelopment process to happen at this site. Bristol City Council had two roles within the redevelopment process, both as the planning authority and the land owner. This meant that there were competing agendas within the Council in terms of delivering the scheme. The member of the planning committee admitted: *"there was a lot of pressure to approve the scheme"*, from within the city council. The head of the Planning committee, Cllr Helen Holland, had to step aside from this role, due to a conflict of interest in the planning application due to her role as part of the Sponsors Group. Nevertheless, the planning committee stood firm and decided to reject a scheme that they felt was wrong for the city.

5.1.2 REGIONAL SUPPORT

The Harbourside Sponsors Group were very supportive of Crest's application and in October 1999 wrote to the local paper, the Bristol Evening Post, outlining the benefits that would be brought forward if this development were to take place. One of the reasons they highlighted for supporting the scheme was that the development would bring forward £18.5m of funding from SWRDA (Evening Post, 1999). It is through funding, rather than strategic policy that the regional support was the strongest, as this funding would be used to enable the site to be decontaminated and pay for the infrastructure links for the scheme. This provides an example of how regional governance provided a powerful ally to, and catalyst for, local authorities wishing to bring regeneration forward. It is doubtful whether at least two of the projects could have progressed without this external (financial) support.

5.1.3 DELIVERING THE PUBLIC GOOD

As discussed in Section 2.1, Crest Nicholson were eventually successful with their third planning application. This is because they completely redesigned their masterplan for the site. This was in part due to the extensive level of public consultation that was undertaken between the 2nd and 3rd applications, where Crest Nicholson and the City Council set up the Canon's Marsh Consultative Group (CMCG) that

included consultation with all the key stakeholders at the site (Bassett et al., 2002). The inclusion of these groups within CMCG meant that many of the issues, such as sight lines between the harbourside and the cathedral were retained in the masterplan. However, several of the interviewees were dismissive of the CMCG approach, with one interviewee calling it “*PR dressed as consultation*”. One of the key members of the Sponsors Group also admitted that the CMCG was a means of “*suppressing the loud noise*” from the protest groups, enabling the development to move forward. Despite this the protesters felt their concerns were listened to and the scheme was eventually given planning consent in 2001.

There were, however, several questions on whether the scheme delivered a ‘public good’. In general all interviewees agreed that the site was an improvement on the derelict site and car park that was there before, but many felt that it could have been “*so much better*”. Despite being approved for outline planning permission several of the buildings constructed during the development have been criticised for their quality in terms of both their construction and design. The Civic Society also continued to challenge each building through the planning process to ensure that they were delivered to a higher standard than was proposed by the developer. With the completion of the final building in 2014, the final public space was opened with the Millennium Mile providing a path through the site from the SS Great Britain to the south of the site, through to the centre of Bristol. In this sense the area has therefore provided a public good in terms of creating a space for people to use and access around the whole of Bristol Harbour.

5.2 GLOUCESTER QUAYS

The redevelopment of Gloucester Quays differed from Bristol, as discussed in section 2.2 the City Council were not the land owners. This meant that the public-private partnership was created between a non-departmental government organization British Waterways and the developers, Peel Holdings. Both parties came to a formal agreement to develop their land together in 2002 and this agreement stayed in place until 2012 when the UK government abolished British Waterways and they became a charitable trust called the Canal and Rivers Trust (CRT). At this point Peel Holdings purchased the remaining development land at the site from CRT. The Gloucester Quays development plan included a shopping centre, a new campus for Gloucester College, housing, a supermarket and a new 4* hotel for Gloucester.

5.2.1 PLANNING APPLICATION

In the early 2000s the planning system in Gloucester was seen to be in a ‘log jam’ with little activity taking place. The College had identified a site within the Peel/British Waterways site to relocate to, but British Waterways were not willing to release the land unless they received planning consent for a shopping centre. The college had been awarded £30m towards the costs of the relocation by the Department for Education and they had secured the sale of their existing site in the city centre to SWRDA, but they were at risk of losing both if an agreement was not met over how the development was to proceed.

In 2003 all the key parties were summoned to Westminster to agree to clear the ‘blockages’ and allow the development to go ahead. Within the meeting it was agreed that British Waterways would release the land and that Gloucester City Council would take Peel/British Waterways planning application to the full council, instead of the planning committee, to ensure that the decision was given the highest priority. British Waterways were criticised by one interviewee for being: “*too commercially minded and not considering the public good*”, when it came to initially preventing the development of the college from going ahead. Planning was eventually granted and the shopping centre opened in 2008.

5.2.2 GLOUCESTER HERITAGE URBAN REGENERATION COMPANY

Due to the issues associated with the redevelopment of their own land, Gloucester City Council, along with partnering organisations set up the Gloucester Heritage Urban Regeneration Company (GHURC) in 2004. This comprised of four main government bodies: Gloucester City Council, Gloucestershire County Council, SWRDA and English Partnerships. Each of these bodies provided funding for GHURC, giving it a budget of £750,000 per annum to facilitate regeneration. The GHURC proved to be a useful vehicle in enabling funding from both SWRDA and English Partnerships, as well as Section 106 funding, to be invested into new transport infrastructure. This included the construction of the High Orchard Bridge, which provided a

link to the shopping centre car parks. In addition GHURC invested £7m in enhancing the links between Gloucester Quays shopping centre and Gloucester city centre.

The GHURC was incredibly inclusive in terms of engagement with both the business community and local community groups, often giving them sight of confidential documents prior to their release. This enabled a dialogue to be open between the community and the decision makers. By doing this GHURC was able to overcome both any local opposition (particularly from shop owners in the city centre) and to break the previously existing 'log-jam'/inertia that had surrounded the redevelopment of the area and the city more generally.

5.2.3 DELIVERING A PUBLIC GOOD

Like Bristol, the Gloucester Quays redevelopment saw the enhancement of a derelict site close to the city centre. Due to a combination of the consultation process and the mixed use development that was delivered, there has been little or no public criticism of the development. This may be because of low expectations, with many interviewees saying that prior to the shopping centre being completed many residents commented: *"We'll believe it when we see it"*. The main criticisms of the redevelopment came from the existing businesses within the city centre and a local covenant was put in place that stated no existing shops would be able to relocate to the site. The shopping centre therefore became an 'outlet centre' rather than a new city centre. Also access from the city centre to the development was put in place through a range of improvements in public connectivity. In terms of the public good, all interviewees were very happy with what has been provided at the site to date. The college has been successful and expanded the number of students, creating footfall in the area, and the shops have created a new destination in Gloucester that was a 'no go zone' prior to 2004. The development has therefore been seen as a success.

5.3 TAUNTON FIREPOOL

Taunton Firepool, has to date been less successful than the other two sites. The land was a mix of ownership between National Rail, who owned the land now known as Firepool Lock, and Taunton Deane Borough Council, who own the former cattle market site. It is more complex than the other two case studies given that it covers several different sites, albeit in the same area but not physically connected. At present Crest Nicholson are in the process of building out the Firepool Lock site, whilst St Modwen's proposal for the cattle market site was rejected in August 2016.

5.3.1 PLANNING APPLICATIONS

National Rail sold their former goods yards (Firepool Lock) to Abbey Manor Developments, who subsequently sold the land to Crest Nicholson. In addition social housing developers Knightstone Housing developed 200 affordable homes on the site, with a £3.5m grant from the Homes and Communities Agency (formerly English Partnerships) in 2012 (BBC, 2012). This provides a public good in terms of the quality and availability of social housing in Taunton.

The second site has been more problematic to deliver. The Cattle market closed in 2001 and Taunton Deane Borough Council sought to redevelop it. The initial plans were to use the site to construct offices, but this plan was unsuccessful as Taunton Deane Borough Council were unable to get an 'anchor' organisation to agree to be located on the site. This meant that St Modwen's second application was based on providing retail on the site, but again this application was rejected. The issues were for similar reasons to both Bristol and Gloucester, in that the aesthetic quality of the design was considered to be poor, with one interviewee describing it as a: *"wriggly tin roof development"*, and the fear that it would take business away from the city centre. The second issue highlighted was the potential for flooding, despite extensive flood alleviation work being delivered by Project Taunton.

5.3.2 PROJECT TAUNTON

Project Taunton was set up as an arms-length organisation by Taunton Deane Borough Council, SWRDA and the Environment Agency in 2004. Project Taunton was described by one interviewee as a “*URC lite*”, as the organization was designed to facilitate development, but without the bureaucratic structure or funding levels of the GHURC in Gloucester. Project Taunton was successful in delivering flood alleviation through the development of Long View Meadow, an area that was designed to capture flood water and prevent the town centre from flooding. Project Taunton failed however to deliver the redevelopment of the cattle market site, primarily due to the global economic downturn reducing the demand in office space in the town.

5.3.3 DELIVERING THE PUBLIC GOOD

In terms of delivering the public good, it is still uncertain what will happen to the cattle market site. The development of Firepool Lock does provide, both social housing and a new road link, although that is yet to open due to a dispute between the County Council and their contractor who constructed the new road. The delivery of the flood alleviation project constitutes a public good, as the land used forms a public park, when it is not flooded, and allows the redevelopment to take place, should St Modwen be successful in being awarded planning permission. It is clear from this application that the planning department at Taunton Deane Borough Council have acted in accordance with planning guidance, both on a national level, and locally in respect to ensuring that the cattle market site delivers a scheme that provides a benefit to the community.

6 DISCUSSION AND CONCLUSION

It is important to note that we have only conducted the first phase of our fieldwork vis-à-vis the case studies and at this stage it is not possible to draw any firm conclusions regarding the issues we are investigating. While we have had access to many of the key individuals (for interviews) and documents a considerable amount of work remains to be done. In particular the private sector developers have been the most difficult to meet with. Moreover, to date we have had limited access to the contracts signed between the public and private sectors (only in the Bristol case have we obtained the contract). Nevertheless a number of things have begun to emerge.

Each local authority has sought to address the development of previously used land in their area in somewhat different ways. As noted above each developed different approaches to the partnership arrangements they put in place. For instance in the case of Gloucester a formal body, the GHURC was set up, while in Taunton an ad hoc arms-length body, Project Taunton, was set up. While in the Bristol case, which took place over a much more extended time period than was the case with the other two, a range of bodies played a role, some ‘informal’ role as with the Harbourside Sponsors Group, which then set up Bristol 2000 to deliver aspects of the redevelopment. Subsequently remaining elements of the development were delivered through a variety of ad hoc arrangements involving the City Council and the developer.

In part these different ‘governance arrangements’ reflected past experiences (or lack of) with regeneration and the local politics of each town/council. In the cases of Bristol and Taunton they also had to contend with the fact that the local authorities were significant land-owners and there was a potential conflict of interest that needed to be addressed. Although interestingly it was Gloucester City Council, which owned none of the relevant land, that decided to go for the most formal arrangement by setting up a URC. Bristol did not do this, even though the option was available post-2000, perhaps reflecting the council’s earlier hostility to the setting up of an Urban Development Corporation and the fact that a developer had been selected before the option to set up a URC was available. In the case of Taunton Project Taunton rather than a URC due to a lower level of funding being made available. The idea was to take the best bits of a URC and create a dynamic organisation that could “*talk to businesses*” and not be seen as an extension of the Borough Council.

The developments also reflected what the relevant planning committees and councils hoped to achieve through the development process and how they chose to interpret relevant national legislation. This refers

not simply to planning legislation but also other environmental and heritage legislation. In the case of the latter two it became clear during the course of our initial work that in all three cases they set certain 'limits' (i.e. acted as a form of regulation) on the developments and what could (and could not) be done. In particular the legislation related to flood risk was a major limitation on the Taunton project, and this required significant public sector investment to ensure the sites were able to meet relevant standards, but this applied, albeit to a lesser degree, to the other two sites as they each were structured around water areas.

What is clear from our initial research is that national bodies, notably English Partnerships, played an important role in terms of providing resources for important infrastructure work (e.g. site remediation) essential to the development of relevant sites. Similarly the regional level, SWRDA, was significant in being able to focus significant resources on the sites, bring people together and where necessary 'knock heads' together. The abolition of the regional level would appear to be a serious loss in terms of current and future developments as LEPs lack the resources and powers to fill the gap left by the abolition of the RDAs. In addition key individuals (or small groups) also played a significant role in bring key actors together, mediating disagreements and addressing uncertainties at critical points in the development process.

One respondent noted that other organisations such as the Confederation of British Industry (CBI) were organized on a regional level and this meant that the staff at each organisation knew each other in a working capacity making it easier to bring proposals forward. The situation is now fragmented and this means that there is a lack of spatial planning undertaken to ensure that schemes join together between sub-regions.

The preceding paragraph points to a wider issue related not just to the termination of the experiment with regional government but also the abandonment of any pretense of engaging in strategic spatial planning (Baker and Wong, 2013). The LEPs may, in some places, offer a partial replacement in terms of 'strategic spatial planning from below' but as Baker and Wong (ibid, p99) argue "The problem is that this may only happen in a few isolated areas, producing pockets of surviving strategic thinking in a surrounding strategic vacuum.". In other word any 'strategic' thinking about planning and (economic) development will take place in a fragmented and isolated manner, arguably accentuating competition between locales and creating yet more 'winners and losers'. Moreover, LEPs are unlikely to take into account issues such as environmental impact(s) and social cohesion.

In all three areas there were either no, or relatively, small numbers of people living there, so this removed many obstacles to the developments. However, there were often significant 'spill overs' from the proposed developments that did elicit, often strong, objections from within the wider city or adjacent areas affected by the developments. In the Bristol case much of the debate was around the impacts on sight lines across the city and the design quality/impacts of the proposed development. In Gloucester the main concern was the impact on existing city centre businesses. While in Taunton similar objections were present along with concerns about the design quality of what was (is being) proposed and the impacts of infrastructure provision (e.g. a road associated with the development).

It also appears that there have been 'renegotiations' around exactly what the developers were to provide in terms of agreements linked to S106, although the full extent of these renegotiations remain unclear at the moment. But this is very much in line with what the literature has highlighted elsewhere (see Burgess, Monk and Whitehead, 2011). Factors such as the economic crisis in 2008 meant that developers needed to renegotiate S106 agreements to ensure they were able to continue the regeneration process. Financial pressures meant that many developers went out of business and this meant that local authorities had to make tough decisions about whether the development should continue without the S106 agreement, or remain unfinished.

Perhaps the most difficult issue to address is the extent to which the developments have been able to deliver projects that are in the 'public interest' or enhance 'public good' (see Atkinson, 2015). Setting aside the tricky issue of defining what these two terms mean theoretically and in practice, in a somewhat simplistic manner one can argue that in the cases of Bristol and Gloucester areas that were previously derelict or used for purposes such as car parking have been regenerated and made accessible to the people of each city. Site visits reveal areas that are now being used by people and they are now undoubtedly vibrant places that people visit and engage in a range of relevant leisure, shopping,

educational and commercial activities. In the Gloucester case there appears to be general satisfaction with the development, although this perhaps reflects a starting point of 'low aspirations'/disbelief that anything would happen. While in Bristol opinions are somewhat more divided and nuanced with a number of our interviewees feeling that more could have been achieved, particularly in terms of the overall design quality of the area and of individual buildings. Concern was expressed over the use made of several of the buildings in terms of their single-use (e.g. as offices) rather than the original mixed-use designation (e.g. the inclusion of more cafes and other leisure facilities), it was felt that more mixed-use of some buildings would have drawn more people into parts of the site and enhanced the presence and flows of people. It also has to be kept in mind that the redevelopment of Bristol site took place over an extended period of time and that there were considerable external changes (e.g. within the national economy post-2008) and internal changes within the city that affected the nature and pace of the development. The Taunton case is rather different, partly because of its fragmented nature and also because of the fact it is an on-going process. Nevertheless, there is a general agreement that these sites need to be brought back into use, the debates are about 'what type(s)' of use, the design quality of what is being proposed and the impacts on the existing city centre.

More generally we need to situate our case studies within debates over the wider planning system and forms of governance. As is well known the wider context in which the UK operates is seen as a 'neo-liberal regime' which has had significant impacts on both planning and governance at a variety of different scales. However, this overarching notion of neo-liberalism has increasingly been recognised as too general and lacking a recognition that there are varieties of neo-liberalism. Moreover, it has been acknowledged that even within a particular country there have been 'phases of neo-liberalism'. For instance Allmendinger and Haughton (2014) have sought to distinguish between the 'roll-back' version of the 1980s, the 'roll-out' variety of the 1990s and 2000s. Our case studies largely fall in what they term the 'roll-out' phase which is characterized by "...a variety of market supportive state forms and modes of governance." (ibid, p11). Arguably the case studies we have considered exhibit examples of how local, regional and national bodies sought to support and facilitate market based developments in different ways related to local contexts. In addition they go on to point out that:

This approach also placed a growing emphasis on partnerships as a means of promoting public and private sector coordination and improved policy integration. In this new accommodation, the state's reworked role was not simply to de-regulate, divest, and open up markets. The role of government was also to reregulate and where necessary invest in ways that reconcile a continuing pro-growth agenda with wider societal issues, not least growing concern about environment and citizenship. (ibid, p12).

We can also detect concerns with these elements in our case studies as each of them has, in different ways, sought to address these wider issues. Part of the problem, however, is that we also need to consider what Taşan-Kok and Korthals Altes (2012) have referred to as the 'capacity to act' and Servillo, Atkinson and Russo (2012) have termed the 'mobilization process'. In both cases the authors are referring to the ability of (local) governance arrangements or 'systems' to get things done. As Servillo, Atkinson and Russo (2012, p.359) point out:

This requires the existence of links, often articulated through organizational arrangements (for example, partnerships) between stakeholders, local authorities, agencies and citizens, in order to identify, create and mobilize assets and develop policies to achieve specific...strategies.

In each of the case studies our local authorities and the associated partnerships they have developed displayed differential capacities to act by mobilizing assets, developing relevant strategies and putting them into practice. Indeed, it is clear that without 'external support' from regional and national bodies they were unlikely to have been able to push the development process along.

In terms of the governance issue and our concern to address the argument that contemporary regeneration processes and their associated public-private partnerships involve complex legal and regulatory activities that frequently involve forms of privatisation which may be subject to 'governance through detail' (Raco, 2012; 2013) articulated through 'government by contract' (van der Veen and Korthals Altes, 2011) or 'planning by contract' and (Raco, 2012; 2013) we have as yet little to say that is concrete. However, our initial work in scoping out the various institutional/organisational relationship in which our partnerships were embedded revealed a bewilderingly complex web of relationship involving national, local, regional, governmental, quasi-governmental, private (for profit) and non-profit bodies. When

mapped out these relationships are most aptly described as resembling 'a bowl of spaghetti'. Such a situation is hardly conducive to transparency and accountability, making it difficult to identify where decisions are taken and who can be held to account for them.

More generally the forms of governance we have observed in our case studies strongly resemble what Levi-Faur (2011) has described as hybrid forms of governance along with hybridized forms of regulation (Levi-Faur, 2010) that involve a range of regulatory forms. He argues:

We need to conceptualize a world order where governance is increasingly a hybrid of different systems of regulatory control; where statist regulation co-evolves with civil regulation; national regulation expands with international and global regulation; private regulation coevolves and expands with public regulation; business regulation co-evolves with social regulation; voluntary regulations expand with coercive ones; and the market itself is used or mobilized as a regulatory mechanism. (Levi-Faur, 2011, p.17)

Disentangling the various forms of regulation (not least that exercised by the planning system) and their relationship will be a major task of our future work if we are to understand how governing and planning by contract operates in our case studies.

ID 1495 | THE GAP BETWEEN PLANNING AND REALITY: THE EVALUATION OF COMMERCIAL LAND USE PLANNING IMPLEMENTATION IN KAOHSIUNG CITY, TAIWAN

Li Sinyi¹; Chao Tsuyuan¹

¹Department of Urban Planning, National Cheng Kung University
p26054127@mail.ncku.edu.tw; tychao@mail.ncku.edu.tw

ABSTRACT: The urban planning system in Taiwan has followed the America and Japan systems aiming at controlling and directing private development rights. The statutory plan, the land use control measures as well as zoning ordinances are the main tools for the conformance-oriented plan. To make the conformity, the land development rights tend to be assigned in advanced along with the collective strategies of zoning plans. In most high-density cities in Taiwan, such land use control and management tools are considered highly important for better development orders and environmental quality. Nevertheless, the overall zoning ordinance implementation in Taiwan is considered weak for the two following main reasons. First, the actual urban development of Taiwan could date back to Qing dynasty and the modern urban planning system has been implemented from 1964. Second, to cope with the existing urban form and speedy population increase, mixed land use was widely adopted in the zoning ordinance. As a result, a variety of the types of land use seem to be acceptable in different zones. For instance, residential buildings are allowed to be in commercial districts as well as most service uses are allowed to be in residential districts. Furthermore, property markets, political influences, and citizens' expectations are three major factors on how developments are actually carried out. As a result, in reality, many land development events might, on one hand, comply with the zoning ordinance. Yet, the actual use afterwards fails to comply with the master plan and planning vision on the other hand. Take Kaohsiung city for an example, approximate 35% of commercial districts in the downtown area are occupied by pure high-end residential developments. It further indicates that the zoning plan in Taiwan has rather weak control power to the actual development.

KEYWORDS: conformance, statutory plan, commercial districts, zoning ordinance

1 INTRODUCTION

The history of Taiwanese planning system has been existed for about 100 years, which has been constantly influenced by two major countries, Japan and America, due to the historical events. According to some characters in planning, such as land use control measures, zoning ordinances as well as statutory plan etc., planning system in Taiwan is regarded as conformance-oriented plan.

However, although Taiwan has built the zoning ordinances, they are weak because of two main reasons. The first is that the existence of cities is longer than planning, and the second is that the land use control in Taiwan tend to be on negative listings, which means the specific land use would be forbidden to some explicit and strict degree. Hence, a variety of land use types are all permitted in different zones. Take the commercial districts in Kaohsiung city, for example, almost 35 per cent of them are high-end residential development with no commercial facilities, which is one of the most famous issues for legal non-conformance.

Owing to the lack of investigation, we cannot know actual land use activities. Therefore, I will focus on a commercial district and take Lingya District, which is located in the central part of Kaohsiung City, as a case study to figure out how the real land use is performed in Taiwanese city. After excluding the underdeveloped area (such as earlier buildings, vacant lands, parking lot, etc.), most of the legal non-conformance structures are religious buildings, churches, temples, for example, as well as the popular issue mentioned above: the high-end residential buildings. Through this study, I want to propose a chance to reexamine the land use system in Taiwan, and to respond to the future amendment of the zoning ordinance in Taiwan.

2 PLANNING IMPLEMENTATION: CONFORMANCE VERSUS PERFORMANCE

According to the concept advocated by Andreas Faludi in 1989, there are two types of plan, which are 'Project plans' and 'Strategic plans'. The former belongs to blue print, and the determinate effect must conform to the specifications. As for the latter, they belong to the projects that are coordinated by multitude actors. They should be allowed to have negotiations and the future vision always remains open (Andreas Faludi, 2000). With these two sorts of plan types, they separately reflect two major planning systems — Conformance and Performance-oriented planning— in contemporary planning mainstream.

In conforming planning, it matches the forms, manners, or characters to develop its project, whereas in performing planning, it shapes the claims, promises, or requests through the plan (Umberto Janin Rivolin, 2008). With the frontal description, project plans will connect to the conformance-oriented planning, and strategic plans prefer to link to the other, performance-oriented planning. However, performance plan cannot apply to planning systems themselves and to planning as a whole (Umberto Janin Rivolin, 2008), so performance plans will also involve some concepts of project plans to illustrate the plan.

3 THE HISTORY OF TAIWANESE PLANNING SYSTEM

The construct of Taiwanese urban planning system was basically produced during the era of Japanese reign, which is the year from 1895 to 1945. With the different goals the Japanese government wanted to approach, the history of Taiwanese urban planning could be divided into four episodes: (1) basic investigation and related rule announcement from 1895 to 1900 (2) the practice of the spatial plan in Taipei and Taichung cities as well as the innovation of Taiwanese planning framework (3) extension and correction of the planning areas and the production of the village-scaled plans before the World War Two (WWII) (4) constant revisions the existing plans until the end of the war (Shyh-Meng Huang, 1985).

In general, the plan produced in these years is called 'City renovating (市區改正計畫)', and it was focused on existing village as the boundary of the plan. With the lack of future vision and existing distribution of buildings, the plan in every town was revised again and again (See figure 1). The situation didn't stopped until the 1930s when the dominator realized the important of comprehensive plans.

After the WWII, Republic of China (ROC) got the sovereignty of Taiwan. As a newbie for ROC, Taiwan needed much more attention from ROC to reform the rules, which were handed down by Japan. However, the Chinese Civil War broke out right after the end of the WWII, and it made ROC have no idea to figure out the method to revise the land managing policy. Therefore, at the beginning of the ROC governance, Taiwan provincial government used the pre-existed rules formulated by Japanese (Chun-ping Chiu & Chyuan-Jenq Shiau, 2015).

Because of the failure of ROC, Chiang Kai-shek led the militaries and government to Taiwan and promulgated the Taiwan martial law. With the practice of the martial law, the territorial managing policies as well as the statutory plans were manipulated by the central government. With the industrialization and urban population soaring, urban planning in Taiwan was simplified as a population-oriented land use plan, and every relative rule was legislated by the government. What the planners did were to follow the rule step by step: proposing the need by the spatial and social-economic analysis, then arranging the land use distribution. During the period of the execution of the martial law, the planners were controlled by politicians and related investors, so most of the plans made by the planners suffered the political kidnapping (Tsu-Lung Chou, 2004).

With this sort of constraint, almost every plan was planned by these stakeholders, and what they wanted to achieve was to blueprint everywhere. Besides, what the stakeholders wanted was always focused on the benefits they might get, which was not the perfect idea for the planners. It made many statutory land use differ from what the planners initially expected.

After Taiwan canceled the martial law, the planning system has become more flexible than it used to be, and some NGOs or charities gradually get the right to participate the urban planning. However, every item about planning is still stuck in the related law, and the power of decision-making is also controlled by the government (Tsu-Lung Chou, 2004). Basically, the government would listen to every comment from every stakeholder, but their decisions only pay attention to the development of land use, ignoring the facts about

the real land use behavior as well as the population decrease. Hence, the power of decision-making about urban planning nowadays still not totally belongs to all citizens.

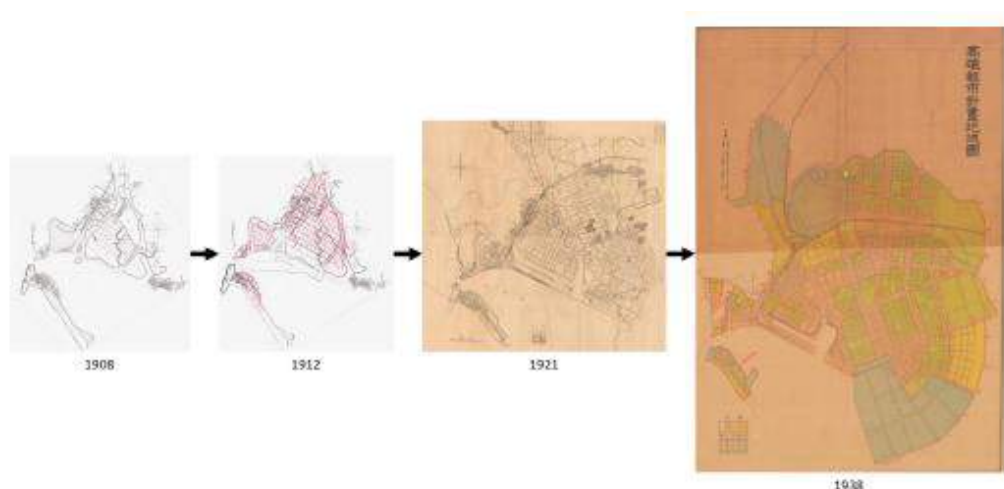

Figure 1-Boundary of Kaohsiung City during Japanese rule (1895~1945)

4 THE TENDENCY OF TAIWANESE PLANNING SYSTEM

Initially, there was no specific vision in Taiwanese spatial plans. However, they were then exhibited in the blueprint planning, and everything the planner made focuses on determinate goal — improving the public health. With the blueprint planning, it manipulated the inanimate objects in immobile environment, but the consequence we originally expect might not happen. According to the process of the evolution of Taiwanese spatial plans, it is clear to know the plans were revised and adopted continually (See Table 1). In this pattern, Taiwanese planning system was close to the conformance-oriented planning.

Year	Location	Year	Location
1900	Downtown of Taipei and Taichung	1917	Zhushan
1905	Extension of Taipei and Hsinchu	1921	Yuli, extension of Tainan, Chiayi, Kaohsiung, Keelung, and Taichung
1906	Changhua and Chiayi	1922	Xingang
1907	Keelung	1924	Doulin
1908	Kaohsiung	1929	Extension of Tainan
1910	Hualien port	1931	Matou

Year	Location	Year	Location
1911	Extension of Tainan and Taichung	1932	Yilan, extension of Taipei
1912	Shoushan, Beidou, Nantou, Magong, Dax, extension of Kaohsiung	1934	Luodong, Dajia, extension of Hualien port (Milun)
1913	Pingtung, Beigang, Taitung, extension of Chiayi	1935	Lukang, Dounan, Caoshan, extension of Taichung
1914	Puli	1936	Yuanlin, extension of Kaohsiung and Beigang
1915	Fenglin	1937	Hailuo, Ruifang, Yuanli, Tongxiao, Xinying, Yanshui, Jiali, Xuejia, extension of Pingtung and Keelung
1916	Extension of Hualien port, Puzi	1938	Qishan, Pan-Chiao, Zhongli, Gangshan, Fengshan, extension of Hsinchu, Changhua, Zhudong, Taidung, Kaohsiung, Hualien port

Table 1-List of Taiwan city plan
Source: Shyh-Meng Huang, 1985, Study of the History of Taiwanese Urban Planning, 1895-1945

After the Japan lose the WWII, the ROC government used the previous planning system in the beginning because of the Chinese Civil War. The planning rule never changed until 1949, the time that Chiang Kai-shek moved to Taiwan, the government practiced the 'Urban Planning Law' in (Tsu-Lung Chou, 2004). With the American financial support, the development of Taiwanese planning system began to be influenced by the other nation, America. Combining the original context and the development after WWII, it is easy to figure out that the planning system in Taiwan now still belongs to conformance-oriented planning.

5 THE ZONING AND LAND USE CONTROL IN TAIWAN

The urban planning in Taiwan is constructed from rigorous zoning system, which contains general zoning constrain and land use density control for each kind of zoning. In general, zoning in each master plan includes residential districts, commercial districts, industrial districts, agricultural districts, etc., every zoning has its own rules for land use control whose images are described in article 32 to 41 of Urban Planning Law. Take the commercial districts for example, according to the article 35, Commercial districts should be "demarcated with promotion of business development taken into consideration. The use of land and buildings may not impede the business activities in such areas."

Based on these articles, every local government has the right to plan their own list to practice the actual land use in different zoning. In general, the lists in every administration can be separated into two systems: positive and negative listings. The former draw up every acceptable type of land use on the lists. That means when a specific type of land does not show up on that, this sort of land use is forbidden. As for the latter, it is totally contrary to the previous. They list the banned categories to avoid citizen developing. Overall, compared to each other, the former are stricter than the latter, and the former may help citizens to keep a high-quality life (Yi-jung Li, 2005).

However, most of the planning districts in Taiwan are negative listings. Only some special district or new town plans use positive one in order to control and limit land use for specific development. Hence, land use control in Taiwan is in accordance with the regulations but not the suitable development.

Except for the classification about the direction of land use, every district has their own subdivision in order to adapt to the local demand as well as achieve the goal of developing density and control (Nan-yuan, Huang, Fang-zi, He, 1979). The standard of these sorts varies from place to place; however, no matter how local government sets the criteria, it follows the unified rules formulated by central government, and population density, road width, area of public utilities, etc. are all included. (Nan-yuan Huang, Fang-zi He, 1979, Keh-Wann Tzou et al., 1990). In general, planners adjust the land use density in order to guide the trend of population growth, besides, the spatial arrangement will rely on the different road width: blocks next to wider roads would be allowed to have higher development density whereas those next to narrower roads has lower, in contrast. At the same time, in order to prevent citizens from using limited public utilities, the setting of land use density will be controlled by the supply of public spaces.

With these two kinds of rules, which includes zoning and density control, land use system would be regulated by not only developing form but also the suitable density. The former can define the direction of the land use while the latter can control the density, which depends on the condition of each block.

6 CLASSIFICATION OF NON-CONFORMANCE IN LAND USE

As the saying by Laurian et al. (2004), a methodology designed to be used by practitioners to evaluate their plans should be based on the way they use those plans. Therefore, the land use implementation in Taiwan should be checked by conformance evaluation. With the examination by evaluation, it is easier to not only figure out the degree of decisions handed down in land-use cases (Carolyn G. Loh, 2011) but also check the progress and the goal that the government sets for the city.

According to the paper from Carolyn G. Loh (2011), she separated the non-conformities into three types: (A) "land use is agriculture or a natural area, but the land is planned for a more intensive use", (B) "the presence of a 'grandfathered' use in an area planned for a different use", and (C) "land-use decisions have

been made, which directly contradicts the plan's future land-use vision". She thought the most disputed one is the last item which are in conflict with the master plan.

However, in the cases in Taiwan, the last type Loh figured out is not the most serious one, because it may get punished by government if they are willing to conduct the searching. Although the planning system in Taiwan is close to the conformance plan, it just means that the plans are blueprint and they are regulated by government with laws. The range of acceptable land use is very wide in every kind of land use, and most of them belong to 'Negative listings', which means that the government has set the forbidden land use for every urban planning division. As long as the project is not noted on this list, it is acceptable for the government.

Despite the categories set by Carolyn G. Loh, I will add one new type: land-use decisions have been made that conform the land-use, but contradict plan's future vision. According to the development in Taiwan, political power was extremely strong, and it interfered Taiwanese planning system in some degree.

Take industrial and residential districts for example, the government encouraged people to combine working to living in the 1970s, which led many legal factories located at residential district, at the same time, residences were also accepted in industrial district (Kuo-Jung Tang et al.,2011). With the strong demand of living space, many building cases focus on industrial districts for high-rise housing because of the higher floor area ratio (Kuo-Jung Tang et al.,2011). In this case, people who want to build firms always get obstacles and difficulty because the industrial districts are full of residences, and the ridiculous thing is that they are legitimate.

Therefore, I will adapt the concept of the former three categories discussed by Dr. Loh to reflect the real condition in Taiwan, and set a new type (Type D) to represent the condition I have mentioned above. In non-conformity (Type A), Loh's idea is basically acceptable in Taiwan, but in the catalog of land use, there are some additional land uses that are close to this concept, including barren land, vacant lot, parking lot, etc.. Therefore, I tend to transfer her explanation into 'land use is agriculture, natural area or some similar low-density use, but the land is planned for a more intensive use'. As for non-conformity (Type B), this type was considered to be an actual land use, but it is originated from ancestral construction, and it might not match contemporary zoning. Combine this concept with Taiwanese density control, I will consider some properties whose floor area ratio are quite lower than the regulation whether they have commercial activities or not. The type C, which is outright non-conformity, was thought of as 'land-use decisions have been made that directly contradict the plan's future land-use map', and I will use this concept directly. The last, the new type of non-conformity I add (Type D) was seen as 'land-use decisions conform to the rule of land-use, but does not match the picture of future land-use'. I will emphasize the actual influence on surrounding space caused by this kind of land use, trying to analysis the result the type D may lead to.

7 CASE STUDY: NON-CONFORMANCE IN THE COMMERCIAL LAND USE IN KAOHSIUNG CITY

According to the definition of commercial districts in Urban Planning Law that I have mentioned above, it informs everyone that as long as people use the land with no interference in commercial activity, it would be acceptable. Besides, based on the Enforcement Rules for the Urban Planning Rule (Kaohsiung), it lists negative listings for every kind of land use. On this list, commercial districts are forbidden to be developed as the industrial districts. Whatever on the list are about manufacturers, cleaning industry, polluting activities, firecrackers, etc., and all of them are widely known as impossible activities in commercial districts. With the rules that normal people would hardly break, their actual land use is always permitted legally.

Take Lingya District as an example, it is located in the downtown of Kaohsiung City, and about 25 per cent of land (the land use for road are excluded) belongs to commercial districts (See Figure 2). With the high percentage of commercial district, their actual use becomes relatively important. Once they do not conform, it also presents that the zoning in this administrative area is fail.

According to the Enforcement Rules for the Urban Planning Rule (Kaohsiung), the commercial districts are separated into different groups based on different floor area ratio (See Table 2). In the cases of Lingya District, most of the commercial districts along the main streets are category 3, 4 or 5 commercial districts

and the density decrease from category 4 commercial districts to 2 with the increase of the distance of the main road.

Type	Building Coverage Ratio (%)	Floor Area Ratio (%)
Category 1 commercial district	40	240
Category 2 commercial district	50	300
Category 3 commercial district	60	490
Category 4 commercial district	60	630
Category 5 commercial district	70	840
Other commercial districts	80	Depends on the rules of each plan

Table 2-List of building coverage and floor area ratio for commercial district in Kaohsiung City plan
Source: Enforcement Rules for the Urban Planning Rule (Kaohsiung)

In general, type A in Lingya District is not a big problem. Most of them now are used for private parking lot. That kind of underdeveloped land use provides some space of infrastructure to sooth the demand of parking, which is helpful for the development of the commerce.

Based on the previous concept of the classification, type B gets the highest percentage. Most of them were constructed as housing, and some of them also serve as business facilities now. Their building type, in general, is a row house with about one to three floors. Besides, according to the observation of their actual construct area, they are not suitable for building coverage ratio as well as floor area ratio, which means that

the housing was well-constructed earlier than the implement of the master plan in Lingya district. Combining the inference above and the additional information received by their appearance, such as early typical design and construct method at early stage, it is acceptable to deduct that these buildings, which are considered as type B, are in keeping with the definition mentioned above.

With the negative listings, type C, in fact, is just a few in Lingya District. However, the land use is rationally non-conform, but legally conform, which is considered to be type D accounts for a large proportion. Most of them were constructed as the high-end residential buildings with no commercial facilities. Basically they did not violate the article of Urban Planning Law mentioned above, but once this sort of land use built gathers, they will block the connectability of the commercial activity, which impedes the regulation mentioned in article 35 of Urban Planning Law: "use of land and buildings may not impede the business activities in such areas". Besides, some blocks in Lingya were constructed as religious buildings, which are permitted in condition based on Enforcement Rules for the Urban Planning Rule (Kaohsiung): The

buildings or land use have no noise, vibrations, special smell, pollutions, breaking the commercial activities, community peace, public safety, as well as sanitary. However, religious buildings are well-known as the center of traditional or religious activities. With such events, it is hard to define if religious constructions break this conditional permission or not.

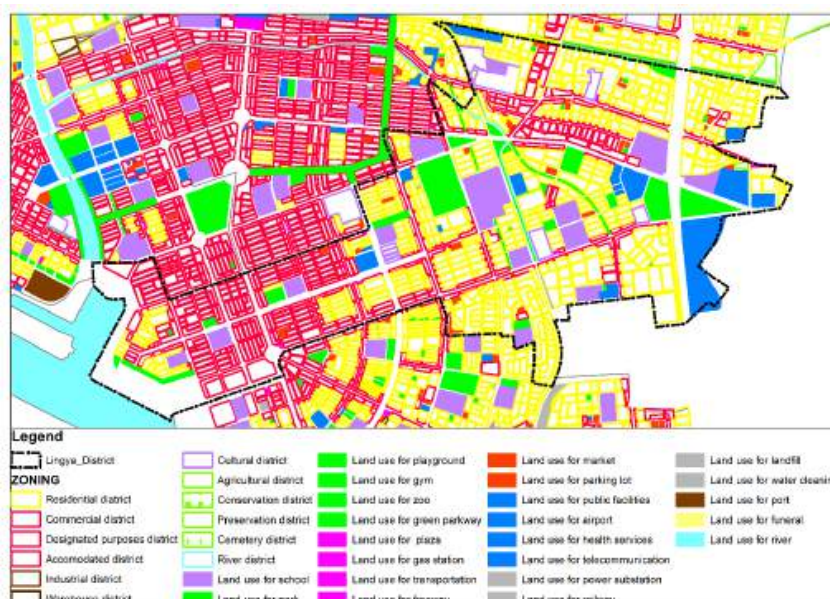

Figure 2-Boundary of Lingya, Kaohsiung City

8 CONCLUSION

According to the case study in Lingya, some of the commercial districts, which are defined as type D were constructed as pure housing as well as religious buildings in major. We think the reason why this two kinds of land use show up is based on the tradition of mixed land use. People in Taiwan are used to developing whatever they want on their own properties. With the negative listings, it is hard for citizens to violate land use control. When we observe them only with a few buildings, everything would be fine, and all of them follow the rules peacefully. However, when we zoom it out in larger scale and tons of constructions crowd in at the same time, every unit will connect to each other, which leads to a much more complicated situation. Once the builders construct something the planner don't prefer, but acceptable land use, the conception of every district would become meaningless, so would commercial district. With the threat the contemporary rules may cause, I think we should pay attention to type B, as well as the revision of relative rules. The reason for the former is that only little land is vacant now, old buildings will regenerate in the future. Therefore, type B may become the target of builders. As for the latter, we hope the planner and the government should face this problem and correct the loophole made by the regulations, preserving enough commercial accessibility and facility in the place they should develop.

1 INTRODUCTION

Since the reform and opening to the outside world, China has begun the largest urbanization expansion in the world. The expansion of big cities and the birth of new central cities are staggering. According to Chinese Academy of Sciences in October 2012 "2012 new urbanization report" data show that China's urbanization rate of the mainland reached 51.3%, an average annual growth of 0.98%. Large numbers of villages and rural lands were swallowed up by urban sprawl. Under the influence of the two yuan system of urban and rural areas, they formed a unique regional spatial phenomenon - "village inside the city". Before mid 90s, the phenomena and problems of villages in cities were not yet apparent. In the middle and late 90s, the process of urban sprawl and suburbanization accelerated, and the urban village began to attract the attention of the city government and all walks of life. It retains the original social structure and social relations network, and changes its economic structure to second and third industries. In the case of this paper, Guangzhou is located in the coastal developed areas, and the number of villages in urban areas is more than more than 130. The traditional village of South of the Five Ridges has evolved into a city village in the process of urbanization, and the continuity of the cultural context and the village tradition is facing challenges.

Since September 2000, the Guangzhou municipal government has proposed the transformation of the village in the city for the first time, and proposed the concept of the transformation of the urban village and the first overall framework of the transformation of the village inside the city. The decision in 2002 through to the point "to implement the transformation of villages, 7 villages to determine the pilot reform. Over the past few years, the reform work has mostly stayed in the blueprint for regional reform, and no substantive progress has been made. In 2005, the government drew on the idea of rebuilding the dangerous buildings, but because of the restriction of fund-raising methods, the reform was carried out slowly. In 2007, under the impetus of the Xinguang express line and the construction of the bridge under the column, the Liede village became the first comprehensive urban village in Guangzhou. As the host for the Asian Games, the transformation of villages as the focus of the government, January 2010 "on accelerating the transformation of the" three old "work opinions" pointed out that the next 10 years to complete the transformation of more than 130 villages, of which 52 completed a comprehensive transformation of villages in 3-5 years. Although the government has introduced a number of reform policies, the problem of villages in cities has not been changed to a great extent.

Clan space refers to the public space used for holding clan activities in the village, including ancestral halls, ancestral houses, ancestral tombs and so on. The concept of clan space in this article is the clan, ancestral hall and its outer space in the village of the city. The clan space is closely related to the clan, and has strong clan color. It reflects the cultural and artistic ideas of the clan in the material form. In the use of the space with the clan as the main features of a clan kinship as a link, with great consciousness, exclusion of non clan members. In the traditional village structure, the clan space is an important spatial composition, and the ancestral hall is the highest rank in the village. The ancestral hall is prominently located in the traditional village, and some are located in the geometric center of the village, and some are located at the entrance of the village or a certain highland. The ancestral hall also plays a leading role in the surrounding residential buildings, and has an influence on its architectural orientation and building height. Apart from the important symbolic value and use value of the villagers and villages, the ancestral temple also has important historical value and cultural value for the society. Most of the ancestral halls were built in the Ming and Qing Dynasties, and they have a long history, which embodies the aesthetic and

craftsman skills of the clans. Most of them are similar to places of historic interest and famous residences. They are cultural treasures.

This paper focuses on the evolution mechanism of clan space in the village of Liede and Chebei village. On the one hand, from the clan of the village to understand space, provide a new perspective for the research on urban village; on the other hand is also transformed into protection, village village ancestral temple building provide the basis for the development of the ancestral temple, in the village reconstruction process can be better protected.

2 EVOLUTION CHARACTERISTICS OF CLAN SPACE

2.1 VILLAGE DEVELOPMENT

2.1.1 CHEBEI VILLAGE

Chebei village is located in the southeast of Guangzhou, Tianhe District. North Zhongshan Road, South Whampoa road. It belongs to Po street. Has been transformed into the Economic Development Co., Ltd. Po, under the jurisdiction of 15 economic cooperatives. Village land area of about 1.6 square kilometers, the resident population of about 9 thousand, 56 thousand of the foreign population. The urbanization process began in 80s. At the end of 50s, the Guangzhou nitrogenous fertilizer factory and other units requisitioned the village with a total land area of 1422 mu. After the reform and opening up, the national land acquisition increased, in 80s the expropriation of the village land 776 acres. In 90s, 2318 mu of land was requisitioned. Since 1979, the number of migrants from the village began to increase. In 1985, the state relaxed the household registration system. At the same time, foreign businessmen to invest and set up factories in Jubei area, attracting a large number of migrant workers, the car industry has been developing rapidly Po village two or three. In 1998, the village collective net income exceeded one hundred million yuan mark.

There are altogether 53 surnames in the village, of which 8 have surnames and ancestral halls. The ancestral hall of the pavilion has a long history, and the earliest ancestral halls were built during the Ming dynasty. There are 23 ancestral halls in the village, of which there are 10 main shrines.

Figure 1 – Spatial location of Chebei Village

2.1.2 LIEDE VILLAGE

Liede village is the first city in Guangzhou to carry out a comprehensive transformation. It belongs to Tianhe District de Tak Street, located in the south of Zhujiang New town. German Liede village has established economic development Co., Ltd., the implementation of the withdrawal of the village system. Before the reform, the land used for Liede village was about 0.3 square kilometers, the resident population was about 8000, and the total population was more than 10 thousand. The current land area is 0.14

square kilometers, and the construction area is 930 thousand square meters. There are nearly 6000 villagers moving back. In the 50-60, the country in the German village gradually 240 acres of land acquisition. In 90s, with the large amount of land requisition, the German village developed second and third industries, and its economy developed greatly. In 1994, the Pearl River new town construction took 2499 acres of land acquisition, and the Pearl River Metro entered the big construction period in 1996 and 1997, and a large number of migrant workers poured into the Liede village. From 2007, the German village was reformed. In 2010, the transformation was completed and the villagers moved back.

There are 81 surnames in Hunter village, including 4 surnames and ancestral halls. Before the reformation, there were 16 ancestral halls in the village, mostly built in the Qing dynasty. All the ancestral halls will be demolished and rebuilt. It was completed in 2009.

Figure 2 – Spatial location of Liede Village

In the course of rapid urbanization in the past 30 years, the village and the German village of Guangzhou have been annexed by the wave of urban construction. They change from the traditional agricultural villages into transitional communities - villages in the city. The spatial structure, the industrial structure, the organizational structure, the population structure, and even the villagers' life style and values have undergone tremendous changes in this process. As an important spatial composition and cultural carrier of traditional villages, clan space has evolved with the development and transformation of villages. Mainly related to space layout, architectural features, the use and economic situation.

2.2 CHANGES IN ANCESTRAL TEMPLE LAYOUT

The ancestral halls of villages in the city gradually disappeared into the dense buildings. The development of villages in cities is forcing the expansion of the urban land boundary, the reduction of streets and alleys, the heightening of buildings and the internal expansion of encryption. In the early stages of the development of village in the city, the ancestral hall at the village exit or road exit was swallowed into the village, and the prominent spatial position was replaced. After the construction activity inside the village is active, the ancestral hall in the tunnel is sheltered from the reduction of the surrounding reconstruction or new construction road, and the position is relatively close to the front. The flat shape of the ancestral hall is three times and two. The area is 6-8 times as many as that of the common folk house, and it is beside the main road of the village. But in fact, in the village location is significant only Liang Su temple, ancestral hall, Qingchuan Songshou Haogong Ci and the same chapter Jane temple. Other ancestral halls generally need access to their roadway, only to the front of the building. In the stage of urban village transformation, the village space has been re arranged, the villagers spontaneous construction behavior stopped, and in the overall spatial structure, the ancestral temple has returned to the prominent spatial position. The relatively independent layout of the ancestral hall in the village after the reconstruction, in the west of the reconstruction area, is close to the main entrance and the location is conspicuous, and has become an important landmark in the Liede village.

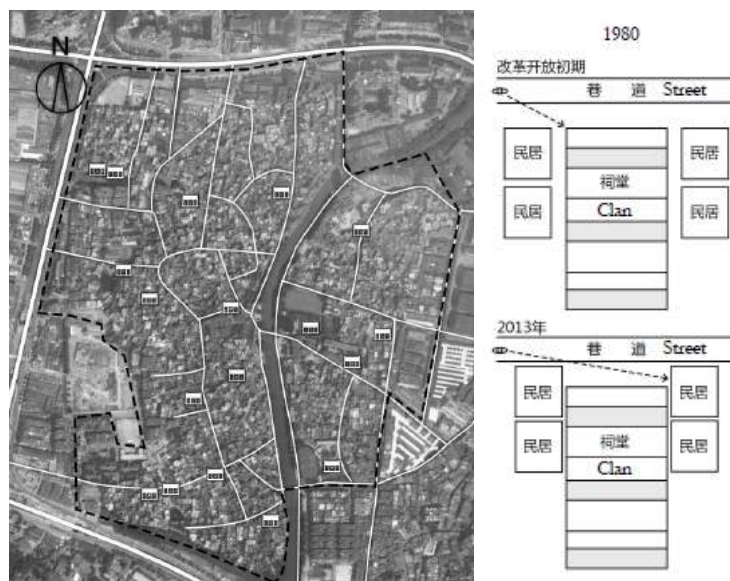

Figure 3 – Spatial location of Liede Village | Figure 4 – Spatial location of Liede Village

Ancestral halls are an important height pole in traditional villages. Today, this traditional constraint is practically useless. The height of the building in the village has been continuously raised, and the number of buildings surrounding the ancestral temple has also been increasing. Originally, the 1-2 floor of the house was rebuilt into 3-4 layers, after the capital recycling and then built, and finally built a shack on the roof. If the urban village transformation, the volume rate will be higher than the villages in the period, is behoove things on the height of the arrogation of ancestral temple. Liede village volume rate of 5.2, the ancestral hall surrounding buildings nearly 40 storeys, although the ancestral hall has 30 meters or so distance, still formed a strong contrast.

Figure 5 –Building height contrast | Figure 6 – Building height contrast

2.3 CHANGES IN ANCESTRAL HALLS

The space pressure faced by the ancestral hall is also making some ancestral temples break through the general plane shape in the stage of reconstruction and expansion. They responded with a more flexible and special approach. No similar practice has been found in the redevelopment of the village. Some of the new ancestral halls in the village abandoned the symmetrical layout and built a subsidiary room on the side of the middle road to expand the space of the ancestral hall. These ancillary rooms and the main building with different styles, strictly speaking, does not belong to the temple, and the middle of the building similar to the formation of two ancestral temple of the plane. Huang ancestral hall is an example. Reconstruction of ancestral temples, built a bungalow on the left side of 50 square meters, as for the clan banquet kitchen. The attached rooms are not decorated and are connected to the middle building. However, it differs greatly from the traditional architecture in that it maintains the symmetry of the ancestral hall to some extent.

Figure 7 –Unilateral subsidiary housing Hall | Figure 8 – One side with auxiliary rooms

The traditional architectural brick, wood and stone as building material, construction cost is more expensive. Chebe village ancestral reconstruction in 2010, the first in the brick wood structure, cost per square meter to 6000 yuan. Two, three with steel and concrete structure, the cost per square meter of only 2000 yuan. Liede village Lee's ancestral hall of brick wood structure, covers an area of more than 1200 square meters, a total cost of about 7500000 yuan. The high cost enabled the villagers to start looking for alternatives. When the ancestral temple was rebuilt and rebuilt, it tried to add the modern building materials such as concrete, steel bar and tile to the construction of the ancestral hall. There are 11 cement houses and ceramic tiles in the ancestral hall, 8 of which are brick concrete or steel concrete structure. In the construction of the temple of Hao Feng and the hall of longevity and longevity, modern building materials completely replace wood and stone.

Figure 9 –Cement beam Figure | 10 – cement column stuck with tile

Figure 11 –Cement beam Figure | 12 –Wood structure

Cultural heritage does not mean the complete duplication of ancestral halls, but rather the preservation and continuation of styles that reflect local culture and historical traditions. In the development of village in the city, the cultural significance of some ancestral temple building blocks has been neglected and forgotten, and the traditional style has been abandoned. In recent years, some of the important building

blocks have been changed more freely during the reconstruction of the ancestral hall in the village. For a comprehensive transformation of Liede village, change problem is more prominent, the new temple in ridge, door and other aspects of the changes in Sook are quite different with the traditional place.

The new ancestral hall in Liede village is a mass producing product. It is not a continuation of the original ancestral hall of the ancient clan names, but also because there is no difference in the aesthetic of the various surnames.

Figure 13 –Ancestral hall ridge contrast | Figure 14 –Detail comparison

2.4 ANCESTRAL HALL USAGE CHANGES

Ancestral halls are public houses in the clans, mainly for clan activities, and provide space for parties and festivals. Around 2000, Guangzhou implemented the policy of changing the village to the village, and the quality of community life of the villagers was concerned. The economic society began to use the ancestral hall as the center of the villagers' activities. After that, the clan actively offered the ancestral halls to the daily activities of villagers as a supplement to the public space. There are 12 ancestral halls open to villagers. The number of people used is about 7-8 people, mainly in the patriarchal clan. The 5 ancestral halls of the village are also available to the villagers, but the number of people used is less than the village, with only 3-4 people. With the increasing use of the ancestral temple, the use of space shows the characteristics of daily life. The use of ancestral hall space mainly focuses on the ancestral hall, the hall and the hall of enjoyment. The outside of the entrance hall is connected with the streets and alleys, and there are benches or stone chairs. The villagers chat here, chat with passers-by and pick up children from school. Enjoy the spacious room, tables and chairs and tea sets are complete, the villagers stay here longer, activities are more diverse, including reading newspapers, playing mahjong, playing table tennis and so on. In the inner part of the ancestral hall, there are walls, lighting conditions are poor, villagers use this space less. All kinds of activities and the clan, ancestral hall itself is not directly related to the general entertainment activities. The ancestral hall is more represented as an ordinary public space, and is no different from an ordinary city center. The etiquette and tradition of the clan are also invalid in use, and the villagers act in daily ways with less taboo and less concern.

Figure 15 –Distribution of ancestral temple users

2.5 CHANGES IN THE ECONOMIC CONDITIONS OF CLAN

The beginning of reform and opening up, chebei village ancestral temple construction, renovation costs mainly comes from the clan members and families to donate. Ancestral temple's limited economic ability, often unable to make ends meet. Under the influence of urbanization, the change of economic structure, the increase of economic income and the economic condition of the ancestral hall have changed greatly. Total revenues from a single donation temple to property rental income into economic agency funding, the clan members and families to donate by. Economic society will be part of the rental property assigned to the main hall, the rental income to the ancestral temple all. On the Qingming Festival, the Dragon Boat Festival, the Chung Yeung Festival and other festivals, or when the ancestral hall was rebuilt and rebuilt, funds were allocated so as to increase the income of the total ancestral temple from a great deal before. Our ancestral property located in Zhongshan Avenue and Jubei Avenue, in the property rental income accounted for a high proportion of total nearly 500 thousand yuan a year. Organized clan activities without clan members to donate tissue. The living place is near the village of Su's ancestral hall, and the annual rental income is nearly 100 thousand. The economic expenses of the ancestral hall in the Liede village are held by the German economic company, and the clan activities after the reconstruction have not been charged to the villagers.

The increase of income has positive effect on the activities of clan activities and the construction and renovation of the ancestral temple. Our ancestral income is mainly used to hold together the clan activities. Qingming worship, a banquet for more than 100 tables, for each member of the tribe to pay 10 yuan of red envelopes. The Dragon Boat Festival Dragon Boat set meal, entertain visiting relatives. The Chung Yeung Festival has a feast for the elderly and 300-500 yuan for the elderly who participate in the retirement. Compared with previous years, ancestral clan activities scale, banquets level to the next level, clan members to participate in the enthusiasm also improved. About one hundred thousand of the total surplus is accumulated annually as a fund for rebuilding and rebuilding the ancestral temple.

3 THE EVOLUTION MECHANISM OF CLAN SPACE

3.1 ALTERNATION OF MANAGEMENT: CONJUNCTION MECHANISM

3.1.1 TURNOVER OF MANAGEMENT ORGANIZATIONS AT THE GRASS-ROOTS LEVEL

The economic society is a collective economic organization in which the village in the city is divided into a certain geographical area, and has undertaken a great deal of community management work. It is the main grass-roots management organization in the village. Its members are elected by villagers and led by district offices. The clan organization for village development, clan members behavior management authority deprived, clan rules and family about loss of control effectiveness. The control of the ancestral hall was weakened. Some harsh and strict rules about the use of ancestral halls have been abolished, management becomes loose, and new activities and functions enter into the inner space of ancestral halls.

The control ability and the right to speak of the clan organization in the village decreased, and the protection ability of the clan space also weakened. In the process of spontaneous and disorderly construction of villages, they were unable to stay out of the situation and were influenced by the outside. The ancestral temple building no longer enjoys the privilege given by the clan, and its rank in the village space is declining, and it is sheltered and besieged by the common folk houses. And the loss of leadership to the surrounding buildings is transcended at a high level

3.1.2 CONNECTION BETWEEN CLAN CONCENTRATION AND ORGANIZATIONAL STRUCTURE AT THE GRASSROOTS LEVEL

The clan members are linked together by clan and ancestral hall. The economic community is divided according to the region, and respect the original boundaries. The division of economic society and the layout of the original clan have a spatial fit, which makes the members of the economic society have the characteristics of close kinship and single surname, similar to the branch of the clan.

From the combination of the clan settlement and the organizational structure at the grass-roots level, the villagers expressed their wishes through the will, so that some decision-making and management behaviors of the economic association also have the value orientation of the clan. The survival and development of ancestral halls have been helped by economic society. The right of the ancestral hall to retrieve the ancestral hall is managed and used by itself. In the distribution of economic, social and collective property, support for the ancestral temple, some of the property will be placed under the ancestral hall, and allocated funds for ancestral ancestral temple activities, or renovation and reconstruction.

3.2 OPPRESSION OF ECONOMIC ENVIRONMENT: TRANSFORMATION MECHANISM

3.2.1 OPPRESSION OF LIVING CONDITIONS

Because of the development of the surrounding urban areas, most of the farmland in the city has been expropriated. Farmers get compensation for land acquisition, but also lost the basic way to make a living. Most of the villagers are under the low education level, their own quality can not adapt to the city's labor demand, after losing farmland, they are faced with enormous pressure to survive. Based on the strong demand for urban low-income housing, the villagers turned to rental housing for income. After the increase and increase of rental income, the survival oppression evolved into pure interest pursuit, and the villagers fought for the space in the village. They built new houses or built additional houses, which increased the rent income and formed a huge expansion force.

Comparatively, the economic income of clan space depends on the exterior. Moreover, the space structure and mode of use are relatively stable, and there is no need for space expansion. In the city village, when the villagers build new and additional houses for expansion, the ancestral hall itself has no outward thrust against it, and is in a weak state of passive coping. This also led to the surrounding residential areas to press the ancestral hall, the roadway space was eroded, and the ancestral hall space structure was compressed.

3.2.2 INDUCTION OF ECONOMIC BENEFITS

The use of ancestral activities in ancestral halls is mainly during the gathering or festive celebrations. Although the outer space is an important component of the clan spatial pattern, the actual use is not much. Relative to the use of other spatial extracts in urban village, the use efficiency and strength of clan space are low, and it has great development value in space utilization. Driven by potential benefits, more use functions are placed in the clan space. The ancestral hall, as a ready-made building space, is used as a complement to public space. Vacant halls are used as parking lots to collect parking fees. A dilapidated ancestral hall for rent as a warehouse or production plant.

The inducement of economic benefits also led to the disintegration of ancestral hall space. City Village rental housing demand, with the rise in urban housing prices, rents are also rising. Without affecting the main function of the ancestral hall, the ancillary space of the ancestral temple will be transformed into a new house for rent, and a more profitable profit can be obtained. Therefore, the part of the ancestral hall was cut, lining two, demolished three temple. Because of the differences in the intensity of the use of the inner space, the inner space of the ancestral hall has been destroyed by the overall economic environment of the village.

3.2.3 CHANGE IN ECONOMIC DEVELOPMENT

After the transformation of villages in the city, the economic development model of villages has changed. Relying on modern management and management, more efficient and intensive. Economic society or villagers no longer rely on space for more benefits, and spontaneous and disorderly construction behavior has been curbed at the root. Under these circumstances, the force of oppression and inducement of the clan space was weakened in the original economic environment of the village.

On the one hand, the space pressure that the ancestral temple faces in the reconstruction is greatly reduced, and there are more abundant land resources to construct, and it has the space condition to rebuild the whole space structure again. On the other hand, after the restoration of the outer space, such as the surrounding roadway, the earth hall and the pond, the integrity of the space has been maintained in the subsequent development. Originally, part of the evolution of villages in the city features, such as the weakening of the characteristics of space nodes, the compression of external space, the use of the use of external space, because the weakening of the impetus, did not re emerge.

3.3 THE IMPACT OF CULTURAL TRADITION - ADAPTATION MECHANISM

3.3.1 THE INFILTRATION OF MODERN URBAN CULTURE

Villages in the city are surrounded in the process of urbanization. Traditional culture is impacted by urban culture. The villagers are influenced by their ideas and values, and reduce their traditional self-identity. In the interview, it was found that the concept of cultural continuity held by the clan members in the rebuilding and rebuilding of ancestral halls was very general. The first problem is the reservation of the clan space, which is regarded as the symbol of the rise and fall of the clans.

The infiltration of urban culture has also changed the way people live. The facilities and services in the city are better than those in the traditional villages, which bring great convenience to the villagers. While enjoying the facilities and services of the city, the villagers also have their identification and dependence. The city's facilities and services are integrated into the villagers' lifestyle, replacing traditional amenities and customs. The traditional ancestral temple banquets, unavoidably by the clan members including one RBI, food cooking, with tables and chairs placed, tableware cleaning, sorting and other aspects of the ancestral hall. These things are trivial and are replaced by catering services or restaurants in the process of evolution.

3.3.2 THE ADAPTABILITY OF CLANS

The clan has stronger adaptability and vitality. It has been adjusted in different societies, different economic systems and different political systems, and has survived for thousands of years. The clan began in feudal society and slave society, and was closely integrated with the regime in feudal times. It was badly damaged after the founding of the people's republic. After the reform and opening up, a new revival has taken place. There are two main changes in modern patriarchal clan system, from closed to open, from authoritative to democratic.

As a symbol of the clan, the ancestral temple is closely integrated with the development of the clan. The changes of clans also lead to the active evolution of clan space and meet the needs of modern society. The change of attitude of the ancestral hall to the people outside the clan has changed from vigilance and resistance to acceptance and welcome, and the openness of the space has been greatly improved. The important decisions of the ancestral temple are mostly voted by the villagers, and the publicity of various matters is more adequate.

4 CONCLUSION

4.1 SUMMARY AND EVALUATION

In the process of rapid urbanization, the traditional agricultural villages were swallowed up by the cities and became "villages in the city". And then experienced the transformation. The clan space in the village also evolved during the process. Study found that by Jubei village, Liede village temple and the villagers, the village clan revival, spatial evolution after power Pactrometer development, rehabilitation and complete the transformation of four stages.

The results show that the development of urban village, the transformation process of rapid changes in the economic environment is intense, force on the evolution of the clan of the huge space, especially in the

villages in the period to the clan space has brought many negative effects. Cultural penetration has also led to some loss of tradition, relative strength is not sufficient protection of the ancestral hall. Government departments or academic structures should intervene in time to provide guidance and help for the evolution of the clan space in the urban village, so that excellent traditional culture can be preserved. The contribution of this paper is to enrich the research object of villages, and village hall space provide the basis for protection and reconstruction.

4.2 ADVICE

To formulate the guideline of ancestral temple in Guangzhou, and to provide the basis for the reconstruction of ancestral temple. In the urban area of the village according to the cultural characteristics of classification, make each kind of villages in the corresponding ancestral shape interpretation guidelines, significance and importance of building components and building decoration peculiar to the ancestral lineage, and gives the retention or transformation of the views. As for the Liede, Jubei is south of the Five Ridges water village is the heritage of the Dragon Ridge retained ancestral temple, the heritage of the village has Hengsha scholarly advice should be reserved and the hall of Taiwan kuixinglou sook. So that the clan has more profound understanding of the ancestral hall, and guide them in the ancestral temple building activities to make more reasonable decisions, so that cultural traditions better pass down.

We should improve the protection and declaration of cultural relics in ancestral halls, and strengthen the protection of ancestral temples of historic value. To strengthen the cultural relics declaration of the ancestral hall of the city and district level cultural relics protection units in Guangzhou, and classify them in a hierarchical manner. Establish the links between the municipal cultural departments, the university scholars and the ancestral halls, so that the government departments and scholars participate in the construction and management activities of the ancestral halls in the villages of the city. On the one hand, it provides consultation and guidance for the clans, and on the other hand, it plays a better supervisory role.

ID 1532 | WHAT FACTORS AFFECT PUBLIC PARTICIPATION IN THE URBAN REDEVELOPMENT PLANNING PROCESS IN CHINA

Wang Liyao¹; Yue Yufeng¹

¹Bartlett School of Planning, University College London
uczllw1@ucl.ac.uk ; y.yue@ucl.ac.uk

1 INTRODUCTION

Since 1978, China has experienced almost the largest scale of urbanisation process in human history due to the demand of rapid economic development (Campanella, 2000). During the last three decades, urban planning in China led by the government had pursued high economic growth rather than higher living conditions of urban residents (Li, 2012). Now, China has entered the later stage of accelerated urbanisation which is identified as the “decelerating, transformative, and diversified” period. It is important to be human-oriented, adaptable to local conditions and environmental friendly in urban planning (Yang and Chen, 2015). In this “New Normal” era, more factors can be involved in the urban redevelopment planning process.

Public participation, as one of these factors, plays an increasingly essential role in urban regeneration. Smith (1973, pp275-295) describes participatory planning as a democratic process supporting value creation, definition of communities and development of residents’ identity, leading to a harmonious society. In the United Kingdom, the “Town and Country Planning Act” passed in 1947 stipulated public participation as a legal step in urban planning, which protected the public rights in the urbanisation process. This participation lead to better policies and implementation decisions in urban planning (Irvin and Stansbury, 2004).

Public participation in China boosted in the 1990s. At that time, the public’s willingness to participate in the urban regeneration decision-making process have increased because of more attention to life quality and individual properties (Zhang, 2015). Meanwhile, the government began to realise the importance of public participation due to conflicts of interest between involved groups in the planning process, such as real estate developers and residents. In 2006, the “Measures for Formulating City Planning” illustrates the necessary of information acquisition and public notification for draft proposals in detailed planning (Wei and Dai, 2015). In 2008, “Urban and Rural Planning Law of the People’s Republic of China” was implemented. It acknowledges public participation in explicit terms, illustrates the public’s rights of awareness, specifies the approach of public participation and emphasizes the importance of participatory planning (Sun and Yin, 2008), providing a legal base for democratic participation in the urban planning process. However, the lack of specific approaches in relevant provisions provides few instructions for the participatory planning practice in China.

This paper will first illustrate the status quo of public participation in urban renewal projects in the New Normal era, following by practical cases in the urban redevelopment planning process in China. After that, it will illustrate several factors, including government policies, interest groups and public consciousness, which may hinder the public from participating in urban planning based on former cases and experiences in Chinese context. Then it will evaluate the practice of participatory planning in China with that process of the neighbourhood planning in London, analysing reasons for the formulation of these factors in different context. Finally, the paper will provide some suggestions which may improve public participation in the urban redevelopment planning process in both China and the Great London area.

2 PUBLIC PARTICIPATION IN URBAN RENEWAL PROJECTS IN CHINA

Metselaar and Priemus (1992) argues the concept “urban renewal” is more than the improvement of the stock of buildings and the restricting of old city districts. It is the systemic intervention relating to economic affairs, public health, culture and social affairs for a higher living condition. From the opening-up policy to the New Normal era, the desire for sustainable communities promotes public participation in practical cases, and social problems led by rapid economic development need to be eased by restructuring and upgrading. However, these renewal processes, including the redevelopment of historical districts, upgrading urban villages, transformation of old residential areas, and so forth, mainly led by local governments who often act as protectors of commercial interests rather than that of public demands (Qian, 2009). To avoid further social conflicts, public participation, as a useful tool, is essential to balance the real needs and these commercialised plans.

Due to a long-term lack of participatory planning tradition, public participation in China is now still in a nascent stage. Most of the research in China remain in the theoretical level because of the lack of successful studies, but progresses have accumulated in the practical level in recent years. The early attempt to introduce participatory planning in urban renewal projects occurs in 2008 in regulatory detailed planning in downtown Beijing. To encourage the confidence and interest of the public, this participatory planning focused on small interventions about social infrastructures which could surely be changed after the participatory process. Further to showing information on noticeboards after the planning process, 259 questionnaires for residents had been gathered before the decision-making process. Participants had rights to comment on the current public services, green gardens, new constructions, public buildings, and parking areas in their communities (Chen and Ye, 2013), but their ideas were deeply influenced and chosen by government-led consultants. With further interviews and seminars, the facilities were changed and partly spaces were repurposed between 2008-2010, which is regarded as a significant case in early participatory planning in China.

A wider and more complex participatory planning in the urban regeneration programme in Haizhu District in Guangzhou started in 2009, showcasing the application of traditional mass media in the participatory renewal process. The renewal programme, relating to complex ownership of households and plenty of demolitions and new constructions, encouraged not only residents, but also citizens, consultants, experts in various fields to participate in, showing the importance of balance among multi-stakeholders. Planners had made 1600 brochures and 1250 leaflets particularly for the public, and got wider feedback for demands of residents. Meanwhile, detailed timelines had been made and published to regular the participatory process, and traditional mass media, including newspaper and TV comments, also pushed this programme further and influencing the process (Shi, 2010).

Although a huge progress had been made in this case, many deficiencies have risen. One of these is the veracity and comprehensiveness of media reports, some public media probably exaggerated the problems, leading to misunderstanding among stakeholders, especially between governments and the public. Additionally, governments still have the right of discretion in final decision-making process. Suggestions offered by the public cannot be judged by clear and explicit items in law, and thus the results of public participation were likely to be ignored, even as evidence for other's interests.

As the increasing practical cases accumulated, the awareness of public participation has been awoken, nevertheless the real role these suggestions gathered from the public play are limited because of the incomplete policy system and top-down planning pattern. In 2015, a new attempt to renewal programme of housing zones implemented in Shanghai, following bottom-up pattern. The programme, "Beautiful Home", aimed to refurbish old housing zones by renewing social infrastructure, refurbishing old buildings, managing traffic roads and parking areas and enhancing the living environment in communities in Pengpu town, introducing the concept of "self-organised communities" and "participatory planning" in the renewal process. The public could participate in all procedures including planning, survey, conceptual development, decision-making, implementation and management (Kuang and Lu, 2015). Clear timelines and procedures and layered implementation led by residents contributed to operational interventions in participatory planning. However, the efficiency of communication was restricted by simple approaches taken in the planning process.

Based on three practical cases above, public participation shows its potential and the essential role in urban renewal projects in China, however, problems and limitations are obvious. First, the top-up planning pattern can hinder the public from participating in decision-making process. Insufficient policies for communication and expression restrict the impact of participatory planning. Moreover, a lack of transparency could lead to corruption and violation operation in planning process among different stakeholders, especially between governments and developers. Second, the degree of involvement of the public does not achieve the expectation in practical cases, and suggestions they offer are too general and hard to be implemented. Third, traditional mass media cannot meet the demand of speed and range of information dissemination, resulting in a lack of veracity and comprehensiveness of communication in the participatory planning process.

3 FACTORS INFLUENCING PARTICIPATORY PLANNING IN CHINA

3.1 THREE FACTORS INFLUENCING THE PARTICIPATORY PLANNING IN CHINA

According to the practical cases and problems discussed above, factors influencing the participatory planning process, especially in complex renewal projects are a lack of explicit public policies, inefficient communication among interest groups and a lack of public consciousness. Among them, a lack of explicit and operable items of participatory strategies at the legal level because of the late start in China is the first and foremost reason. Although the “Urban and Rural Planning Law of the People’s Republic of China” implemented in 2008 provides the right of awareness and public participation in public affairs, detailed strategies and policies need to be made based on local conditions. Nevertheless, the city planning in China is usually decided by governments without the further discussion and vote by the People’s Congress at the local level. Without the efficient and comprehensive solicitation of the public’s opinion, the policies of participatory planning cannot be implemented in practice.

The excessive power of local governments leads to the top-down pattern as the dominate one in urban renewal projects, which may not meet the public’s rights. Insufficient detailed policies about the regulatory procedures and criteria result in the lack of legislative participatory planning processes in projects. In that case, governments prefer to achieve ideal redevelopment planning goals for economic purposes in master plans rather than satisfying the residents. They can also take advantages from the top-down planning system by controlling sources of information to avoid compromises and the long-term participatory process. Moreover, due to a lack of transparency, the delimitation of obligation among governments and multi-stakeholders is vague, causing the corruption and inefficiency in the implementation process. Besides, without an effective feedback system, the redevelopment planning process may cause conflicts between the public and government officers, especially in land use and demolition.

Secondly, inefficient methods of information disclosure and communication among interest groups adverse to the participatory process. Ambitious interest groups such as real estate developers are reluctant to show detailed procedures and design plans and invite the public into the decision-making process because their commercial benefits might be limited by the public’s opinions. Moreover, their profits are relatively combined with that of the local government, so sometimes this subtle relationship between stakeholders and the government can form “interest coalition” in the renewal process. In the coalition, the government can gain not only the revenue but implicit benefits by renting the land use rights (Wu, 2007), and stakeholders, would prefer to influence the policy-makers for maximum profits. Thus, the public become vulnerable groups in the urban redevelopment planning process.

Furthermore, scholars and planners, as coordinators, cannot develop a larger impact in the participatory process because of inefficient means of communication. Some argues the monopoly of plans and skills by scholars makes it easier to gain profits for the “interest coalition”, and measures must be taken to restrict the power of planners (Yan, 2011). However, the planning process can be time-consuming and led to uncertain results without the coordinator role and efficient methods of communication. To protect the equal right to know among stakeholders, symmetry of information and feedback systems for the public are essential in the urban regeneration process.

Thirdly, a lack of public consciousness prevents the public from deep participation in urban regeneration projects. With a long-term absent of public participation in the decision-making process in public affairs, the public considers participatory planning as a symbolic process, and treats this legal procedure casually. Meantime, due to the lack of professional approaches and knowledge, their voice has limited operability, offering the reason for the government and interest groups to exclude the public from policy-making process. Furthermore, the lack of professional knowledge leads to a lack of citizen responsibility and public consciousness, forming a vicious circle in participatory planning. In practical cases, residents draw much more attention on their own profits than the whole living environment and social sustainability. Further to that, some are reluctant to compromise and communicate with planners and other interest groups when facing with disputes. Thus, strategies and procedures of public participatory planning can be implemented smoothly in small projects, but it is hard to be done in district-scale or city-scale projects.

In recent years, planners and mass media act an important role in the public education by doing surveys, delivering booklets and teaching technical terms and citizen rights to the public in participatory

programmes. However, the propaganda has territorial limits. Urban renewal projects are still controlled by the government and interest groups in most cities in China.

3.2 EVALUATION OF NEIGHBOURHOOD PLANNING IN LONDON

In 2011, neighbourhood planning was encouraged in the Government's scheme through The Localism Act 2011, whereby powers are devolved from central government and transferred to communities. Similar to the participatory planning in urban regeneration programmes, most of the neighbourhood planning concentrate on the renewal and upgrading of current communities for a more sustainable future. For example, Hackbridge was chosen as one of the original 17 communities to be front-runners in the neighbourhood planning (DCLG 2015). Following the Sutton Local Plan, the survey and participation began in 2012, and the final neighbourhood plan was proposed in March 2017. The comparison of the long-term participatory planning at a neighbourhood level in London and the third participatory case above in Shanghai can show different strategies and procedures in the planning process.

Compared to the case in Shanghai, residents in Hackbridge have stronger public consciousness and more professional knowledge due to the democratic tradition in city planning, which benefits for the self-management in the whole process. This self-managing group acted as the link among all the stakeholders and organisations, enhancing trust between the local authority and residents. Further to that, explicit strategies were made at the beginning of the participatory plan, completing with timelines and detailed schedules. These strategies can be various in terms of borough plans, but the overall procedure is decided. Moreover, the information is transparent and shown timely on specific websites and homepages in Twitter and Facebook, reducing the potential of information asymmetry and offering opportunities for a wider range of citizens to participate in. With multiple methods in the participatory process, residents are willing to involve into the decision-making process.

Additionally, cultural events such as photography and painting were held in communities by the consultation group, enhancing the sense of identity for residents.

However, the disadvantages of this participatory neighbourhood planning are shown in the draft proposal. Strategies and approaches are vague and weak to be implemented probably due to the result of compromise of stakeholders' profits, but a long-term decision-making process with limited operable results can sometimes be disappointed. Further to that, most of interventions offered by residents are for small-scale, while strategies proposed by authorities are general ones for the further development. Different concerns may lead to the difficulty of the communication. Also, considering the issue of funding and complex ownerships in this case, to what extent will the participatory result will be implemented remains unknown.

4 SUGGESTIONS

Factors above show the complexities that public participation presents in the Chinese context in the urban redevelopment planning field and its differences with the neighbourhood planning in London. As Klimova (2010, pp.32) reports, aiming to improve participatory practices in renewal projects in China, ladder of public participation by Plummer and Taylor (2004 cited in Klimova, 2010, p.32) shown in Figure 1 should be used to interpret the whole procedure of democratic participation. Public participation will not in its first stage of "Notification and attendance" if the government, scholars and the public itself make concerted efforts.

Figure 1 - A ladder of public participation in China
source: Plummer and Taylor, 2004, cited in Klimova, Z., 2010. Public Participation in Urban Renewal Projects. Master Degree. Lunds University.

Firstly, detailed policies should be made to regular participatory procedures in which responsibilities of each stakeholder need to be defined at all level. Since in the new “Urban and Rural Planning Law of the People’s Republic of China”, detailed steps of participatory planning have written as the compulsory terms, terms relating to regulating participatory steps in the local level should also be made soon in the future, such as operational methods of distributing responsibilities and economic profits in urban renewal projects. Additionally, strategies of encouraging general education of planning knowledge and citizen rights need to be taken in the participatory planning process. With the explicit policies at all level, multi-stakeholders will involve into the participatory process with clear authorities and responsibilities, working as a virtuous circle in urban planning.

Secondly, the necessary of community planners and individual consultation groups has shown in the participatory planning process. As coordinators, these experts, not sharing the common interests with other stakeholders, are expected to establish a planning administrative system which is not controlled by the upper-level planning bureau (Li, 2012). This neutral system is responsible for balancing the interests of the local government, all the stakeholders and the public in practical planning projects. In that case, suggestions from this third section system can be advantageous to the public to some degree.

Thirdly, digital media can work as an efficient method of communication and information disclosure, and stakeholders can communicate in real time. Now, new platforms combining social media with big data are popular. For example, it is easier to monitor the traffic condition in a certain district by gathering the commute information based on daily records on phones. Based on that, new attempts have been tried in Beijing. Planners invented mini programmes on Wechat, one of popular social medias in China, to ask for comments on busy roads in rush hour. Citizens can definite these roads in real time by clicking on the phone screen. In this way, the veracity and comprehensiveness of information can be guaranteed and the statistics is easier.

Inspired from that, mini programmes can also be invented in mobile phones and on online websites as efficient platforms and feedback systems, contributing to the symmetry of information in the urban redevelopment planning process. In that case, the public can keep abreast of the projects, join in the survey and interviews, vote for their favourite designs and monitor the process though online platforms. However, such systems are still at the early stage, deeper data analysis need to be done in the future by inter-disciplinary groups. Such methods can also be implemented in the participatory planning at a neighbourhood level in London for more effective procedures and a strong result.

5 CONCLUSION

Learned from the practical cases in China and the neighbourhood planning in London, three main factors has been proposed including a lack of explicit public policies, inefficient communication among interest groups and a lack of public consciousness in the urban redevelopment planning process in China. By now, the publish of Urban and Rural Planning Law has been regarded as the promising beginning of the participatory planning in the early stage in Chinese context. Following the general items in law, detailed strategies and consultation groups at a neighbourhood level are necessary, and the essential role new mass media plays can optimise procedures in practical cases. A new order can be expected in the New Normal era in urban redevelopment planning process, of which the structural change will contribute to the social and cultural sustainability.

ID 1537 | URBAN REGENERATION PROJECTS IN BRAZILIAN CITIES: HEGEMONIC DISCOURSES AND POLICY MODELS

Maria Lucia Refinetti Martins¹; Alvaro Luis dos Santos Pereira¹; Sofia Arrias Bittencourt¹

¹University of São Paulo / LabHab

malurm@usp.br; alvarolsp@yahoo.com; sofia.ab@gmail.com

1 INTRODUCTION

The central purpose of this article is to analyze planning traditions, regulatory frameworks and the social construction of legitimizing discourses on urban regeneration in Brazil. It presents an overview of the main argumentative lines underlying the discursive construction of the notion of public interest in the context of urban regeneration initiatives in Brazilian cities and shows how the convergence of different, and eventually conflicting assumptions and propositions related to urban development have provided ideological support for the widespread assimilation of urban regeneration initiatives as socially desirable interventions. It comprises the following sections: Introduction; The construction of the arguments; The Urban Reform; Sustainability; The strategic planning of cities; The trajectory of urban regulation and regeneration policies in Brazil; The recent process; Conclusions.

The point of departure of an urban regeneration project is the recognition of a certain urban situation as problematic, and the assumption that an intervention aimed at fixing it is socially desirable. These projects are backed by narrative constructions addressing what the urban problems are, and what sort of

measures should be adopted in order to fix them in a way that is consistent with what is assumed to be the public interest⁴. Though the notion of public interest is disputed and contingent, taking on different characteristics according to the context, the evocation of this concept is always present in urban regeneration projects. The justification of urban interventions promoted by the state inevitably requires the formulation of discursive constructions aimed at showing their alignment with the notion of public interest, regardless of how this is conceived. In the case of urban regeneration projects targeting previously developed land, which usually affect a variety of both particular and collective interests, a verifiable connection between their alleged purposes and the pursuit of goals embedded in interests of a higher kind is necessary if they are to attain a minimum level of legitimacy and political feasibility. Referring to the public interest may be regarded as an unavoidable argumentative step to justify urban regeneration projects.

These discursive constructions are usually based on more or less explicit assumptions of what the socially desirable patterns of urbanization are, and also of why certain policy arrangements are more suitable than others to improve them. In this sense, thinking of the relations between urban regeneration projects and discursive formulations on the public interest develops in two dimensions of analysis, which could be summarized as a programmatic one and an instrumental one. The first is dominated by questions like the general goals and strategies of urban development that underlie urban regeneration projects, and the reasons why these projects are expected to generate positive impacts in the city. The second discusses the way in which they are implemented, the alleged reasons for the choice of certain kinds of regulatory arrangements rather than others. These two dimensions are somehow intertwined, both reflecting broader trends of the contemporary urban development models. However, the distinction may be useful for analytical purposes.

Rather than being built upon a one-dimensional line of reasoning, the discursive constructions backing urban regeneration policies are usually based on an amalgam of different principles and claims which are somehow associated with the notion of public interest. Their power rests on the ability to make urban regeneration projects be perceived as expressions of the public interest by a diversified set of agents at different geographical levels, and, by doing so, setting favorable ideological conditions for the formation of strong developmental coalitions. The formation of coalitions imposes the necessity of accommodating interests and claims that may be contradictory. If the shaping of public interest narratives within urban regeneration projects requires some degree of openness of policymakers to the diversity of aspirations and existing needs in cities, this notion is also employed as a powerful rhetorical device to hide conflicts and forge political consensus. Though the way these narratives are woven may change according to local features, it is also possible to identify discursive constructions that are recurrently applied to legitimize urban regeneration projects on a public interest basis, which makes them hegemonic discourses.

The term 'urban renewal', attributed to intervention in the pre-existing urban fabric, became commonplace, according to Compans (2004) with the end of World War II, in view of the need to rebuild the European cities destroyed by the conflict and to respond to the housing deficit accumulated over the previous decades. Later, in the 1970s, with the restructuring of production and the economic recession, programmes were started to convert abandoned and degraded port and industrial areas. The simultaneous crisis of public finance led to a framework of pragmatism that sought association with private initiative in configurations with a greater or lesser degree of state intervention, depending on the context.

Urban regeneration projects with private sector involvement were highly developed and important in Brazil during the 1990s. Since then there have been a proliferation of policies of this kind, which has also entailed the continuing development of a directly or indirectly related legal and regulatory apparatus. It is important to stress that this process has been spatially uneven. Though urban regeneration initiatives are spreading throughout an increasingly broader geographical base, they are still highly concentrated in major cities and metropolitan regions. This trend is even more explicit if considering the situations in which these projects are carried out with a relevant involvement of the private sector

In this scenario, certain local experiences in major cities have been playing a substantial role in shaping the regulatory landscape of urban regeneration projects, and these local experiences have been even more influential than national legislation and programmes. A number of urban regeneration processes recognized as successful experiences within hegemonic discourses have been assimilated as benchmarks for the formulation of regulatory arrangements related to this kind of intervention, and have become referential models in various Brazilian cities. The city of São Paulo has played a particularly important role

as a laboratory of regulatory arrangements related to urban regeneration initiatives at least since the 1990s, and the influence of regulatory arrangements originally conceived in São Paulo can be seen in specific projects promoted in other localities and even in national legislation, which has incorporated some of its instruments and given them the status of standardized regulatory tools applicable in the country as a whole. More recently, the city of Rio de Janeiro has also become a centre of the development of urban regeneration policy frameworks. Taking the previous experiences of São Paulo as an inspiration, this city has deployed complex schemes of urban regeneration with private sector involvement. The latter have been regarded as more sophisticated than those previously structured in São Paulo, and also as potentially influential models for further generations of interventions of this kind.

Cities like São Paulo and Rio de Janeiro can be seen as uncharacteristic of the Brazilian scenario, with specific attributes related to their size, economies and managerial capacity that are far from being a generalized pattern throughout Brazilian cities. Thus, the urban regeneration schemes in these cities cannot be simply transferred to smaller towns as ready-to-use regulatory frameworks. Even if they are willing to replicate urban regeneration models developed in São Paulo and Rio, most smaller towns and cities do not have the necessary economic and institutional conditions to enable them to function. However, these major cities do exert an influential role on defining policy paradigms, guiding governmental agendas, exporting regulatory frameworks, which means that they act as incubators of policy arrangements of this kind.

Urban regeneration actions are loosely regulated at the national level if regarded from a more "programmatic" perspective. There is nothing like a comprehensive national plan of urban regeneration, and neither is there a well-structured federal policy to guide or support these initiatives at the municipal level. There is also a lack of legal and regulatory devices clearly defining urban regeneration as a goal to be pursued by local governments. The connections between federal regulations and urban regeneration are limited to general principles that exert an indirect influence on initiatives of this kind.

In order to present the Brazilian context, two policy instruments used in urban regeneration processes will be scrutinized: the urban operation and the public-private partnership. These two modalities are linked to different processes and origins, but they have in common the fact of being urban instruments which enable the articulation between the public power and the private initiative with the purpose of expanding the capacity of promoting urban interventions that will allegedly benefit society in the future. While the urban operations come from an urban matrix ideology, in which a goal of urban renewal is present, whatever the content that it acquires, the public-private partnerships are based on large public infrastructure works which are mainly focused on the field of production or on sectorial policies that require large-scale equipment, such as in the case of health, with the need for the construction and management of large hospitals. They therefore come from a management matrix.

The following sections of this paper present an overview of the main argumentative lines underlying the discursive construction of the notion of public interest in the context of urban regeneration initiatives in Brazil. They seek to show how the convergence of different - and eventually conflicting - assumptions and propositions related to urban development provided ideological support to the widespread assimilation of urban regeneration initiatives as socially desirable interventions. In this sense, these sections explore the recent evolution of the ideas of 'urban reform', 'strategic planning' and 'sustainability' within urban policy debate in Brazil and their influence over the imaginary of urban regeneration. The last two sections address the regulatory framework related to urban regeneration policies in Brazil. They present an overview of the roles played by different governmental spheres in structuring these policies, their level of institutionalisation and the legal and regulatory instruments more directly employed in their implementation.

2 THE CONSTRUCTION OF THE ARGUMENTS

There are three levels of the Brazilian state, with federal, state and municipal legislative and executive authorities. The complex framework of plans and regulations takes place in these three political-administrative spheres, but the tradition of Urban Planning and Regulation has always been at the local level, that of the municipalities. This shows the fact that the urban question has traditionally been the "particular interest" of the municipality.

The overlapping of the urban question with the national sphere has always been very fragile, historically passing through some periods of regulation and others of almost invisibility, but this issue gained visibility when the Ministry of Cities was created in 2003, as will be seen later in the “The Recent Process” section. The construction of these instruments (Urban Operations and PPPs), validated in Brazilian Law, is a result of the form that ended up by acquiring a set of concepts and principles formulated in a context in which the domain of discourse was that of social development but were materialized in another more liberal and pragmatic period.

Different and even conflicting concepts and principles of different natures were used and linked to support urban renewal proposals and to present them as socially desirable actions. In this sense, the instruments currently used in Brazil bring together elements derived from traditional Urban Regulation and its practice, and the diverse ideas present in the debate on urban policy in Brazil, namely Urban Reform, Sustainability Ideals and Strategic Town Planning.

3 URBAN REFORM

The references to Urban Reform come from the “Basic Reforms” formulated at the heart of great mobilization of intellectuals and social movements in Brazil in the early 1960s, with a view to overcoming social inequality and technological backwardness. According to Maricato (2008: 8),

“Those with the greatest repercussion and visibility were the proposals for Agrarian Reform, Educational Reform and Health Reform. But, despite having less critical mass, the Architects joined this national movement. In 1963 a National Congress of Architects held in Petrópolis in the state of Rio de Janeiro proposed Urban Reform, with public control of land use and social housing as central issues of a manifesto resulting from this important event.”

Shortly after, military intervention interrupted this process for a considerable period by establishing a centralized system of government and suppressing elections for state governors and state capital mayors, who were now nominated by the government in Brasília.

From the end of the 1970s the model began to run out of steam, and social movements expanded. In smaller cities and towns and in those around the state capitals, where the mayors continued to be elected, various experiences of participation and democratization of public actions were undertaken, with the interaction of social movements. In this context, and with the mobilization, claims and proposals of the urban social movements, it was possible to once again launch the ideals of Urban Reform.

In 1987, the Popular Amendment for Urban Reform was presented by a wide field of popular urban movements, trade unions and professionals, non-governmental organizations, university sectors and civil servants. The amendment clearly states what is coming, beginning with the title: ON URBAN RIGHTS, with the following two articles (Emenda Reforma Urbana, 1987):

“Art. 1 - Every citizen has the right to decent urban living conditions and social justice, and the State is obliged to ensure:
I - Access to housing, public transportation, sanitation, electricity, public lighting, communications, education, health, leisure and security, as well as the preservation of environmental and cultural heritage.
II - The democratic management of the city.”
Art. 2 - The right to decent urban living conditions requires the exercise of the right to property in the social interest in the use of urban properties and subordinates it to the principle of the state of necessity”.

With reservations and cuts, the proposals were partially incorporated into the Constitution, forming the Chapter of Urban Policy, as part of the section named “On the Economic and Financial Order”. The chapter is made up of articles 182 and 183, with a central focus on the institution of the social function of property and the city. As the state of Brazil is at three levels, as mentioned, with federal, state and municipal levels of legislative and executive authority, the elaboration and approval of the State Constitutions and Organic Municipal Laws followed those of the Constitution.

Approved in 1990, the Organic Law of the Municipality of São Paulo reaffirmed and detailed the provisions of the Constitution stating that, in order to ensure the fulfillment of the social function of the property, the Municipality shall: I. Prevent distortions and abuses in the economic fruition of urban property and speculative use of land as a reserve of value; II. Ensure the suitable use of the potential of urban land for building, respecting the limits of the installed capacity of public services; III. Ensure the fair distribution of the costs and charges arising from the works and services of the urban infrastructure and recover for the community the increase in real estate value resulting from the action of the Public Power. The right to build shall be exercised in accordance with the principles set forth in this Chapter and criteria established by municipal law (Art. 151). In these terms, the city becomes a public, collective good, with the fruition of any real estate subject to this condition.

The inclusion of the Urban Order as the attribution of the Government, from the text of the Constitution itself, reiterates this nature of a collective asset attributed to the Government, which has the responsibility, according to the Constitution, of “the defence of social interests” (CF, art. 127), whose functions include the protection of “diffuse and collective interests” (CF, art. 129, III). However, according to the Constitution, the principles expressed in the Urban Policy chapter would only come into force after the national regulatory law, as in the terms of the law in articles 24 and 182. However, this regulation of the two articles of the Federal Constitution regarding Urban Policy and its developments, incorporated at state and municipal levels, required thirteen years of persistence, mobilization and negotiation, until the approval in 2001 of the City Statute - Federal Law n 10,257 / 2001.

As the expression of more than two decades of struggle by popular, trade union and professional movements after the proposal and collection of signatures for the Popular Amendment of Urban Reform, the City Statute resulted in a negotiated project which included some of the demands of the social movements but also the counterpart of elements favourable to capital, as required by the real estate development and production sectors.

It was this set of developments that, in a context of democratic advancement, provided the basis for the establishment of principles that pointed in the direction of a fair city, an urban order based on a comprehensive notion of public interest. These are the principles of the Urban Reform movement, which unfolds into guidelines such as: more intensive use of areas with good availability of infrastructure, services and jobs; preventing speculative retention of unused real estate properties; reduction of social and spatial inequalities between different regions of the city; balanced distribution of the costs and benefits of the urbanization process through the establishment of a redistributive tax system; socialization of the gains associated with “urban surplus values”. This last principle is the one that provided the justification to charge the granting of development rights, which would also constitute the core of urban operation's financial engineering, as discussed below in more details.

The articulation between, on the one hand, the ambiguity of the meaning of “diffuse and collective interests” in an unequal society such as Brazil, and, on the other, the conflict between the various sectors of capital that contain the materiality of the city as their object of production, has been modulating the design of new urbanistic instruments. It is in these terms that an instrument such as the Urban Operation Consortium will emerge and expand in major capitals and large cities, with varying formats and specificities.

4 SUSTAINABILITY

Sustainability is one of the themes coined in the twentieth century as a facilitator of dialogue in a context of disputes. Based on an environmental approach, resulting from the perception of the finiteness of natural assets, it has ended up as a broad spectrum concept, able to include very different interpretations, allowing for convergence in declarations and agreements, without however signifying a convergence of understanding. Sustainability, as a guarantee of availability of natural resources for present and future generations, is the thematic core that unites different agendas.

Behind the word there is an ideological dispute that is not explicit. The neoliberal consensus model that depoliticizes social relations, concealing or naturalizing all forms of conflict, also includes the term Sustainability. This magic word, this widely held unanimity, incorporates the most diverse and antagonistic contents.

The City Statute, for example, establishes among the general guidelines of the Urban Policy the "guarantee of the right to sustainable cities, understood as the right to urban land, housing, environmental sanitation, urban infrastructure, transportation and public services, work and leisure, for present and future generations" (art. 2, I).

The National Policy for the Environment, as conceived in the law that creates the National Environmental System (Law No. 6.938 / 81), aims to preserve, improve and recover the environmental quality conducive to life, aiming to ensure, in Brazil, the conditions for the socio-economic development, the interests of national security, and the protection of the dignity of human life (art. 2). The Decree n ° 99.274/90, which regulates it, explains that the National Environmental Agenda is the document that recommends the themes, programmes and projects considered as priorities for the improvement of the environmental quality and the sustainable development of Brazil (art 7º § 4º).

On the other hand, for the World Bank, a sustainable city (Rivière d'Arc, 2001) is one that contains: Competitiveness - an effective land market, an efficient traffic circulation system, a broad and available communications system; Quality of life (liveability) - a decent standard of living, the ability to overcome urban and environmental degradation, the provision of cultural resources and "amenities"; Good governance – organization to simplify and reduce exchanges / decision flows, overcome corruption, have explicit rules; Bankability - Credibility as a borrower.

In short, sustainability viewed as a socially just, environmentally balanced, or economically balanced pattern of urban development allows for a broad field of legitimacy and consensus around the term, but not of content.

Therefore sustainability is one of the key terms of functional approximation and a central argument for Urban Operations that, prioritizing the "competitive" city's economic perspective, ensures functional quality conditions and the infrastructure required by large corporations, without extracting this cost directly from the public budget. More than this, it aggregates the positive image of sustainability as expressed both in Brazilian international commitments and in its environmental and urban development legislation.

In this field are included questions as environmental preservation, the expansion of green areas, drainage management, and the quality of water bodies, as well as the compact city model, which avoids peripheral expansion, reducing impact on natural areas, providing transportation and expanding the supply of social housing.

These two meanings of sustainability – one in the economic sense, other in the environmental one – give indirect support to urban regeneration in the sense that it can promote better local environmental conditions, support the shift towards a compact city model that avoids sprawl and consumption of natural sites, and also foster financial sustainability.

So that, if one hear just the formal justification, everything seems positive in this broad spectrum of discourse on urban development. Who could be against it?

5 THE STRATEGIC PLANNING OF CITIES AND TOWN PLANNING WITH RESULTS

In Europe the economic recession of the 1970s provoked a reaction from local governments and key economic actors to "promote cities" in order to attract investments, generate jobs and renew the productive base of cities. In addition, according to Nickson (1998), the World Bank and the Inter-American Development Bank, after two decades of ignoring local government programmes in the late 1980s, have become strong advocates of decentralization and the institutional strengthening of local governments. Firstly, given the demands of structural adjustment policies, they recognized the benefits of decentralization in helping to overcome the state's fiscal crisis by incorporating the vast and untouched fiscal potential of local governments. Secondly, they saw local governments as an institutional arrangement to produce services more efficiently and effectively. Thirdly, local governments could play an instrumental role as a more efficient administrator of poverty reduction programs during structural adjustment. Thus, the local element is seen less as "government" than, pragmatically and instrumentally, as "local administration". The Habitat Agenda adopted at the United Nations General Assembly in

December 1996 stressed the importance of decentralization as a transfer of power and the attributions of central government to cities.

It is in this context that, inspired by concepts and techniques from business planning, comes the proposal of the Strategic Planning of Cities. It was disseminated in Brazil and Latin America “by the combined actions of different multilateral agencies (The World Bank, Habitat) and international consultants, mainly Catalans, whose aggressive marketing systematically disseminated and promoted the success of Barcelona” (Vainer, 2000, p. 75).

A Strategic City Plan is, according to Castells and Borja (1996), a joint action between the local government and the main economic and social agents in carrying out a transformation of urban infrastructure to facilitate the transition from the traditional industrial model to that of a qualified tertiary centre and a change of image to suit the new requirements of the global economy and international competitiveness. According to them, the Strategic Plan is based on building a strong and positive image of the city “supported by an offer of infrastructure and services (communications, economic services, cultural offerings, security, etc.), which attract investors, visitors and user with money to the city and which help its 'exports' of goods and services, and of professionals, etc. The local government have to act as the promoter, with the role of creating the conditions that enable actions to be made by public or private agents (through planning, political campaigns, economic compensation, etc.)” (Castells & Borja, 1996, 160). In order to make the Strategic Plan viable, it is also necessary to promote the city internally with its inhabitants, fostering a sense of belonging, collective will and trust, and belief in the future. Castells and Borja believe this internal promotion must be based on visible works and services, both monumental and symbolic, and those aimed at improving the quality of public spaces and the well-being of the population.

This vision of urban and economic development thus requires a solid political leadership, visible authoritarianism or considerable marketing work in order to bring together the expectations of entrepreneurs, trade unions, community organizations, scientific institutions, NGOs and inhabitants in general, around certain projects. In summation, it is eloquent the alignment of the urban regenerations with the pragmatic and entrepreneurial logic advocated in the discourse of strategic planning.

6 THE TRAJECTORY OF URBAN REGULATION AND REGENERATION POLICIES IN BRAZIL

Brazilian cities are made up of superimpositions, as Benedito Lima de Toledo (1981) wrote when referring to São Paulo: three cities in a century (mid-nineteenth to mid-twentieth): “The city in mud (taipa)” with its churches and the two storey colonial houses; the “palimpsest”, seen in the mansions and neoclassical and eclectic public buildings; and, at the end of the 20th century, the modernist skyscrapers “Designs for a Metropolis”.

These transformations in the centre, and the city expansion through subdivisions of land in the outskirts, were triggered by private owners and interests, with little public intervention, and were seen as “progress”. Only at more authoritarian moments there have been plans for major public interventions, such as the São Paulo Avenues Plan (1930) or the remodeling of Rio de Janeiro, the Agache Plan (1930).

Up to this point, according to Villaça (1999), public intervention consisted of the beautification plans beginning in 1875 in Rio de Janeiro, with the Plan of the Engineers (the first general plan on a monumental scale), which took up a large part of the public budget. He states that the term “urban beautification” was used to characterize the performance of city halls and clearly expressed the proposals of the dominant classes for the cities, in some cases to crystallize and spatially demonstrate the domination of the State, in others such as São Paulo to show the victory of capitalism, with the beginning of the rise of the industrial bourgeoisie, and to aesthetically resemble the great world capitals and to feel driving away the recent slave-owning past (Villaça 1999: 171, 243).

In 1929, the Arthur Saboya Code was established, regulating works in the city of São Paulo that extended the scope of its predecessor, the 1886 Code of Postures of the Municipality. This norm was reference for numerous cities and was regularly amended until 1972, when the General Law of Zoning No. 7.805 / 1972 was adopted, using the zoning model for the whole city, with differentiated indexes of land use and occupation, according to the district. In order to stimulate certain actions by private investors, the first

flexibilizations of utilization coefficients appeared, allowing planning gains for certain uses such as schools and hospitals.

It was during the 1970s, with the increase in verticalization, that, inspired by international experiences, the term "built surface" was coined: the emergence of an area built on the same plot or territorial boundary. This concept alerted to the fact that that more area had been created without the corresponding donation of public area as required in the cases of land parceling. In this period, the norms of land use and occupation, aiming at inducing some form of urban design, proposed different development potentials according to the area of the city.

In parallel with this process in the 1970s, the Law 101/71 was created, which dealt with the establishment of a public company (EMURB) with the purpose of developing urban renewal programs associated with projects contained in the Integrated Development Master Plan (PDDI), a legal document that translated the guidelines of the Basic Urban Plan of 1968: the implementation of a metro network in the São Paulo, the construction of expressways, as well as the redevelopment of areas along the first line of the new metro.

Among the measures was the proposal that the expropriations to be made by the metro for the implantation of the stations would be greater than what was effectively necessary, as these areas could then be marketed, with higher rates of utilization, resulting in profits for the metro, for the continuation of works and the expansion of lines. EMURB was the first attempt of using a public company governed by private law in the provision of public works.

From the end of the 1980s, urban planners began to be aware of the unfairness of the differentiation of development rights across the city, which attributed more intense conditions of use to certain lots, without any counterpart on the part of the owner of the lot for this differential, and the notion that this differential was equivalent to a "surplus urban value" generated not by the merit of the owner, but by all the investments made in the city, became clear. The idea that these owners should be charged some counterpart, an "onerous concession", that they should repay to the "public" the value of this virtual lot, to which they would have access by means of the higher utilization coefficient, was thus consolidated.

In 1986, this flexibilization took on a new dimension, with the adoption of Law no. 10.209/1986, which introduced the Interconnected Operation, establishing as a counterpart to the potential construction gain the production of social housing. This device was applied to areas with favelas in the most wealthy and expensive regions of the city.

From 1990, a new concept for Interconnected Operations was no longer aiming at removing favelas. The practice of charging for the granting of additional development rights was generalized to the entire city, and the resources generated were directed to housing policy. The cost of the concession was estimated by municipal technicians according to certain rules and criteria to assess the earning potential that the expansion of the building potential would provide to the entrepreneur. This practice continued until it was contested by the Court of Justice in 2001.

As a result of the history of failures in the legal field, a new concept, the Urban Operation was constructed and proposed in the 1985/6 Master Plan, which was approved after the expiry of the statutory time limit.

Later, drawing on a strategically designed format, based on well-elaborated discourses and a negotiation process to include certain social demands and achievements, the idea of the Urban Operation Consortium was included in the Plan drawn up in 2002/2003 and approved in 2004. It basically consists of an infrastructure and urban improvement plan targeted to a delimited area of a city, where the works are paid through the sale of development rights to be used within the area.

7 THE RECENT PROCESS

At the same time that the constitution was completed in 1988, establishing a series of social rights, a government with a neoliberal platform took office in 1990. Countering this governmental platform, a wide political mobilization, bringing together housing movements, representatives of the urban reform movement, academics, the Workers Party (PT), and other stakeholders, demanded a stronger commitment from the central government in terms of social policies in general, including playing a greater

role in the field of housing and urban policy. After the victorious campaign of Lula for President, this political agenda started in 2003 to be institutionalized, with the creation of the Ministry of Cities as its emblem. Initially, the Ministry team included several actors engaged in the political mobilizations for the construction of a progressive urban agenda in the previous decades. One of the first actions carried out by the group in charge of the Ministry was to initiate a broader attempt to structure coordinated national sectoral policies, targeting areas like housing, mobility, sanitation, and waste management.

The role of federal institutions in this area had diminished significantly since the macroeconomic crisis of the 1980s. The roll back of federal interventions in this field can be understood as a combined effect of macroeconomic conditions and institutional changes witnessed during the two last decades of the twentieth century and was influenced by features like the cutbacks in social expenditure of the central government in a context of fiscal crisis, the privatization of state owned companies previously providing public services, and the municipalist paradigm affirmed by the Federal Constitution of 1988, which had devolved a wide range of attributions to local governments. Many municipalities, however, lacked the necessary financial and institutional conditions to adequately perform the roles assigned to them by the Constitution, which prevented, in the majority of cases, the expected quality gains as a result of greater autonomy, from actually taking place.

This process, however, suddenly suffered a significant setback. The fragile political balance of Lula's first term of office obliged the government to make a deal with other parties to ensure governability. The strategy was to extend the space of conservative political parties in the composition of the government, with the consequence that the control of the Ministry of Cities was transferred to a right-wing political party, resulting in the formulation of sectoral urban policies being relegated to a marginal position within the governmental agenda. Some policies were developed, while others were almost paralyzed during the following years. One of the policies affected by this political shift was the "Urban Centres Regeneration Programme".

This program had been launched in 2003, the first year of the government, and was the most explicit federal initiative directly related to urban regeneration, focusing on supporting municipal governments engaged in urban regeneration initiatives by providing financial aid, transferring federal properties located in urban centres, and helping local governments to implement actions related to institutional development and capacity building.

Its concrete results went little further than the publication of a policy guidance document, with no consistent set of concrete actions. The federal government provided some financial support to isolated urban regeneration initiatives promoted by local governments, but it failed to build a comprehensive program with systemic impact.

Municipal regulations in some cities provide relatively comprehensive legal backgrounds for urban regeneration projects, and it is common to find systemic definitions of targeted areas for urban regeneration within municipal master plans. In São Paulo, for instance, a recent municipal decree established a specific methodology for the formulation of urban interventions, covering issues like the definition of envisaged goals, participatory mechanisms, and the establishment of financial and regulatory instruments. However, it is important to stress that the level of complexity of municipal regulations related to urban regeneration is very uneven throughout Brazil. In many towns and cities, regulations of this nature are very basic, or even totally absent.

When we consider the regulatory devices of an instrumental nature, in addition to the government level programmes, there are federal regulations such as the City Statute that play an important role as a background for urban regeneration initiatives. Most of the tools employed to implement urban regeneration projects with private sector involvement are regulated at the federal level, and even though some of these instruments were initially enacted by municipalities, most of them have been subsequently incorporated into national legislation.

The Urban Operation Consortium is the most emblematic instrument of this kind now in Brazil. The conception of this regulatory tool can be traced back to the 1980s, as previously shown. However, the first time it was used within an urban regeneration project which was actually implemented was in São Paulo in 1995, with the creation of the Faria Lima Urban Operation Consortium. Before it, the intervention in the centre of São Paulo, called the Urban Centre Operation, utilized the award of building rights in order to obtain resources to invest in infrastructure works but did not arrive to implement a consortium mode

Afterwards the Urban Operation Consortium was then included among the urban instruments established by the City Statute, which was enacted in 2001. This law outlines the general conditions for the use of this instrument in Brazil, establishing a general basic pattern for its use by municipalities, and is particularly representative of the penetration of a market oriented logic in urban regeneration projects. In brief, an urban operation consortium as designed in the Faria Lima project consists of an infrastructure and urban improvement plan targeted to a specific area of a city and sponsored through the sale of additional development rights by the municipality within the area of intervention. It requires the enactment of a specific municipal law, which must define the area of the project, the envisaged improvements, the total number of additional development rights within the area, the governance regime, among other aspects. The rules concerning the commercialization of development rights within urban operations are also regulated at the federal level. These rights are traded by municipalities through the issuance of financial bonds called CEPACs (Certificate of Additional Building Rights) and their subsequent auctioning on the stock exchange. The CVM (a national independent authority responsible for the regulation of capital markets) is the competent authority to establish the general regulations concerning the trading of CEPACs and transparency in the management of urban operation consortia. It is also entitled to authorize the issuance of CEPACs in individual urban operations and to supervise their development. The norms issued by CVM explicitly define CEPACs as a capital market instrument, illustrating the financial rationale underlying this urban redevelopment scheme. This regulatory tool is present in two of our case studies, the Água Espraiada Urban Operation Consortium in São Paulo, and the Rio de Janeiro Porto Maravilha Project.

Another regulatory tool of growing importance in the field of urban regeneration interventions carried out with private sector involvement is the public-private partnership (PPP). This contractual instrument was firstly introduced into the legal system in Brazil by legislations at state level. By the early 2000s, several provinces had started enacting local PPP laws and launching privatization programs based on this instrument. A national PPP law was enacted in 2004, outlining the general conditions for its utilization. Certain municipalities also enacted local PPP laws, regulating in greater detail this contractual regime at the local level. This regulatory instrument has a broad scope as it is not specifically targeted to urban regeneration projects, but to actions combining the building of infrastructure and the provision of public services in general. Before the enactment of PPP laws, the delegation of economic activities to the private sector was regulated by a general law of concessions, which was enacted in 1995 to support the process of privatization carried out in that period. This was more directly suited to the concession of profitable activities, in which the concessionaire could be remunerated through the payment of tariffs by final users. The most important innovation of the PPP laws was to design a contractual regime in which the remuneration of the concessionary may combine tariffs and direct transfers made by the State. Arrangements of this kind were not legally impossible in the previous period, but there was no adequate contractual instrument to support them. Thus, the introduction of PPPs should not be regarded as a groundbreaking legal change, but rather as an incremental step in a longstanding process of legal and institutional reforms oriented towards supporting privatization. Another issue addressed by the PPP laws was to establish mechanisms to assure the security and profitability of concession holders. In a general sense, the introduction of this contractual regime enhanced the attractiveness of a wider range of activities for private agents, expanding the room for privatization. PPPs started being used in urban regeneration programmes in the early 2010s. The Porto Maravilha Project in Rio de Janeiro, which involved a comprehensive PPP contract covering a wide set of public works and the provision of public services within the area of intervention by the concessionary, may be considered a hallmark of the use of this contractual instrument in the specific field of urban regeneration initiatives. This paradigmatic experience gave rise to a proliferation of initiatives focused on urban regeneration using this instrument. Most experiences of this kind are still at the formulation stage or at a very initial phase of implementation, but the PPPs may already be considered a well-established model for urban regeneration within hegemonic policy discourses.

8 CONCLUSIONS

The diffusion of urban regeneration projects as a common trend of hegemonic conceptions and practices of urban planning is rooted in the recognition of these interventions as potential solutions for problems and challenges faced by contemporary cities in general. The strength of discourses portraying urban

ID 1552 | THE SUBSTANTIVE IMPACT OF A PROCEDURAL RULE: THE CASE OF THE DUTCH 'LADDER' FOR SUSTAINABLE URBANIZATION

David Evers¹

¹PBL Netherlands Environmental Assessment Agency

david.evers@pbl.nl

1 STEPS TOWARDS SUSTAINABLE URBANIZATION

Since the dawn of the new millennium, the Netherlands, world famous for its protected Green Heart, growth centers, mainports and prohibition of out-of-town shopping malls, has been busy dismantling its national planning (Zonneveld and Evers 2014). In 2012, it opted to decentralize, deregulate and replace all remaining national urbanization policies with a single procedural rule called the ladder for sustainable urbanization. The 'ladder' owes its name to the three steps that local zoning plans must consider when granting rights for new urban development (see text box below). In short, they must argue that (1) a regional need exists, (2) explain the siting within the urban fabric and, if out-of-town, (3) consider multimodal accessibility. This substantiation should be included in the plan's explanatory notes.

Like many regulatory instruments, the ladder is a procedural rule aiming to achieve substantive ends, in this case, reining in the overproduction of housing and commercial property on car-dependent greenfield sites which had characterized post-2000 urban development in the Netherlands (Janssen-Jansen and Mulders 2012). One could easily be forgiven for not believing that a requirement to explain planning decisions in non-binding explanatory notes would overcome the powerful economic logic of land development. Indeed, an initial evaluation found the application of this rule in local plans to be clearly inadequate (Evers 2015a). Even so, the ladder – and more particularly its enforcement through the court system – has since been blamed for hampering development and in the summer of 2017, less than five years after it entered into force, it was relaxed.

Given the benefit of several years of implementation history, it is now possible to shed light on the impact of this instrument in more detail and reflect on whether the ladder was as ineffective its proponents had feared or as obstructing as its detractors had claimed. The research draws on an analysis of hundreds of

explanatory notes over the 2012-2016 period, a review of jurisprudence and 43 structured interviews conducted with a random sample of municipal planning officials in 2016. A guiding principle of the evaluation are the concepts of 'conformance' and 'performance' in planning theory (Faludi and Mastop 1998). Conformance, as the word implies, indicates the degree to which the rule is followed in practice, in this case whether a zoning plan that should have applied the ladder, actually did. Performance goes a step further, asking whether this application affected planning practice in a meaningful way. It can be assumed that conformance is a necessary but insufficient condition for performance.

Spatial Planning Decree (Bro) Article 3.1.6, Section 2 Section 2: The explanatory notes of a zoning plan enabling new urban development must contain the following: a) A description of how the foreseen urban development satisfies a current regional need; b) If the description in part a shows that a current regional need exists, a description shall be provided of the extent to which this need could be accommodated in the existing urban area of the region in question by reusing, refurbishing or transforming available space; c) If the description in part b shows that the urban development cannot be accommodated within the existing urban area of the region in question, a description shall be provided of the extent to which this need will be met at locations that are, or can be, suitably connected by different modes of transport.

This paper will first provide a brief overview of the literature on plan and policy assessment to contextualize the evaluation undertaken for the ladder. Next, the terms conformance and performance will be operationalized and the methods of the empirical research explained. The last section presents the results and conclusions.

2 LITERATURE REVIEW

Even though planning generally gravitates towards ex-ante evaluations (i.e. survey before plan), assessing the impact a plan or planning policy ex-post has a long tradition as well (Talen 1996; Seasons 2003). Generally, this draws on the policy analysis literature, and more specifically implementation studies. One of the most important insights to emerge from this literature is that a great gap can exist between what is written on paper and what happens in actual practice (e.g. Pressman and Wildavsky 1973).

What is the nature of the policy being evaluated? The ladder is a procedural rule with the ambition to achieve substantive aims (sustainable urban development) and in this sense, works indirectly. This resembles other instances of institutional design, where "[t]he tacit assumption is that changing the rules of the game will affect gameplay in a durable and predictable way, and that this will ultimately result in substantively different outcomes" (Evers 2015b, p. 428). Specifically, the ladder seeks to influence urbanization processes by mandating that plans argue why the development meets a regional need, and if applicable, why a greenfield site is necessary for this and whether the location is multimodal. Because the ladder is essentially a policy instrument prescribing an assessment be made, assessing its impact has the character of a metaevaluation. In this respect, we can turn to the extensive literature on the effectiveness of environmental impact assessments (EIA), which have similar aims and mechanisms as the ladder (e.g. Chanchitpricha and Bond 2013). Like the ladder, an EIA assembles information about the desirability of a development project given its potential impact with respect to alternatives. Like the ladder, the EIA's purpose is to improve decision-making (Oliveira and Pinho 2010). And, finally, like the ladder, it seeks to contribute to sustainable development. On reflecting on how to study the effectiveness of EIAs, Sadler (1996) made a distinction between procedural effectiveness (if and how the procedures were implemented as required), substantive effectiveness (the extent to which the EIA led to actual change) and transactive effectiveness to the mix (whether these changes were cost-effective). Baker and McLelland (2003) added the criterion of normative effectiveness (the extent to which normative goals were achieved).

These notions correlate well to a distinction made in planning theory between conformance and performance (e.g. Barrett & Fudge 1981 cited in Faludi 2000, p. 305). Conformance relates to the extent to which practices comply with rules or development follows plans. Most conformance research in planning is carried out when clearly defined objectives are present, such as housing targets in particular locations (Bontje 2001; Korthals Altes 2006, Alfasi et al. 2012). In the case of a procedural rule like the ladder,

conformance is tantamount to the 'procedural effectiveness' identified by Sadler (1996) above. In other words, if the explanatory notes of a plan granting urban development rights contain the necessary substantiation, it is ipso facto in conformance.

Performance, on the other hand, regards how rules work themselves through organizational practice. This is particularly important for strategic plans where targets are long-term and hard to quantify. According to Faludi, a vocal proponent of this evaluation method, "[p]lans perform their role if and when they help decision-makers make sense of their situations, and so they need to be evaluated in this light" (Faludi 2000). With respect to the EIA literature, this notion of performance carries with it elements of both 'substantive' and 'normative' effectiveness.

I contend that in the case of the ladder, both conformance and performance is relevant for understanding its effectiveness. It is reasonable to claim that non-conformance means that this rule has not meaningfully affected municipal planning practice (performance). Conversely, the faithful application of the ladder (conformance) may entail some degree of organizational effort (performance), unless this was already standard procedure at the municipality. Performance is vital, however, since the ultimate substantive aim of the ladder, to make urban development in the Netherlands more sustainable, means going beyond simply applying the rule, but internalizing it and acting accordingly.

3 METHODS

This study takes the aforementioned distinction between conformance and performance as a point of departure, elaborating on these terms from the insights gained from the EIA evaluation literature. The research draws on an analysis of explanatory notes, a review of the relevant case law and structured interviews. Some results have been published (in Dutch) by the Netherlands Environmental Assessment Agency.

In our evaluation of the ladder, conformance is defined as the extent to which the explanatory notes of a local plan falling under the requirement contains explicit argumentation on the points stipulated by the ladder. This was performed in two steps. The first was to determine whether a particular (randomly selected) zoning plan provided for 'new urban development' as defined in the regulation, whereby application of the ladder was compulsory. This was not as straightforward as expected and often required close reading. As a result, plans were sorted into the following categories (1) noncompulsory (no significant urban development), (2) unclear/indeterminate, (3) possibly compulsory (small-scale building or rezoning uses in existing buildings), (4) clearly compulsory (significant new or expanded zoning for residences, industry or retail). Afterwards, the explanatory notes were scanned and the application of the ladder, if present, read. A score was then awarded according to how well the ladder was applied: (A) complete and proper application, (B) an argument given why it was not applied, (C) partial or incorrect application (e.g. cursory remarks, skipping steps), and (D) not applied and/or mentioned (it was assumed that if a plan made no mention of the ladder, it did not apply it). Obviously, of all possible combinations, the most relevant cases are 4A and 4D. The analysis was carried out using a sample of approximately one thousand explanatory notes in the 2012-2014 period (randomly drawn from a pool of approximately 5,000 plans) and repeated two years later using the same methodology for the 2014-2016 period. During this time, ladder case law was followed in order to keep track of how key issues were being interpreted, such as the evolving definitions of 'new urban development' and 'existing built-up area', but no changes were made to the methods in the two periods for the sake of comparability.

The performance of the ladder was carried out using mixed methods. The first entailed a reflection on the data obtained during the conformance analysis. As stated, performance was considered absent in cases of noncompliance: it is unlikely that the ladder had a significant effect on the plan if it was not even mentioned. A sample of 200 explanatory notes of zoning plans were therefore randomly selected that did mention the ladder and sorted according to type of urban development being granted and the kind of argumentation being put forward. This analysis was more qualitative and entailed subjective interpretation as regards quality of argumentation. Like the conformance analysis, this analysis was carried out twice for the 2012-2014 and 2014-2016 periods respectively.

The second method to measure performance concerned structured interviews with planning officers from 43 randomly selected municipalities. The interviews were carried out by planning students from the

University of Amsterdam in the spring of 2016 using a standard set of 18 questions and were approximately 60-90 minutes in length. The results were single-blinded in so far as the respondents were told that the interview was about the effects of national planning policy on local planning in general and not on the ladder specifically. This allowed some strategic questions to be posed at the beginning of the interview on ladder-related issues to see if the respondents would spontaneously mention it on their own behalf and volunteer information about its impact. The ladder was only raised as a topic after the respondents had reflected on the impact of other national and European policies on plan-making in their municipality, making their assessment of the ladder more consistent and balanced. Towards the end of the interview, respondents were invited to reflect on the meaning and significance of the ladder (i.e. how it compares to the Dutch planning concept of 'good spatial planning') and to share their opinions on the ladder and provide advice to the national government. The interviews were transcribed and analyzed qualitatively by hand (coding in margins and tallying in Excel). In order to protect the privacy of respondents, the results are presented anonymously.

4 RESULTS

The degree of conformance and performance of the ladder will be presented along the lines of the four criteria for effectiveness of EIAs discussed earlier, but using terminology more attuned to planning. As stated, Sadler's 'performance effectiveness' strongly resembles the concept of 'conformance' in plan evaluations and will be treated first. The remainder of the paper evaluates the performance in several sections. First, the performance in terms of 'substantive effectiveness' or the impact of the ladder on municipal planning (both in terms of content of plans as well as the planning process) will be assessed. This will lead to a discussion about 'normative effectiveness', that is the extent to which the ladder is aligned with the municipality's own policy objectives and broader notions of 'good spatial planning'. Finally, the matter of 'transactive effectiveness' will be considered by presenting some results about the added value of the ladder as an instrument vis-à-vis some of its perceived side effects.

4.1 CONFORMANCE

As explained, the level of conformance is ascertained in two steps: (1) whether a given plan enables 'urban development' and therefore is required to apply the ladder and (2) whether this plan applied the ladder. This exercise was performed on approximately 1,000 plan explanatory notes in 2014 and repeated two years later. Each time, approximately 250 plans were found to enable urban development and thus these plans comprised the units of analysis.

The two periods reveal remarkable differences in conformance. In the 2014 assessment only 8% of plans applied the ladder in full and 72% did not apply it at all (Evers 2015a). It is reasonable to assume that the low level of conformance with the rule is related to the 'pipeline effect' of plans slowly making their way through the system when the ladder entered into force in October 2012. A second factor concerns the awareness of the existence of this requirement, a matter which was greatly enhanced after the Dutch administrative court struck down some plans for non-compliance in late 2013. Both explanations would suggest improved compliance in the future, an expectation which was confirmed by the 2016 assessment. In the second period about half of the plans applied the ladder in full: about six times as many as in 2014. The figures strongly suggest that this instrument is becoming institutionalized in local planning practice, especially considering that an additional 24% had made an attempt (i.e. partial or incorrect application). In this period, the ladder was widely discussed in professional trade journals and seminars, further contributing to awareness and, presumably, conformance.

4.2 PERFORMANCE

Since the ladder is the last existing national rule on urbanization, its performance is no trivial matter. In order to investigate the extent to which it impacted local planning practice, a number of tests were carried out. First, the argumentation in the plans was evaluated. Second, the opinions of the 43 municipal planners were analyzed about how and if the ladder affected planning content and processes and how they felt about these impacts.

4.2.1 SUBSTANTIVE IMPACT

As a first step to understand the performance, a random sample of ladder texts were read (200 in each period). Already in the selection of plans for further analysis, it became abundantly clear that awareness had improved: about twice as many plans mentioned it explicitly in 2016 than had in 2014, confirming the analysis on conformance above. Another interesting difference related to the kind of plan being made: a greater share of plans enabled development, but these developments were generally smaller and, saliently, under the legal threshold for the ladder as defined in the jurisprudence (i.e. 10 housing units, up from about 5 in the 2014 analysis). Obviously, the degree to which plans are legally required to apply the ladder will affect its impact on local planning practice and substantive outcomes. Since a majority of plans are now under the threshold, they do not have to consider regional need or provide arguments regarding siting or multimodal accessibility. This means that the ladder is ineffective in curbing, and indeed may even encourage, piecemeal urban sprawl. Moreover, in both periods only a small fraction of plans (less than 10%) pertained to commercial property development, which was at the root of the problems surrounding poor siting, multimodal accessibility and oversupply/vacancy, and a major reason why the ladder was introduced in the first place. One can therefore question, purely based on these figures, the real impact the ladder has had on municipal planning.

A reading of the argumentation itself casts further doubt on the impact of the ladder on substantive planning decisions. Of the three steps, by far the most attention was devoted to the first (regional need). For new housing, the plans generally stated that the foreseen development fit within the allotted capacity granted to the municipality within a provincial or regional strategy. The justification for commercial development, particularly retail, was more substantial and generally included quantitative needs assessments carried out by consultancies. With respect to the second step (siting), the ladder applications resembled ex-post rationalizations of decisions already taken; it did not seem like the ladder was guiding decision-making. Reasons for greenfield locations included the need for large parcels, open space (for luxury developments) or costs. Finally, the third step (multimodality) was rarely applied, or unconvincingly (e.g. that the site was multimodal because it could be reached by taxi as well as a car, or that public transport could be supplied at a later date).

The 43 interviews carried out in 2016 largely confirm the impressions gleaned from the textual analysis. When asked what the most important change had occurred over the past 10 years in their municipal planning, only 10% mentioned the ladder spontaneously, and only one respondent called it the most important change. Matters like the economic crisis, more vocal citizens, regional cooperation and a shift in planning doctrine towards more pro-development planning were considered far more important. The following questions on ladder-related issues (including one explicitly on national policy) elicited more mentions, bringing the total up to half of respondents. Still, the impression is not one of great significance (later, it was evident that all respondents were familiar with the ladder).

To measure the substantive impact further, the planners were asked whether the ladder had led to changes in plan content in their municipalities. Nine felt that it did have tangible impacts, and two provided examples of plans being abandoned or resubmitted. In most cases, the application led to a reduction in the number of homes or type of homes being zoned (only one regarded the second step, resulting in a different location for development). One of the most important impacts on local planning was a new fixation on qualitative analyses to argue that a 'regional need' existed. This was viewed as particularly difficult (but not impossible) to do in areas of slow growth or demographic decline.

4.2.2 PROCEDURAL IMPACT

The impact on planning processes was also discussed. In theory, the ladder is a new requirement, requiring extra time and effort to research and/or write up justification. Estimations ran a large gamut: some claimed it could be done in less than a day or even 'in about an hour', while others revealed that they had been dealing with the ladder application for over a year. One planner bemoaned the fact that a plan had been held up for a long time in court because the ladder had not been applied, and when it was applied, it was just a simple one-page explanation. Finally, as most zoning plans are written by consultants, many respondents admitted that they had no direct experience of how much time and effort was required. In general, the respondents agreed that the larger the plan, the more work was required for application. Another factor was the quality of the planning environment. The existence of regional housing visions, accurate and up-to-date information and the like expedite the writing of ladder applications. The

most important impact on planning processes, however, was on intermunicipal coordination. The ladder acted as a clear stimulus to work together on surveying the number of plans in the region to gauge the level of regional need.

4.2.3 DESIRABILITY

The previous sections dealt with the level of impact, but not whether this was regarded as positive. Although this was not explicitly asked, the respondents volunteered a great deal of opinions which were subsequently qualitatively analyzed. This was done by ranking opinions on a Likert scale. The findings revealed that respondents were almost exactly divided about the desirability of this instrument.

The intent of the ladder was rarely questioned. Instead, its various effects and side-effects became the object of scrutiny. The most frequently mentioned positive effect was that the ladder forced municipalities to reflect on and articulate their spatial decisions. It was praised for improving transparency and awareness about sustainable urban development. Some claimed that this led to better plans and breaking through old habits like viewing greenfield development as a default. Its acceleration of regional coordination was also viewed positively. Finally, a few respondents felt vindicated by the ladder because it obstructed, in their view, the cravings of overzealous local politicians for development. This was especially applicable to politicians elsewhere in the region: 'the ladder is useful for the other municipalities' a respondent candidly remarked.

Many criticisms were voiced as well. For the most part, these pertained to implementation. Some felt enforcement through the courts had injected a new uncertainty in the planning process. Stakeholders overcompensated for this by concentrating on quantitative analyses to prove their point, resulting in an arms race of information, which only benefited consultants. One respondent lamented that "the ladder gave us extra costs, hardships, risks and time-consuming procedures. It slows down the system and gives opponents ammunition to fire at the plan." It can also strain relationships with stakeholders; municipalities find themselves having to defend the rule to developers who are skeptical or openly hostile to the idea.

4.2.4 ADDED VALUE

Since 2012, municipalities drawing up zoning plans enabling new urban development must apply the ladder – requiring an explanation about regional need, location and, in the case of greenfield development, multimodality. These are rather standard considerations for zoning plans and arguably should have always been included, in one form or another, in the explanatory notes. Indeed, a close reading of a sample of the notes of non-complying plans in 2014 found that almost half had applied the ladder implicitly or inadvertently by treating these issues somewhere in the notes without having explicitly mentioned (and probably being unaware of) the ladder. This calls the added value of imposing additional argumentation into question.

To explore this point further, the responses to the interview questions on impact were examined in more detail. The ladder was often seen as having no effect because 'we were already doing that' in the municipality. One respondent explained "plans were always well-argued, but now it's just being written down" while another joked that the national government had stolen their idea. The reflections on the meaning of the ladder with respect to the notion of 'good spatial planning' (in the Spatial Planning Act, all zoning must be done in accordance to this principle) also indicate that the two are very closely related: only 14% felt otherwise. The rest believed the ladder to be tantamount to, part of or an instrument towards good spatial planning. The latter, like the ladder, means trying not to waste space and being transparent in decision-making. Given this, one can seriously question the added value, or at least the novelty, of this instrument.

5 CONCLUSION

The results of four years of implementation history seem to indicate that the 'ladder' is becoming institutionalized in local practice and impacting planning practice both in terms of content and process. Conformance has improved dramatically since 2014. From the interviews in 2016, there are some clear

examples that the ladder influenced decisions to alter and reduce the amount of urban development or, in a few cases, opt for a different location. On the other hand, some developments have occurred that demonstrate a blatant disregard for the spirit of the ladder, while still following it in letter. Moreover, given that a majority of plans are too small to be required to apply this rule, the ladder is powerless to affect piecemeal urban sprawl.

Arguably more important are the impacts the ladder has had on the planning process: it has proved in some cases costly and time-consuming and created tensions with stakeholders. On the other hand, it has stimulated regional coordination, something which enjoys widespread support. The jury is still out regarding the desirability of this instrument on balance; the municipal officers interviewed were highly divided in their opinions. Nevertheless, the national government has decided to rewrite the ladder in order to make it less demanding. The first step, which had the most significant impact, has been weakened (the term 'current regional need' has been replaced by the more vague 'need') and the third step on multimodality scrapped. The lighter version of the ladder will enter into force in the summer of 2017, inevitably sparking a new round of jurisprudence and evaluation.

ABSTRACT: Slovenian planning legislation states that the main objective of spatial planning is to enable coherent spatial development by the consideration and coordination of different development needs and interests and assuring public benefits, especially in the areas of environmental protection, the conservation of nature and cultural heritage, etc. Coordinated planning approaches aim to contribute to a balanced and sustainable spatial development, which is also one of the biggest challenges of contemporary urbanism. The problem in facing this challenge is in the actual realization of urban projects which is often hindered due to the financial obstacles. Lack of financial resources in both public as well as private sector contributes to an increasing necessity for collaboration between public and private investors. Not rarely only the involvement of a private partner into a project which is in a public interest makes the investment possible. If the process goes smoothly, this way the city's development needs as well as the desires of private investors are met - shared investment in the urban projects may contribute to the fulfillment of economic objectives of the private investor and spatial planning objectives of the planning authority at the same time. The PPP tool has been introduced into Slovenian spatial development practice rather recently. Most often the improvement of the quality of the living environment through brownfield redevelopment, built-structure renovation, energy efficiency improvements etc. are achieved by the implementation of PPP, which also contributes to a more controlled creation of urban space and increases the flexibility of the traditionally rather ossified planning process in Slovenia. The paper presents the most common forms of PPPs used in all eleven Slovenian urban municipalities. The ongoing research attempts to define different types of urban projects that are suitable for implementation in a form of PPP, and other different instruments that municipalities have at their disposal to facilitate the use of PPP within a specific current context of post-socialist neo-liberal system in Slovenia. Through the examination of concrete PPPs different approaches to activate land or buildings in public ownership with private capital are recognized, risks, benefits and potential problems revealed and possible solutions to overcome the obstacles identified. Different examples show the relationship between public and private partners in terms of investments, responsibilities and benefits during the realization of an urban PPP project which greatly reflect the fact that PPP as a tool has not got a long tradition yet.

1 INTRODUCTION

Public-private partnership (PPP) plays an important role as an instrument of planning and implementation of public infrastructural projects, including urban projects that affect the dynamics of urban development. PPP sector in Slovenia remains underdeveloped. The Public-Private Partnership Act (ZJZP, 2006) was only adopted in 2007. PPP mechanisms provide for private investments in public projects and public investments in private projects, insofar as the latter are in public interest: for instance, building, maintenance and management of public infrastructure, and, in certain cases, performance of public services or activities, insofar as those are in accordance with terms and conditions, valid for public utilities in general. The main advantage of PPP is provision of investments without or with minimal burdens for public finances. Through PPP projects, private economic initiative and its efficiency are introduced into construction and use of public infrastructure, while at the same time, usually by default, all of the costs of the public infrastructure are in a largely borne by its users, as a general rule in proportion to the frequency of use.

This paper is based on the work commissioned by Slovenian Research Agency and Ministry of Spatial Planning of Slovenia. This is an ongoing research project being implemented in a cooperation between

Urban Planning Institute of the Republic of Slovenia and University of Ljubljana – Faculty of Architecture and Faculty of Law.

The paper presents the results of the first two phases of the project. It reports the key results of interviews conducted with, first, representatives of local authorities and, second, investors. The main goal of the interviews was to determine the level of the current practices in the PPP sector in Slovenia. It furthermore identifies the models of PPP that are in use in Slovenia and proposes the needed improvements of PPP system. It also identifies possible urban development projects that can be implemented by the usage of PPP in future.

2 METHODOLOGY

We tried to determine the current level of PPP mechanism use in Slovenia in two ways: by assessing materials and data from publicly available data bases, and by conducting semi-structured interviews with representatives of relevant municipal departments and municipal services from all 11 Slovenian city municipalities, and with representatives of private investors.

Our goal was to test developmental needs and plans of city municipalities, their up-to-date experiences with the PPP model (their preference or non-preference for the mechanism in principle, problems encountered in the use of the mechanism, etc.), and both the plans and needs of the municipalities, connected to PPP mechanism project implementation in the future.

For each interviewed group we set up the questions on the basis of a prior review of literature and sources and available data on existent PPP practices in Slovenia. The basic structure of the questionnaires was tested through informal talks with representatives of local public administration, state public administration, and investors. On the basis of informal talks we were able to establish common features, valid for the majority of the city municipalities, such as: key motivations for the application of the PPP mechanism; assessment of the suitability of the legislative framework; key obstacles to the implementation of PPP; financial aspects of the implementation of PPP and forms of incentives for a larger participation of private capital; key open questions and dilemmas; guidances for improvement of the existing PPP system.

Interviews with private investors provided insight into their perspective on PPP: why they opt or refuse to opt for participation of this sort; their proposals for changes of the existing PPP system in Slovenia; the types of PPP-model urban projects of interest to private investors; the types of PPP-model projects they are already involved with. We were also interested in the types of goals pursued by private investors involved in PPP-model project, and whether those were markedly different from the goals pursued in projects lacking a public partner; the reasons for absence from participating in PPP-model projects; the needed changes on the part of the public partner (state, municipality, etc.) in order to be able to realize more PPP-model urban projects, as well as on the part of the private investors; financial and other mechanisms that should be established in Slovenia in order to allow private investors to realize PPP-model projects in an increased and simpler way.

Interviews with the representatives of city municipalities were conducted in the period from November 2016 to December 2016, and those with the representatives of the private investors in May and June 2017, for the most part at the headquarters of institutions involved. On the basis of the results and informations we gained, we were able to identify the PPP-model-based urban projects that can, and the ways in which they are able to, contribute to dynamic and controlled urban development.

3 EXAMPLES OF RELEVANT PRACTICE

According to Corrigan et al. (2005) a successful PPP depends on ten crucial steps: 1) consistent development of a public-private partnership, 2) creating common vision, 3) mutual understanding of partners and key shareholders, 4) clear definition of both risks and rewards for all shareholders, 5) establishing a clear and rational process of decision-making, 6) ensuring fulfillment of obligations of all shareholders, 7) ensuring consistent and safe project management, 8) frequent and early communication, 9) arranging a fair structure of negotiation, 10) establishing mutual trust as a basic value (eg Corrigan et al., 2005). Scholars (Tasan-Kok and Zaleczna, 2010; Kościelniak and Górka, 2016; Moskaluk, 2011)

point out main benefits for the public partner involved in the PPP-mechanism-based projects: engaging private partners provides part-financing of the project, thus shifting financial burdens away from the public budget. Furthermore, private capital limits and reduces the risk of bringing implementation or construction of a project to a halt, thus increasing the possibility of infrastructural improvement. Cooperation with a private partner enables and enhances the use of the latest advanced technologies, transfer of knowledge and exchange of experiences. Efficient management of projects and human resources reduces the time necessary for the investment performance and significantly lowers the costs involved. Participation of the private sector lowers the risk of political pressures. Market benefits include both efforts of local administrative services in locating private investors and thus outside sources of financing, and promotion of cooperation with the private sector. On the other hand, benefits for the private sector, involved in PPP-based projects, include: potential high rates on return on the investment and furthermore, cooperation with the public sector may result in a transfer of knowledge and experiences, all of which both partners may find useful in future projects. Last but not least, long-term investments into these kinds of projects provide security for the private capital, which may also count on various market benefits (Kościelniak and Górkab, 2016).

Kościelniak and Górkab (2016) also give a good example of a successfully managed and realized PPP-based set of urban projects. They address projects such as investments into transport infrastructure, environmental protection, and development of residential renewal. Furthermore, they write about projects, directly affecting basic needs of the population: environmental management, public transport and communications, sports, tourism, recreation, residential construction, revitalization of degraded areas, development of science and technology. These reflects a wide range and variety of possible urban projects to be implented by PPP.

Another increasingly important aspect of managing the contemporary city life is its brending. In European context this is often related to the issue of cultural heriatage preservation and development and PPP mechanisms offer some useful approaches. Zhao (2015) cites the example of Chinese cities that have, in dire need of renewal of their architectural heritage, found the necessary funds – and consequently faster ways of project realization – in a linkage with the private capital. The private sector has been allowed to directly market the heritage. Since the private capital was directly interested in the success of the projects involved, both marketing and »city branding« proved to be extremely effective, leading to the establishment of a financial current with positive effects.

Global practice has developed numerous types of PPP models. They are useful for different types of projects. Their differences consist of the following (internet sources 1 and 2):

- 1 what type of relationship exists between the parties involved in the PPP (grantor of concessions – public partner, concessionaire – private partner);
- 2 who is responsible for the design and the preparation of project documentation;
- 3 who finances the implementation of different phases of the projects;
- 4 who implements the construction, renewal or other forms project implementation;
- 5 who manages or who is responsible for the operation and maintenance of the completed project;
- 6 who and when becomes the final owner of the completed project.

Below we will mention a few examples of PPP models currently in use in Slovenia.

4 COMMON FORMS OF PPP IN SLOVENIA

The most common types of urban projects, implemented by PPP mechanism, that we have encountered in conducted interviews, are the following:

- 1 construction of sheltered accomodation for the elderly (mobilization of publicly owned land through private capital being the most common form);
- 2 construction of educational facilities (for insance, kindergartens);
- 3 implementation of urban infrastructural projects (construction and maintenance of roads, construction of markets, etc.);

- 4 upgrading of energy infrastructure in publicly owned facilities (schools, kindergartens, health clinics, administration buildings, sports facilities, cultural facilities; often part-financed by cohesion funds);

Speaking of PPP projects in economic sense, there are several different relations between public-and private-law entities. Below we cite some examples of the PPP models, encountered in our interviews. Hopefully they will at least partly illuminate the complexity of the PPP phenomenon in Slovenian practice. It needs to be noted that in some cases combinations of models exist in practice.

4.1 MODEL DFBOT (DESIGN-FINANCE-BUILD-OPERATE-TRANSFER)

This model is used for energy-efficient sanitation of public facilities, owned by the City Municipality of Ljubljana, including construction, technological and energy sanitation of facilities, with the goal/consequence of improving energy efficiency of said facilities and thus lowering energy use. Sanation encompasses 125 municipality-owned buildings of the following types: kindergarten, school, health centre, administration building, sports facility, cultural facility. Concessionaire (being a natural or legal person) will, as stipulated in the agreement, contractually provide energy performance services, implement measures to achieve energy performance and manage energy maintenance services (internet source 3).

4.2 MODEL DFBTO (DESIGN-FINANCE-BUILD-TRANSFER-OPERATE)

Should realization of certain objects of energy-efficient sanitation in certain facilities prove to be either economically unviable or impossible to conduct according to the model DFBOT, model DFBTO will be implemented. If use of neither model proves to be impossible, a combination of both will be used. Energy-efficient sanitation of public utilities owned by the City Municipality of Celje is planned in a similar fashion and will be implemented in kindergartens, schools, business premises, cultural facilities, sports facilities, health facilities, public-law institutions (internet source 4). Energy-efficient sanitation of 23 facilities in the City Municipality of Novo mesto, energy-efficient sanitation of public facilities of the City Municipality of Koper and in other cities are to proceed in a similar way.

4.3 MODEL DBOT (DESIGN-BUILD-OPERATE-TRANSFER)

A successful example of this type of PPP model is construction of kindergartens in the City Municipality of Slovenj Gradec. In this particular case, existing buildings are to be demolished and new ones to be built, maintained, insured, operated in an energy-efficient manner and finally transferred into public ownership. The private partner provides for the obtaining of the building permit and for the construction project. The private partner also assumes responsibility for all risks connected to the demolishing of the existing and the construction of the new buildings, as well as those connected to operating the facility. The private partner has the right and the obligation to perform the services of acquiring the building permit, of demolishing the existing buildings, of construction of the new buildings, of ongoing maintenance, of insurance, of energy management and of charging users of the building. The private partner charges the users for the use of the facilities for the period of 15 years. After the expiration of the concession contract all buildings are to be transferred – without compensation – into the ownership of the city. The concessionaire covered 60% of the costs of construction, while the municipality as the grantor of concessions covered the remaining 40% (with 15% of its own participation and 85% co-financed by the EU). Implementation of the PPP model in the construction of the kindergarten enabled the municipality to save 30% of the cost. The whole process from designing the project to its implementation to 15-year maintenance is to be provided by the concessionaire.

4.4 MODEL BOT (BUILD-OPERATE-TRANSFER)

This model was used in the construction of the market place in the City Municipality of Celje. The market place was built by the private partner. On the basis of the concession contract for construction, operation and maintenance the private partner was to operate the market place for the period of 10 years. However,

after 5 years the private partner went bankrupt. The municipality solved the problem by buying a share of the liquidation proceeds and continued to operate the facility on its own.

4.5 COMBINED MODELS

Sometimes two or more models are combined. Two models have been used in the construction of the sheltered accommodation for the elderly in Ljubljana (more on that below); namely for the public part of the project the construction concession model DFBTO (Design-Finance-Build-Transfer-Operate) and for the private part of the project the construction concession model DFBOO (Design-Finance-Build-Own-Operate). The private partner has been granted the right to operate and provide care for the entire complex of sheltered accommodation for the elderly (both the public and the private part) in ways and under conditions stated in the PPP contract. Division of the project into public and private part was agreed upon by the public and the private partner during the private-partner-selection process.

5 MOBILIZATION OF PUBLICLY OWNED LAND THROUGH PRIVATE CAPITAL

We will now have a detailed look at one of the most common current forms of use of PPP mechanism in urban development in Slovenia, e.i. mobilization of publicly owned lands through private capital. This chapter presents an example thereof in the case of construction of sheltered accommodation for the elderly and problematizes this sort of contribution to a controlled and dynamic urban development.

This particular urban project using the PPP mechanism concerns the establishment and construction of two buildings, intended for sheltered accommodation for the elderly, and the operation and supply of the established sheltered accommodation facilities through the partnership period. The private partner had two years to prepare the project documents, gain the building permit, construct the buildings and finally transfer the apartments to the public partner. The complex in question is Sheltered Accommodation Apartments Mijaks (internet sources 5 and 6), in the Šiška-Dravljje part of Ljubljana. 54 housing units were built in 2016, with total GFA measuring 4,477.76 m². All apartments have already been sold. Apart from the construction of the sheltered accommodation the contract also stipulates arrangement of 46 exterior parking spaces and of surrounding environment, as well as provision of supply and arrangement of management for the entire part. The value of the entire project is 5,498,684 Euro (excluding VAT). The PPP model implemented in this particular project is the construction concession model DFBTO (Design-Finance-Build-Transfer-Operate) for the public part and the construction concession model DFBOO (Design-Finance-Build-Own-Operate) for the private part of the project. The public partner of the project is the Public Housing Financing Fund of the City Municipality of Ljubljana. The following criteria for the selection of the private partner were used: the total area offered of sheltered accommodation apartments that was to become part of the public part of the project and was to remain in the ownership of the public partner; the share of the rented apartments offered in the private part of the project; the market rent on sheltered accommodation apartments offered in the private part of the project; the sales price of sheltered accommodation apartments offered in the private part of the project.

For the purpose of the realization of the project the public partner granted to the private partner the building right for the area, the extent of and duration of which had been agreed to during the process of selection of the private partner. The City Municipality of Ljubljana is the owner of the land area of roughly 4,045 m², invested into the project and exclusively intended for the purpose of construction of sheltered accommodation. Total financial contribution of the public partner amounts to 1.153,900 Euro (excluding VAT) and includes the land area, the building right, and the communal tax. As well, the public partner puts at the disposal of the users of the sheltered accommodation the shared use of the public park, which they will be able to share with the care recipients of the Šiška Elderly Home that stands in the vicinity of the project. In accordance with the contract of public-private partnership the public partner has to establish mechanisms that will ensure efficient protection of public interest.

The private partner finances the project in its entirety and is responsible for the design, land preparation and construction of the two buildings, intended for the sheltered accommodation, acquires the building permit and other corresponding administrative permits, necessary for the transfer and functioning of the sheltered accommodation apartments, such as the operating license. The private partner has been granted the right to operate and arranges supply for the entire building complex (both the public and

private part) for the entire concession period in the way and under the conditions, stipulated in the PPP contract. The private partner also assumes the larger part of business risks involved with the implementation of the PPP, risks connected with financing the entire project, risks connected with designing the project, acquiring the building license and construction and all other connected risks. The City Municipality of Ljubljana acquires 10 sheltered accommodation apartments that represent the public part of the project, together with the corresponding share of common spaces. The public and the private partner sign a contract on division of floor property of the constructed buildings (which has in principle already been agreed upon during the private-partner-selection process). Based on the contract on division of floor property the public partner transfers the agreed-upon share of the property rights in the part of the land and buildings, corresponding to the private part of the project, to the private partner. The share of land and buildings, corresponding to the public part of the project, remains the property of the public partner.

The private investor has therefore found a »market niche« in the project of construction of sheltered accommodation and successfully established cooperation with the public sector, aimed at improving living conditions and quality of life for the elder population of Ljubljana. The city gains a complex of sheltered accommodation, adapted to persons in the »third age« of their lives who are thus provided with a new, higher quality of living. At the same time, the burden on retirement homes is lessened and the active part of the elderly population can age more comfortably. Sheltered accommodation apartments are one of the important aspects of improved quality of life. The public sector and the private sector have jointly, the former through ensured unding and investment, the latter with its own means, contributed to the accomplishment of those goals. Construction of sheltered accommodation apartments in Ljubljana, implemented through the PPP mechanism, is a good example of a dynamic, controlled urban development.

6 FINDINGS

This chapter, based on conducted interviews and research of sources, will present the main characteristics of the implementation of projects, based on the PPP mechanism. It will discuss the motivations and advantages of such urban projects, main risks and key obstacles, and proposals for improvements of the existing system. The chapter will also introduce a typology of urban projects that can be achieved through the use of the PPP mechanism, in order to ensure dynamic and yet controlled urban development.

6.1 MOTIVATIONS AND ADVANTAGES OF PPP MECHANISM IN CITY MUNICIPALITIES

Based on an overview of PPP projects that have been (or have failed to be) carried out and semi-structured interviews at city municipalities, we have established that two main motivational factors are important in order for the public partner to resort to the use of PPP mechanism:

- 1 overcoming financial capabilities and constraints encountered by the municipalities and
- 2 achieving objectives within shorter delays, meaning that the municipality no longer needs to wait to accumulate enough financial means in order to undertake the project on its own.

The bigger the investment, the higher the motivation for the use of PPP, since bigger investments usually mean a combination of several forms of financing, such as budget resources, EU grants, resources of private partners. In this way the municipality appears less indebted, its administration is relieved of the additional bureaucratic burden, and the municipality can divert its resources into other developmental projects that cannot be implemented through PPP mechanism, while at the same saving money at the PPP-based projects which might not be otherwise directly economically viable. All of the above may also contribute to developments in the urban space and, consequently, to faster growth, since financing or cofinancing various developmental project also encourages municipal economy. Furthermore, in this way private capital means are directed towards public benefits and improvements in quality of life of the local population (such as construction of sheltered accommodation, kindergartens, etc.). Private investments into, for instance, construction of kindergartens can thus quickly positively contribute to city life and to satisfaction of the population (instant rectification of deficiencies, better working conditions, more economically efficient structures, etc.). Participation of private capital in public projects can lead to fast and efficient developmental interventions. PPPs often mean a search for alternative, smart solutions, but also a more rational approach to solving the urban developmental challenges (since projects are approached in

an economically more reflective fashion). Participation of the private sector, pursuing its own interests, is an additional testimony to the commercial viability of the scheduled projects. PPP mechanism represents both a more rational approach to financing and to risk sharing. PPPs are a good economic model for project cases with financial effects and therefore assured economic viability. One of the incentives for the PPP-based projects is the possibility of absorption of the EBRD funds. EBRD cofinances projects through consulting and other services up to the execution of the project itself. In this way a municipality can, for instance, order project documentation, expanded energy inspections and investment documentation for all facilities and buildings it wishes to make more energy-efficient without implementing its own resources.

6.2 RISKS AND GENERAL OBSTACLES IN THE IMPLEMENTATION OF PPP-BASED URBAN PROJECTS IN SLOVENIA

Private partners involved with PPP-based urban projects often assume several risks, such as the risk of financing the entire project, designing, land preparation, acquiring the building permit, the risk of construction/demolishing buildings and associated risks. They have to acquire additional administrative permits, necessary for the transfer and operation of already constructed objects, such as the operating license. Then there are risks connected to object maintenance – energy-efficient sanitation can, for instance, easily lead to a too large consumption of energy products. In short, private investors may face a myriad of risks.

Constraints and problems faced by the municipalities in the implementation of PPP-based urban projects include (but are not limited to): systemic obstacles, inappropriate organisation of municipal administrations, lack of cadres and knowledge, unrealistic expectations on part of either the public or the private partner, possible unreliability of the private partner (for instance, bankruptcy). There is a lack of knowledge and information on what, with whom and on which contents PPP-based projects should be concentrated, so as not to try and implement them with public resources alone. There is little successful practice; insofar as it exists, it is not being well-promoted. There are doubts about the PPP-based projects, usually based on negative stories or negative public opinion. PPP has acquired a generally negative connotation, no doubt partly for the fear of connection between PPP and corruption (since PPP represents a junction between the public and the private). Fears are often based on the long-term perspective of PPP contracts. There is too little cooperation between smaller municipalities in solving spatial and urban challenges, as well as too little action towards common projects that might be PPP-based. Partly to blame is the legal basis. Currently existing Public-Private Partnership Act was tailored for larger projects and larger city municipalities equipped with administrative services, strong project offices with several employees, etc., while the current state of affairs of PPP-based project implementation in Slovenia would require smaller projects. On the other hand is the act too complicated, often requiring minute details, and too demanding in certain segments. Since every PPP-based project is a specific one, such stickling for detail makes the implementation very difficult. Potential private partners often express strong mistrust. Any review of the state of affairs must necessarily point out several open questions and dilemmas, connected to the financial implementation of PPP-based projects on municipal level: combinations of financial resources and insurance, financial risk-taking (vulnerability of the public partner), expediency of combining different sources of financing, ambiguities in connection with the use of cohesion funds and CTN mechanisms, implementation of larger projects with a larger number of shareholders, and other dilemmas.

6.3 PERSPECTIVES OF THE PUBLIC PARTNER ON THE PPP-BASED PROJECTS: OVERCOMING THE BARRIERS ON THE PART OF CITY MUNICIPALITIES

Having reviewed the information passed on by the city municipalities, we must conclude that simplifications of certain segments of legislation and simplifications of procedures are sorely needed. The existing Public-Private Partnership Act from 2006 is outdated and deficient, and in certain segments written too broadly. Provisions for a more detailed definition of the preliminary procedure are lacking. Such provisions would contribute to a preparation of better materials, suitable to informed and responsible assessment in municipal councils. Also needed is a database with a proper selection of good examples of implemented projects and/or cases from past practice. The PPP system has to be corrected and adjusted to the level, suitable for the Slovenian environment. A division/distinction between larger and smaller

projects, adjusted for specifications of each, is necessary. The government needs to take a more goal-oriented approach towards PPP and provide better administrative support, which in practice means a stronger role for individual government ministries. Establishment of a new authority (for instance, a regional authority, that would conduct supervision, promote examples of successful practice and provide integration of projects from municipalities with similar challenges) could be a major answer to problems encountered by smaller municipalities with meagre cadres. Our municipal interlocutors have also expressed a desire for the establishment of a management body that would, together with competent ministries, form »rules of the game« necessary for adequate absorption of funds, intended for financing urban development projects. Also needed are additional financial instruments and incentives on the basis of concursus. The question of the absorption of European Cohesion and the current status of its use needs to be solved in the light of State aid. Development of financial instruments for a better absorption of EU resources deserves a special emphasis. Also needed are support mechanisms for cases in which one of the partners (usually the private one) is unexpectedly unable to meet its obligations and the responsibility for the further development of the project falls on the shoulders of the other partner (usually the public one).

Other suggested measures include: development of »know-how« through promotion and exchange of experience and information on good practices in Slovenia, training of professionals in municipal administrations, development of study programmes with specific emphasis on PPP. Furthermore, professional support institutions (from competent ministries) should provide unambiguous answers to municipalities as far as problems and unclear cases are concerned. The municipalities have expressed a strong desire for the establishment of an advisory body that could help them with questions regarding the implementation of PPP-based projects.

6.4 PERSPECTIVES OF THE PRIVATE PARTNERS ON THE PPP-BASED PROJECTS

Having reviewed the information from investors, we can conclude that private businesses are strongly interested in PPP-based urban projects and that they in that regard possess directions, useful to the potential public partners. Investors that we have interviewed have been carrying out the following projects: construction of residential neighbourhoods, construction of sheltered accommodation apartments, central activities, renewals of degraded urban areas, construction inside cities. Investors submit their willingness for cooperation and implementation of all types of PPP-based projects that would contribute to the quality of urban space and individual groups, communities, neighbourhoods and inhabitants, projects that would raise competitiveness of cities or parts of cities or towns, and projects that would result in an adequate above-average financial gain. Such projects include: renewals of residential neighbourhoods, new energy-efficient types of apartments, commercial buildings and facilities, service activities (better logistics, work organization and lower management costs), shopping malls, logistics of centres, warehouses, etc. One of the investors submits to have worked on several projects but no on PPP-based ones; he blames the frequent passivity of the public sector. The investor claims that while the public partner was invited to participate, there was complete lack of interest on part of the latter. The same investor cites several possible programmes that might be of interest to public partners: university programmes, public administration, services in the broad city area, parking houses for public programmes. Lack of interest on part of the public partner simply means that potential private investors carry all risk. Private investors are the most interested in projects in which the public investment comes in form of the land. Several different PPP-based projects have already been realized in this fashion (the case of sheltered accommodation apartments). However, according to private investors, the public partners are often prone to overvaluing their lands.

Private businessmen involved in PPP-based projects pursue different goals. Judging by the interviews, investors are often pledged to achieving public good, not the least because it is good for their public image. Such goals are achieved through participation in projects that contribute to the development of the city and its functions – aspects usually associated with the public sector. Naturally they also follow the motive of making a profit which should generally be much higher than bank interests or in accordance with the risks involved (5–15%).

Investors see a major problem in lack of suitable land or lack of their mobilization, often due to questions of ownership. Another important factor for lack of interest on part of investors is modest or slow return on invested capital. They see possible incentives in subsidies for private partners who would thus, based on

previously fixed percentage of profit, be able to decide on cooperation even on less attractive, more peripheral locations. They also propose simplifications of laws and rules governing the implementation of PPP-based projects. Private investors also emphasize successful implementation of PPP-based projects requires market-based equal rules and duties for both public and private partners. They emphasize the importance of trust and equality in relations between the partners. They wish for more safety and reduced risks, provided by reasonable deadlines for documentation certification and project implementation. In this sense, the system of public service contracts needs to be improved, as well.

When it comes to the development of financial and other mechanisms that would enable more simple and more frequent private participation in the realization of PPP-based projects in Slovenia, private investors see a positive sign in ongoing battles between banks and insurance companies. Insurance companies offer better conditions than banks. Municipalities should not meddle with particular project but merely fulfill their end of the bargain. Subsidies for private businesses are necessary. Greatly desired is stability of the scale of public service contracts – the state, cities and municipalities should have a roughly equal yearly number of such contracts, instead of perpetuating delays and five-year gaps. Banks should provide credit to private investors without extreme interruptions. Banks should support such investments and private investors. Private businessmen should be adequately qualified and, above all, professional. Investors should not be politically involved. The availability of land and the preconditions for construction should be better regulated. There is a lack of developmental and implementation mechanism as well as a lack of professional analytic documentation and studies of potential locations (a number of untapped potentials that might be of interest to private investors). Frequent problems leading to implementation difficulties include fragmented ownership and lack of proper documentation. A proper solution would be a combination of positive components of both partners: for instance, a city might possess a strategy but is operatively weak, while the private partner knows how to operatively implement a project. Fast-operating private investors are contrasted with alleged slowness of the public sector.

6.5 POSSIBLE PPP URBAN PROJECTS FOR A DYNAMIC AND CONTROLLED URBAN DEVELOPMENT

The future planned development of urban municipalities in accordance with their specific characteristics could implement several urban projects, based on the PPP principle, which would – through use of appropriate models – contribute to a more dynamic and controlled urban development. Based on the review of the development plans of Slovenian city municipalities, as well as the outcomes of the interviews with relevant stakeholders, here below we propose some possible spheres of future urban development based on PPP:

1. Revitalization of historical urban centres: comprehensive refurbishment of public and private building fund (housing, public buildings...), including upgrading of energy infrastructure, stationary and architectural renewal, and organized maintenance and management of building stock, public and trafficked areas, etc.
2. Revitalization of degraded industrial areas: development of existing degraded industrial areas, renewal of infrastructure and development of models of infrastructural management, renewal of industrial buildings, etc.
3. Residential housing: construction of residential buildings, solving the housing problem (residential cooperatives, housing schemes for younger and elderly citizens, flat-sharing communities, intergenerational centres, etc.), sheltered accommodation for the elderly, construction of affordable accommodation of all types, establishment of day centres / intergenerational centres, programmes for persons with difficulties in finding accommodation, and provision of suitable accommodation units.
4. Public space development: renewal of urban open public spaces – public squares and streets, parks and green spaces, platforms, playground and multi-purpose facilities, meeting places, etc.; modernization and upgrading of public infrastructure and footpaths; supplementing equipment and regulation of open public spaces – greening measures, public street lighting, installation of urban furniture and other urban equipment, information and orientation markings, facilitation of accessibility for persons of reduced mobility, etc.; public park arrangements, tree rows, sports parks, urban lawns.

5. Traffic: provision of alternative parking spaces for residents and users (construction of underground parking garages, management of parking platforms/public parking spaces; management of public traffic, comprehensive management of roads, bicycle lanes and pavements.
6. Tourism: land use planning conducive to comprehensive tourism products, development of youth tourism, revitalization of castles, thematic paths.
7. Urban marketing: promotional activities, construction of markings and comprehensive graphical presentation, information portals for residents and visitors, etc.; design and marketing of tourist attractions and products, managing urban infrastructure for public events.
8. Education: upgrades and extensions of spatial capacities of school and kindergartens and their energy networks; construction of campuses, technological parks, business incubators; management of coworking spaces.
9. Sports facilities and areas: systemic renovation and upgrading of sports and recreational areas and infrastructure, management of sports halls interiors, provision of sports grounds, playgrounds, etc.
10. Infrastructural arrangements: renovation and upgrading of urban market places, renovation of water and sewerage system; waste recycling centres, etc.
11. Energy efficiency: improvements in energy efficiency of buildings, energy-efficient sanitation of public lighting network, etc.

7 CONCLUDING REMARKS

The review of the state of the art after 10 years of PPP mechanism being introduced to Slovenian spatial development practice gives a clear evidence that public and private partners are still trying to find their common way to make best use of PPP. In order to make the PPP mechanism more widely used a number of measures have to be introduced, among others institutional support in a form of an advisory body to advice both public and private partners when they encounter unbiquities or obstacles in implementing PPP projects. Furthermore new ways of cooperation between local authorities need to be introduced if they want to implement bigger PPP projects of regional relevance in cooperation with private investors that will be eligible for cohesion funds. New financial mechanisms to support the private partners have to be developed too in order to attract private investors to less attractive locations. Another striking obstacle is of a socio-cultural nature and relates to the relatively negative public image of PPPs in Slovenia that shall be improved by presenting examples of good practices to professional and wider publics. A proper implementation of PPP tool into Slovenian urban development practice however proves to be a suitable tool for a controlled and dynamic urban development in the future.

ID 1561 | CONSULTANCY FIRMS AS INTERMEDIARIES: THEIR PERCEPTIONS ON COMMUNITY INVOLVEMENT IN URBAN DEVELOPMENT (WORK IN PROGRESS, PLEASE DO NOT CITE WITHOUT PERMISSION)

Everardus Michiel Stapper¹

¹University of Amsterdam

e.w.stapper@uva.nl

1 INTRODUCTION

Consultancy firms are key-players in urban development as they are knowledge depositories, and have knowledge of regulations, real estate development, and planning processes in the western world. They are intermediaries for public and private parties and can play a role in the exchange of policy ideas and views. The responsibility of translating community interests in informal and formal agreements in urban development is increasingly outsourced to consultants. As external agents, they can shortcut institutional boundaries and find new ways to engage with communities and other stakeholders in urban development projects (UDPs). This study explores the role of consultants in urban planning practices. Specifically, their role in how to involve communities in the planning processes and how to incorporate community interests in urban development. This study is part of a broader research, aimed to investigate community-linked incremental urban development and its ability to find smart solutions to address economic, social and environmental challenges. The following research question is stated: 'Which perceptions on community involvement in urban development do employees of consultancy firms have and how do they incorporate or forfeit community interests in urban development?'

To explore the role of consultants in urban development I have chosen for a single case-study. A single case study helps to explore in depth the perceptions of consultants on the involvement of community interests in urban development. I also explore the relationship of consultants with their clients. The relation between consultants and their clients is described ranging from the idea that consultants are neutral actors because they are hired by their clients to the idea that consultants are some kind of 'shadow government' or 'consultocracy' (Hodge and Bowman, 2006; Saint-Martin, 1998).

In the first section of the paper I summarize the existing literature on the role of consultants in urban development. In the second I describe the methodology I use to answer the research questions. Next, in the third section, I describe which agreements consultants can use to incorporate community interests. In the fourth section, I describe three possible perspectives consultants can have on involving communities in

urban development and in the fifth section I reflect on the relationship between the client and the consultant. We end the paper with a conclusion and suggestions for further research.

2 CONSULTANCY

Saint-Martin (1998) linked the growing tendency of involving consultants in producing and executing public policy to the increase of New Public Management (NPM) methods by public authorities. In his historical institutional analysis of the influence of consultants on public policy he describes how especially right-wing politicians aim for involving consultants in public policy, in order to reform bureaucratic processes in Canada, the UK and France. The involvement of consultants gave credibility to policies because they came from the private sector and were seen as more efficient (Saint-Martin, 1998). The increase of involvement of consultancy firms in public policy has led some scholars to argue that consultancy firms have become a new bureaucracy, they introduce the term 'consultocracy' or 'shadow government' (Grijzen, 2010; Hodge and Bowman, 2006; Saint-Martin, 1998). Hodge and Bowman (2006) describe consultancy firms as the sellers of solutions for complex policy problems for public authorities that the public authorities themselves cannot fix. This has resulted in a flourishing market for consultancy firms. For consultancy firms, there is a direct interest in keeping the market expanding; government reforms are business cases for consultancy firms. However, there is no direct link between increased spending and increased influence. Consultancy firms are benefiting from the demand for private sector solutions, but public authorities, in democratically governed nation states, have created the demand (Hodge and Bowman, 2006). McCann describes how public-private coalitions hire consultants in order to create urban plans. Often the consultants claim to use collaborative, inclusionary methods to create urban plans, but McCann shows in his single-case study of the new planning vision for Lexington how they reproduce existing power relationships (McCann, 2001). In a survey under planning officials and consultants, Loh and Norton (2014) explored why public parties hired consultants. They found that both consultants and their clients think that the benefits of outsourcing planning activities outweigh the disadvantages of higher costs and the lack of local knowledge (Loh and Norton, 2014).

Grijzen (2010) has investigated the involvement of consultants in regional spatial planning in the Netherlands. Her research argues that consultants are hired to solve problems of cooperation and coordination. She argues that governments struggle to find new ways of involving communities. Consultants can solve those problems because they have an outside position and can overcome bureaucratic obstacles.

This gives them the ability to design and implement policies with multiple stakeholders, issues, and regulations. Consultants can help to create new ways for communities to get involved and therefore enhance democratic legitimacy. However, they also can erode democratic legitimacy. Public policy can become inconsistent and ad-hoc, especially concerning the participation of citizens. Furthermore, partly through the 'revolving door' mechanism, where former public officials are hired as consultants, consultants can become too focused on the institutions and organizations they have connections with. This can create the problem that consultants are becoming indispensable for planning practices and public officials lose too much expertise and knowledge (Grijzen, 2010).

3 INCORPORATING COMMUNITY INTERESTS INTO UDPS

Consultants can use three types of agreements to incorporate community interests into UDPs. They can use informal agreements, formal agreements and contracts to incorporate community interests. Informal agreements are the least powerful agreement and contracts are the most powerful type of agreement. Informal agreements are agreements that are not formalized and mainly used to manage and improve relationships. An example of an informal agreement is an assurance to a citizen that his concerns will be taken into account in the new plan. Informal agreements are made because legal terms are not able to capture the relationship between stakeholders (Scheper, Oh, et al. 2014; van der Veen and Korthals Altes, 2011). Formal agreements are agreements that are written down but are not enforceable by court. An example of a formal agreement is a summary of the commitments that are made by public officials concerning community during a public hearing. Lloyd (2015) notes that increased use of legal agreements to manage governance networks is accompanied by the introduction of formal agreements that are not

enforceable by court. He defines those agreements as 'soft contractualism'. Soft contractualism is the way of managing relationships between stakeholders and guide cooperation. They mainly regulate communications between stakeholders, cooperation in policy development, the exchange of knowledge and they regulate the confidently of information within a project (Lloyd, 2015).

Contracts are the most powerful agreements in urban development, because they can force stakeholders to act. According to Van der Veen and Korthals Altes (2011), contracts in urban development has four functions. The first function regulates the exchange of goods and services. The second function concerns the procedural rules. The third function is the planning function, which contains the conditions for the realization of the project. The fourth function names the instruments for realizing public goals (van der Veen and Korthals Altes, 2011).

4 METHODOLOGY

In order to find out which perceptions employees of consultancy firms have on the involvement of communities in urban development, I will use the Q-method. Q-method is a method were respondents have to sort statements in a normal distribution ranging strongly disagree to strongly agree. After the statements are sorted, I perform a factor analysis to analyze the perspectives about community involvement there are within the consultancy firm. After the Q-sort I have asked the employees questions in a semistructured interview. The semi-structured interview is used to reflect on the sorting of the statements.

Furthermore, I asked questions concerning how the employees engage with communities and how the client influences the relationship between the employee and the community.

Q-methodology is designed to identify clusters of perceptions. The method is a mix of quantitative and qualitative approaches. The Q-method consists of six phases. First, a research question is stated. Second a broad spectrum of statements about the research question is created. The statements are based upon quotes from a range of sources and perspectives. Third, a sample is taken out the spectrum of statements that will function as the Q-sample. The sample should represent diverse opinions and a broad range of concepts. The fourth step requires a respondent to rank the Q-sample. Each statement has to be arranged in a normalized distribution ranging of nine categories ranging from strongly disagree to strongly agree. This step reveals the subjectivity of the respondent because the respondent controls the ranking of the statements. The fifth step is to correlate the sorted Q samples using a factor analysis. The sixth step is interpreting the data (Cuppen, Bosch-Rekvelde, et al. 2015; Robbins and Krueger, 2000).

Originally the q methodology was created in order to erase bias and design an objective method to measure subjectivity. However, the researcher has six moments in which it can decisively influence the research questions (Kampen and Tamás, 2013). Therefore, it is important to not claim the absence of the researcher but to make explicit when the researcher is a presence and to make the research process transparent (Robbins and Krueger, 2000).

The Q-sample of this study consists of six statements about making informal, formal and legal agreements with communities in urban development. Of those six statements, three statements are positive about using informal, formal or legal agreements in order to incorporate community interests and three statements are negative about using informal, formal or contracts in order to incorporate community interests. Five statements cover opinions about how and when communities should be involved in urban development. This will define how the consultant think about how and when communities should be involved in urban development. Twelve statements follow about the political, social and economic utility of community involvement, six of those statements are negative and six are positive. Those statements measure why the consultant find community involvement in urban development important or not. Then sixteen statements follow about the role of communities, civil society organizations, the private sector and public authorities in incorporating community interests in urban development, eight of those statements are negative and eight are positive (see table 1). Those statements are based on the typical stakeholders in UDPs (Janssen-Jansen, and Van der Veen, 2016).

Statements	Neutral:	Positive:	Negative:
Using informal agreements, formal agreements and contracts		3	3
Process of community involvement	5		
Political aim of community involvement		2	2
Economic aim of community involvement		2	2
Social aim of community involvement		2	2
Role of public parties in involving communities in UDPs		2	2
Role of market parties in involving communities in UDPs		2	2
Role of NGOs in involving communities in UDPs		2	2
Role of citizens in involving communities in UDPs		2	2
N	5	17	17

Table 1: Categories of statements used in the Q-sort (authors)

Employees of AGA were asked to sort the Q-sample. The first eight employees that sorted the Q-sample were selected by senior employees of AGA. They are selected because they work in different departments of AGA, what helps to get a broad range of views on community involvement. I have used snowball sampling to perform the next three Q-sorts. During the ranking of the statements, the employees have been asked to articulate their choices by thinking out loud. This was helpful by analyzing the outcomes of the research.

5 FACTOR ANALYSIS

The factor analysis showed that there are three factors with an eigenvalue higher than one. Based on convention, only factors with eigenvalues greater than or equal to one are considered significant (Raje, 2007). Next, I performed a Varimax rotation to identify the three significant factors. The standard error for a factor loading is calculated by the expression $1/\sqrt{N}$, multiplied with 2.58(SE). This gives the indication of a meaningful relationship between the participants Q-sort and the factor type (Raje, 2007). Thus, in this research, loadings of or more than 0.41 are significant at the level 0,01. Ten of the eleven Q-sorts were loaded within the three factors (see table 1). Respondent 5 loaded in both factor 1 and factor 3 and is therefore excluded from this study. Here I describe the three perspectives that resulted from our Q analysis.

Respondent	Factor 1	Factor 2	Factor 3
1	0.70x		
2	0.57x		
3	0.66x		
4			0.73x
5			0.55
6		0.69x	
7			0.70x
8		0.74x	
9	0.70x		
10		0.64x	
11			0.77x
% expl. Var.	22	17	19

Table 2: Loadings Q-sort in factor types (authors)

5.1 CITIZEN EMPOWERERS

The respondents of this factor identify strongly with the statements 38 and 39, which state that the bureaucracy of the government obstructs the involvement of citizens in UDPs and that civil servants perceive protesting citizens as complainers. The respondents that identify with this perspective are clearly negative about the government. In interviews, they tell that the bureaucratic procedures, between civil servants and citizens and within the government itself, of civil servants temper the involvement of citizens. The perspective also agreed, although to a lesser extent, to statements 16, 17 and 25. Those statements note that involving citizens in UDPs is beneficial for social cohesion, that involving citizens in UDPs is an adequate instrument to fight spatial inequalities and that the involvement of citizens in UDPs is necessary as counter force for civil servants and the private sector. Again, those statements show a negative perspective on the government. However, it also shows that the respondents that identify with this perspective think that involving citizens in UDPs will have an important impact on society. In the interviews, they put emphasis on the knowledge citizens have about the area of an UDP. Furthermore, they believe that citizens have energy and good ideas to improve UDPs.

The respondents strongly disagree with the statements 13 and 37, which state that citizens have enough legal and political means to influence policy and that civil servants look after everybody's interests. Again, a statement that is negative about the government and a statement that points out that new legal and political tools are necessary to let citizens influence policy. One consultant noted that citizens do not have enough insight in how to influence legal and political procedures. According to the consultant are those procedures often too slow and technocratic for citizens.

To a lesser extend the perspective also disagreed with statements 22, 26 and 28 which state that it is more important that an UDP is beneficial for economic development than that the interests of citizens are safeguarded, the reason to not involve citizens in UDPs is that do not have sufficient knowledge and expertise to be valuable contribution to a project and that the involvement of citizens in UDPs only succeeds through the help of NGOs. This shows that the consultants that identify with this perspective are positive on the role of citizens in urban development and are convinced that the interest of citizens should be decisive in an UDP. Often the consultants note that citizens the local knowledge of citizens is very valuable for UDPs.

I label this perspective the citizen empowerers, because the respondents that identify with this perspective are very critical on the role of the government but strongly belief that if citizens can improve UDPs. They also think that if citizens play a significant role in the UDP, it will benefit social cohesion and challenge inequalities. The following quote is a good example of the logic of a 'citizen empowering consultant':

"I think that the knowledge and expertise resides with citizens instead of on the other side of the table. People know a lot, people work, they are not stupid. I really think it is ridiculous if you think like that. It is not respectful towards the citizens. They know the

environment and make use of it. The designs only become more beautiful. [respondent 3, 2016]”

5.2 PROFESSIONALISTS

The respondents of the second factor identify strongly with statements 18 and 27. The statements note that if citizens can get involved in an UDP only loud citizens participate and that citizens in UDPs only focus on their own private interests. This respondents that identify with this perspective are therefore negative on the role of citizens in UDPs. The consultants argue in the interviews that it often costs much time and money to let citizens participate, which is not necessarily a bad thing. When citizens participate they often struggle to see the benefits of the UDP for the broader community.

To a lesser extent this perspective agreed with statements 1, 6 and 15, stating that it is important to write agreements with citizens down, conflicts in UDPs often emerge because it is not thought through how agreements with citizens are made and the involvement of citizens make it easier to solve political problems. The high scores of those statements put emphasis on the necessity of making clear agreements with citizens and that they can solve political problems. The consultants state that when clear agreements are made with citizens, political problems can be avoided.

The respondents strongly disagree with statements 4 and 34 which state that new legal instruments are needed to involve citizens in UDPs and that the government listens more to the private sector than to citizens. The respondents that identify with this perspective note that citizens already have much legal possibilities to get involved in the urban development process and that therefore both public and private parties have to listen to the concerns of citizens.

They also disagree, although to a lesser extent, to statements 20, 28 and 30. Those statements note that citizens are involved in UDPs to hide budget cuts, that the involvement of citizens in UDPs only succeeds through the help of NGO and that the position of citizens is voiced the best by NGOs. The consultants note that often participation processes are expansive and that NGOs are mostly focused on the interest they represent and not necessarily with the interest of citizens.

I label the consultants that identify strongly with this perspective the professionalists. I have chosen for the term professionalists because they believe that much conflict within UDPs comes from not thinking through well enough how agreements are made with citizens. They are also note that if citizens have too much influence, it would take too much time to develop a project. The following quote is representative for the logic of the professionalist consultant:

“As long as you know what their interest are, and if you know their struggles, than you can give them the feeling that they are being heard. You cannot develop a project that everybody likes, that is just not possible. Than you have to go into another trajectory [if citizens obstruct an UDP], legal frameworks are available. We live in the Netherlands luckily, where everything is neatly organized, if you identify the possible threats and plan the process well. [respondent 8, 2017]”

5.3 BALANCERS

The respondents of the third factor strongly agree with statements 18 and 25. Those statements reflect that that if citizens can get involved in an UDP only loud citizens participate and that the involvement of citizens in UDPs is necessary as counter force for civil servants and the private sector. The respondents that identify with this perspective, note the importance of involving citizens, but acknowledging that they do not reach every population group. One consultant noted that it is very hard to reach elderly people, lower educated people or people with a minority background.

To a lesser extent, they agree with statements 1, 5 and 32 noting that that it is important to write agreements with citizens down, that legal agreements scare citizens and that the private sector sees citizens as a way of doing market research. The consultants that identify with this perspective note that writing agreements down has symbolic importance. This happens mostly in summaries of public hearings

and is important because it symbolizes that the concerns of citizens are taken into account. The consultants noted that the private sector is mainly driven by making profit and therefore is not very interested in giving citizens influence.

The respondents strongly disagree with statements 11 and 13. Those statements note that citizens should have to feeling that they are involved but should not have real influence, that citizens have enough legal and politics means to influence policy. One of the consultants that identify with this perspective has written a book on how he was not taken seriously as a citizen when a new station was built near his home. He stated that everybody that worked in urban development should participate once in a whole urban development process that learn how important it is to take citizens seriously. Another consultant described how political and legal instruments are mostly used by politicians, civil servants and the private sector but not by citizens.

They disagree to a lesser extent to statements 23, 26 and 35. Those statements express that the involvement of citizens in UDPs saves money and time, that the reason to not involve citizens in UDPs is that do not have sufficient knowledge and expertise to be valuable contribution to a project and that the private sector listens better to citizens than the government. The consultants that identify with this perspective explain in interviews that the participation process for citizens often does not save time or money but that it is necessary because the citizens have local knowledge about the area. They also point out that every stakeholder has his strengths and weaknesses.

I classified this perspective as the balancers. They are looking for a new balance between the community and other stakeholders. I have chosen for this definition because the consultants argue that the involvement in UDPs can be beneficial but that the interest of the citizens should be weighed against the interests of other stakeholders. The following quote reflects the logic of a balancer-consultant:

“The private sector wants to reduce costs as much of possible. The government has the role to balance between both sides [private sector and citizens], but they also have to deal with politicians and maybe NGOs and they have to deal with many more interests than only the interests of the triangle [of citizens, private sector and government]. And citizens often don’t look beyond their own interest. They do not really think about the rest. This can change, if you organize the process well and focus on the interests of other stakeholders, but at first instance they do not think beyond their own interest. [respondent 4, 2016]”

5.4 REFLECTION ON VARIATION OF THE Q-SORT

Giving an explanation for the question why consultants identify with a certain factor type is based on this research difficult. The working experience, departments and functions are quite spread across the different factor types (see table 2). However, the two community managers working in the spatial planning department are both citizen empowers. This makes sense because their job is to involve communities in urban development. This could suggest that frontline workers tend to be more often citizen empowers. However, more research is needed to explain the variation of factor types within the consultancy firm.

Respondent:	Factor type:	Working for Antea in years:	Working experience before Antea:	Department:	Function:
1	Citizen Empowerers	27	No	Infrastructure	Project manager
2	Citizen Empowerers	11	Public party	Water & environment	Environmental specialist
3	Citizen Empowerers	6,5	Market party	Spatial planning	Community manager
9	Citizen Empowerers	11	No	Spatial planning	Community manager
6	Institutionalists	14	Public party	Real estate & law	Real estate /legal adviser
8	Institutionalists	24	No	Architecture	Architect
10	Institutionalists	11	Public party	Planning	Project manager
4	Balancers	1,5	Public party	Real estate & law	Real estate/legal adviser
7	Balancers	27,5	No	Spatial planning	Project manager
11	Balancers	6	Market party	Contracts	Real estate/legal adviser

Table 3: factor types with department and function of the respondents (authors)

6 RELATIONSHIP BETWEEN THE CLIENT AND THE CONSULTANT

The relation between consultants and their clients is described ranging from neutral actors to a shadow government (Grijzen, 2010; Hodge and Bowman, 2006; Saint-Martin, 1998). In the interviews, I asked the consultants why clients hired them and how they disagreed with clients on the topic of involving communities in urban development. The consultants told that they were mostly hired because of their expert knowledge. The expert knowledge can be divided in two types of knowledge, knowing how to get things done and knowing certain skills. Two consultants also mentioned that they are sometimes hired because of trust issues between communities and public authorities. The consultants are then presented as mediators between all the stakeholders. One of the consultants nuanced their ability to be seen as neutral actors, because could give them the benefit of the doubt, but that they were still seen as intermediaries of public authorities or the private sector.

When inquired how the consultants disagreed with the clients the answered mostly with advice. They present alternatives to the preferences of the client and they can strongly urge to choose for an alternative. But in the end the decision is the decision of the client. When asked to give examples of situations where the consultants disagreed with the clients, they often gave examples where they disagreed with politicians. One consultants described a situation that an alderman ignored the outcome of a participation process and the consultant had to go with the decision of the consultant. However, the consultant actively reached out to citizens to point to their rights and how they could legally object against the decision of the alderman. Thus, based on their own perception, consultants, not surprisingly, do not seem themselves as part of a shadow government. This does not mean that they are neutral actors, because they have their own experience, skills and knowledge. Their experience, skills and knowledge shapes the way they give advice to their clients. Giving good advice is the essence of the consultant's job, and a good adviser also gives advice that is contrary to the client's opinions. However, in the end, the consultants will follow the decision of the client.

7 CONCLUSION

The findings of this study suggest that at least three perspectives on the involvement of communities in UDPs exist in the consultancy firm Antea. The variation of perspectives within one consultancy firm implies that consultants are not neutral actors, but that they have their own experience and beliefs that will shape their interactions with communities. Furthermore, the perspectives show that the consultants have very different attitudes towards the government and their relation with communities.

The citizen empowerers are consultants that are the most passionate about incorporating community interests. They argue that new legal and political instruments are needed to cater for the involvement of enthusiastic citizens in UDPs. Contrary to the citizen empowerers, the institutionalists are more skeptical about the involvement of citizens in UDPs. They argue that citizens are mostly focused on their own private interests and that it is very important to make clear agreements, based upon existing procedures, with citizens to prevent conflict in UDPs. The balancers are consultants that note that it is very important to incorporate community interests, but that the group of citizens that participate lacks diversity and that they tend to be focused on their own interest. Agreements should be written down, but legal obligations for citizens are too farfetched.

8 DISCUSSION AND FUTURE RESEARCH

The limit of this research is that it is a single-case study of an engineering- and consultancy firm. More research is needed on if this or other variations exist in other types of consultancy firms. Furthermore, observations of consultants that cooperate with citizens is needed to validate the interviews with the consultants. Next, an international comparative study could explore whether the variation is typically Dutch or that there is an international pattern.

With the limits of this research in mind, the findings of this study suggest consultants have quite different perceptions on involving communities in urban development. More research on this topic is needed, and therefore I propose three propositions that should be explored further. The first proposition states that citizen empowerers are more successful in incorporating community interests in urban development than professionalists and balancers. Citizen empowerers could benefit from their positive perception of citizens, but this could also mean that they have blind spots concerning the real needs of communities.

The second proposition that could be explored is the proposition that balancers are more successful in incorporating community interests because they acknowledge that not every population group is reached in their efforts to involve communities. Therefore, they are more inclined to find new ways to involve communities.

Based on the q-sorts and the interviews, the proposition that the interests of communities weigh less than the interests of other stakeholders could also be explored. Most consultants mentioned that in the end the interest of communities are taken into account when possible, but that community interests are not the dominant concern in their work.

ID 1595 | FLEXIBILITY IN URBAN RENEWAL PRACTICES: THE CASE OF TURKEY

Sezen Tarakci¹; Sevgiye Sence Turk²

¹Istanbul Arel University; ²Istanbul Technical University

sezentarakci@arel.edu.tr ; turkss@itu.edu.tr

ABSTRACT: In Turkey, urban planning is provided through the regulatory planning system. However, significant changes in the planning system since 2000 have triggered a shift in the planning system which is defined as regulatory in theory, towards a flexible planning system in practice. A flexible system is also evident in urban renewal practices. Flexibility in urban renewal implementations occurs in two different ways. Firstly, urban renewal practices are excluded from the regulatory planning system due to a project-led approach instead of a plan-led approach. Urban renewal practices are applied in accordance with special laws that have been in effect since 2004. These special laws bypass the hierarchy that exists within the regulatory planning system. Moreover, development rights, which are prepared in accordance with the regulatory planning system, expire once an area is declared an urban renewal area. This situation enables a great deal of flexibility in urban renewal practices, in sense of giving of new development rights. Secondly, the legal regulations regarding urban renewal differ from the legal tools of the regulatory planning system in that the former give both the central and local administrations discretionary power on various issues, such as the identification of the renewal area or the completion of the implementation.

KEYWORDS: Flexibility, regulatory planning, urban renewal, practices, Turkey

1 INTRODUCTION

Cities are affected and governed by various internal and external factors, such as processes of capital accumulation in the country, along with efforts for institutionalisation this brings about, in addition to the demands of their administrators. Differences in the process of capital accumulation between countries create differences in terms of not only opportunities, but also of problems. This difference also varies

depending on the countries' periodic characteristics, as well as the qualitative and quantitative data. As changes occur in factors such as international relations, political structure, mode of production and social structure, they create differences within the dynamics of space and therefore the problems and expectations of its users. Consequently, this process brings about discrepancies in administrative structures and planning actions (Tekeli, 1994; Ramazanoğulları, Turgut, 2004).

The purpose of this paper is to analyse this flexibility and its consequences that have resulted from the legal regulations regarding urban renewal via examining actual urban renewal practices. The extent and content of such a flexibility, which has emerged due to legal instruments regarding urban renewal since 2004, have changed over time in Turkey. This situation directly affects the results of the implementations.

In the first section of the paper, the features and characteristics of the regulatory planning system in Turkey are evaluated. In the second section, we will go through how flexibility has increased in Turkey's planning system and urban renewal practices from past to present. In the third section, flexibility and its consequences that have emerged in the legislation about urban renewal practices since 2004 are comparatively evaluated through various examples. Finally, in the fourth section, the structure and consequences of such a flexibility provided by the legal resources in urban renewal practices in Turkey are evaluated.

2 CHARACTERISTICS OF TURKEY'S PLANNING SYSTEM

Planning systems are divided into plan-led regulatory planning systems and project-led discretionary planning systems (Özkan and Turk, 2016). The plan-led planning system is designed to lead the development of space in accordance with the decisions of the plan. It is transferred to the development plan of the new use decisions of the land in order to apply these decisions which have definite results (Rivolin, 2008). Rivolin (2008) defines the planning system in his study as being based on "hierarchy," and technically "legally binding," characterised by "certainty" and "rigidity."

One of the important characteristics of the plan system in Turkey today is the existence of a "hierarchical" order (Demir, 2009). Planning legislation consists of hierarchically interdependent planning scales (Demir, 2009; Kanlı, 2003; Özkan, 2012). In addition, each subscale is expected to involve more information and detail compared to the scale above and include the necessary information and data of its unique scale, while at the same time preserving the main decisions of the scale above (Ersoy, 2000). However, since the regulatory planning system cannot respond to the dynamics of a city within the last 25-30 years of planning history in Turkey, it is a fact that the upper scale planning approach has been disregarded by the local administrations, and urban space development has become dependent on small-scale projects instead of plans, due to the influence of neoliberal policies. Today, especially the development of big cities, it is almost entirely dependent on small scale projects (BIB, Urbanization Forum, 2009). There is a view suggesting that for a plan to be binding for all real and juristic persons and to acquire a legal document status, it needs to be adopted and approved by political decision makers (Keles, 2012). In Turkey, Reconstruction Law No. 3194 states that local spatial plans shall go into effect following the approval of the city council. In this sense, the framework presented by the planning approach and implementation is a regulatory system that highly depends on "certainty" and that sets the standards for all cities at the national level (Ünlü, 2006). In addition, plans that reach the suspension time limitation and are finalised are worthy of legal document status, with significant consequences that bind real and juristic persons (Keles, 2012). For this reason, each local spatial plan is a whole within itself and has its own legal qualifications (Özkan, H. A., 2012). Therefore, it is evident that Turkey's planning system is a regulatory plan-led system that depends on precision in terms of development legislation. However, today's planning processes are evolving towards a more project-led approach, which is becoming increasingly preferred as an alternative (Munoz Gielen & Tasan-Kok, 2010). Urban renewal practices in particular stand out with project-led approaches.

3 AN EVOLUTION TOWARDS "FLEXIBILITY" IN PLANNING SYSTEMS AND URBAN RENEWAL PRACTICES IN TURKEY

In Turkey, the most significant transformation particularly for the big cities was through the immigrations in the 1950s, resulting in housing, employment, and transportation becoming the main problems of the metropolitan areas. Cities began transforming horizontally and vertically at a fast pace (Özden, 2008). The increasing emergence of gecekondu in the suburban areas also took place in this period. These gecekondu areas are among the first areas where a need for urban renewal in Turkey emerged (Kütük İnce, 2006). The gecekondu phenomenon, which sheds light on the social history of the cities and encompasses the foundation of social and physical life, is going through a different phase following the urban renewal policies of today (Şen & Türkmen, 2014).

With the influence of neoliberal policies at the end of the 1970s, urban development was increasingly shaped by private sector dynamics. As the private sector settled into a more and more influential role, the public sector became more and more passive (Tasan-Kok, 2008). Consequently, an illegal urban texture emerged during the 1980s due to general building amnesty legislation that aimed to solve the issue of gecekondu; while destructions also took place on a large scale and functional transformations began (Özden, 2008). For example, in Istanbul's Başibüyük District, 48% of the area benefited from the amnesty law and received 'land allocation certificates' (tapu tahsis belgesi). Gecekondu that received land allocation certificates began transforming into apartment blocks (Şen & Türkmen, 2014). Consequently, structures that arose thanks to the amnesty law, especially in Istanbul, shaped the discourse in urban renewal approaches (Dinçer, 2011). Furthermore, legal and institutional structures of urban planning were deregulated with the introduction of neoliberal policies (Gür & Türk, 2014). Even though central planning has always been crucial for determining urban and regional policies in Turkey, a new era emphasising local administrations began with the help of institutional regulations during the neoliberal economic transformation process that started in the 1980s. Nevertheless, these regulations also adopted an inflexible, normative and rigid approach and no new regulations were introduced that could respond to the ever-changing real estate investment and implementation styles (Tasan-Kok, 2006). To manage the change in urban space, the planning system offers a perspective based on plan-led approaches. "Local spatial plans" at the urban scale are inflexible and rigid (Ersoy, 2000; Keleş, 2012; Özden, 2008; Tasan-Kok, 2006; Özkan and Türk, 2016; Famous, 2006). In this sense, in the process of change management in the urban space, it was far from providing the necessary flexibility, potential for interpretation or opportunities for contribution (Ünlü, 2006). The bureaucratic restrictions were then overcome in alternative ways, due to these shortcomings in the regulations.

In the 1990s, changes in the urban space began with the influence of globalisation, and large office buildings and shopping malls led to extensive transformations in the urban space (Özden, 2008; Güzey, 2016). For example, several changes were made in the residential areas in Istanbul and their usage: With the construction of the second bridge over the Bosphorus and peripheral highways, financial centres were built on these axes (Ergün, 2006). In addition, during this period faulty urbanisation policies and partial implementations have increased in urban areas, whereas central and local governments failed to develop urban spaces, construct residences and establish mechanisms to inspect the urban structures in terms of their eligibility for local spatial plans. As a result, this horizontal one-storey illegal housing turned into a vertical multi-storey illegal configuration. The need for urban renewal thus increased, given all the aforementioned negative developments (Köktürk & Köktürk, 2007).

Moving towards the 2000s, urban renewal was emphasised again as a risk mitigation tool for natural disasters following the sensitivity after the Marmara and Düzce earthquakes. There emerges the issue of both modernising the settlements that are already built and reconfiguring the earthquake-prone residential quarters, especially in the metropolitan areas. For this reason, urban renewal has been an important component of urban development. Special urban renewal projects were introduced by the local administrations, and developed through a cooperation between the public and private sectors. These projects were implemented in high-rent areas and considered as the only alternative for the improvement development plans (ıslah imar planları) for squatter settlements (Genç, 2014). However, the flexibilities and open negotiation processes in the relations between local administrations and the private sector, as is the case in countries with discretionary planning systems, did not emerge here. On the other hand, the stable and rigid framework of local spatial plans, compared to the dynamism of the social space, might fail to produce urban spaces (Ünlü, 2006). At this point, urban renewal projects have progressed on project-

led approaches, developing a dynamic structure in contrast to the static local spatial plans. This situation was also supported by new legislation concerning some special urban renewal projects.

In the recent years, Turkey's planning system has adopted an approach that makes decisions based on fragments of the cities instead of considering the city as a whole. This situation encompasses an increasingly flexible and project-led approach. For this reason, planning becomes an implementation tool that can accommodate different and flexible applications according to market demands. New land use decisions that are requested in fragments across the urban land, or changes to the existing land use decisions, spread rapidly and create differences across the city (Tasan-Kok, 2006). However, the pressure to increase the capital/land ratio due to the rising land prices in rapidly growing cities, and the resulting demand for high density reconstruction of the non-functional or decentralisation of industrial zones into urban fringes, and an increased demand for the reconstruction of licensed or unlicensed residential buildings, along with the projects of local administrations that are in competition to receive the capital in the era of globalisation have raised the momentum of urban renewal practices (Kocabaş, 2005). For this reason, numerous large-scale, mixed-use, prestigious redevelopment projects have been proposed by the private sector. Haydarpaşa, Galata Port and Dubai Towers projects can be given as examples for these implementations. Some of the urban renewal practices today are considered to be due to commercial developments in central areas, where the private sector has a high demand, and of housing projects that target the high-income group (BIB, Urbanization Forum, 2009).

4 "FLEXIBILITY" IN THE LEGISLATION ON URBAN RENEWAL

The concept of planning has changed through the impact of transformations and dynamics created socially, economically and politically, on a national and international level. Also, decision-making systems are affected by macro-level structural changes, such as globalisation and neoliberal policies (Munoz Gielen & Tasan-Kok, 2010). The discussions between planning systems are about the dilemma of flexibility versus certainty. In the planning literature, there is a reoccurring pair between the concepts of regulatory planning and strategic planning (Rivolin, 2008). Faludi (1987, p. 260), on flexibility, states that "Flexibility helps to achieve as much certainty as possible in a world." Moreover, the regulatory planning system has shown a move away from certainty towards flexibility. At the same time, the developments regarding sustainability and economic growth have led to rigid, inflexible discretionary planning systems that fail to realise the strategic policy vision (Steele & Rumig, 2012). In a comparative study, the European Commission found a two-way trend in planning practices: countries with regulatory planning systems actually tend to be flexible. On the other hand, countries with strategic planning systems are seeking greater certainty (European Commission, 1997). In fact, many planning systems show a combination of the features of regulatory and strategic planning systems. This two-way trend suggests that the ideal planning system is somewhere in between deterministic and flexible (Steele and Rumig, 2012).

Over the past 30 years, more flexibility and less rigid rules have become a common trend in planning practices (Munoz Gielen & Tasan-Kok, 2010). In cities that have a planning system based on rigid rules, planning seems to be challenged in developing a creative approach that will balance the needs of the market with the public interest given the new developments. Instead, it appears that there is a corrective-regulatory trend to approve new developments within the rules and constraints of the existing system. Within this framework, local governments have made efforts to revise existing plans by evaluating individual requests rather than developing strategies for new developments in the city as a whole (Tasan-Kok, 2006).

Generally speaking, flexibility has developed both as a reason and a consequence of the legal change in the political, institutional-administrative, and plan-making processes. Nevertheless, this has become more evident when local governments turned towards a more entrepreneurial and participatory approach. Inclusion of the partnership between the public and the private sector at each stage of the supply and development of services on the urban land to the processes of plan making and implementation has affected the concept of flexibility. In this respect, factors such as the balance between neo-liberal policies and public and private sector actors in urban planning, countries' unique planning approaches, economic processes, financial strength of the public sector and the investment demands of the private sector affect the tendency towards the concept of flexibility (Özkan, 2010).

A flexible system also comes forward in terms of urban renewal practices. Flexibility in urban renewal practices occurs in two different ways.

First, urban renewal practices are excluded from the regulatory planning system due to the project-led approach instead of a plan-led approach. Urban renewal practices since 2004 are applied with special purposed laws. These special purposed laws bypass the hierarchy that exists within the regulatory planning system. Thus, development rights, which are prepared in accordance with the regulatory planning system, expire once declared to be in an urban renewal area. Urban renewal practices are a tool of intervention that affects directly property rights. The 35th item of the Turkish Constitution states the entitlement to property rights by persons and that these rights cannot be limited except for public benefit. Although the right to property is protected by the Constitution, establishment of healthy living spaces is enabled by the renewal projects that aim to restore 'derelict' and 'obsolescent' areas economically, socially, physically and environmentally in the long term. From this point of view, the right to property, which is protected by law and can only be restricted for the public welfare, is interfering with the urban renewal projects (Tarakci and Turk, 2015). For this reason, the concept of "property rights" has been key since the beginning of urban renewal projects and determines the way in which urban renewal projects are managed through categorising its residents. Property rights are a concept based entirely on the document of property and defines the extent to which the inhabitants are involved in the projects. Since Turkey's urbanisation policies depend on day-to-day politics, the periods during which the property documents were received have resulted in the formation of various types of properties even in the same neighbourhood. Urban renewal practices are constructed on a system based on the legal status of property (Şen & Turkmen, 2014), such as holders of land allocation certificates, holders of land titles and those without any certification. The land allocation certificates distributed in the 1980s with the amnesty law allocate the right for actual utilisation to gecekondü owners. Thus, the owners of the gecekondus have gained some legal rights. This confusion of property consequently creates profound distinctions between those who have land allocation certificates and land registration (title) documents, and those with no documentation. Those who have legal property are equipped with the power to refuse the offers of municipalities. On the contrary, those who have no documents are more willing to participate in the projects by accepting offers in negotiations (Kuyucu & Ünsal, 2010). Moreover, changes occur in the structure of property and actual situations arise due to numerous unlicensed constructions (Göksu, 2006). The existence of different property structure gives the power of discretion to authorities on both important issues such as valuation and expropriation. This situation enables a great deal of flexibility in urban renewal practices.

Second, urban renewal legislation gives discretionary power to both central governments and local administrations on various issues, such as determination of the renewal area or completion of the implementation, unlike the legal instruments of the regulatory planning system. The main actors of the urban renewal implementations are central and local governments. TOKİ and the Ministry of Environment and Urbanization are the most important actors for urban renewal in terms of central governments. In 2004, TOKİ received significant authorisation in urban renewal areas with Law No. 5162. Relocation of the low-income groups both living in gecekondü areas and collapsing city centres to remote areas by TOKİ has become one of the staple policies during this period. Finally, the Ministry of Environment and Urbanization has become the main actor of urban renewal projects with Law No. 6306 since 2012. The ministry takes the authorisation for the determination of urban renewal areas, making and approving plans regarding these areas and certifying the constructions to be built on these areas. In short, the Ministry is the sole authority in the implementation of an urban renewal project from the beginning to the end (Gür, Türk, 2014). For example, the risk of earthquake is the most emphasised rationale for urban renewal in Turkey. The JICA report regarding the risk of earthquake (IBB-JICA, 2002) stated that there were more than 400 districts that required large-scale redevelopment or strengthening. The Istanbul Earthquake Master Plan (METU, ITU, BÜ, YTÜ and IBB, 2003) has further improved this analysis. However, Tarakci and Türk (2015) revealed in their study conducted throughout Istanbul that the urban renewal areas declared by the Ministry were not identified in light of the results of the JICA Report and the Istanbul Earthquake Master Plan, but instead based mainly on the housing market. This situation was enabled by the power of discretion given to authorities by the urban renewal legislations. From the point of view of the local administrations, it is stated that the contribution of the public sector to the partnership is the planning of land use and supply of land, municipal services and infrastructure services, and most importantly, establishing and sustaining the communication between the public and the private sector (Özden, 2008). With the introduction of the recent legal instruments, the authority of the central government has increased, while the role of local administrations has decreased regarding urban renewal. This situation demonstrates that discretionary powers are mostly held by the central government.

The above-noted situation clarifies that the central and local government units have played important roles in urban renewal practices. These roles have been shaped by the special legal resources listed below, targeting urban renewal that have gone in effect since the beginning of the 2000s:

- North Ankara Entrance Urban Transformation Project Law No. 5104, dated 2004
- Law on Protection and Usage of Historical and Cultural Immovable Assets by Renewal Law No. 5366, dated 2005
- Municipalities Law No. 5393 Item 73, dated 2005 and Amendment Law on Municipalities Law No. 5998, dated 2010 acting on the aforementioned item.
- Transformation Law for Areas at Risk of Natural Disaster Law No. 6306, dated 2012

The common point of the aforementioned legal arrangements is that they redefine planning as a structure that is flexible and that regulates spatial development taking into account market dynamics, instead of an obstacle that impedes project implementation. In this respect, the flexibilities for urban renewal projects by these laws are explained in detail below.

4.1 FLEXIBILITIES THROUGH THE NORTH ANKARA ENTRANCE URBAN TRANSFORMATION LAW NO. 5104

The North Ankara Entrance Urban Transformation Law that came into effect in 2004 aims to restore the spatial structure of the implementation areas of the North Ankara Entrance Urban Transformation Project, improve the appearance of the environment, and provide a healthier residential layout to ultimately increase the standard of living.

The key aspect of the North Ankara Entrance Urban Transformation Project is its aim to create an identity for the area around the protocol road and northern peripheral areas that suits the image of the capital city (Kütük İnce, 2006). The project has a total area of 1580 hectares and has a projected population of 70,000 people. The project is implemented in stages, and the first stage covers an area of 400 hectares. Within the first stage, there are 18,000 housing units, 47 hectares of special recreation area, 2 hotels and congress centres, 18 hectares of pond area, a total of 3 km-long roads, tunnels and viaducts (www.toki.gov.tr). The project is carried out through a public-private sector partnership. A company named TOBAS and the Metropolitan Municipality are the main actors in the project. The financing of the project is mainly through the cooperation between the private sector and the local administration (Kütük İnce, 2006).

With the law, hierarchy and authority in Turkey's planning system have been intervened by allocating the authorisation of making plans to the municipality. Moreover, flexibility has been ensured by granting the power of discretion to the municipality about whether the current plans would be continued or new plans be developed. According to this law, old development rights will no longer be valid and new development rights will be determined by the local spatial plan.

According to this law, the project is implemented within the framework of the agreements made between the property owners and title holders. In cases where no agreement can be reached, real estate properties owned by land owners can be expropriated by the municipality.

In addition, owners of uncertified constructions and gecekondus who do not have a land allocation certificate but who certify that it was made before 1 January 2000 can also be entitled to the right of property. The title holder whose land allocation certificate states an area of 400 square metres can take a residence whose size is determined by the city council. The owners of the property with fewer than 400 m² in the land allocation certificate are charged with the housing contract.

The North Ankara Entrance Urban Transformation Project is developed in an effort to satisfy the land owners instead of owners of the gecekondus. The approach for renewal suggests getting rid of the gecekondus in the area completely and building common spaces and high-rise buildings (Kütük İnce, 2006). Moreover, the city council holds the authority of the distributions at the end of the project and there are no objective criteria for distributions, as it is based on agreements. That is, the city council has been authorised to determine the qualifications of houses and workplaces that will be given to real estate owners in accordance with the land amounts, the size that is required for property right ownership and the qualifications of the houses that will be given to owners of the gecekondus with land allocation certificates.

However, the criteria for application of these acts are not explained by the law or its regulations. At this point, flexibility in the distribution of ownership at the end of the project has been enabled by allocating a great deal of discretionary power to the municipalities.

4.2 FLEXIBILITIES INTRODUCED BY LAW ON PROTECTION AND USAGE OF HISTORICAL AND CULTURAL IMMOVABLE ASSETS BY RENEWAL NO. 5366

Regarding the areas declared as protected areas in 2005 and the renewals to be made in these areas, the Law on Protection and Usage of Historical and Cultural Immovable Assets by Renewal No. 5366 has gone into effect as an important tool for carrying out urban renewal implementations.

It is a well-known fact that 'derelict' and 'obsolescent' areas in the historic parts of the city host the poorest groups. These areas have been abandoned by upper income groups and have become a shelter for the poor. These regions provide easy access to workplaces because of their central location, while offering cheap accommodation facilities. After the 1980s in Turkey, these regions have drawn investors' attention due to the potential of rents and have become the most important targets of transformation and renewal projects with the support of local governments (Türkün & Sarıoğlu, 2014).

By the law, municipalities are given broad authority with regards to the establishment of renewal project zones, preparation of projects and implementation of these projects. The renewal zones are identified by the absolute majority vote of the total number of members of the municipal general assembly in special provincial administrations and of the city council in cities whose decisions (and in the case of metropolitan cities, upon the approval of the decisions of the district city councils by the metropolitan city council) are then presented to the cabinet by a proposal from the Ministry of Environment and Urbanization. Even though the local administrations are the first authority for identifying the area, it may be implemented with the decision of the central administration. Here, the broadened authority given to local governments with regards to urban regulations is thus indirectly under the control of the central administration.

For example, Tarlabaşı in Beyoğlu, Istanbul was declared a "Renewal Zone" with the decision of the cabinet on February 20, 2006, with a similar rationale to those in other parts of the world. Twenty-one city blocks were declared urban renewal zones with this decision. In the first stage, the implementation procedures and principles of the Tarlabaşı Stage One Renewal Project, consisting of only nine city blocks, with the decision of the Beyoğlu City Council on November 10, 2006 (Türkün & Sarıoğlu, 2014). The Tarlabaşı project is also part of the protected area of Beyoğlu. For this reason, after being declared a renewal zone based on the law, "renewal protection" was implemented in parts of the area, while other parts were under "conservation only", in accordance with the Law on the Conservation of Cultural and Natural Assets.

Nevertheless, the renewal zone, prepared for approval by the cabinet, which is the highest policy maker of the government, is grounds for debate on the basis of urban rights, urban governance, and that its boundaries are based on observational and subjective data (Dinçer, 2010). The fact that the declaration of the urban renewal zone is not based on scientific criteria is one of the problems brought about by the law (Özden, 2008). Since the criteria for determining the area are not identified in the law and its regulations, local governments have been given the power of discretion in this respect and flexibility is provided.

In a process starting for the first time with the declaration of renewal zones in the Beyoğlu District on February 20, 2006 with reference to the law in question, five more renewal zones were identified within the same year. The renewal zones in the Beyoğlu District vary greatly in size and location. Those in Fatih and Eminönü, on the other hand, are located near the coasts and city walls, with the historical heritage site of Süleymaniye and Kapalıçarşı sections being the biggest renewal zones in the centre (Dinçer, 2010).

One of the most important aspects of this law is the common emphasis on "project" rather than on "planning". This is to such a degree that the law in question mentions simply "renewal projects", without reference to local spatial plans, drawing up a plan, and approval, or in short, with no information on anything with regards to planning (Özden, 2008). The law in question makes no mention of a relation between the projects and the local spatial plans in use for the zone the projects refer to. As things stand, it is understood that the urban renewal projects will be implemented individually in the determined protected areas and that areas of reinforcement such as housing, commercial etc. will be formed in accordance with

the principles stated in the zoning plan (Üstün, 2014). Various decisions made by the state council state clearly that for the implementation of local spatial plans, it is an absolute requirement to include a local spatial plan and that implementations in violation of the purposes prescribed by the current local spatial plans are unlawful (Üstün, 2014). This shows that the law offers in general an approach far from an integrated approach of planning, in refusal to be a natural part of the planning process, and promoting fragmented/small scale solutions (Özden, 2008).

Even though the regulations in the law do not specify a plan-project relation, it specifically emphasises the concept of a preliminary project. The regulation of the law entitles the approval of the preliminary project following the approval of the renewal project. Furthermore, it rules that renewal implementation projects should be prepared on the basis of renewal preliminary projects. However, with regards to principles of urban planning, it is unacceptable that a renewal zone declared in a protected area is described only in terms of architectural preliminary projects and implementation projects. This is because in renewal zones that are restricted to regulating the physical space, detracted from the planning discipline, not only are historical and cultural heritage values threatened but also implementations emerge which cause the deterioration of the socio-economic equilibrium (Dinçer, 2010a). Current practices indicate that the protection-renewal relationship in conservation areas is not properly constructed in some places, and that renewal applications do not take the original texture of the area sufficiently into consideration (BIB, Urbanization Forum, 2009). For instance, in Neslişah and Hatice Sultan neighbourhoods (Sulukule), an area of about 9 hectares was declared a renewal zone in 2005. By law, the project was carried out jointly, in accordance with a protocol signed by the Fatih Municipality, the Istanbul Metropolitan City, and TOKİ. Even though the said project was cancelled on the basis that it was "not in line with urban development principles and not in public interest", it was completed by the time the decision was approved (Üstün, 2014).

Within the scope of this law, for evacuating and demolishing the structures within renewal zones during the implementation process of the projects, the primary method is agreement. Where no agreement can be reached, the method of expropriation for the estates in the possession of juristic persons is used. However, in order to expropriate, a public interest ruling is required. Still, in areas declared as renewal zones, the matter of possession casts a much broader impact than simple expropriation. Following the declaration of a renewal zone, the sales and leasing values of the estates reach a much different price level than the free market rates (Dinçer, 2010a). For example, it is known that the price per square metre for the 360 Ofis Project built and sold after the Tarlabası Urban Renewal reached \$7,500. All five-storeys of the registered building right next to this project, on the other hand, was expropriated for 760,000 Turkish liras (\$420,000). This means that this person whose building was expropriated will be unable to buy even a 100m² office from this project (Türkün & Sarıoğlu, 2014).

On the other hand, the regulation of the law in question states that if it turns out that the usual expropriation process leads to delays in the implementation of the project, urgent expropriation may be employed following the provisions of Article 27 of Expropriation Law No. 2942, consulted when under extraordinary circumstances; in addition to the criteria with which to determine possible delays not having been explained. This way, administrations are provided with a certain flexibility to tend towards urgent expropriation.

When the regulations in the law are considered as a whole, an approach emerges that regards the renewal zone as an entire project area. At the same time, it is stated that the renewal project can be made in the parcels, provided that the authorised person considers it appropriate and the integrity of the project has not deteriorated. However, the expenditure of this renewal project or its permit processes is not defined. Moreover, it is also ruled that individual projects that are not completed on time may be completed or expropriated by the administration in order to preserve the integrity of the project. The administration is provided with a discretionary power with regards to this choice. When considered in terms of the right to property, this situation restricts the individuals' right to disposition of their properties in their own discretion and allows the right to an individual project only with approval from the administration (Üstün, 2014).

Likewise, the law in question suggests that in addition to municipalities and public or private institutions, implementations of renewal projects may be carried out by a partnership with TOKİ. Nevertheless, it is stated that all inspections and supervisions during the implementation would be performed by the municipality. Since there are no detailed instructions in the law and regulations that refer to which principles this relation is based on, a project partnership will be formed, a certain flexibility that may allow

differences in individual implementations. That being said, it encourages implementations in renewal zones via exemption from all kinds of taxes, levies, duties and fees.

4.3 FLEXIBILITY FROM AMENDMENTS TO MUNICIPALITY LAW NO. 5393 AND MUNICIPALITY LAW NO. 5998

Municipality Law No. 5393, which regulates the duties, powers and responsibilities of city municipalities as well as their working procedures and principles in 2005, was one of the studies carried out within the scope of the Local Administration Reform studies. Article 73 of the law defined the roles and responsibilities of cities with regard to urban renewal, and cities started acting as the local authority in urban renewal. When Municipality Law No. 1580 and Reconstruction Law No. 3194, which were in force before Municipality Law No. 5393, are inspected, it is observed that the matter of implementing renewal projects is not defined in clear terms and that the cities are not authorised for renewal projects. It should also be noted that before Municipality Law No. 5393, there were significant restrictions with regard to intervention by cities in earthquake risk zones (Tarakçı and Türk, 2015).

In 2010, Amendment to the Municipality Law No. 5998 went into effect for amendments to Article 73. With this law, the authority of the metropolitan municipalities has been extended. The law in question rules that the area to be declared an urban renewal zone should be no smaller than 5 and no bigger than 500 hectares and that more than one place related to the project area may be declared one urban renewal zone, provided that the total is no less than 5 hectares. On the other hand, there are no parameters for determining the size of the area. For example, in the Maltepe district of Istanbul, a 93-hectare area has been declared Başibüyük Neighbourhood Urban Renewal Zone. The initial work on urban renewal in the area started with the "Protocol Regarding the Urban Renewal Project in Maltepe, Istanbul" signed by TOKİ, the Istanbul Metropolitan Municipality, and the Maltepe Municipality on February 24, 2006 (Şen & Türkmen, 2014). A total of six 14-storey blocks were built in this area by TOKİ in the first stage and the process is ongoing. The most recent development is the approval of the land use plan for the area by the Istanbul Metropolitan City Council on March 18, 2017. This law assigns to metropolitan municipalities the authority to declare urban renewal zones within metropolitan borders, to make plans of any scale and the implementation of these plans, to grant construction and occupancy permits and undertake all sorts of development processes as such for the declared zone, and to exercise authorities given to cities with Reconstruction Law No. 3194. With this law, the authority of district municipalities in urban renewal zones is reduced and almost all of the authority is transferred to the metropolitan municipalities. For example, 66% of the urban renewal zones in Ankara belong to the Ankara Metropolitan Municipality due to this law (Bektaş, 2014). This provides the cities with a broad discretionary power for urban renewal practices, which completely disregards the integrity brought about by the Reconstruction Law. The decision of the Supreme Court dated October 18, 2012 and numbered E:2010/82 and K:2012/159 states that "It is a requirement that the power of discretion in the implementations of urban renewal and development projects should be given to cities through the rules in question. As cities are areas of constant change and improvement, which leads to difficulties in predetermining the ever-changing needs of a city, it is not possible for the law to prescribe in detail how these needs might be satisfied," acknowledging the existence and necessity of the power of discretion.

Bektaş (2014) reveals that following Municipality Law No. 5393 in 2005 and Law No. 5998 in 2010, declarations of urban renewal zones gathered momentum and that when the years of declaration in Ankara are examined, a 26% section was concentrated in the year 2005. At the same time, an 80,000-hectare residential area of Ankara includes about 45% urban renewal zones, which further proves the extent of these zones. In addition to urban renewal implementations being a planning option, declarations of urban renewal zones cover nearly half the city's residential area (Bektaş, 2014). This shows that in a city as important as Ankara, half of the city is under a regulatory planning system whereas the other half is under a discretionary planning system. However, this distinction is not in two different areas, but the renewal areas are located in different parts of the city. For this reason, regulatory planning dominated by 50% of the city is ineffective with fragmented interventions.

4.4 LEGISLATIVE FLEXIBILITY ABOUT THE TRANSFORMATION LAW FOR AREAS AT RISK OF NATURAL DISASTER LAW NO. 6306

In 2012, the Transformation Law for Areas at Risk of Natural Disaster (Law No. 6306) entered into force as an important and controversial legal tool for urban renewal. The main purpose of the law is stated as identifying areas of disaster risk and structures outside of these areas, and thus improving and/or disposing of them in order to create healthy and safe living environments in accordance with the rules of science and art, as well as with common standards in those fields and lands where risky structures are located. The ultimate goal stated is to ensure that no further casualties occur in the face of any disaster, and to transform cities into healthy and safe living environments (www.csb.gov.tr).

The purpose of this law is to identify risky areas for disaster, as well as other urban and rural lands in which risky structures outside these areas are located, and to specify the procedures and principles of improvement, liquidation, and renewal. Risky areas and risky structures, which constitute the basis of the law, are defined in Article 2. According to this definition, risky areas are those that bear the risk of causing loss of life and property due to the ground structure or the construction on the ground. These areas are determined by the Ministry or the Administration and later confirmed by the cabinet upon the proposal of the Ministry. Risky structure refers to a structure, within or outside the risk area, that has completed its economic life or is determined to bear the risk of collapse or serious damage on the basis of scientific and technical evidence.

With this law, upon identification of "risky areas" and "risky structures," a generalised authorisation is given to the Ministry of Environment and Urbanization for the "improvement", "liquidation" and "renewal" of structures existing in all risky areas for disaster across the country. It has been stipulated that municipalities and special provincial administrations or TOKI can only utilise these areas and structures upon assignment by the Ministry.

Here, the most fundamental change introduced by Law No. 6306 is the authorisation of the central government in the process, while in all laws enacted since 2004 local administrations had been granted discretionary powers and the flexibility in the planning system had been regulated for local administrations. Especially considering the broad framework of the definitions for risky structures, risky areas and reserve spaces, the greatest flexibility is provided in the authorisation for planning; and thus, the Ministry of Environment and Urbanization is granted the flexibility to conduct any type and scale of plans as preferred.

Article 57 of the Constitution imposes important duties on the state in terms of housing legislation. The state is obligated to take necessary precautions for the residence of its citizens in healthy housing. The measures taken under Law No. 6306 can be considered as measures to meet the need for healthy housing (Simsek, 2015). Based on this reason, Law No. 6306 grants administrations a very broad authority and with this authority, flexibility is provided both in planning and implementation. This flexibility is especially in terms of the central government. In addition, construction companies seem to have a significant say in these processes. However, there would be much benefit in including the municipalities in the implementation. The municipalities' coordination of relations between the construction companies and their owners can facilitate implementation. The law prevents this function of the local administrations by giving more authority to the Ministry (Üstün, 2014).

The first of the flexibilities in the law relates to the identification of risky areas, reserve spaces and risky structures, which forms the basis of the law. Thus, according to Law No. 6306, the Ministry of Environment and Urbanization, municipalities, metropolitan municipalities and special provincial administrations have been authorised to identify the urban renewal areas. A risky structure can be identified on the basis of certain concrete criteria, despite being impossible to be fully defined. However, the criteria for identifying risky areas have not been determined in concrete terms, but are left to the discretion of the administration. For example, the Derbent district (Şen & Öktem Ünsal, 2014), which is located next to the Maslak-Büyükdere Hill and has the highest land prices in Istanbul, 92% of which is composed of gecekondu, is worthy of attention for its unresolved urban renewal issues especially since the beginning of the 2000s. As a solution, the area was declared a "risky area" on 03.01.2013 by the decision of the Council of Ministers. This verdict for a risky area was annulled as a result of the lawsuit filed by the residents of the neighbourhood, in 2014, by the 13th division of the state council on the grounds that the area was declared risky based on "observational and general information, not a technical report." However, with another decision of the Council of Ministers on 03.01.2017, the area was once more announced as risky.

Likewise, the characteristics of the reserve space, whether it is risky or not, were not clearly defined in the law, and the appointment of reserve spaces was left to the discretion of the administration. The Ministry of Environment and Urban Planning has identified 8 reserve areas of 34,704 m² in the European side of Istanbul.

The second flexibility granted by this law is the restriction of use. The Ministry may request from the relevant authorities not to provide electricity, water and gas to the structures in risky areas or to risky structures. This restriction of use was not found contrary to the Constitution. According to the decision of the Constitutional Court dated 27.02.2014, numbered E: 2012/87 K: 2014/41, it is considered reasonable action to stop providing electricity, water and gas services for residents who refuse to evacuate the buildings that are at the stages of "evacuation and destruction," and thus force their evacuation. However, withholding the services of electricity, water and gas in accordance with this regulation is a threat to an individual's right to health. This may lead to the abnegation of a public benefit (health) which is superior in terms of ensuring the continuity of the project. On the other hand, the above-noted regulations are not compatible with the principle of uninterrupted provision of public services or the social state principle (Üstün, 2014).

The third flexibility presented by the law relates to the stakeholders of the risky areas, real estate where the risky structures are located and reserve spaces. The law states that decisions can be made by at least two thirds of the stakeholders after liquidation in these risky areas, on the real estate where the risky structures are located, and at the reserve spaces. The land shares of the stakeholders not participating in the decision making are then sold to the rest of the stakeholders by auction based on their market value. In cases where sales are not made to the stakeholders, it is purchased by the Ministry for its market value. The ratio of 2/3 stipulated by law has been criticised for not being based on objective data and life experiences (Özsunay, 2015). However, the explanation has been that this regulation was made out of the ordinary with a broader perspective on the law, due to an intention to accelerate the procedures. However, the most fundamental issue here is the obligation to take the shares of the stakeholders who do not participate in the majority. This is considered a new situation where the consequences of non-participation are outlined as exclusion from that community (Kürşat, 2013).

The fourth power granted by this law that provides flexibility concerns the expropriation of private property (land) on which a structure has been demolished. It is stipulated by law that such land can be urgently expropriated by the Ministry, TOKİ or the Administration, if at least two thirds of the property owners cannot reach an agreement. Urgent expropriation in such cases has been included in the decision of the Constitutional Court dated 27.02.2014 numbered E: 2012/87 K: 2014/41. It is stated in the court decision that the expropriation by the relevant public institutions and organisations of real estate at disaster risk not utilised by their owners at their own will, as part of the reorganisation of the real estate's residential status, is of public benefit.

The fifth of the flexibilities provided by the law is that persons for whom rent or temporary work or housing allowance can be made are: owners and tenants of the structures evicted by agreement, or workplace owners. It is unclear whether it is possible to grant discretionary power to the related institutions and organisations within the boundaries specified by the rule in the "can be made" statement (Simsek, 2015).

5 GENERAL EVALUATION AND CONCLUSION

While Turkey has a plan-led regulatory planning system (Özkan & Turk, 2016), a project-led system is adopted with laws relating to urban renewal. In addition, a discretionary planning approach becomes evident in the laws, with discretionary powers given to the central government but also to the local administrations. The purpose of this report is to analyse the flexibility created by the legal regulations on urban renewal and its consequences based on actual urban regeneration practices. As summarised in the table above, the flexibility resulting from the legal means of urban renewal has increased over time and has shifted from local administrations to the central government. Throughout the process, discretionary powers have been increased with every law. However, negotiations, which are the basis for discretionary planning systems, have never been defined in the law. Although all laws presume that "agreement forms the basis", the right to expropriation and even urgent expropriation creates pressure on property owners. Negotiations for agreements in cases where there are no equitable and equal rights do not have the attributes of an actual negotiation.

The scale and content of the flexibility that emerged in Turkey due to the legal means related to urban renewal, which has emerged since 2004 up to the present day, have changed over time. When this situation is considered in terms of planning systems, we find that while the planning system was initially a regulatory system instead of a discretionary one, the laws for urban renewal areas have developed a discretionary system. A project-led approach has been adopted in urban renewal practices, moving away from the previously more plan-led system. Especially the concept of a preliminary project mentioned in the law creates loopholes in the planning system. That is to say, a phrase stating that a preliminary project will be implemented in the designated area ensures that there are no limitations on structure heights and population densities and enables the developer to identify design criteria to a great extent. Thus, municipal planning units cannot interfere with building heights, dimensions and shapes of structures, floor areas, architectural features, residential typologies, etc., based on plan decisions. In actuality, these specifications are made very strictly in the traditional planning approach in Turkey. The freedom granted to the developer by the planning unit, with no guidance or restrictions imposed, causes the implemented projects to develop in an incompatible fashion to the texture of the surrounding residential areas (Özkan & Türk, 2016). Furthermore, loopholes are created through urban renewal plans in the planning approach of laws referring to the regulatory planning system. This is because these plans have been made in a fragmented fashion. Moreover, authorising only one institution throughout the process, starting with planning of any type and scale until the end of the building license procedures causes a lack of supervision.

On the other hand, starting with the identification of the area to undergo urban renewal, a significant amount of discretionary power is given to the administrations in the restriction of use and the identification of property right ownership. The process involves granting discretionary power first to the municipalities, which are then transferred to metropolitan municipalities, and finally to the central government. The latest legal regulations in particular seem to transfer the powers held by local administrations to the central government, causing almost all of the urban renewal areas to be managed, identified and planned by the central government. For example, the first findings of research done in Ankara reveal that 94% of risky areas fall within regions previously declared as urban renewal areas according to Article 73 of Municipal Law No. 5393 (Bektaş, 2014). This demonstrates that the wide-reaching authority assumed by the central government has been used without changing the quality or the justification of the urban renewal areas. The latest legal regulations in particular seem to transfer the powers held by local administrations to the central government, causing almost all of the urban renewal areas to be managed, identified and planned by the central government. As deduced from the Constitutional Court's decision published on 23rd of July 2012 in the Official Gazette, both the aforementioned discretionary power and the project-led approach to the planning system are found reasonable.

It appears that all of the flexibility gained through both a project-led approach and discretionary power benefits the private sector. Most of the flexibility interventions seem to increase the profit of the private sector, accelerate the process, and provide the land. On the other hand, it is evident that as a result of such flexibilities caused by law, the leaseholders as well as property owners especially in gecekondu areas and historic city centres suffer financial as well as psychological damage.

Another important issue is gentrification, which is the most discussed issue for urban renewal practices in Istanbul. The most fundamental problem of urban renewal areas such as Tarlabaşı, Sulukule, and Ayazma has been the gentrification in these areas. Studies show that gentrification is not a problem caused by local governments, but rather a consequence of greater powers to restructure and regulate urban production, and thus the displacement of the urban population (Uzun, 2015). In urban renewal practices, the newly created social and technical infrastructures cause the unit prices of housing to increase, and the actual property owners cannot live in the area; the projects are conducted according to the demands of national and international capital, and as a result, these areas are gentrified. In the urban renewal applications on a single building scale, however, the property owners become residents along with other people in the same income group preferring to reside in the area, and thus, there is less gentrification (Gür & Türk, 2014).

Differences in urban problems require different scenarios and different methods to be applied in urban renewal applications. For this reason, it is a good measure to create the appropriate arrangements for different cities and situations. However, general arrangements are necessary in terms of the procedures, duration, limitations on individuals, and the relationship of the plans and projects with plans on higher levels. Otherwise, the administration may have an unlimited discretionary power, as well as various

solutions for similar situations based on different laws, and the constitutional principle of equality will suffer (Üstün, 2014).

1 INTRODUCTION

Traditional planning relies on a cycle of plan formulation/implementation/revision to keep planning instruments up-to-date and more or less effective in face of evolving planning contexts. The inability of static physical plans to respond to changes in the planning context (such as shifts in demographic trends, varying demands for certain land-uses, requests for new facilities or infrastructures, or the obsolescence of others) has been the subject of a long line of inquiry in planning theory. The frequent revision of a plan may help in increasing the plan's adherence to the changing reality, but in essence, a plan becomes increasingly obsolete from the moment it is crystalized in a fixed regulation and maps. As a response, several innovations have been introduced to the planning practice so as to allow the plan to remain as suited as possible to the evolving planning context, such as scenario planning or flexible planning (Friedman 2007).

Climate change and, more specifically, Sea-Level Rise (SLR), introduces a new dimension of variability which is yet to be adequately addressed by planning theory and, especially, practice. Our point-of-view is based on the idea that SLR is instilling the planning setting or context, with an uncontrollable (at the local/regional scale) change to the planning setting, and one that cannot be planned- or zoned-out.

The natural variability and uncertainty over the evolution of a given area are arguably the principal reason planning is required in the first place, so some degree of uncertainty over the outcome of a given planning cycle has always been a major preoccupation of the planning process. Nevertheless, we have developed solutions and means of averting or promoting certain outcomes (by way of zoning, by-laws, incentives, taxes and building restrictions). These solutions have tended to require that the outcomes be reasonably predicted from the onset, so that the planning solutions may be adopted in order to prevent them or promote them (Hopkins, 2001).

For most urban transformations, these outcomes are the result of purely anthropogenic actions, whether they be a single major decision from a public entity (such as the relocation of a container terminal) or the consequence of a multitude of individual decisions (the gentrification of a given neighborhood). Being the consequence of human action, most of these alterations can be planned for and, more importantly, controlled through the introduction of mechanisms encouraging or discouraging the said changes.

This is not the case with SLR. It cannot be controlled as a phenomenon, as it will occur regardless of any decisions one may introduce at the local level. And it is an undesirable change for most urban settings, as infrastructure and urban development were not designed to face it. But, unlike most other undesirable changes to the planning context, it cannot be "planned-out". It is unreasonable to ignore the effects SLR will have over shorelines and safety ratings of coastal protection infrastructure, and yet most planning

instruments are still not equipped to address the specific challenges posed by this threat, as they are unequipped to deal effectively with high levels of uncertainty.

What we propose is a model of agile/pro-active planning that addresses precisely the issue of dealing with uncertainty. We advocate that this model is especially suited to address planning with SLR: whereas SLR cannot be “planned-out”, it can certainly be “planned-for”, by adjusting the planning mechanisms to allow speedy and effective adjustment of its actions and respective tasks as new knowledge, including assessment of impacts or innovative adaptive solutions, become available. Our model allows an expedite adjustment of the planning process so that the dynamic nature of the changes being experienced by the planning context itself may be adequately addressed by the planning framework, and subsequently planned for.

Our main contention is that a static (or rather, “episodic”) plan as the result of arbitrary planning cycles is no longer an adequate response to an ever-changing, and highly unpredictable, planning context. If the complexity of the urban phenomena and ecological processes were already compelling arguments for introducing flexible and adaptive planning frameworks, we trust the intrinsic variability introduced onto the system itself by climate change will make the adoption of adaptive planning frameworks, more than a possibility, rather a necessity.

The difficulty in adapting environmental planning frameworks to these new challenges arises not only from the unique nature of sea-level rise, but equally from the frequent unwillingness of policy-makers to adopt new solutions, especially when these will have potential impacts over the existing status quo. Depending on the geographical context, these will range from the rejection of expanded public budgets or mandates for environmental planning, resistance to all measures that may have impact over existing property rights, the outright disavowal of sea-level rise as a legitimate issue, the inflexible defense of existing jurisdictions and mandates, or resistance to the introduction of planning mechanisms that would entail the sharing of decision-making power.

2 PLANNING WITH UNCERTAINTY

The inability of traditional planning to adequately respond to highly dynamic and uncertain planning contexts has led to the identification of a necessity to instill the planning practice with greater flexibility and a capacity to adjust to a shifting planning context. While revision can help realign the plan with ongoing strategies, in essence, a plan becomes increasingly obsolete from the moment it is crystalized in a fixed regulation and maps.

Planning has, therefore, typically depended on the certainty of outcomes in order to fully succeed: the “good” outcome of the planning practice is that, at the end of the plan’s implementation, reality will “adhere” as closely as possible to the planned outcome. Also, it typically relies on a reactive stance of revision based on the shortcomings identified ex post as a result of an earlier plan’s implementation. In contexts of high uncertainty, this often means the plan is permanently attempting to “catch up” with the planning context.

2.1 UNCERTAINTY IN PLANNING

In contexts of high uncertainty, though, the expectation of entirely predictable outcomes is often questionable. It is exactly in settings where levels of uncertainty are higher that we tend to speak of “failed planning”, or “unruly” or “uncontrolled” development.

Urban planners tend to underestimate the importance uncertainty plays in the evolution of the planning context (Christensen, 1999), be it due to the difficulty in isolating and identifying factors of uncertainty or because of the increased levels of complexity added to the planning process by uncertainty.

Unlike other concepts in urban planning, uncertainty has been somewhat difficult to clearly define. We think its useful to draw from a couple of notions: according to Keynes (1937), it is equated to the impossibility of defining the relative probability of a certain outcome being achieved as a consequence of one’s choices; Mack (1971) introduces uncertainty as complementary to knowledge, the gap between what

is known and what needs to be known in making correct decisions; Abbot (2005) is “a perceived lack of knowledge, by an individual or group, that is relevant to the purpose or action being undertaken.”

Some factors commonly identified as having a great influence over the level of uncertainty in the planning process are: i) context; ii) time frame; iii) assumptions; iv) complexity. Besides these factors, uncertainty can also be triggered by events of uncertainty. Simply put, an uncertainty can be triggered by events generated within the planning process itself or by changes to the planning context. Abott (2005) reinforces this notion, distinguishing between process uncertainty (or uncertainty in planning) and context uncertainty (or uncertainty to planning).

2.2 ELEMENTS OF AN AGILE AND PROACTIVE PLANNING FRAMEWORK

As a response to the shortcomings of traditional planning, including its inability to adequately address uncertainty, several solutions have been proposed that allow the plan to remain as suited as possible to an evolving planning context.

Flexible planning proponents (Rosenhead 1980, Friedman 1997, Allen 2003, Desfor and Jorgensen 2004) highlight the benefits of quickly adjusting the solution to suit new challenges or changes to the planning context; Adaptive planning (Cooper et al 1971, Kartez 1987, Lessard 1998, Holling et al 2001, Kato and Ahern 2008, Crawford and Davoudi 2009), which has seen strong support as a necessary adjustment to planning as response to climate change, similarly presupposes that the planning exercise is capable of adjusting to changes in the context without compromising overarching objectives, or that it is capable of reformulating those objectives accordingly in a timely fashion; Collaborative planning (Christensen 1985, Healey 1998, Innes 1999, Camacho 2005, Saavedra and Budd 2009) highlights the importance of stakeholder involvement from the early stages of planning, both as a way of investing different interests in a common goal and by facilitating the incorporation of local or expert knowledge in the formulation stages.

It is clear to us that increasing the robustness/resilience of planning requires a reassessment of some of the pitfalls of traditional planning, namely its inability to readily cope with uncertainty, and that the elements proposed by flexible, adaptive, scenario, and collaborative planning are all valid and useful starting points to generate a comprehensive model that could instill flexibility and agility to the planning practice, while not deviating so far outside the typical legal framework for land-use planning, so as to allow a relatively straight-forward adoption within existing planning limitations.

As a result, we propose an Agile/Pro-Active Planning Framework, that relies on a project management framework capable of incorporating a broadened set of actors/stakeholders, an iterative ongoing reassessment of the plan's tasks and actions according to a continuous monitoring of the performance of key indicators, and thus allow a rapid readjustment of the plan to incorporated the latest knowledge and adjust readily to changes to the planning context.

We highlight ahead some elements that we consider relevant in setting up an agile and proactive planning framework.

2.2.1 PERFORMANCE

The more traditional conformity perspective of plan evaluation/ex post monitoring focuses on the evaluation of the adherence of the plan's results to what was initially planned (intentions, objectives, goals...). The performance perspective, on the other hand, assumes that mere conformity is insufficient to evaluate a plan's success. As uncertainty is an integral part of the planning process, what was planned for from the onset may become inadequate during the plan's implementation. The plan is approached, under the performance perspective, as a framework for decision-making and its evaluation should be based on how (well) it is used, how it influences the decision-making, and also how those decisions affect the outcomes.

2.2.2 EFFICIENCY AND EFFECTIVENESS

The concept of performance, widely used in management, incorporates two essential concepts: that of efficiency and effectiveness. Drucker simplified the distinction between the concepts: “effectiveness is doing the right thing, efficiency is doing the thing right”. Effectiveness (“doing the right thing”) means using the best strategies and related actions to achieve a competitive advantage. In planning, this means achieving the set goals. Efficiency (“doing the thing right”), on the other hand, draws on the balance between outputs and inputs to the system, and is focused on the conclusion of a process resorting to the least amount of resources. While efficiency is entirely focused on the process, effectiveness is concentrated on the achievement of goals/objectives (Sudit 1996).

This raises the question of how to evaluate the plan’s performance and which tools to use in its evaluation.

2.2.3 PERFORMANCE EVALUATION

Performance evaluation is an important element in determining the level of success of a process. According to Neely et al. (1995), performance measurement is the quantification of the efficiency and effectiveness of an action. This narrow definition has been expanded by others, and Gates (1999), Otley (1999) and Ittner et al. (2003) think of performance evaluation as the assessment of the strategic performance that informs the strategies with the greatest potential in achieving the desired outcomes, (re)aligning process management (goal definition, decision-making...) with those objectives.

2.2.4 FLEXIBLE MANAGEMENT

Flexibility in the planning process renders both the plan and the planning process more adaptable and less restrictive, which may be paramount to their ability to react to, or even anticipate, changes to the planning context. According to this perspective, the flexible management of the plan presupposes rendering it with the capacity to resist fluctuations without disintegrating (Ascher 1998) that is, to instill it with the capacity to integrate and resolve uncertain or unpredictable situations, during its implementation stage.

According to Correia (1994) planning should always preserve a strategic stance, meaning that within a stable framework of objectives and guidelines, there should be the capacity to inflect, shift or adjust the implementation of actions and tasks.

As a response to the dynamic nature of planning, the plan should be equipped with management mechanisms capable of rendering flexibility to the plan’s implementation. This dynamic can be related to either time or complexity. The flexibility conferred to the plan will only be successful if the essential element to inform the necessary adjustments –knowledge – is permanently up-to-date and available to planners and decision-makers. Knowledge, here, meaning the information systematically gathered through monitoring and evaluation of the planning procedures.

Howell et al. (2010) propose a project contingency framework (UC-Framework), which identifies three management models/styles: “plan driven”, “problem structuring”, and “agile”. The first model, “plan driven”, is framed within the traditional approach to project management, which suggests a project is composed of a set of activities that require programming and execution, according to a pre-set plan. The main objective is the achieving the goals within the prescribed timing, cost, and scope. It is most effective in low-uncertainty contexts. The second model, “problem structuring” is suited for contexts of high uncertainty, such as exploratory projects. In project management, this is acceptable for risk ventures or innovation, but it may be inadequate to deal with land-use planning contexts, where total failure is not an option. The third model, the “agile” model, from which we will derive some elements of our proposal, is especially adequate in contexts that express one or more of the following elements:

- The objectives of the project may have been ill-defined in the early stages;
- The process is highly iterative, and involves partial execution of targets, followed by a redefinition of these targets based on the feedback from the implementation.

In an ideal scenario, this constant reassessment during implementation would make the model independent from the level of uncertainty, but in actual planning practice, where a comprehensive and robust plan is required, the level of flexibility is necessarily somewhat constrained and does not allow permanent reassessment.

Shenhar (2012) addresses, among others, the issue with how to adapt management in an “agile” framework to a specific context. He links this with the necessity of instilling the strategic aspects of project management with operational concerns during implementation. The author develops the methodology so as to expand the dimensions of success, which include efficiency, but also results/outcomes and preparedness for the future. So as to achieve success in the project, Shenhar and Dvir (2007) advocate that we should accept the reality that virtually all projects go through shifts in their paths, accepting this is a normal situation to be dealt with, rather than an exception. They recommend therefore the adoption of a flexible approach to decision-making support and successive waves of planning, in coping with the idea that not everything can be planned for in advance.

To address unexpected events that result from the interaction between a project and its context, Soderholm (2008) posits that there are 3 important practices that may be adopted during an ongoing project implementation: re-opening, revision, and fine tuning. Re-opening of a project means to trigger the redefinition of activities, timelines and costs, yet maintaining the integrity of the project (same general objectives established from the onset) in spite of significant changes.

One of the recurring ideas in project management is that a project requires “programming”, that is, it is expected that the preparation of the project in its early stages sets up the conditions for it to achieve its goals. Yet, in projects with long timeframes, such as land-use plans, it is virtually unavoidable that there be changes to the activities and resources, resulting from changes to the context. Once the need to alter actions and specific objectives becomes too extensive, a revision might be required. We highlight here that, if one takes for granted that changes to the context will indeed occur, the main factor influencing the continued adequateness of the plan to the context is its ability (or inability) to adjust actions and specific objectives while preserving the main strategy/goals as viable and desirable. The ability to cope with change and still thrive is a possible definition of a resilient plan, which is a major objective of our proposal.

3 A SOLUTION: AGILE AND PRO-ACTIVE PLANNING FRAMEWORK

3.1 WHY GO FOR AN AGILE/PRO-ACTIVE SOLUTION

This alternative planning framework builds on a number of earlier sources on adaptive and flexible planning, and is aimed at greater applicability from a practitioner's perspective. It focuses on the success of the process, and not in achieving a static outcome. It requires a continuous questioning of whether the initial goals are (still) achievable. At any point, the “trajectory” can be adjusted, as long as the adjustment is supported by results of an ongoing performance assessment.

The framework presumes that there is no single, perfect solution to a/the problem, but a number of solutions that can be applied, abandoned or combined throughout the process, as long as they are still beneficial in adjusting the trajectory so as to best achieve the desired outcomes. For this to work, the plan should be seen as a combination of document, process, and a platform facilitating stakeholder interaction.

A first step is to build a roadmap, setting out major goals/objectives that the plan should/must achieve as a measure of success. The outline of this roadmap should be clear, well-structured, simple, and focused on establishing clear measures of performance, rather than static solutions. The process management should be agile/flexible and quick to adapt to changes to the system, or when monitoring identifies a divergence that may compromise the plan's overall success.

As well as a decision-support tool, developed in close interaction with decision-makers and coordinating planning staff, the plan should also include/set out a platform for participation, where frequent meetings between stakeholders (naturally including individual citizens and NGOs), scientists, and planners can inform, help improve, and allow cross-breeding of solutions implemented by multiple actors.

3.2 ELEMENTS OF AN AGILE/PRO-ACTIVE SOLUTION

Our model is based on an iterative interaction between stakeholders and an evolving knowledge base, through which the planning process advances and quickly responds to changes to the planning context by way of an agile management of tasks and actions, through the ongoing performance assessment of state

indicators. It therefore centers on a pro-active stance to quickly address the plan's divergence from the original path, allowing a quick reassessment and incorporation of corrective solutions.

It is comprised of three major elements: a Knowledge structure, where information, expertise and policy are kept permanently updated and available; a Platform promoting formal and informal communication and knowledge exchange among decision-makers, stakeholders, and experts; and the planning Process, which is the “swivel joint” through which the interactions between the Platform and the Knowledge base feed off each other, promoting the early readjustment and evolution of the planning process.

Figure 1 – An Agile/Pro-active Planning Framework

3.2.1 KNOWLEDGE

The element Knowledge consists on a repository of all the permanently updated information, necessary to inform the planning process and its stakeholders. It must be able to respond to the dynamic and solicitations of the planning process.

We perceive this Knowledge element as multi-faceted, and composed of distinct components, namely: database, document, expertise, policies.

Database is the interface over which the contents of all the knowledge components (document, expertise, policies) are stored and accessed. The technology available for data storage and processing has greatly developed in the last few decades, and this resource is yet to be fully explored by planning. Planning Support Systems (PSS) have been affirmed as a possible solution, based typically on web-GIS platforms that allow for a flexible and dynamic knowledge exchange platform. Yet, more traditional historic archives (now mostly digital) storing the full backlog of the process, should not be foregone, as they are essential to retrace past decisions or events, and their consequences to the planning process. The combination of both, as well as insuring the continuity in the team tasked with information archival and its exchange, is essential to ensure that past and current information and expertise is adequately stored and circulated among stakeholders and decision-makers.

The Document is the permanently-updated blueprint of all elements that are enacted at any given time. For the agile/proactive management of the process it is essential that the most up-to-date and comprehensive version of all documents is made widely available among decision-makers. These can be equated mostly to a repository of all the “decisions” already produced by the planning structure, and must be widely-known and accessible to all actors so that the ongoing decision-making process remains updated and informed. It should emphasize especially the elements of the plan's programming that are active or have already been decided at any given time, such as the Strategy, Objectives, Actions and Tasks.

Expertise comprises all the contributions by experts, as well as the sectoral documents, that inform the decision-making. These include the latest available solutions or findings from the scientific community, but also inputs from local actors about specific local issues (local knowledge) and technical maps/reports from public institutions (census data, geological maps, infrastructure networks...).

Policies are the outputs of the ongoing interaction between stakeholders, experts and decision-makers. Decision-makers are ultimately those responsible for deciding which policies are to be transposed onto document. Some policies may be left out of the document because they are unsuited to the overall

strategy/objectives, while others may remain “in the backburner” until they become feasible/adequate to be incorporated onto the document.

3.2.2 PLATFORM

The Platform is the forum, the “space of dialog” for interaction between decision-makers, experts, and stakeholders. It should be designed to promote easy and frank bilateral or multilateral communication among actors, and be composed of both formal/scheduled instances of interaction (meetings) but also encourage more frequent, informal, contact among two or more actors.

We distinguish three main types of actors, although it is possible for one person or group to be involved in the plan in more than one capacity:

Experts produce scientific knowledge as an input to the Plan, which may be incorporated into the knowledge database as expertise. It is a prime source of knowledge that should inform decision-making and ultimately influence the plan’s policies and documents.

Decision-makers are traditionally politicians, although planning should encourage collaborative decision-making whenever deemed appropriate, and planners can, and should, influence the decisions of politicians. The decision-makers are tasked with the ultimate decision to select which policies to enact or include in the plan’s document, and establishing or adjusting the plan’s programming accordingly (strategy, objectives, actions and tasks).

Stakeholders are all actors that hold a stake in the planning process, out of self-interest or because they are invested in a collective stake. We include here the general public (and especially local communities), NGOs, and private stakeholders such as corporations, investors or private landowners. Public agencies often hold significant stakes in the planning process, because of their mandates or as landowners.

Stakeholder involvement is fundamental in promoting the plan’s awareness and, even viability. From the planner standpoint, encouraging the collaboration of stakeholders in the decision-making process can allow the adjustment of solutions so as to promote receptivity to the plan’s document, but also, ideally, result in inputs to the knowledge database deriving, for example, from local expertise. The involvement of stakeholders from early on in the process will also increase the chances of the plan’s implementation being well received and, thus, the plan’s success.

3.2.3 PROCESS

Whereas Knowledge and Platform are “static” structures for any given moment in time, even if capable of permanent adjustments, Process is the set of elements and structures that promote the dynamic interaction between elements of knowledge and the platform. It is the Process that promotes the discussion of planning solutions, between stakeholders, experts, and decision-makers with the aim of transferring their inputs from the Platform onto the Plan’s Knowledge Database, as policies, expertise, or, ultimately, document. These elements of the Knowledge Database, in return, feedback to the Platform, where actors will process new information in order to promote the discussion of elements resulting from the plan’s implementation (monitoring).

The Process should, therefore, promote a dynamic assessment of the plan’s evolution: the latest knowledge in the database, deriving from monitoring, should influence new decisions, which in turn feed onto new policies, which may alter the plan’s programming (if needed), generating an updated knowledge database (the helix shown in Figure 1). This constant evolution is the basis of an agile (because of its flexibility and stakeholder involvement) and proactive (because of its ability to incorporate the latest knowledge) planning process.

3.3 APPLYING THE AGILE/PROACTIVE MODEL

The document, explained before, should be seen, at the plan's enactment, as the roadmap for the implementation of the agile/proactive model. After "programming" the initial roadmap, there is the need to articulate the findings (derived from monitoring the plan's implementation) and new knowledge (resulting from inputs from the platform) so they can feed back to the improvement of the document, promoting its "agile" updating whenever necessary.

While the initial programme should be as good and comprehensive as possible, it will be based on the set of information (database) available at the moment of its creation. It will include an assortment of tasks that are aimed at achieving the objectives and strategy (an "ideal trajectory"), but time is likely to introduce changes to planning context that make the original path unattainable. As a consequence, tasks need to be changed accordingly and the overall "trajectory" of the planning process may be compromised. This adjustment can be conducted in an expedite and timely fashion (pro-actively), as soon as the divergence from the desired path is detected (Figure 2). Acting early to correct the trajectory may allow alternative actions or tasks to be implemented that will still allow the general strategy to remain robust, while minimizing the divergence from the original "targets". Unfortunately, as is more often the case, it is only once a plan's strategy or objectives come under jeopardy that action is taken (a reactive stance). This delay in addressing the issue may entail an extensive revision of the plan's formulation, and by then the achievement of the original targets may no longer be feasible.

Figure 2 – Proactive and reactive stances in adjusting the plan to changes in the planning context

Our model is based on a performance and context assessment, and we propose that the level of disruption introduced to the system may be minimized by: 1) the permanent updating, completing and recirculating of all the information stored in the database, and 2) by selecting an adequate tool for the analysis of the most recent information, so that decision-makers are able to adjust the "trajectory" in an agile manner.

For the first issue, we believe that the use of Key Performance Indicators (KPI) can be useful in that it is a reasonably well known methodology that is compatible with most planning structures and does not require any major adaptation to the legal framework for planning in order to be implemented. The careful selection of the KPI should be focused in creating an "early warning" system, that will be triggered once certain thresholds, that may compromise the plan's integrity, are surpassed.

Therefore, the indicators should be oriented to carefully portrait the level of "effectiveness" of the proposed courses of action and well time-delimited. It should be triggered whenever a task or objective is underperforming, and significant deviation from the planned target should inform corrective measures. We propose the development of specific KPI for each task/action, centered on performance, complemented by compound indicators of effectiveness for the objectives centered mainly on results.

It is from the interpretation, by planners and decision-makers, of the results of the KPI's permanent monitoring at the moment t that the information on the plan's ongoing performance is derived, and input to the database. In case some significant performance issues are identified, a partial correction of the "trajectory" should then be considered in as early as possible (t'), so as to minimize the risk of mid- to long-term failure of the planning exercise (Figure 2).

The second issue highlighted is the selection of an adequate tool for the analysis of this most recent information, as a decision-support tool that facilitates the adjustment of the plan's "trajectory" at the project management level. This management should not be focused exclusively on the results of the performance assessment, but also on the input of the stakeholders, experts and decision-makers resulting from the interpretation of the outcomes of that assessment. With that in mind, we propose the use of a Balanced Scorecard (BSC) or similar methodology that can facilitate each actor's interpretation of the results and promote a weighing of alternative solutions on how to address the underperformance and possible corrections to the plan.

For the KPI assessment and the interaction with the Platform (the actors) to be successful, it is important that a clear "strategic map" of all the actions and respective indicators be kept updated at all times, highlighting both the expected outcomes of each task, but also the indication of how each task is linked to, and is expected to affect, the achievement of its respective Action, and how the set of actions would promote the achievement of their Objective.

Ideally, a KPI would trigger an "alert" that a certain task was underperforming in a timely fashion, allowing the correction of that specific task without compromising the integrity of the plan. This would be a major aspect in promoting an "agile/proactive" plan, as it would be able to quickly respond to changes to the context, while preserving its overall objectives and strategy intact (Figure 3). Only in case of a task being compromised would a revision of the action be required, and so forth.

Figure 3 – Efficiency indicators trigger early warnings, promoting the frequent adjustment of the plan's programming (tasks and actions) without compromising the plan's formulation.

If adequately implemented, this strategy would keep a plan's overall strategy viable and up-to-date in face of significant disturbance to the planning context., only requiring full revision in case of a major shift in planning paradigms or deep changes to the legal framework (Figure 4), that is, events capable of triggering alerts on the performance of effectiveness indicators. These exceptional events would then provoke a redefinition of the plan's formulation, including the overall strategy, and the reassessment of objectives, actions and tasks.

Figure 4 – Only in the event of an unpredictable shift in paradigm or deep change to the planning context, triggering alerts on the performance of effectiveness indicators, would a redefinition of the Plan's formulation be required.

Efficiency indicators, being linked to actions and tasks (Figure 3), are fundamental in triggering alerts once they underperform. These alerts are early warnings that problems in the execution of the process are occurring, such as insufficient resources, inadequate timing, or problems with their implementation. Since we are within the domain of process, it is the strategic map of actions and tasks that should serve as a reference and be tweaked so as to adjust the plan to the new challenges. These changes should be

produced swiftly, and adjusting them appropriately will avoid the need to revise the formulation (strategy and objectives).

In a well-formulated plan, the effectiveness indicators (Figure 4) should be designed so as to be triggered only by events which could compromise the integrity of the plan's formulation, such as significant and unavoidable changes to the planning context, or major unforeseeable events (natural disasters, deep economic depression...) that would require a complete revision of the objectives and strategy. Once that revision is started, a reassessment of the actions and tasks would ensue.

3.4 SEA-LEVEL RISE: MANAGING THE UNMANAGEABLE

We take planning in the context of accelerating sea-level rise (SLR) as a case-study for the application of our model. SLR introduces a new dimension of variability which is yet to be adequately addressed by planning theory and, especially, practice. With Sea-level rise (SLR), land-use planning faces a challenge: in that it is not necessarily the planning practice that is failing to adequately predict changes to its planning context (at least, not according to its traditional standards), but rather that the "uncontrolled variable" (SLR) is too unpredictable or too untamable to allow traditional planning, or even scenario planning, to closely predict/adapt to it. This phenomenon cannot be planned-out or zoned-out (unlike most man-made uses or activities), it will occur regardless of any decisions taken at the local level, and represents a threat to most coastal urban settings, as infrastructure and urban development were not designed to face it.

The traditional stance towards SLR adaptation, and indeed most natural hazards, has been a Reactive stance: adopting reactive measures to deal with impacts already being experienced by the system. It often relies on the vulnerabilities of the system being revealed by events through the failure, or near-failure of the system as a whole or in some of its aspects (reactive adaptation over a vulnerable system);

More recently, though there is increasing pressure to instill planning with a pro-active stance (): early adoption of pro-active measures, which attempt to anticipate future impacts and mitigate them by increasing the system's resilience ("readiness") so as to withstand SLR without losing fundamental capabilities to perform up to an acceptable standard (proactive adaptation for a resilient system).

The level of uncertainty SLR introduces to the planning context render planning with SLR a perfect example where we believe the adoption of an agile/proactive model of planning would be ideally suited.

Lempert (2000) states brilliantly the sort of questions planners are faced with regarding SLR:

The key step in solving a complex problem is often asking the right question. Prediction-based policy analysis requires that we ask 'what is likely to happen in the future?' We believe that the proper question is 'what actions should we take, given that we cannot predict the future?' The answer we propose is that society should seek strategies that are robust against a wide range of plausible climate change futures. By definition, robust strategies are insensitive to uncertainty about the future. For risk-averse policy-makers, such strategies would perform reasonably well, at least compared to the alternatives, even if confronted with surprises or catastrophes. Robust strategies may also provide a more solid basis for consensus on political action among stakeholders with different views of the future, because it would provide reasonable outcomes no matter whose view proved correct. Clearly, robust strategies are desirable. The question is, do such strategies exist and, if so, do we have the means to find and assess them?

3.4.1 APPLYING THE AGILE/PRO-ACTIVE MODEL TO PLANNING WITH SLR

Our model addresses several of these issues specific to planning with SLR:

1. By incorporating in the Plan's database information that is kept "on the backburner", that is, expertise and policies that are not a part of the document at a given time, but that may be introduced to it readily in case of a shift to the planning context, we increase the ease of quickly adjusting the plan to that new reality, while preserving its integrity. A perfect example of this

would be a solution for sea-level rise adaptation, such as the relocation of a neighborhood, which would be prepared in advance but that, due to its cost, would only be enacted into the plan after a certain threshold of SLR was surpassed. Having prepared for that scenario in advance, would allow experts and local stakeholders to debate the merits of alternative solutions and possibly reach new ones that may be beneficial to more actors (Birkmann 2010). Also, having been the subject of ample debate by the time of their adoption, these solutions would likely be met with greater receptiveness, when compared with reactive, hasty, decisions. The ease of implementing the necessary tasks would therefore be much facilitated and the plan's overall robustness much improved;

2. As our framework presupposes the establishment of formal and informal communication channels among actors in the platform (including experts and decision-makers), this would allow the plan to be constantly instilled with the best and most up-to-date science and adaptation solutions, allowing for an improved and speedy consideration of new data or technology;
3. The timeframes for adaptation are very long (Hallegatte 2009), and not compatible with the typical political cycles (Wilson 2007). Therefore, strategic adaptive strategies require stable planning frameworks, capable of generating multi-year, or indeed multi-generational, commitment to a certain strategy. By "shielding" the Strategy as the stable consensus that is unlikely to require revision unless there is a major paradigm shift, our model proposes that reassessment based on KPI be mostly confined to the adjustment of tasks, without compromising the overarching strategy of the Plan. It is therefore well-suited to implement long- to very long-term strategies such as climate adaptation;
4. The model addresses another major problem with climate adaptation: most solutions being advanced for dealing with SLR in urbanized waterfronts are far from consensual, whether because they demand hard land-use planning choices to be made, because they are not economically feasible, or simply because they are controversial. Also, one stakeholder's dream solution may be another one's worst nightmare (for instance, phased withdrawal or large seawalls). By emphasizing the importance of the Platform in establishing frank and open communication among actors, and allowing the timely debate of solution before they are enacted in the Document, our model allows tough solutions to be matured through debate before being implemented.
5. Implementing a proactive approach to planning requires the recognition that uncertainty and complexity are inherent to the planning process, as our model explicitly does. Planning for a specific goal or threshold can prove inadequate in case real trends fall outside the estimates, unless a certain degree of flexibility is preserved and instilled onto the adopted solutions.

Since most adaptive planning solutions tend to fall into the category of hard (and unpopular) decisions, which are precisely those that tend to get more readily removed from plans by decision-makers, they are also especially unsuited for the traditional planning style, which tends to follow closely the political cycles (Wilson 2007) and therefore neither have the time, nor the interest, of introducing these unpopular measures, except in a reactive stance to an already occurring phenomenon (such as the aftermath of a natural disaster).

Our model, falling well within the scope of the flexible, adaptive planning models, promotes pro-active stances, where future disruption is addressed in a timely fashion, by slowly circulating among the actors in the Platform before the tasks are finalized, while the overarching objectives and strategies of adaptation can be established as integral to the Plan for its earliest iteration. This would allow the solutions to be matured as a component of the Plan over a few political cycles, even if the specific tasks remain in discussion, therefore distributing the burden of "hard choices" over a large number of decision-makers and political cycles.

Although one can hardly manage for uncertainty, it is possible to manage for the risks that uncertainty may introduce to the plan's integrity. This can be achieved through thoughtful strategy and goal-setting, by allowing for ready and effective revision, complemented by a clear definition of the actions necessary to preclude failure or achieve improvements, and a constant updating of the planning framework with revision of the tasks' performance and possible revision of actions and objectives, within a stable and long-term strategy. This is a radical departure from the static planning framework of recent, where the "plan" as a product is the ultimate goal of the planning practice, regardless of how well it responds to the solicitations of the planning context itself.

4 CONCLUSIONS

Current planning structures tend to deal poorly with uncertainty and variability. This is especially evident in planning with SLR, where the level of uncertainty is vastly increased by an uncontrollable variable. In traditional planning structures, the typical revision occurs after a certain static scenario collapses, and therefore a new scenario for the end-result of the planning process is “required”. These are all “static” scenarios, which get redesigned over time in reaction to the plan’s underperformance. By then, typically a full revision of the Plan is required, and adaptation to changes to the planning context are slow and, typically, not very effective.

Our model builds on theories of flexible and agile project management and flexible, adaptive and collaborative planning to create an agile/pro-active planning framework, which may address more adequately the high level of uncertainty present in today’s planning contexts.

By taking uncertainty as a given, and not an unexpected event, the model accepts readily the need for speedy and easy adjustments according to early signs of underperformance, provided by indicators. The permanent monitoring of the plan’s implementation should track its performance in pursuing the strategy and objectives, and whether the selected actions and tasks are being successfully executed. The open channels of communication among experts, stakeholders and decision-makers would process the new information and produce or revise tasks and actions so as to allow the plan’s overall performance and strategies to remain valid over a changing planning context. By acting readily and pro-actively, the plan’s “trajectory” may be corrected early on, avoiding the collapse of the overarching objectives.

Our vision is therefore that planning should be inherently dynamic and pro-active, and that it should recognize the uncertainty of the planning context from the onset. This uncertainty should be dealt with by increasing the plan’s resilience, and this can be achieved by broadening the range of solutions by involving experts and local stakeholders in a constant strive to gather the latest, best, knowledge and making it readily available to decision-makers. Another aspect we highlight is the possibility of reserving some solutions “in the backburner”, as policies that may be incorporated at a later date or a given indicator crosses a certain threshold.

ID 1610 | THE NEW “PLANNING AMNESTY” IN PORTUGAL: HOW FAR SHOULD PLANS ACCOMMODATE NONCOMPLIANT DEVELOPMENT?

Inês Calor¹; Margarida Pereira¹; Fernanda Paula Oliveira²

¹Interdisciplinary Center of Social Science, FCSH, Universidade Nova de Lisboa, Portugal;

²Faculty of Law, University of Coimbra, Portugal

icalor@hotmail.com

1 INTRODUCTION

In 2014, Portugal introduced legislation¹ imposing amendments on statutory plans to accommodate illegal structures “that are incompatible with land management instruments or land use restrictions” applied to productive units such as industrial, farming, waste management and quarries. The initial deadline for application was January 2016, but was extended until June 2017². This amendment also introduced “subtle” changes, to include buildings in which construction had not been finished, and some types of warehouses. The pressure for a solution to illegal development arose from restrictions on real-estate transactions and conditions placed by the EU on eligibility for its funding mechanisms. Though not

¹ Decree-Law 165/2014, from November 5.

² Law 21/2016, from July 19.

special legal framework was designed since the 1970's¹. However, the ongoing process for semi-informal settlements relates mostly to the provision and payment of urban infrastructures and not to buildings – after tenure regularization it still requires a second step of building legalization to the same standards as required in formal land. Despite the mature level of the planning system, national planning literature is short in addressing the issue of non-compliant development in private property. For political, social and economic reasons, planning enforcement is seen as a burden on public administration.

But illegal and noncompliant development is not an inconsiderable problem, especially regarding illegal housing in the district of Lisbon (Rolo, 2006; Silva & Farrall, 2016). Estimates point out to 158,000 illegal dwellings built between 1970-1981 and a total of 314,400 in the sum of 12 districts (Cardoso, 1983, p. 350). A more recent study shows that the phenomenon is not only from the past, and about 285.000 dwellings were built without a building permit between 1991-2011 (Calor, 2017). This number is similar to Andalusia Autonomic Community in Spain (about 300.000 dwellings) but lower than the Greek estimate (1 million buildings with different uses). The reason why the discussion was been absent from planning agenda in Portugal is probably related to the social inconsideration of building illegalities, the absence of government recognition of the problem and the lack of legal framework.

In amnesties, design “details” do make a difference. There are two major differences to other planning amnesties (i.e. Greece, Italy and Turkey): (i) the Portuguese amnesty applies only to a selective use of buildings and (ii) it allows/promotes the formalization of buildings and extensions in areas where development restrictions were before more strict: natural parks, coastal areas, environmental and agriculture reserves. It is worth mentioning that it only applies to private property, not to squatting settlements or semi-informal ones.

2 THE PORTUGUESE PLANNING AMENSTY

2.1 LEGALIZATION BACKGROUND

Ad hoc legalization has been the main way of dealing with illegal development in Portugal and has gained increasing relevance due to the restrictions on selling implemented in 1999². The number of legalization submissions has continuously increased since then, becoming a “burden” in land development (Calor & Pereira, 2015). In regular mode, legalization (or retrospective permits, as they are called in Britain) is theoretically very strict and depends on compliance with plans at the time of approval. In municipalities, bending planning rules to allow legalization is a common and accepted way to avoid the personal and political costs of demolition or imposing changes to buildings. Despite its significance, Portuguese legislation only incorporated “legalization” in 2014 (article 102-A of the Decree-Law no. 555/99, of December 16). In the same year, the new “selective” planning amnesty for economic activities was implemented (Decree-Law no. 165/2014, de November - RERA³). Oliveira & Lopes (2016) call the sum of these pieces of legislation (together with the old law for regularization of semi-formal settlements) the new “legalization policy”.

Exceptions for non-compliant development of economic activity were previously set in Portuguese law before 2014, but because they were in separate pieces of law (one for each of the economic activities⁴) they had less visibility. Their impact was reduced because plan amendments were optional, and in fact hardly any occurred. The reason why the amnesty program was selective to economic activities (and not general to other buildings use, as in other countries) is not entirely clear and it poses some obvious questions of proportionality, social-fairness and the point of having a binding planning system. For one, housing illegalities (especially extensions) are far more frequent and, second, no exception is made in law for those built out of necessity or even for those illegally built before plans implementation (Calor, 2013). National economic growth, inherent in economic activity, may be of public interest, but non-compliant buildings for other uses do not have a compatible solution.

¹ Decree-Law no. 804/76 of November 6 and Law no. 91/95, of September 2.

² Decree-Law no. 281/99, of July 26.

³ RERA is the abbreviation to “Regime Extraordinário de Regularização das Atividades Económicas”.

⁴ For example, Article 69 of Decree-Law no. 209/2008 (Legal framework of the Exercise of Industrial Activity)

From a social perspective, amnesties give advantages to developers who, at first glance, did not care to follow the rules. In an opinion article, Schmidt (2014) wonders “what message this piece of law transmits to the many compliant entrepreneurs who put significant effort in fulfilling environmental and public health law? That crime pays? As is evident, it is also a problem of disloyalty provoked by the state.” The economic boost can be seen as public interest (job creation or maintenance of the existing ones and seizing the opportunity of economy growth to access European Funds) but may be regarded as too “selective”. Regularization of development driven by a developer’s profit (not necessity) may aggravate the already high mistrust of the Portuguese legal and planning system.

2.2 AMNESTY TIMMING AND PROCESS

The time-window of RERAE was originally scheduled to finish by January 2, 2016. However, Law no. 21/2016, of July 19 (extemporaneously) extends its deadline between that date and July 24 of 2017. Although not mentioned in the preamble, this law also extends the scope of situations and activities that can be regularized. Since July 19, RERAE can also be applied to the “regularization” of buildings which have not been started, have started and then ceased, or have been suspended for more than one year, provided there were some kind of building or physical structures (whether started or finished). Besides industrial, farming, waste management and quarries, it now also allows the regularization of “establishments and farms intended to support agricultural activity, agriculture, horticulture, fruit growing, forestry and beekeeping, such as warehouses, outbuildings and cold-storage plants”.

The process of application foresees the need to obtain, in advance, a declaration of municipal interest issued by the municipality and a study of economic viability of the company. The owner should submit the application to the responsible body (different, according to the activity¹) and pay a fee (variable accordingly to administration body and municipalities). After acceptance of initial documents, it is subject to evaluation by a multilevel Government Commission, and a decision is made during a “council meeting” with representatives of all bodies with jurisdiction over the land or activity. Accordingly to CCDR representatives, very few submissions have been denied. If operating conditions are considered adequate, a two-year permit is issued. Municipalities are then required to promote an “automatic” amendment to general master plans within that period. Regular plan amendments are usually long, highly bureaucratic and expensive. It is still uncertain and unclear how the “automatic” amendment process will be undertaken and the costs involved. Nothing being said, it is likely that they will be mostly, if not entirely, supported by municipalities.

2.3 AMNESTY IMPACT

The reach of the amnesty can, somehow, be measured by the number of submissions. As there was no previous published data, we asked the coordinating body (CCDR²) for quantitative data that would allow a general perspective. In this paper, we provide data from 2 out of the 5 regions in Portugal: (i) North and (ii) Lisbon & Tejo Valley Region. These are expected to be the regions with more applications (having more dynamic economic activity). A total of 687 applications were submitted in both regions until March and April 2007.

¹ IAPMEI for industries Type 1 and 2 (“heavy” industry); Municipalities for industry Type 3 (“light” industry); DRAP for farming; CCDR for waste management and; DGEG for quarries. It is unclear which body is responsible for agriculture structures.

² CCCR is the abbreviation for Comissão de Coordenação e Desenvolvimento Regional.

Figure 3 – Applications under RERA in North region, by sector and municipality submitted before March 6, 2017.
Source: CCDR-North

In a future investigation it would be interesting to understand if these numbers are a result of high numbers of illegalities or, as we believe might be more accurate, a consequence of a more active approach from municipalities (in creating expectations and incentivizing owners into submitting an application).

Figure 4 - Applications under RERA in Lisbon & Tejo Valley Region, by sector and municipality submitted before April 18, 2017. Source: CCDR-LVT

2.4 EXPECTED RESULTS

The newness of the diploma and the embryonic state of progress of the regularization process, have not allowed them to achieve their full potential; but, considering its expected length, we believe it will not reach owners' expectations. Affordability, and short term results are considered by Potsiou (2014) as key to achieving positive results, and these effects are not expected from the Portuguese amnesty.

The legislator's choice to impose the change on the planning instruments seems inconsistent with the proposed objectives. By demanding that final regularization be made through conventional legalization, and making it dependent on the change to plans, the process does not meet the interests of timing and costs for the entrepreneurs. On the other hand, the costs of plan amendments will be up to the municipalities.

3 CONCLUSIONS

Planning amnesties are not new in South European countries, having been implemented in different stages and forms. The Portuguese amnesty is a "selective" one because it relates only to certain types of economic activities; therefore, the number of submissions cannot be compared to broader planning amnesties in other countries. Quantitative data from the North Region and Lisbon & Tejo Valley Region show that the numbers are not very significant. Only in a few municipalities have "visible" numbers, being industry the activity with the biggest share.

Plan amendment costs are relevant but have not been given much consideration, which will very likely delay municipalities making the "punctual" amendments that are required to complete the process. Mandatory plan amendments require a long time and it is unlikely that municipalities (especially small

ones) will have the human and financial resources. Economic interests behind planning prevail over spatial planning principles and, as in all planning amnesties of this nature, there is a sense of injustice to compliant individuals.

1 INTRODUCTION

How to take into account various players' values? How to balance interests of various parties engaged in city development? How to divide resources between various groups? How to prepare city strategies so that no one feels omitted? Urban planners face these questions all the time during their work. It is a challenge to meet the needs of several groups: developers, local authorities, lobbyists, environmental activists, and – last but not least - citizens. These are just few groups whose interests shall be considered and taken into account while preparing new plans and strategies. The purpose of the paper is to encourage a discussion on possible solutions and answers to the questions listed above.

An overall description of the Polish spatial planning law is followed by presentation of methods derived from operational research as it seems that multi-criteria decision analysis (MCDA) might serve urban planners with several promising tools. Methods such as Analytic Hierarchy Process or PROMETHEE Group Decision Support System could aid the planning process at local or regional level. The paper offers a brief description of these methods and discusses examples of how to use them in everyday work of urban planners in order to make the policy making process more transparent and objective.

2 SPATIAL PLANNING SYSTEM IN POLAND

To describe the spatial planning law in Poland, an overall picture of the country's territorial division is necessary. According to the Constitution, the territorial system of the Republic of Poland ensures the decentralization of public power. The institutions of the state have competence at one of the four levels of territorial division: central (country), regional (voivodeship), supra-local (poviat), and local (commune). The inhabitants of communes form a self-governing community in accordance with the law. The local governments participate in the exercise of public power. A substantial part of public duties statutorily lies in the jurisdiction of the communes, which they perform in their own names and under their own responsibilities. There are several acts and regulations which constitute the Polish planning law. The Act on Spatial Planning and Management issued on 27th March 2003 states that the spatial planning system shall be managed adequately to the territorial division of the country at all governmental levels. The basic instrument of spatial planning in Poland is the local spatial management plan. Its regulations are binding and serve as the basis for implementing planning decisions. An attention should be paid to a relatively large number of bodies, institutions, and groups involved in the decision making process and the fact that the interests of these parties may sometimes be in conflict. Therefore, developing a new approach which would take into account all important challenges of urban policy making seems to be unavoidable in the next years. Following factors seem to be crucial (Ossowicz, 2003):

- the essence of city governance: definitions (city management, city governance, spatial policy, urban policy, etc.), features of governing, city governance in the light of organization and management theory, uncertainty and risk in spatial planning;
- local government: its role and tasks, structure, features, and management instruments;
- urban planning: actors, features and attributes of the local level spatial planning, models of integrated planning in cities, models of strategic planning (including models taking into account the specificities of public organizations management);
- city finances;
- controlling and monitoring.

The participation of local society is described in the Spatial Planning and Land Development Act from 2003 in the article 11 and 17. Both articles of the Act allow the local society to submit remarks to planning documents and to take part in public discussions on them. However, these rights are not always executed by the local community, as "they do not believe that it can change anything in their life or in the local unit" (Feltynowski, 2015). As OECD (2016) notices, indicators of social capital and social trust are exceptionally

low in Poland; however, a culture of public engagement in the planning process is growing. According to the Spatial Planning and Development Act from 2003, public participation has three goals:

- to inform the society about making up of new plans,
- to receive feedback from actors involved in the planning process,
- to accept (or reject) the resulting feedback.

In general, two main steps can be distinguished; firstly, society is offered proposed changes and may submit their observations or hints and secondly, the local plan is presented and undergoes public discussion. The legal aspect of issuing a plan, including public input and engagement, is checked by the regional authority. Nevertheless, public engagement is perceived to be rather limited, “formal and only protecting interests of inhabitants and owners, while failing to encourage municipalities to offer alternative development solutions” (OECD, 2016).

Consequently, large number of players involved in the decision making process and policy formulation requires new approach and new methods in order to ensure fair participation of all stakeholders. Not only tools supporting coordinated and transparent process shall be developed, but also several improvement within legal frameworks shall be carried out; otherwise, the planning process will remain limited and archaic.

3 METHODS

There are several methods that could aid the spatial planning process and structure decision making problems. It seems that urban planners may look for solutions among methods derived from other disciplines. MCDA (multi-criteria decision analysis) or MCDM (multi-criteria decision making) is a sub-discipline of operational research and was developed in 1960s in the business sector. MCDA is used in the situation of having multiple, usually conflicting, criteria. Such situations we approach in everyday life, e.g. when choosing a car we take into account price, size, fuel consumption, safety, comfort, etc. Instead of following the intuition, the decision making process could be made more rational with use of the MCDA methods. The development of MCDA is related to the computer development, which enabled to decision makers to conduct complex analyses of multi-criteria problems. MCDA addresses mainly discrete ill-defined problems (no optimal solution) with not very large sets of alternatives. It can be used to conduct following operations: choice, ranking, or sorting (Xu, Yang 2001). Therefore, it can be used to choose (new location for an investment, team of workers, investment plan), rank (cities, regions, universities, students), or sort (research projects, cities).

Value function can be used to derive preferences for the alternatives. To give an insight into these methods, the Analytic Hierarchy Process (AHP) can be briefly described; the method is based on mathematics and psychology and it is widely used to help decision-makers in the fields of business, transportation, or education. The most important feature is the group decision making, where each decision-maker can have different priorities and values. The problem is decomposed into sub-problems. The pairwise comparison of various aspects of the problem and pairwise comparison of criteria are conducted independently. The decision-makers can either provide concrete data or just use their individual and subjective judgement. Those evaluations are computed in order to obtain a comprehensive evaluation of the decision problem. The capability to compare incommensurable elements distinguishes the AHP from other MCDA methods (Saaty, Peniwati 2008).

The second group (methods based on outranking relations) is widely known mostly for two approaches, i.e. ELECTRE and PROMETHEE. Outranking methods were first developed in France in the late sixties following difficulties experienced with the value function approach in dealing with practical problems. As in the value function approach, outranking methods build a preference relation among alternatives evaluated on several criteria. It is a binary relation S on the set X of alternatives such that xSy if there are enough arguments to declare that x is at least as good as y while there is no essential reason to refute that statement. In most outranking methods the outranking relation is built through a series of pairwise comparisons of the alternatives (Bouyssou 2001). ELECTRE I is the first outranking method and it gives a good notion of the ideas behind outranking. Other outranking methods are more advanced as they accept differences in the strength of the decision maker's preferences as well as the possibility of the decision maker being indifferent with respect to two alternatives (de Boer et al. 1998). Another outranking method is

PROMETHEE (and its descriptive complement geometrical analysis for interactive aid which is better known as GAIA). The fields of application are similar as in the aforementioned AHP technique. The main advantage of the PROMETHEE method is the clear reasoning which helps decision makers build well-structured framework for the decision problem. It is useful for solving complex problems with several criteria that need to be evaluated. The method could be applied to: choosing the best location for an investment, ranking action projects or investment plans, allocating resources. The information requested by PROMETHEE and GAIA is particularly clear and easy to define for both decision makers and analysts. It is based on a preference function associated to each criterion as well as weights describing their relative importance. Usually there is no alternative optimising all the criteria at the same time, therefore a compromise solution should be selected.

The algorithms, most common uses, and possible extensions of AHP and PROMETHEE methods are well-described in literature. The algorithm of PROMETHEE is following:

Step 1: Using the data contained in the evaluation matrix, the alternatives are compared pairwise with respect to every single criterion. The results are then calculated and expressed by the preference functions, which are calculated for each pair of options and can range from 0 to 1, where 0 means that there is no difference between the pair of options (indifference), 1 indicates a strong preference, and value between 0 and 1 indicates weak preference:

$$P_j(a, b) = F_j [dj(a, b)] \quad \forall a, b \in A$$

where:

$$dj(a, b) = gj(a) - gj(b)$$

For criteria to be minimised, the preference function should be reversed or alternatively given by:

$$P_j(a, b) = F_j [-dj(a, b)]$$

In order to facilitate the identification of preferences six types of particular preference functions have been proposed (Brans and Mareschal, 2005). Additionally, such parameters as threshold of indifference or threshold of strict preference can be used.

Step 2: Aggregated (global) preference degree for each pair of alternatives on each criteria is calculated:

$$\pi(a, b) = \sum_{k=1}^q P_k(a, b) \cdot w_k$$

Step 3: Positive and negative flow scores are calculated:

$$\phi^+(a) = \frac{1}{n-1} \sum_{x \in A} \pi(a, x)$$

$$\phi^-(a) = \frac{1}{n-1} \sum_{x \in A} \pi(x, a)$$

Step 4: Net flow score is calculated in order to obtain a complete ranking of alternatives:

$$\phi(a) = \phi^+(a) - \phi^-(a)$$

Step 5: Group decision making. The global evaluation and GAIA analysis for group decision-making are carried out so that all the decision makers are advised on the potential conflicts. The last step of the process is summarized as follows:

$$P_i(a, b) = F_i[\phi_i(a) - \phi_i(b)] \quad i = 1, \dots, m$$

where $P_i(a, b)$ denotes the preference of alternative a to alternative b for DMi.

$$\pi_{gdss}(a, b) = \sum_{i=1}^m P_i(a, b) w_i$$

where $\pi_{gdss}(a, b)$ is defined as the weighted sum of $P_i(a, b)$ for all decision makers with w_i as the weight for DM_i . The PROMETHEE partial and complete rankings are obtained from the following equations:

$$\phi_{gdss}^+(a) = \frac{1}{m-1} \sum_{x \in A} \pi_{gdss}(a, x) \text{ and } \phi_{gdss}^-(a) = \frac{1}{m-1} \sum_{x \in A} \pi_{gdss}(x, a)$$

$$\phi_{gdss}(a) = \phi_{gdss}^+(a) - \phi_{gdss}^-(a)$$

Therefore, PROMETHEE GDSS can capture multiple decision makers' beliefs, calculate them, and provide better insight into the decision making problem (Tavana et al, 2013). The second method, namely Group AHP, serves the same purpose; however its algorithm is different (Saaty and Shang, 2007; Saaty and Peniwati 2008):

Step 1: Creating a pairwise comparison matrix A . The matrix A is a $m \times m$ real matrix, where m is the number of evaluation criteria considered.

Step 2: The normalized pairwise comparison matrix A_{norm} is computed:

$$\bar{a}_{jk} = \frac{a_{jk}}{\sum_{l=1}^m a_{lk}}$$

Step 3: The criteria weight vector w (that is an m -dimensional column vector) is built by averaging the entries on each row of A_{norm}

$$w_j = \frac{\sum_{l=1}^m \bar{a}_{jl}}{m}$$

Step 4: Computing the matrix of option scores:

The matrix of option scores is a $n \times m$ real matrix S . Each entry s_{ij} of S represents the score of the i th option with respect to the j th criterion. In order to derive such scores, a pairwise comparison matrix B is first built for each of the m criteria, $j=1, \dots, m$. The matrix B is a $n \times n$ real matrix, where n is the number of options evaluated. Each entry of the matrix B represents the evaluation of the i th option compared to the h th option with respect to the j th criterion. Second, the AHP applies to each matrix B the same two-step procedure described for the pairwise comparison matrix A , i.e. it divides each entry by the sum of the entries in the same column, and then it averages the entries on each row, thus obtaining the score vectors $s(j)$, $j=1, \dots, m$. The vector $s(j)$ contains the scores of the evaluated options with respect to the j th criterion. Finally, the score matrix S is obtained:

$$S = [s^{(1)} \dots s^{(m)}]$$

Step 5: Ranking the options. Once the weight vector w and the score matrix S have been computed, the AHP obtains a vector v of global scores by multiplying S and w , i.e.: $v = S \cdot w$

Step 6: Checking the consistency index. Consistency Index (CI) is obtained by first computing the scalar λ as the average of the elements of the vector whose j th element is the ratio of the j th element of the vector $A \cdot w$ to the corresponding element of the vector w .

$$CI = \frac{x - m}{m - 1}$$

Step 6: Group decision making. We can consider two issues in group decision making. The first is how to aggregate individual judgments, and the second is how to construct a group choice from individual choices. For the purpose of the study presented in the next chapter of this paper, weighted geometric mean is used to conduct aggregation of individual judgements (AIJ):

$$c_{ij} = \exp \frac{\sum_{k=1}^N w_k \ln a_{ij(k)}}{\sum_{k=1}^N w_k}$$

Both methods can be used while solving decision problems with several alternatives evaluated on several criteria by several decision makers. An example of how to use Group AHP for the purpose of spatial planning is discussed in the next chapter.

4 EXAMPLE – CHOOSING A SITE LOCATION

In Poland, participatory processes have recently been applied more frequently; however, their performance is still low in terms of engaging key actors and sharing decision-making power with them (Cent et al, 2014). While making important decisions related to formulation of city policies, several bodies and parties are involved in the process. The possibility to take into account all players' needs and objectives is a key challenge for city authorities. In this chapter, a theoretical example use of Group AHP method is offered.

Let us assume that city authorities are facing a problem where to locate a new bridge. The actors involved in the process might be:

- Department of Transportation – a body within a municipality which is interested in improving transportation system and road network while taking into account limited budget of the city,
- Department of Environment – a body which main focus is on environmental protection,
- Urban Development Department – a body consisting of urban planners, who try to balance costs of investments with their functionality and aesthetical function in order to improve citizens quality of life.

All these actors take into account the same criteria, such as: cost of building, impact on transportation network, design and aesthetics, impact on environment. Of course, each decision maker can have different from others values and preferences on the criteria and available alternatives. By conducting pairwise comparison of the adopted criteria, we can gain an insight into the opinion of each decision maker. Furthermore, consolidation of decision makers' preferences allows for numerical and transparent presentation of the decision making process. Results of pairwise comparison of criteria by each decision maker and consolidated results are presented in the Table 1. All calculation were conducted using MS Excel.

	Department of Transportation	Department of Environment	Urban Development Department	Consolidated (according to DMs weights)
Cost of building	26%	10%	7%	13,6%
Impact on transportation network	56%	26%	48%	48,5%
Design and aesthetics	6%	4%	26%	11,1%
Impact on environment	12%	60%	19%	26,9%
weights	0,3	0,3	0,4	1

Table 1. Consolidated decision matrix for criteria

Similarly, decision makers can conduct pairwise comparison of alternatives (instead of criteria). Partial ranking of bridges can be also consolidated into one global ranking. The results of this calculation are presented in the Table 2.

	Department of Transportation	Department of Environment	Urban Development Department	Consolidated (according to DMs weights)
Bridge A	28%	24%	10%	18,9%
Bridge B	65%	67%	64%	67,8%
Bridge C	7%	9%	26%	13,3%
weights	0,3	0,3	0,4	1

Table 2. Consolidated decision matrix for alternatives

Furthermore, the Group AHP method allows for calculating consistency of decision makers. In the first case (evaluation of criteria) consensus equals 61,8%, while in the second case (evaluation of alternatives) consensus reached 90,3%. Results obtained within this case study can be further used to obtain global ranking: to combine consolidated alternatives with consolidated criteria, or – with use of other methods – to provide other rankings with additional input provided by experts. The case study offered above is an example of how to use Group AHP for providing better insight into decision making process, but PROMETHEE GDSS could be also used for this purpose.

5 CONCLUSIONS

The paper offers an example of bringing together group decision support systems and urban management in order to make the decision making process within spatial planning more rational, transparent, and inclusive. Large number of players involved in planning procedure demands comprehensive and fair methods which can ensure that each player's voice is taken into account. Consequently, looking for solutions outside the discipline of spatial planning seems to be unavoidable. Methods discussed in this paper can be used to better structure the decision problem and to obtain ranking of alternatives, while incorporating evaluations provided by various actors, whose interests may sometimes stay in conflict. Numerical approach to the planning procedure seems to be an interesting solution, which shall be further developed.

Moreover, observations of planning practices and literature review suggest that comprehensive and transparent grasp of various stakeholders' views and opinion is rarely happening. Shortcomings of the current legal framework and planning reality in Poland discourage some members of local community to participate in the planning process. Therefore, establishing new approach supported by innovative methods ensuring fair treatment might in the next years an interesting challenge for urban planners and researchers.

ID 1663 | A SOCIO-JURIDICAL CRITICISM TO URBANISTIC LAW FOR A NEW URBAN STRATEGY IN NATAL/RN/BRAZIL

Ana Mônica Medeiros Ferreira¹

¹Universidade Federal do Rio Grande do Norte

anamonicamf@gmail.com

1 INTRODUCTION

The principle of the dignity of the human person is a moral, social and juridical value inherent in the person, that is, every human being is endowed with this precept, and this is the highest principle of the democratic state of law.

While it is a right the idea of dignity in a collective dimension concerns tolerability per temporal, spatial and cultural circumstances. Thus, the city must be the place of the exercise of the dignity of the human person.

Based on this idea and based on a dialectical perspective, the research proposes to discuss the effectiveness - notably ineffectiveness - of the norms of urban law, through the confrontation between the Federal Constitution, the City Statute, the Metropolis Statute, and the Municipal Master Plan in the State of Rio Grande do Norte located in Brazil.

For purposes of this work, effectiveness is understood as the conformity of the actual situation to the legal situation granted or determined by the standard. In this sense, the first stage of the work consists in the revision of the literature focused on the legislation and legal instruments of urban law that regulate the urban space in the municipality of Natal.

Next, we intend to criticize the illusion of urban law and the predominantly positivist conception that predominates both in the elaboration of legislation in Natal-RN and in the application of such norms. In addition, to investigate the causes of noncompliance with norms of urban law, it is necessary to study the city and society in which we live, the relation of identification and belonging of the individual with the city in which he lives, what mechanisms of participation Effectiveness of such individuals. In other words, we must understand in depth the ideas of democracy and justice, from the precepts of freedom and equality to the understanding of our reality. In this sense, the objective is to evaluate if the usual means and procedures used in the city of Natal-RN in the legitimization of public decisions in the sphere of urban policies, are backed by social legitimacy, once we experience the daily practice of civil disobedience in relation to the laws in the coexistence of the legal city and the illegal city.

Thus, it is essential to discuss the right to the city from the study of popular participation. Therefore, it is urgent to rethink conceptually law as a science, specifically the role of urban law and urban plans in the current Brazilian scenario, and the necessary change from its normative-rationalist character to a more pluralistic view that the promotion of less unequal social and territorial justice.

2 THE RELATIONSHIP BETWEEN URBAN STRATEGY AND POPULAR PARTICIPATION

Thinking about a new urban strategy also means rethinking political participation and social control in city management. In other words, the understanding of the city can only be reached from the unit of two levels of analysis: that of capital and that of society where the individual is first a citizen with all the rights that the term implies (Carlos, 2015). It is also important to emphasize here the original relationship between the words city and citizen, which appears long before the established legal provisions. According to the etymology of the words, both derive from civilians. In this way, city (civitas) is a political community whose participants, the citizens, organize and govern; And citizen is the individual who enjoys the right of city, that is, is the subject that belongs to a certain place.

Here it is important to mention the theoretical contribution of Ellen Wood (2011) in her work "Democracy against capitalism: the renewal of historical materialism", where the author warns against the dangers of the uncritical use of the terms citizenship and civil society. For democracy to recover its true meaning of government by the people or the people, it is necessary to radically transform capitalism, an economic and social system that gradually removes several spheres of social life from popular and democratic control. He explains that since capitalism generates, among other things, new forms of domination and coercion beyond the reach of the instruments created to control traditional forms of political power, it also reduces the emphasis on citizenship and the achievement of democratic accountability (Wood, 2011)

According to our Federal Constitution, urban policy must necessarily be a product of popular participation. But the issue is not just legal. Brazil has no tradition of effective instruments of participation or sharing in solving problems in the public sphere. It should be noted that the constitutional command of guaranteeing popular participation and the State's duty to carry it out is not sufficient. Another element must be added: the political and programmatic commitment of the government, which commands the different portions of the State.

Regarding the specific social control for urban policies, it is basically that popular participation permeates the state's performance in the management of the city since the 1970s (Ataíde, 2015). Currently the social control in the municipal scope in the current context of the Urban Planning and Management System of the Municipality is provided for in article 93, paragraphs 1 and 2 of Complementary Law No. 082/07. The Council of the City of Natal - CONCIDADE is the central articulator of the sectoral councils (Municipal Council of Urban Planning and Environment - CONPLAM, Municipal Transit and Urban Transport Council - CMTU, Municipal Council of Housing of Social Interest - CONHABINS and Municipal Council of Basic Sanitation - CONSAB) and counts on the popular participation obeying the criterion of territorial and sectorial representation, being composed by fifty two members.

It appears that the existing councils are still often based on the classic idea of social control, consolidated until the beginning of the country's re-democratization as a set of methods conducted by the State with the purpose of establishing the social order and the purpose of disciplining individuals. In other words, still far from a dialogical relationship between the State and Society, which allows the broad participation of the organized sectors in the formulation, monitoring and verification of policies, at a more general level to the plans, programs, and projects in their different stages of development. Implementation, including the allocation of resources.

It is believed that the essence of social participation is embodied in the universalization of social rights, in the expansion of the concept of citizenship and in a new understanding of the role and character of the State, understood as the arena of political conflicts where different groups of interests vie for space and meeting their demands, from a public debate.

For example, in all the meetings that participated, the bills were brought ready for the approval of the council, without the least concern for popular participation in the various instances of the process that go from the discussion to the formulation and implementation of the public policies presented. That is, in the current scenario, even with the existence of a theoretically democratic and representative model, one must question the legitimacy of urban policies and programs.

It is well known that Brazil's problem is not a lack of law or regulation. The denial of the right to the city in Natal / RN (as elsewhere) is expressed in land irregularity, housing shortage and inadequate housing,

precariousness and deficiency of environmental sanitation, low mobility and quality of collective transportation and degradation Environmental (Maricato, 1996). At the same time, wealthier elites and layers continue to accumulate more and may enjoy a pattern of exaggerated luxury consumption (Harvey, 2009).

In the words of Professor Ermínia Maricato (1996), it is exactly in the context of this contradiction expressed in urban segregation that violence explodes and the power of organized crime grows in the city. The hegemonic paradigms of urban planning and urban planning have revealed their limits and are failing to respond to the contemporary problems of large cities.

This idea is based on Habermas's theory (2001), it is believed that the list of problems that currently imposes must be thought of in a political agenda capable of giving the individual confidence in participating in the actions of the state and provoking The transformation of society. The diagnosis of social conflicts becomes a series of political challenges only when the egalitarian institutions of rational law are connected to an important premise, namely, the admission that the citizens of a democratic collectivity can configure their social and Can develop the necessary action for the intervention.

It is often verified that the Administration is not in favor of the participation, even in folders that historically adopt models in "democratic" thesis. Take, for example, a public hearing. In this the citizens can expose their ideas in person, by dialoguing with a public manager democratically elected or with those responsible for conducting the public policies indicated by him or under his hierarchical control. In concrete terms, what is perceived is that there is no complementarity between the ways of participating. There is no dialogue for the construction of concrete proposals and projects. What we have are spaces where the manager publishes ideas previously constructed without the popular participation and the audiences serve only to give a certain appearance of popular legitimacy.

From the moment that it is considered that participation, as a fundamental right, would be based on the popular sovereignty already emphasizes a visibly political aspect of the administrative participation. In this way the participation should be effective, with real possibility of intervention in the decisions of the public power and in the directions of the society in which the citizen is inserted.

For Habermas (2001) the legal concept of self-legislation must gain a political dimension and be broadened in terms of the concept of a society that acts upon itself in a democratic way. Only in this way can one read in the existing Constitutions the project of implementing a just and well-ordered society.

We understand that in order to overcome certain occult forces, or at least that is how they present themselves, such as financial capital, political oligarchies and real estate speculation, we must renegotiate the relationship between the State and society as a way to avoid mitigating decision-making and participation spaces Popular, as a means of curbing legislative authoritarianism and thus trying to save what remains of a "democracy" (if one can use that term after our theoretical study and the clash with the reality of the motherland).

From this perspective, from the lessons of Lefebvre and the idea of popular participation as a corollary of democracy, we must think of a new urban strategy where the right to the city manifests itself as a superior form of rights: the right to full liberty, individualization in socialization, Habitat, and habitation, as well as the right to work (the participant activity) and the right to ownership (other than the right to property). However, for urban society to represent social emancipation, it is necessary to renew critical theory and to overcome the limits imposed by urban law.

3 TO RE-THINK THE URBAN LAW

The present stage of evolution of urban society, characterized by complexity, seems to threaten the consistency and coherence of law. In Brazil, the distance between constitutional idealities and social realities is indicative of this diagnosis. Official law, to maintain its coherence and consistency, in the face of what is traditionally understood as deviation, dysfunction, or social contradiction, ends up producing its own operational continuity and, therefore, distancing itself from the society that legitimizes it.

Given this context of ineffectiveness of legal monism, legal pluralism presents itself as an alternative capable of representing the opening of the legal system before the society that surrounds it, increasing its effectiveness. In other words, it is no use concentrating all efforts for the legal city if the illegal cities and the irregular cities where individuals live, not less citizens or subject human beings coexist in the same space and time.

At this point, the contribution of Boaventura de Souza Santos in the works "Renewing critical theory and reinventing social emancipation" and "The criticism of indolent reason: against the waste of experience", which affirms that the final crisis of modernity is more visible as an epistemological crisis (a crisis of modern science) than as a societal crisis (a crisis of the capitalist world).

For the author, modernity collapsed as an epistemological and cultural project (Santos, 2011), which opens a wide range of future possibilities for society, one of them being a future non-capitalist and socialist eco (The postmodern opposition).

It is believed in the reflection on the epistemology of a disciplinary field of human knowledge that we can unravel its limits, pose new questions, and overcome old obstacles. In the case of the legal field, it is necessary to realign its praxis with the praxis of academic research, which means to return to the legal world the primacy of rationalist doubt and critical historical configuration.

In the words of Boaventura de Souza Santos, the emancipatory scientific knowledge of law aims to discover, invent, and promote the progressive alternatives that social transformation may require. It is an intellectual utopia that makes possible a political utopia (Santos, 2011).

Thinking about the right to the city implies thinking about Urban Law, as well as the instruments and structure that can perform this task, which in turn refers us to the debate on public policies and social policies, as well as a global analysis of the Democratic State of Law itself. At this point are the theories of Henry Lefebvre with his critique of knowledge and theories of Boaventura de Sousa Santos in the perspective of an ecology of knowledge for social transformation.

As opposed to the natural environment, the cities, in which most of the contemporary population lives, constitute the built heritage. In this sense, we can define urbanistic law as the branch of law that regulates the production of the built environment. Specifically, about its installment, occupation and use.

The definition of these functions in contemporary cities requires adequate planning in the sense of separating and integrating the different uses and investments to be made by the public and private sectors. In addition, increasingly frequently, the production of the built environment must consider the need to preserve environmentally sensitive areas located within the urban perimeter of cities.

In this sense, the urban master plans stand out as an instrument of the municipal planning process aimed at the integrated achievement of objectives in the physical, economic, social, and administrative fields. Alongside this function, after the 1988 Constitution, the master plan becomes a basic instrument of municipal urban policy with a view to the full development of the city's functions. But in reality, the state never stopped the monopoly of law, and it is important to recognize the sociological existence of a constellation of rights and its rejection by the political order. In addition, it is essential to understand that law has contributed decisively to the dichotomy of the state / civil society that hides the nature of power relations in society (Santos, 2011).

It is well known that one does not change the world and urbanism at once, but using the lessons of Boaventura de Souza Santos it is important to do two things: to work within the conventional university and to create parallel institutions. For a long time, we will have to act like this. This is characteristic of a time of transition: working the old to renew it, being necessary to reinvent knowledge-emancipation. We are at a time when it is necessary to think of a critical utopia (Santos, 2007).

4 THE IMPORTANCE OF DIALOGIC ADMINISTRATION FOR A NEW URBAN STRATEGY

In recent decades, the transformative movements of the contemporary state have sought not only to reassess the ends of the state, but also to re-examine the typical functions of the social state model and the way in which such functions were commonly performed.

With the rise of phenomena such as the network state (Castels, 2002) and Public Governance, a new form of administration emerges, whose references are dialogue, negotiation, agreement, coordination, decentralization, cooperation, and collaboration.

Thus, the process of determining the public interest starts to be thought from a consensual and dialogical perspective, which contrasts with the dominant imperative and monologic perspective, averse to the use of communication mechanisms internal and external to the administrative organization.

Explicit JJ Gomes Canotilho (2006), referring to the expression Good Governance, whose normative meaning would be "responsible conduction of State affairs", that Public Administration not only addresses the direction of government and administration matters, but also the responsible practice of Other powers of the State such as the legislative power and the jurisdictional power.

According to Odete Medauar (2003), the consensus-negotiation activity between Public Authorities and individuals, even informal ones, began to assume an important role in the process of identifying public and private interests, under the protection of the Administration. It no longer holds exclusivity in the establishment of the public interest; Discretion is reduced, the practice of unilateral and authoritative decision-making is tempered. The Administration must be turned to the community, getting to know better the problems and aspirations of society.

According to our Federal Constitution, urban policy must necessarily be a product of popular participation. But the issue is not just legal. Brazil has no tradition of effective instruments of participation or sharing in solving problems in the public sphere.

It should be noted that the constitutional command of guaranteeing popular participation and the State's duty to carry it out is not sufficient. Another element must be added: the political and programmatic commitment of the government, which commands the different portions of the State.

As already mentioned, it is often verified that the Administration does not favor participation, even in portfolios that historically adopt "democratic" models.

Specifically, what is perceived in Natal and in several cities throughout the country is that there is no complementarity between the ways to participate. There is no dialogue for the construction of concrete proposals and projects. What we have are spaces where the manager publishes ideas previously constructed without the popular participation and the audiences serve only to give a certain appearance of popular legitimacy.

Probably still a remnant of the authoritarian view of management derived from the liberal matrix of administrative law. This is because administrative law was developed based on the liberal model of state, in force from the 16th century onwards. XIX, a period in which imperativeness (a notion expressing the authority of the State in relation to individuals, resulting from sovereignty) ended up conforming the institutes and categories of this legal branch (Oliveira and Schawanka, 2009).

By this power of empire, typical administrative action was forged, which was manifested through administrative acts, whose essential attributes were subject to the notion of authority. Such a vision can no longer thrive in the present context. In this sense, several administrative emphasize the importance of consensual as a line of evolution and transformation of Public Administration in the 21st century.

Thus, giving more scope to the citizen, the contours of participation as an implicit fundamental right, could be more adequately unveiled by thinking of it as a political right.

Exemplifying the right to popular participation and the right to the city in the local context it is necessary to remember the total lack of commitment of the public power with the accomplishment of the councils provided for by the Statute of the City.

In this context, the study intends to study the role of Urban Law in a broad way for the necessary social adequacy and its current importance for the regulation of the urbanization, occupation, and land use in cities (Pinto, 2000).

The proposed criticism is based on the understanding that the norms and the current juridical-institutional framework are in disassociation with reality from the beginning of its conception and are presented in the service of the hegemonic strategy of capital.

Such discussion is inserted in the context of the concept of Networked State and of Public Governance, while the new public administration in the 21st century. It turns out that it is urgent to discuss Public Governance in the study of Law as not only a new generation of administrative and State reforms, but mainly the foundations that aim at joint action, carried out in an effective, transparent and shared manner, By the State, by companies and by civil society, aiming at an innovative solution of the social problems and creating possibilities and chances of a future sustainable development for all the participants of the life in cities.

5 FINAL CONSIDERATIONS

We tried to proceed to the conceptual reconstruction of the right to the city from a political conception by essence. This idea is fundamental to address the issue of legitimacy and legitimation of public

decisions within the city of Natal-RN as well as has an influence on the analysis of the experiences found associated with new urban practices.

It is not our intention to make closed conclusions about the subject. On the contrary, the purpose of these reflections was to promote the debate about the relation between law and urbanism, specifically to verify the difficulty of a true popular participation and effective exercise of the right to the city in the current context of the study of the urban right from the lessons of Henri Lefebvre and Boaventura de Sousa Santos and walk towards new possibilities.

It is believed, therefore, that deconstructing certainties to meet new certainties is part of the course of knowledge. Research demands discernment in the choices and preserves its essence in the exercise of the options of how to do science, especially when it comes to thinking the law without reproducing the private logic, which is almost always the logic of profit, combined with the absence of effectively democratic instruments, often worsening social inequalities, and contributing to injustices in the space sphere.

In other times the scientific article would begin with the normative text, probably extolling the force of articles 182 and 183 of the Federal Constitution of 1988 and the great progress achieved with the Statute of the City. And, it would probably develop all of it from the rhetoric of the legal instruments of planning and management of the cities characteristic of urban law.

However, the study of the right to the city took other dimensions after joining the universe of social sciences. Our pre-established ideas have turned into real dilemmas; That is, it ended up bringing some dissatisfaction with what was being investigated. This discomfort provoked by the theoretical debates led to the development of this brief study. The answers we have about the right to the city and popular participation do not seem satisfactory to us. In fact, not even the questions on such topics seem to us to be well formulated to address the crux of the problem. It does not only matter to encourage the creation of collegiate bodies of urban policy or public hearings for the implementation of the democratic management provided by the Statute of the City, but we must go further.

It is noteworthy that there is something intrinsically wrong in the way that science and urban law have adopted to maximize their effectiveness in converting the model of sociocultural modernity in cities with capitalism. The problem to be discussed is how the state can choose its priorities to give meaning to true

social participation. To overcome the problems of the city we believe that only the mobilization of the community can transform our reality.

We realize that an important challenge is the recognition of the rights of popular participation and the right to the city by the population. It is hard to claim what you do not know. We stand for collective and conscious participation. And not a maneuver for politicians. As we have tried to argue, the effective participation of the population in management indicates the potential of this space in constituting a public sphere of concertation between the different actors and their respective interests around socially agreed public policies. In conclusion, we can walk towards the utopia of the right to the city from the popular participation, which is essential for an urban strategy beyond the fetishism and technicality of urban law.

Based on all that has been exposed the only conclusion we can come to is that the dialogue about the right to the city as utopia and rights of participation is essential to minimize the effects of inequality and domination in cities. However, the paths to effective implementation are diverse and deserve further study. It is hoped that this will be a first step towards utopian aspiration and the strengthening of new urban strategies with a view to promoting the right to the city.

ID 1703 | CORRUPTION AND ORGANIZED CRIME IN THE FIELD OF URBAN PLANNING

Francesco Chiodelli¹

¹Gran Sasso Science Institute
francesco.chiodelli@gssi.it

1 ILLICIT FORMS OF URBAN DEVELOPMENT AND GOVERNANCE

Although corruption and organized crime are the focus of a great many recent studies published in political science, sociology, and criminology, very few of these studies pay much attention to the spatial dimension and urban scale of these phenomena (Hall, 2013; Weinstein, 2008). For example, the inquiries that pivot specifically on the problems of corruption and organized crime in the domain of urban planning are a handful¹. This omission is somewhat bizarre given the extent of the phenomena in question. For instance, according to Transparency International (2013), some 21% of people interviewed in countries all over the world admitted they had paid bribes for “land services”, and another 21% had greased palms for “registry and permit services”, which includes land registry and building permits. In fact, many researchers have noted that corruption is particularly rife in the planning sector (Chiodelli & Moroni, 2015; Cullingworth, 1993; Gardiner & Lyman, 1978; Murray & Frijters, 2016). Moreover, the research available at present entirely lacks in-depth case studies that would provide greater insights into the real mode of operation of corruption in a specific political-institutional system.

The present paper is a first attempt to fill this gap. In particular, it conducts a detailed study on some recent episodes of corruption in the field of urban planning in the municipality of Desio, close to Milan (Italy). These episodes took place in an environment characterized by the rooted presence of a mafia-type organization known as the ‘Ndrangheta². The analysis aims to shed light on the various types of corruption that prevail in the planning field related to the case in question. It outlines the main issues at stake, the key public agents involved, and the stages of the planning process most vulnerable to corruption. This makes it possible to formulate some general hypotheses about the main institutional factors determining corruption in the planning domain, and about the role of mafia-type organized crime within this framework.

To be noted is that this inquiry provides also new input to the ongoing discussion regarding the “dark side” of planning. Several authors have dwelled upon the regressive aspects of planning and its use as a tool to consolidate the political agenda of dominant groups (see for instance: Chiodelli, 2017; Gunder, 2003; Flyvbjerg; 1996, 2015; Yiftachel, 1995, 1998). To date, however little or no research has sought to ascertain how planning is employed (and the incentives that it generates) for unlawful ends, such as favoring real estate operations by organized crime, or enabling certain individuals in positions of power to obtain special personal benefits through corrupt practices.

For this reason the present paper is divided as follows. The first section provides some background details, in particular those linked to the presence of organized crime in Desio. The second section gives a detailed report on various instances of corruption related to the local master plan of 2009. The next section enquires into the particular kinds of corrupt practices which have taken place in the case studied. It also presents some general hypotheses as to the factors determining corruption in the planning domain. The last section is devoted to the conclusions.

¹ The most comprehensive study currently available on corruption in the planning field is by Gardiner and Lyman (1979); among recent theoretical contributions to the discussion, see Chiodelli and Moroni (2015). Other research concerns specific countries: for Spain, see García-Quesada, Jiménez, & Villoria (2013, 2015), Jiménez (2009), Jiménez, Villoria, & García-Quesada (2012); for Italy, see Cappelletti (2012), Granata and Salvoldi (2012).

² On the specific features that distinguish mafia-type organized crime from mere organized crime, see Sciarone and Storti (2014). For an overview on the ‘Ndrangheta, see Sergi and Lavorgna (2016).

2 THE CONTEXT: ORGANIZED CRIME, CORRUPTION, AND URBAN DEVELOPMENT IN DESIO

2.1 THE 'NDRANGHETA IN LOMBARDY AND DESIO

Since the 1990s several judicial investigations have brought to light a phenomenon that is new to Italy: the infiltration and settlement (Sciarrone and Storti, 2014) of mafia-type organized crime in various regions of northern Italy (Sciarrone, 2014)¹. The north was for long considered off-limits to mafia-type organized crime, a phenomenon generally associated with the south of the country. However, Lombardy has been infiltrated, and the kind of organized crime currently most common in this region is the 'Ndrangheta, which originates in Calabria (the "toe" of Italy) (Sergi & Lavorgna, 2016). The 'Ndrangheta in Lombardy is conspicuously present in Milan, and in boroughs scattered across the city's metropolitan area (Chiavari, 2011; Ciconte, 2010; Rossi, 2015; Storti, Dagnes, Pellegrino, & Sciarrone, 2014).

The most extensive judicial investigation so far conducted on the 'Ndrangheta's presence in Lombardy goes by the name of "Endless" [Infinito]. The investigation was conducted over a span of several years, and in 2011 led to the conviction at first instance of around 160 individuals. The Infinito probe revealed the presence of various 'Ndrangheta locali (cells)²

The municipality of Desio has around 40,000 inhabitants, and lies some ten kilometers north of Milan³. It sits in an extensively built-up area with many factories and production units, all closely connected with Milan from an economic and functional point of view.

Desio was one of the first cases of 'Ndrangheta's infiltration in northern Italy (Tribunale di Milano, 2010b). In fact, the Desio cell had already begun its activities in the 1970s (Storti, Dagnes, Pellegrino, & Sciarrone, 2014), extending its tentacles into various fields, both legal and illegal. It operates also in the real estate sector, where its returns are guaranteed through close contacts with politicians and bureaucrats in the public administration⁴. According to the magistrates involved in the Infinito inquiry, in fact, the Desio cell has managed to "permeate the nerve center of the local political system [...] to such an extent that we can readily state that members of the local 'Ndrangheta cell can rely on several important figures in public office to avoid obstacles and achieve their aims within the public administration" (Tribunale di Milano, 2010b, p. 688).

Following the publication of assorted material evidence (photographs and wiretaps) linked to the Infinito investigation, in November 2010 most of the members of the Desio council handed in their resignations, causing the collapse of the local government.

'Ndrangheta, corruption and town planning in Desio

An inquiry carried out after the Infinito investigation revealed widespread corruption in the field of urban planning and development in Desio. It was particularly linked to the 2009 local master plan [Piano di governo del territorio, PGT]. Among those involved in this system of corruption were politicians, municipal civil servants, and entrepreneurs.

Note that the inquiry into the PGT of Desio is separate from the Infinito investigation, and not explicitly linked to the activities of the 'Ndrangheta cell in Desio. There are two points, however, that should be stressed.

¹ On the factors that occasioned the transplantation of mafia-type organized crime to northern Italy, see Varese (2006, 2011).

² The term "cell" [locale] refers to an offshoot of the core 'Ndrangheta group that usually comprises one or two 'ndrine (families) from the same district of the Calabria region in the south of Italy. A cell operates in a distinct area (e.g., in one or more council constituencies) on a practically 'exclusive' basis, which means that there are no other competing cells in that area. Although each cell has autonomy in its activities, there is a higher-level structure that coordinates the various cells (Gozzoli, Giorgi, & D'Angelo, 2014).

³ In 2009 Desio passed from the Province of Milan to the newly-created Province of Monza and Brianza.

⁴ For an explanation of why criminal activity is rife in the building sector, see for example Lavezzi (2008).

Firstly, the judicial inquiry revealed that several key figures in the PGT investigation were in touch in various ways with individuals linked to the 'Ndrangheta. One of them was Rosario Perri, at the time director-in-chief of the planning office of Desio Municipality. According to the judicial inquiry, he had been "leaned on" by members of the 'Ndrangheta cell of Desio (Tribunale di Milano, 2010b, p. 697). Massimo Ponzoni, the then regional alderman for environment affairs and a local real estate entrepreneur, reportedly on several occasions came in contact with members of the 'Ndrangheta in Lombardy (Tribunale di Milano, 2010a). The latter, again according to the magistracy, channeled votes to Ponzoni during the regional elections of 2005 (Tribunale di Monza, 2012). More in general, as Ricchiuti observes (2013), "from the wiretaps, videos, and photographs, it has come clear that numerous political exponents and individuals in the administration have close relations with figures linked to the 'Ndrangheta."

Secondly, to be noted is that the cases of misconduct uncovered by the magistracy form part of an array of illicit dealings connected with Desio's urban development (which suggests that the incidents identified by the inquiry are probably only the tip of the iceberg) (L. Fregoni, the current director-in-chief of the planning office in Desio, personal communication, 8 April 2016). This context of widespread illegality is part and parcel of the climate of intimidation, omertà (code of silence) and impunity that the presence of the 'Ndrangheta has generated in Desio (Storti, Dagnes, Pellegrino, & Sciarrone, 2014), whose existence, in fact, was well known to anyone living and working in Desio long before the Infinito inquiry was launched (D. Cassanmagnago, alderman for urban planning in Desio from 2011 to 2015, personal communication, 3 March 2016).

Therefore, even though nothing emerged to prove any direct interference by organized crime in the formulation of Desio's PGT, as we shall see in Section 5, the presence of the 'Ndrangheta most likely indirectly fostered the instances of corruption analyzed here.

3 THE CORRUPT PLAN

3.1 INSTANCES OF CORRUPTION RELATED TO THE 2009 LOCAL MASTER PLAN

In April 2014 the Monza court issued a judgement at first instance in the trial concerning several matters linked to the 2009 Desio PGT¹.

The trial pivoted on three people – Massimo Ponzoni, Antonino Brambilla, and Rosario Perri – all sentenced in the first degree to several years in prison. At the time of the events, Ponzoni was the regional alderman for the environment, and regional coordinator of the Forza Italia party². Brambilla was the alderman for urban planning in Desio. Perri was director-in-chief of the planning office in the Desio municipality. In many cases, the corruption mechanism worked as follows: Massimo Ponzoni applied pressure on Antonino Brambilla and Rosario Perri so that certain decisions were taken in favor of specific people or companies, from whom Ponzoni received various benefits (such as money for himself or funds for his political activities). Meanwhile, in exchange for their services – and thanks to Ponzoni's intervention – Brambilla and Perri obtained consultancy posts for both public bodies and private companies, and even public offices (both were appointed aldermen for the Province of Monza and Brianza), together with money and material benefits of other kinds (Tribunale di Monza, 2014).

The most salient instances of corruption in the investigation concern similar occurrences whereby, broadly speaking, the 2009 PGT allowed building on land that had previously been assigned to agriculture, with

¹ The inquiry was dubbed "Pellicano" (Pelican) by the newspapers, which borrowed the name of one of the real estate companies at the centre of the investigation. This was one of the few recent cases in which the Italian magistracy has focused its inquiries exclusively on corruption in the planning sector. Given the methodological difficulties of studying corrupt practices (Ades & di Tella, 1997), the documents of the magistracy are therefore extremely useful: the wiretaps, interrogations, and reports made available furnish a detailed picture of the entire affair that would otherwise have been impossible to reconstruct. The judicial material was integrated with detailed investigations in the field conducted by the author from May 2015 to September 2016.

² Forza Italia is the political party created by Silvio Berlusconi in 1995. The party governed the Lombardy Region from 1995 to 2013, through the presidency of Roberto Formigoni.

various advantages accruing to the indicted trio or persons associated with them. An example is provided by the events regarding the so-called “Transformation Area No. 2” [ATR No. 2] (see fig. 1)¹.

The ATR No. 2 concerns a portion in the northeast of the Desio council area, which is prevalently farmland and hosts a rural hamlet dating to the seventeenth century with several historic buildings. The 2009 PGT envisaged a change in zoning from farmland to development, for which two large building projects were proposed: a scheme of residential units next to the historic hamlet, and a mixed shopping and office complex in the northeast segment of the area (Comune di Desio, 2009a, pp. 183–84). The change in zoning land-use alone would have netted the owners some 16 million euros (Tribunale di Monza, 2012, p. 97) – on top of which we can add the value generated by the sale (or rent) of the buildings constructed on the parcel of land in question.

To be noted is that the PGT authorized this transformation of the zone even though the same plan elsewhere acknowledged the unique value of the area as one of the very few remaining stretches of Desio’s territory with significant environmental and historical value (Comune di Desio, 2009a, pp. 145–47). This, moreover, is the reason why the Milan Provincial Authority [Provincia di Milano] – which by law was empowered to express judgement on the Desio master plan and the compatibility of its contents with the broader Provincial Territorial Scheme [Piano Territoriale di Coordinamento Provinciale] – issued a detailed report strongly advising against the transformation of the area in question, and urging that the planning decision be rescinded.

The situations of the other three ATRs in the plan followed a similar pattern: the zones switched from farmland to residential, commercial, or tertiary areas. Overall, the value of the land of the four ATRs in question rocketed from 8.7 million euros before the PGT to 62.3 million after (Tribunale di Monza, 2012, p. 97). According to the judicial report, in all the cases mentioned the reason why the local master plan allowed the building development of these green areas can be traced back to corruption practices and illicit pressures.

That said, illicit behavior and corruption were not exclusive to the manipulation of land-use for these four areas. For instance, in the case of the ATR No. 4, the areas ceded by the real-estate developer to the Municipality in exchange for the reallocation of end-use were less than the amount required (54,000 sq.m instead of 72,000); urbanization levies were far less than those envisaged by law (2.7 million euros instead of 5.7); and the gross surface area of paving effectively awarded by the Municipality for development was around 3,000 sq.m more than the quota required. Note that these figures were not established in the PGT, but specified in the detailed scheme [Piano di attuazione] and in the planning agreement [Convenzione urbanistica] relative to the transformation area in question – according to Italian law, in fact, the development of a plot zoned as a building area in a local master plan requires the drafting and approval of a detailed scheme and a planning agreement that provide all the specifics of the project.² To this back-story we should add that a portion of the area scheduled (amounting to around 2,000 sq.m) was purchased by the real estate company from the Municipality for a sum below the market price (i.e. 160,000 euros instead of the likely market value of around 400,000 euros); furthermore, certain bureaucratic problems regarding the ownership of the development area were sidestepped by the Municipality so as not to slow down the planning procedure of the area scheduled (amounting to around 2,000 sq.m) was purchased by the real estate company from the Municipality for a sum below the market price (i.e. 160,000 euros instead of the likely market value of around 400,000 euros); furthermore, certain bureaucratic problems regarding the ownership of the development area were sidestepped by the Municipality so as not to slow down the planning procedure of the area scheduled (amounting to around 2,000 sq.m) was purchased by the real estate company from the Municipality for a sum below the market price (i.e. 160,000 euros instead of the likely market value of around 400,000 euros); furthermore, certain bureaucratic

¹ According to the regional by-law on urban planning, the “Strategic Plan” [Documento di Piano] must contain clear indications of the transformation areas [Ambiti di trasformazione], i.e. areas of considerable size on which significant transformations are intended to take place. The Strategic Plan is one of the three documents that compose the local master plan, together with the “Public Services and Facilities Plan” [Piano dei Servizi] and the “Regulatory Plan” [Piano delle Regole].

² For instance, the exact location of each building unit, the layout of the streets, the areas that the private party must cede to the Municipality, the sums that the private party will disburse as a contribution to public works.

problems regarding the ownership of the development area were sidestepped by the Municipality so as not to slow down the planning procedure¹. (Tribunale di Monza, 2014)

The judicial inquiry uncovered further illegal business regarding other urban developments, albeit of less magnitude than those cited above. This concerns, for instance, some other cases of change of end-use and personam: specific areas were assigned with building rights for the main purpose of benefiting specific landowners, who had ties with the three figures indicted in the trial. Another instance is the deliberate delaying of the necessary joint signing of a planning agreement between the Municipality and a developer so as to exert pressure on the latter to sell a building to one of the indicted parties for a lower price.

Generally speaking, as the court itself wrote, all these operations were “openly in contrast with the principles of impartiality, standard procedures, and proper conduct of the Public Administration [...]”. The only logical explanation for such conduct lies in the presence of a set of private interests served by public officials, and in the relative ‘payoffs’ that those public officials received in exchange” (Tribunale di Monza, 2012, p. 70).

3.2 THE REST OF THE PLAN

The judicial inquiry concerned a limited number of the land transformation cases envisaged by the PGT (mainly the four ATRs) (see fig. 1). And yet one gains the impression – despite the lack of substantiating evidence – that other sections of the PGT may also have been subject to illicit pressures. This impression is given by various factors.

The 2009 PGT foresaw the urbanization of around 1.4 million square meters of council land. A small portion of these transformations (some 400,000 sq.m) concerned the four ATRs involved in the judicial inquiry; the rest regarded the so-called “Infill zones” [Ambiti di completamento]. These were lots which, on paper, ought to be fairly small in size and located within the built-up area, and which were hence presented as “filler” schemes for the existing urban fabric (Comune di Desio, 2009b, p. 51). In practice, however, a fair number of these appointed infill zones included empty parcels of land outside the built-up area, some of considerable size, others in actively cultivated farmland (see fig. 1).

Fig. 1 – Areas of urban expansion (Transformation areas and Infill zones) envisaged by the 2009 Desio PGT. Source: Comune di Desio (2009a) (elaborated by the author).

¹ Planning laws impose that a prerequisite for the approval of a detailed plan is that the subject proposing the transformation must effectively be the owner of all the areas in question. In the case of the ATR No. 4, when the detailed plan was approved, the private company did not yet own a land parcel involved, which was instead still owned by a public subject.

It is very unlikely that the decision to convert all these tracts of land into buildable areas took place without any form of illicit maneuvering. Indeed, accusations of assigning building permits “on the basis of surnames” were voiced on various occasions during City Council meetings on the PGT (Comune di Desio, 2009c, 2009d). Note, for instance, the words of a professional close to the municipal administration (D.C., personal communication, 17 May 2016): “Rumor has it that in many cases the business of marking out areas for infill operations was done systematically: if you wanted a given plot to be zoned as a building area, you had to pay someone off. And, in fact, if you look at the plan, there are some glaring cases of atrocious decision-making.” Similarly, during the draft phase of the plan, there was widespread talk of property shifting hands, basically plots of agricultural land that soon afterwards were relabeled as buildable in the 2009 plan (R. Corti, Mayor of Desio from 2011 onwards, personal communication, 28 May 2015). Some of these rumors were confirmed by the judicial inquiry (Tribunale di Monza, 2014).

Moreover, the sheer size of the buildable areas inserted in the 2009 PGT is striking when seen in light of the fact that the Desio Council’s territory is already densely urbanized: in the year 2012 that area amounted to 67% of the council’s total surface (9.84 sq.km out of 14.66) (PIM, 2015). At the same time, within the town itself there are various pockets where revitalization and densification projects are possible (Comune di Desio, 2015; A. Lanzani, planner in charge of the new PGT of Desio, approved in 2015, personal communication, 3 March 2016). The 2009 plan, in fact, makes repeated reference in the clearest of language to the importance of limiting the urbanization of new land, and conserving the scant agricultural land still pertaining to the community: “The consumption of land has reached levels of serious alarm. [...] We are facing a] process of ongoing assault and rampant consumption of the territory and natural amenities. [...]One] of the main issues that planning must tackle is the urgent need to retrieve, regenerate and conserve our agricultural land” (Comune di Desio, 2009b, pp. 137–38). In spite of such outspoken declarations of principle, the plan itself has enabled the urbanization of no less than 1.4 million square meters of vacant land, equal to 10% of the council’s entire territory (a third of its unbuilt surface area). Paradoxically, this choice is justified by its proponents by the need to protect green areas (Comune di Desio, 2009a, 2009d): in exchange for the building permits conceded, the Administration has apparently had the opportunity to obtain significant areas of land which it would subsequently safeguard or transform into greenspace amenities. However, in the eyes of the Monza Court, these justifications are hardly defensible (Tribunale di Monza, 2014). In fact, the conservation of unbuilt spaces of land may be easily accomplished without having to convert spare terrain into buildable land, the simplest way being to re-zone (or to keep the end-use of) these areas as greenspace.

Note that these contradictions between the declarations of intent in the plan and the technical choices effectively made recur in several other passages of the document. Take for example the question of heritage conservation. Here and there the plan proclaims the need for Desio to safeguard the meagre remaining testaments to its past (Comune di Desio, 2009b, p. 25). This heritage is declared to be in need of special conservation schemes aimed at preserving “its fundamental original features” (Comune di Desio, 2009b, p. 29). Among the few heritage sites that the plan identifies (a total of four), one is the rural hamlet lying alongside the ATR No. 2 cited earlier. Nevertheless, as noted above, despite the clarion call for conservation of the said area, in the same breath the plan advances a scheme for a massive building program that would utterly disfigure the area’s original nature. The Tribunale di Monza (2014) is outspoken on the matter: for the Court, the declarations of the planners regarding the “technical reasons” for such planning choices are “seriously disconcerting” and betray “professional incompetence or dishonesty”.

Consider that the 2009 PGT was actually drawn up by some noted planners currently holding positions at one of Milan’s main public universities. So far the magistracy has excluded them from any legal liabilities, while underlining the fact that their *modus operandi* “does not honor the profession, given that these technicians merely accepted the requests of the politicians involved in the procedures and drew up the plan according to those requests” (Tribunale di Monza, 2012, p. 71). One of the planners involved in the PGT admitted to receiving heavy political pressure not to oppose the urbanization of certain areas; so heavy, indeed, that she was forced to reach a “compromise” (Comune di Desio, 2008). What emerges from all this is that the PGT provided a sort of “technical cover” for the background operations (some of which were wholly illicit) that certain political figures aimed to actuate in order, for example, to keep the political parties opposing their strategies quiet (Corti, personal communication, 28 May 2015; Lanzani, personal communication, 3 March 2016).

4 DISCUSSION: FORMS AND DETERMINING FACTORS OF CORRUPTION IN THE PLANNING DOMAIN

4.1 FORMS OF CORRUPTION

The instances of corruption in the Desio case concern two distinct phases in the planning process (see Table 1).

Phase	Planning Documents	Object of the corrupt transaction	Main figures with decisional power and/or influence
Drafting the local master plan	Local master plan [PGT]	- assigned end-use of the land - building quotas	Political bodies (e.g., Local Planning Commission, executive committee of the Municipality, City Council) and town-planners
Implementing the decisions of the local master plan	Detailed scheme [Piano di attuazione]	- buildable surface area - ratification of developer's requirements prior to plan approval	Technical bodies (planning office, and its director-in-chief)
	Planning agreement [Convenzione urbanistica]	- urbanisation taxes - amount of areas ceded by the real-estate developer to the Municipality in exchange for authorized development - procedure timeline	
	Other	- price of public areas to be purchased from the Municipality	

Table 1 – phases, types, and parties involved in planning corruption

The first is the phase in which the PGT was drafted and approved, and during which the crucial factor was the assignment of land-use and building quotas. What the corruptors wanted was to have specific areas designated for building development and to obtain high building quotas. Decision-making on the PGT was largely in the hands of the political branches of the Municipality and the planners assigned to drafting the plan; hence, we might suppose that, in this phase, the person most involved in maneuvering things behind the scenes was the alderman Brambilla. The planners themselves admitted that many choices were largely expressions of political intent, and were not based on a specific technical rationale. Similarly, Brambilla was credited as being the “artificer and inspiration” behind the plan (Comune di Desio, 2009d). It must be stated that in all the cases cited, the planning decisions followed the formal procedures to the letter: they remained within the legitimate bounds of political involvement, and were carried out in compliance with the procedures prescribed by the law. Nonetheless, the magistracy deemed that, despite the formal respect for the legal procedures, the decisions were made for illicit ends, i.e. in favor of specific private interests – for instance, those of the owner of the land now re-assigned as developable, and those of the politician who gained private rewards in exchange for his role in the decisions taken (Tribunale di Monza, 2014).

A second phase of the corruption process in Desio concerned implementation of the general decisions taken in the master plan. In this case the situation is more complex than in the previous one, owing to the complexities of implementing a master plan decision in Italy. The stakes were also varied. The main technical documents involved in the illicit pressures were the detailed schemes and the planning agreements.

In some cases, this illicit pressure was applied to obtain fraudulent benefits, such as a reduction of the standard urbanization levies disbursed to the Municipality by the private developer. This kind of operation works by bending the interpretation of planning regulations, or through outright fraud. This is made feasible by two factors. The first is the ambiguities of Italy's planning regulations, which leave a certain margin for interpretation in several instances. The second is that those who deliberately bend these interpretations are probably well aware that the sheer mass of intricacies, complex procedures, and myriad technicalities that characterize the Italian planning system ensure that scrutiny is very difficult and the fraud will almost

never come to light. Although many planning decisions are in fact submitted to democratically elected bodies – such as the Local Planning Commission, the Executive committee of the Municipality and the City Council^{second} is that those who deliberately bend these interpretations are probably well aware that the sheer mass of intricacies, complex procedures, and myriad technicalities that characterize the Italian planning system ensure that scrutiny is very difficult and the fraud will almost never come to light. Although many planning decisions are in fact submitted to democratically elected bodies – such as the Local Planning Commission, the Executive committee of the Municipality and the City Council^{second} is that those who deliberately bend these interpretations are probably well aware that the sheer mass of intricacies, complex procedures, and myriad technicalities that characterize the Italian planning system ensure that scrutiny is very difficult and the fraud will almost never come to light. Although many planning decisions are in fact submitted to democratically elected bodies – such as the Local Planning Commission, the Executive committee of the Municipality and the City Council¹ – their supervision covers only the basics of a given decision, and approval is often almost automatic. In fact, the political bodies in question are either pressed for time or lack the qualifications necessary to assess the technical details of the planning procedures that they are required to vote upon. These technicalities are entrusted to the municipal planning office, and they are the responsibility of the office's director-in-chief, who is therefore a key figure in the entire cycle of planning procedures.

In other cases, illicit forms of pressure take advantage of the margin of discretion legally permitted by the decision-making system. This can happen for instance during the negotiations of terms for a planning agreement. Here too no formal procedures are actually violated; and yet, according to the law, any public decision to make special concessions to a specific private citizen is unlawful if it is not ultimately in the public interest: witness the case above in which a parcel of public land was sold for far less than its market price. It is worth stressing that an illicit special treatment can also be geared to work against a private individual: for instance, the above-mentioned threat to delay a planning procedure is a form of illegal pressure that can be exerted on a building developer. As in the preceding case, once again the director-in-chief of the municipal planning office is a key figure, since he is directly in charge of these procedures.

4.2 THE FACTORS DETERMINING CORRUPTION

There are various theoretical models to explain the emergence of corruption in the public sector. Each of them emphasizes a particular aspect of the phenomenon (see Jain [2001] and Johnston [1996] for a review of different models). For example, certain approaches focus on the socio-cultural characteristics of a specific context (such as ethical norms and social values); other models stress the rational calculation of the costs and benefits brought by a certain illegal transaction.

Particularly interesting for the purposes of this study is the “neo-institutional” model, which emphasizes the burden of the internal dynamics and characteristics of a given institutional system. According to Vannucci and Sberna (2014, pp. 202–4), the spread of corruption in a specific period of time within a given political-institutional system (Ct) may be expressed with the following formula:

$$Ct = f(R; D; I; -A; -MC; Ct-1, t-2, \dots)$$

where R represents the economic returns generated by a public decision; D is the degree of discretion allowed to the public authority in creating, distributing and expropriating those returns; I is the potential of reserved information available to public officers to use for corrupt transactions; A is the degree of accountability within the public bodies; MC stands for the “moral weight” of the illicit transaction; C t-1, t-2,... is the backlog of corrupt practices, and how this inheritance fosters further involvement in corrupt dealings (ibid.).

What emerges from our study of the Desio case is that both the presence of organized crime and certain features inherent to the planning system itself influence the variables contained in the above formula.

¹ In Italy, the Planning Commission is composed mainly of the councillors; also the alderman for urban planning and the director-in-chief of the planning office usually attend the meetings of the commission. The commission analyses all planning decisions in detail, and expresses non-binding assessments on them. The Executive Committee is chaired by the Mayor and it is composed of appointed aldermen. The City Council consists of the elected councillors.

In our case, the presence of the 'Ndrangheta appears to contribute to the proliferation of corrupt practices in the planning field especially because of its influence on the moral costs (MC) and the mounting backlog of corruption (C t-1, t-2,...). In fact, the cell's presence in Desio has probably fostered the spread of many kinds of illicit dealings within the council administration for several decades, generating a climate of lawlessness and impunity in the town (Storti, Dagnes, Pellegrino, & Sciarrone, 2014). In this way, the cell has managed to lower the "moral cost" of fraudulent behavior in Desio, greatly increasing that "inherited backlog" of corruption in the building and urban development sectors. For example, Cassanmagnago (personal communication, 3 March 2016) speaks of a well-tested mechanism to control and share out building programs and real-estate operations in Desio: "there was a well-oiled mechanism in place whereby several political figures steered the planning decision-making processes, aided by technicians within the planning office and the collusion of estate agents." Likewise, Fregoni (personal communication, 8 April 2016) mentions numerous shady deals in Desio's planning sector over the past decades, particularly ones aimed at speeding up the issue of building permits, or reducing the risk of site controls.

While the presence of organized crime weighs on the moral costs (MC) and the backlog of corruption (C t-1, t-2,...) contained in Vernucci and Sberna's formula, the remaining variables seem to be linked mainly to the characteristics of the planning system. Let us consider these one by one.

Economic returns (R). In a great many cases, the economic returns generated by the planning field through public decision-making are considerable. A simple line drawn on a planning chart can determine whether or not a lot is developable, exponentially affecting its value¹. In the case of the four ATRs of the 2009 PGT for Desio, the mere identification of those areas as buildable land increased their value by over 50 million euros. A similar added value, obtained simply by the stroke of a municipal decision, becomes a huge incentive for landowners to put pressure – legal or otherwise – on those within the public administration with clout in the decision-making process.

Discretionary margin (D). These planning decisions, with their promise of huge returns, are characterized by a high degree of discretion. This is due to both "internal" and "external" reasons.

One of the internal reasons is the fact that the technical rationale of planning is particularly weak; the consequences are that, in many cases, it is subordinated to a political rationale, meaning that the main reasons for a great many planning decisions are of a political nature (Alexander, 1981; Chiodelli, 2012; Flyjberg, 2002, 2003; Mazza, 1995, 1999; Reade, 1987). Put briefly, there is no decisive technical basis to the planning choice made; that is, there is no "natural necessity" to determine whether a certain area is zoned as residential (and in what ratio) or left as farmable land. Obviously, this gives a great deal of discretionary power to the decision-makers. As said, during the drafting phase of the Desio PGT, for example, the planners commissioned admitted that some of the crucial choices related to land-use were of a distinctly political nature; for one, no technical factors were decisive in pinpointing the ATRs.

Among the external reasons is the fact that, at least in Italy, the public officials involved have few constraints in terms of their decisions on planning issues, for instance in terms of land-use and building quotas assignments (Moroni, 2007). To this we may add the fact that in Italy – as in other Western countries – during certain phases of the planning process, urban planning regulations explicitly allow a margin of discretionary negotiation between public and private. This refers, for instance, to the contents of the detailed scheme and planning agreement.

The Desio case reveals that there is also another type of discretionary power, which comes into play with the interpretation of the planning regulations: some of these norms allow a margin of discretion, because they are either incomplete or ambiguous. Consider for example when the schedule for signing the planning agreement is largely at the discretion of the municipal officer in charge: this kind of broad margin can clearly be used in an unlawful manner, as indeed happened in Desio. To sum up, as Epstein (2005, pp. 12) states, "The amount of discretion built into the [planning] system is simply inconsistent with the rule of law".

¹ 13 Due to the current crisis in Italy's building sector, today the economic returns from changes in land-use have diminished drastically; consequently one would expect the incentives for corrupt practices of this type to have diminished accordingly.

Reserved information (I). For certain planning decisions, the municipal officials can use their inside knowledge of confidential details as bargaining chips for personal gain in the course of illicit transactions. For example, they may have information on which areas will be assigned as developable in a local master plan. Here too, the case of Desio is instructive: it was rumored at the time that several properties changed hands in the run-up to the plan's approval (Corti, personal communication, 28 May 2015). The judicial inquiry confirmed those rumors: for instance, individuals later implicated in the inquiry purchased certain areas of ATR No. 1 a few years prior to the approval of the PGT on the basis of Ponzoni's promise to them that those lots would become developable. As indeed they did with the 2009 PGT.

Accountability (A). The degree of accountability in planning matters is often remarkably low. This is the result of two internal factors¹.

The first is linked to the aforementioned fact that many planning decisions (e.g., land-use assignments) are not based on an ineluctable technical necessity; in many instances, they are the result of discretionary power of a political nature. It is therefore extremely difficult to wind back and determine whether such decisions were made by means of unlawful pressure, also considering the fact that, from the outside, they are often procedurally correct – what is illicit is the motive behind the decisions made. This is exactly the case of several instances reported in the judicial inquiry on the 2009 PGT. Again, it is hard to prove the true motive behind a given planning decision, and this can only come about through lengthy and complex judicial investigation. “The background standards – shared benefit, public interest, convenience, necessity and so on – are so nebulous that even where there is a system of judicial review it is difficult to work out the grounds on which decisions have been made and whether they are right or wrong” (Esptein, 2005, p. 11).

The second factor is tied to the fact that, in certain phases of the planning process, the issues at stake are highly technical and complex. Take for example the calculation of the fees owed for urbanization, or the areas to be ceded to the public domain. It is therefore difficult, not only for the citizenry but also for the town councilors who vote on such decisions, to recognize choices that may have been made under illegal circumstances. Here the Desio case once again offers a useful yardstick: several choices cited regarding the detailed schemes for some of the ATRs turned out to be illegitimate; but, despite the fact that all these choices were submitted to the Local Planning Commission, which included several honest and scrupulous councilmen, nobody managed to detect the grave legal problems that were later detailed by the magistracy.

5 CONCLUSIONS

It is likely that criminal activities such as corruption and operation by organized crime groups exact a heavy toll on the spatial development and governance of a great many of cities worldwide. Despite the gravity of this fact, there is a glaring lack of empirical study on this phenomenon, and how it affects the urban planning domain in particular. With this in mind, the present paper hopes to start filling this gap. The analysis of what took place in the town of Desio (Italy) provides a particularly interesting illustration of the mechanisms involved: it has brought to light various aspects of how corruption manages to infest Italy's planning machinery. In particular, the Desio case enables us to pinpoint the critical moments in the planning process in which illicit dealings take place, and it illustrates which are the main public actors involved and what in particular is at stake.

For example, we have illustrated how corrupt practices can impact on both the local master plan, and the detailed schemes for implementing the master plan's decisions. The stakes change, however, depending on the phase, and likewise the kind of individual involved also changes, as well as the forms that corruption takes. In short, with reference to the draft phase of the master plan, the illicit activity aims principally at influencing the allocation of land-use and the relative building quotas allowed. This takes place mainly through operations that are formally correct yet driven by illicit motives, namely to ensure directly and specifically the advantage of both the corruptor and the corrupted (at the public's expense). The role of the political component (in this case, the alderman in charge of planning) is fundamental in enabling illicit operations of this kind of to work. With reference to the implementation of the master plan

¹ It goes without saying that the meagre level of accountability for planning decisions in Italy is linked also to factors not inherent to the planning system, such as, for instance, the sluggish and inefficient judicial system.

choices, the planning decisions become involved in more complex and nuanced forms of corruption. The latter affect various phases and documents pertaining to the implementation schedule (e.g., the detailed schemes and the planning agreements); they aim to obtain illicit benefits of different kinds (e.g. a reduction in development taxes, greater areas for building, fast-tracking the bureaucracy); and they assume various forms (including both directly illegal dealings, but also formally correct ones driven by illegitimate motives). During this phase, a key role is played by the technicians in the municipal planning office, particular the director-in-chief.

Generally speaking, analysis of the Desio case seems to corroborate the claim that corruption in the planning field is “in part due to certain features of the existing planning systems that offer various ‘incentives’ that encourage corrupt practices” (Chiodelli & Moroni, 2015, p. 451). The presence of organized crime – which forms the shadowy backdrop to the scenario discussed here – is a constant enabler of these illicit practices, for instance, because it fosters a climate of basic impunity and exemption within the political and institutional spheres. However, it is probably not their main and direct cause.

The above hypotheses concerning the incentives to corruption offered by the features of a planning system require further in-depth study and verification. However, if these hypotheses prove to be true, they can provide critical input for institutional expedients (e.g., an overhaul of planning procedures) that may hopefully reduce the incentives that the current planning system offers to corruption. Of course, this would not eliminate corruption entirely from the planning field (a fundamental role is played by the ethics of planners, politicians, and public officials; along with mechanisms of oversight and sanctions for wrongdoing); nor is it by any means the only way to combat corruption. But it would be a great improvement on the current situation, with its pervasive corruption in areas of urban governance and development, about which we still know very little, and to which few solutions can therefore apply.

ID 1732 | THE EFFECT OF LEGISLATIVE FRAMEWORK IN CONSERVATION PRACTICES: EXAMPLE OF TURKEY

Zeynep Özdemir¹; Burcu Yaşlak¹

¹Istanbul Technical University

zeynepozdemir37@gmail.com ; burcuyaslak@gmail.com

1 INTRODUCTION

In the last decade, site conservation and ideas against site conservation such as transformation and renewal have become considerably contradictory subjects in Turkey. The implementation on these subjects and new projects are also taken into consideration as research studies. Along with these implementations about conservation and renewal, it is important to think what is expected for cities in near and distant future.

In conservation and renewal studies, apart from their architectural, artistic, historical and esthetical values, cities should be evaluated with their social values. Moreover, it is a fact that they have a living identity.

As is known, the historical background of a built environment is the most important features that creates the identity of an area. Therefore, the conservation of historical environment has become an important component for the planning process. Important experiences have been obtained related with planning site conservation areas in Turkey, however there are significant problems in implementation especially at administrative level. Foremost among these problems are the troubles in the process of conservation planning and difficulty in creating a healthy relationship between urban planning system and conservation plans. Currently, urban areas and site conservation areas are planned within different legislations and organizational structure. Moreover, contradicting laws and regulations for site conservation areas result inconsistent implementations which different from each other in the same urban area.

The aim of this paper is to compare two legislations on protected areas in terms of functioning and implementation and investigate contradictory parts of these two legislations on public and personal property rights by comparing them item by item. Also, analyse the differences between these two legislations that based on conservation and renewal is another purpose of this paper. To answer the question “Are these legislations protecting or renewing?” we analyze causes and consequences of verdicts of Supreme Court on two public prosecutions. One of the Supreme Court decisions examines the obtained results, which are based on objection to protection and renewal studies within the scope of No.2863 Law on the Conservation of Cultural and Natural Property and the other No. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets. In conclusion, the urban conservation areas, in accordance with the no. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets, Renewal area announcements and projects in site area are excluded from the conservation plan approaches, principles and processes of the historic area. Because city planning and protection plan decisions are not co-produced, problems arise. As a result, the difference of these two laws are examined and evaluations are done regarding the solutions to these problems generated in urban spaces.

No. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets and announcements and projects of renewal areas in site conservation areas are segregated from site conservation planning approach of the area. Therefore, this situation creates the problem, which is the inability of producing urban planning and site conservation planning decisions together.

2 ANALYSING CONSERVATION AND RENEWAL LAWS WITHIN THE SCOPE OF LEGAL LEGISLATION FOR HISTORICAL AREAS IN TURKEY

In this part, ‘Law no: 2863 Law on the Conservation of Cultural and Natural Property’ and ‘Law no: 5366 Law on Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets’ are analysed item by item in order to understand their similar and contrasting sides with regard to process and implementation.

2.1 EXAMINATION OF LAW NO: 2863 ON THE CONSERVATION OF CULTURAL AND NATURAL PROPERTY

The aim of this law is “to define movable and immovable cultural and natural property to be protected, regulate proceedings and activities, describe the establishment and duties of the organization that shall set principles and take implementation decisions in this field”(Url-1).

In the law, concepts cultural such as property, natural assets, site, conservation, protection, conservation area conservation development plan, street improvement projects and implementation, interaction-transition area are also defined. Among these concepts, an article in the description of conservation development plan is important for this study. According to this article, the plan should take the interaction and transition zone into consideration and aim to conserve the cultural and natural assets in accordance with sustainability. What is more, the plan should be prepared on a base map and it should include a field

research, which involves archeologic, historic, natural, architectural, demographic, cultural, socio-economic, property and settlements data. Another important subject is that in article 7, which is related with identification and registration process, immovable cultural and natural property, and natural sites are described. The identification of immovable cultural and natural property and natural sites shall be coordinated by the Ministry of Culture and Tourism by obtaining the view of the relevant institutions and organisations the activities of which will be affected(Url-1).

Article 9- "Immovable cultural and natural property to be protected and conservation sites shall not be interfered with physically or by any way of construction, and used for service or modified for use contrary to the decisions of the Regional Conservation Councils within the framework of the resolutions of the Superior Council for Conservation. Substantial repair, construction, installation, sounding, partial or complete demolition, incineration, excavation or similar works shall be regarded as physical intervention and intervention by way of construction". The significance of conservation councils is mentioned(Url-1).

About who has the authority and administration on decisions taken related with conservation;

Article 10 – "The Ministry of Culture and Tourism shall be authorized to take the necessary measures or have others take the necessary measures to conserve immovable cultural and natural property, regardless of ownership or administration, control or have public institutions and organisations, municipalities and governorships carry out control". It is stated that the authority and method belong to the ministry(Url-1).

In the law, descriptions about expropriation areas are made. Moreover, information about how conservation development plans are prepared in the transition period with conservation rules and conditions of use in site areas.

Article 17 – (Amended: 14/07/2004 - 5226/8 art.)

- a. The proclamation of an area as a conservation site by the Regional Conservation Council shall halt all kind of planning implementation of any scale in this area. If applicable, any planning decisions and notes of the scale of 1/25.000 pertaining to the surrounding interactive area of the conservation site shall be revised by taking into account the status of the conservation site and be approved by the relevant administration.

(Amended: 8/8/2011-KHK-648/42 md.) Until completion of the conservation plan, the Regional Conservation Council shall determine the principles and terms of use to apply for the transition period within three months. Afterwards, the descriptions will shed light on the comparison and analysis of adjudications(Url-1).

In Article 57 the functions of the conservation councils are determined as follows:

Article 57 – (Amended: 17/06/1987 - 3386/14 art.) Regional Conservation Councils shall have the following duties and powers bound to the resolutions of the Superior Council for Conservation:

- a. To register cultural and natural property to be protected as determined by the Ministry,
- b. To group cultural and natural property to be protected,
- c. To identify terms and condition for building in the transition period within three months after the registration of conservation sites,
- d. To examine and decide conservation plans and all kind of related alterations,
- e. To determine the conservation site of immovable cultural and natural property to be protected,
- f. To delete records of cultural and natural property to be protected that have lost their specific characteristics,
- g. To make decisions on implementation relating to immovable cultural and natural property to be protected and conservation sites(Url-1).

2.1.1. EXAMINATION OF REGULATION ON THE IMPLEMENTATION OF THE LAW ON CONSERVATION BY RENOVATION AND USE BY REVITALIZATION OF THE DETERIORATED HISTORICAL AND CULTURAL IMMOVABLE PROPERTY

With the following additional paragraph: (Additional paragraph: 04/02/2009 - 5835/3 art.) "The Regional Conservation Councils for Preservation of the Cultural and Natural Properties which are set up as per Law No 5366 to approve any renovation projects in the renovation zones declared pursuant to Law No 5366 of 16/6/2005 On Preservation by Renovation and Utilization by Revitalizing of Deteriorated Immovable Historical and Cultural Properties Law, have the task and authorization to carry out the works which are specified by this article."

This article shows that both boards of the two laws have the same authority for the same places. Therefore, this results authority confusion for the two boards where one of them aims conservation and the other aims renovation(Url-1).

The traditional structures of urban areas, which are defined as urban sites with their cultural properties, and the traditional tissue can gradually lose their original qualities for various reasons. As a result, it is foreseen that in areas, which are registered and identified as site areas by Cultural and Natural Heritage Conservation Board should be restored in accordance with the development of the region, and No. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets went in effect.

2.2 EXAMINATION OF LAW NO: 5366 ON RENOVATING, CONSERVING AND ACTIVELY USING DILAPIDATED HISTORICAL AND CULTURAL IMMOVABLE ASSETS

Article 1- The purpose of this Law is to ensure that metropolitan municipalities, district and first-tier municipalities within boundaries of metropolitan municipalities, provincial municipalities and district municipalities, and municipalities with populations above 50,000, and special provincial administrations for the areas outside the purview of such municipalities, reconstruct and restore, in a manner consistent with area development, the areas registered and announced as protected areas by the cultural and natural heritage conservation boards and protection zones of such areas which have been dilapidated and are about to lose their characteristics, create zones of housing, business, culture, tourism and social facilities in such areas, take measures against risks of natural disasters, renovate, conserve and actively use historical and cultural immovable assets(Url-2).

This Law covers the procedures and principles relating to the designation of renovation areas which shall be formed according to the purposes specified above, the determination of technical infrastructure and structural standards, the design, implementation, organization, management, supervision, participation and utilization of the projects.

DESIGNATION OF AREAS

Article 2- Renovation areas shall be designated by a resolution of general provincial councils in case of special provincial administrations, and that of municipal councils in case of municipalities, passed by the simple majority of the full membership. The resolutions passed by general provincial councils in case of special provincial administrations, and by municipal councils in case of non-metropolitan municipalities shall be submitted to the Council of Ministers. In case of metropolitan municipalities, such resolutions as passed by district and first-tier municipalities shall, upon approval by the metropolitan council, be submitted to the Council of Ministers. The Council of Ministers shall decide within three months whether or not to implement the project in question (Url-2).

The implementation in the areas accepted by the Council of Ministers may be designed in consecutive phases within a program.

Phased projects and programs shall be implemented by a resolution of the council passed by the simple majority of the full membership and the approval of the mayor in case of municipalities, or of the governor in case of special provincial administrations.

All immovable assets within the boundaries of the designated area shall be subject to the renovation project to be realized under this Law after the cultural and natural heritage conservation board approves the renovation projects prepared by the municipality and the special provincial administration in question.

Renovation projects within boundaries of metropolitan municipalities but not prepared by metropolitan municipalities shall be approved and put into effect by the metropolitan mayor after such projects are prepared by district and first-tier municipalities and adopted in the councils. Expropriation and implementation shall be executed accordingly (Url-2).

Procedures and principles relating to the establishment of technical infrastructure and structural standards for the renovation areas, the management and organization of such areas and the participation of the right holders or local people shall be laid down in a regulation.

IMPLEMENTATION

Article 3- In the areas designated as renovation areas, special provincial administrations and municipalities shall implement or cause public entities or natural or legal persons to implement the renovation projects which special provincial administrations and municipalities have prepared or caused to prepare. In such areas, it shall be possible to implement the projects jointly with the Housing Development Administration or cause the same to implement them (Url-2).

In metropolises, district and first-tier municipalities shall alone or jointly implement or cause to implement the projects not initiated by metropolitan municipalities.

In respect of implementations in plots within the renovation area, the owner of the plot may implement the renovation with exact preservation of the building and plot provided that the integrity of the project be preserved, the design approved by the municipality be fully observed and the building be used for the purposes as designated by special provincial administrations and municipalities. In such cases, it is essential that the implementation be started and completed simultaneously with the project. Otherwise, special provincial administrations and municipalities shall apply the provisions of this Law (Url-2).

During the implementation of renovation projects, special provincial administrations and municipalities may make necessary arrangements including refinements and impose prohibitions for the renovation projects in order to implement necessary measures in the areas designated as the Ministry of Public Works and Settlement as running risks of natural disasters. Procedures and principles relating thereto shall be laid down in a regulation (Url-2).

Special provincial administrations and municipalities shall execute or cause to execute and finalize all control, supervision and monitoring actions during the implementation. Such actions shall be entrusted to specialist persons, institutions and teams according to the nature of the project. Implementations in the renovation area shall be exempt from all taxes, duties, charges and fees.

Regional boards of conservation of cultural and natural heritage shall be established as many as necessary pursuant to Article 51 of the Law No. 2863 on Conservation of Cultural and Natural Assets. The projects approved by the board shall be implemented by the special provincial administration or the municipality (Url-2).

RESTRICTIONS ON PROPERTY RIGHTS AND EXPROPRIATION

Article 4- The special provincial administration or the municipality may impose temporary restrictions of construction, utilization or operation on the existing immovable properties in the areas declared as renovation areas until the project is completed (Url-2).

Mutual agreement shall be the fundamental rule in dealing with the evacuation, demolition and expropriation of buildings located in the renovation areas. Where an agreement is not reached, special provincial administrations and municipalities may expropriate the immovable property owned by natural persons or private law legal persons. The expropriations to be effected under this Law shall be considered as expropriations with the purpose of realizing the housing projects stated in the second paragraph of Article 3 of the Law No. 2942 on Expropriation. Expropriation actions shall be executed pursuant to the same Article for those immovable properties for which no owners are identified in the land registry, a trustee has been appointed or on which there are disputes or legal action pending, and on which property rights or non-property rights have been established. For expropriation actions, special provincial administrations and municipalities shall be authorized to obtain decrees of heritance from courts, have trustees appointed or take action according to the owner last recorded in the land registry (Url-2).

Special provincial administrations and municipalities may, if they deem suitable, instead of expropriating the immovable property, purchase the property, exchange it on the basis of land for flat, or establish limited property rights through usufruct rights or right of construction as regulated in the relevant Articles of the Turkish Civil Code No. 4721(Url-2).

(Amended fourth paragraph: 27/4/2008-5793/45 Art.) The immovable properties owned by the Treasury located in the renovation area, excluding those which are allocated for public service, those which have preliminary permit or rights of easement established, the places covered under the Law No. 2565 on Military Forbidden Zones and Security Zones, civil and military airports and areas within the obstacle plans, shall be transferred free of charge to the special provincial administration or the municipality executing the project upon a proposal from the Ministry of Finance and by the Decree of the Council of Ministers. Transfer transactions shall be exempt from all taxes, duties and charges. The immovable properties which are not used in accordance with the transfer purpose within five years from the transfer date shall be registered free of charge, ex officio in the name of the Treasury. Fifty percent of the revenues derived from the said immovable properties after deducting project and implementation expenditures shall be transferred to the Treasury.

At places declared as renovation areas, the immovable properties covered under the renovation project may not be sold, leased, allocated or be subject to preliminary permit or right of easement by the Treasury until the transfer transactions are concluded(Url-2).

But it is foreseen that, there will be changes in property owners and other uses of the area as a result of the sua sponte implementation authority which is given to administrations with the Law no: 5366. Therefore, the most important axis of the law to be analysed contextually is the contradiction between planning discipline and the description of renewal area (Dinçer,2008).

The extreme example of sua sponte implementation authority, which is given to administrations, is that it made investors partners with property owners. The law does not seek for agreement. Moreover, if landowners do not come to a mutual understanding, it is possible to expropriate. This creates a one-sided power to administrations. In conservation areas the municipalities, which preferred this model rather than using public resources, created with Cultural and Natural Heritage Conservation Board, evaluates the historical district as an ordinary tender area(for example Beyoğlu Municipality) (Dinçer,2008).

INAPPLICABLE PROVISIONS

Article 7- The provisions of other laws contrary to those of this Law shall not apply to the renovation areas covered under this Law, without prejudice to the obligations arising from international law(Url-2).

This article of the law invalidates housing and property rights written earlier in the Turkish Constitution.

In the application regulations, the descriptions of concepts such as Cultural and Natural Heritage Conservation Board, renewal area, renewal concept project, renewal implementation project are given. It is crucial to understand these descriptions in order to understand the authority scope of both laws (Url-4).

Article 4-d) Conservation regional council: shall mean In accordance with Article 3 of the Law, The conservation of Cultural and Natural property Regional Council shall be established in accordance with Article 51 of the Law on the Conservation of Cultural and Natural Property No. 2863(Url-4).

- e. Immovable culture and nature assets: shall mean In accordance with the Law No. 2863, they are registered and declared by Cultural and natural property conservation council as immovable cultural or natural assets.
- f. Renewal area: shall mean an area of which boundaries are approved by the Council of Ministers upon the proposal of the competent authority in the Regions registered and declared as sites and conservation areas and conservation areas within this area,
- g. Renewal preliminary Project: that is concluded by the conservation of cultural and natural assets in accordance with Article 2 of the Law, It represents the preliminary reports of static, plumbing, electricity, transportation and infrastructures, and architectural preliminary project, which will be the basis for the renewal implementation projects.
- h. Renovation implementation Project: Shall mean is concluded by the conservation of cultural and natural assets in accordance with Article 3 of the Law, Historical and cultural immovable assets within the renovation area, constructions to be repaired or reconstructed and Survey, restitution, restoration projects state to the urban design, landscaping, architectural, static, mechanical-electrical installation and infrastructure projects which are envisaged in the development legislation(Url-4).

PARTICIPATION AND INFORMING THE PUBLIC

Article-7 "Property owners who are in the area of renovation by the competent authorities or Meetings are held to inform the people of the region about the implementation and their views are taken and their participation is ensured (Url-4).

The competent authority may organize consultation meetings with universities, professional organizations, civil society organizations ,public institutions and neighborhood representative and may inform about the projects by means of press and publications tools" (Url-4).

In the article 7, the participation is defined. However, this definition does not overlap with the concept of participation in the latest examples of planning discipline and implementation. It is observed that the regulation has a centralism scope and mandatory rules for planning and project process. The concerned ones are only informed about the result, are not included in the process. In other words, the process is totally left to administration's initiative (Dinçer,2008).

ESTABLISH OF THE REGIONAL CONSERVATION COUNCIL

Article- 12 In accordance with Article 51 of the Law on the Protection of Cultural and Natural Assets, number 2863, the Regional Conservation Council is formed as necessary to limit the powers and responsibilities to the renewal areas and to conclude the renewal projects (Url-4).

The ministry of Culture and Tourism has assumed the procedure of law enforcement in site areas. Moreover, it is validated that boards responsible for renewal areas will follow the same procedure as in Cultural and Natural Heritage Conservation Boards. In this respect, the Resolution on the Grouping, Maintenance and Repairs of Immovable Cultural Property No. 660 dated 5.11.1999 of the Supreme Council conservation is a binding document (Dinçer, 2008).

Thus, from today in the declared renewal areas with the Law no: 5366, the regulations and resolutions of Cultural and Natural Heritage Conservation Board has started to implemented. This slightly diminishes the concerns about conservation of physical tissue in historical heritage areas(Url-4).

Article 17- Following the decision of the Regional conservation council The renewal preliminary Project which is done or made by the competent authorities enters into force with the approval of the mayor in the municipalities and the governor in special provincial administrations (Url-4).

Within the borders of the municipality of the metropolitan, the Renewal preliminary project, which to stay out of the metropolitan municipalities's applications, enters into force with the approval of the mayor in the Metropolitan municipalities after the acceptance of district and the first-tier municipal councils(Url-4).

Renewal implementation projects are prepared on the basis of renewal preliminary projects and are implemented after approval of the Regional protection council.

PARTICIPATION IN THE PROJECT

In the applications of the parcels in the renovation area , the building which owned by natural and legal persons with the public institutions and organizations and to be preserved or renewed in the same way can be done by natural or legal persons or public institutions or organizations Provided that it is approved by the competent authority and the integrity of the project is not impaired. It is essential that this type of application be started and finished simultaneously with the project. The competent authority may expropriate such premises which are not completed on time, as if they could be completed by themselves.

As can be understood from the article 22, the statements in the regulation about project participation contrast with participation principle of planning (Url-4).

EXPROPRIATION

Article 24- The way to deal with the evacuation, destruction and expropriation of the structures in the renovation areas is essential. In cases where no agreement is reached, Immovables owned by natural or legal persons may be expropriated by the competent authorities. expropriations which made pursuant to Law are considered as expropriation.for the realization of Settlement Projects of the second paragraph of Article 3 of the Expropriation Law No. 2942 (Url-4).

Even though it is not stated in law, in the regulation's article 24, which organizes expropriation, it is mentioned that: "...If it is understood that the ordinary expropriation process will cause delay in the implementation of the project, urgent expropriation can be made according to the provisions of Article 27 of Law No. 2942..." This important verdict strengthens the administrations and brings the expropriation of all ownership within the renewal area in a short time. These expropriated ownerships are marketable to third parties and this creates a situation against public interest (Dinçer,2008).

Under the light of all these analysis, the differences and similarities of the laws are shown in the table below (Table 1).

No.2863 Law on the Conservation of Cultural and Natural Property	No. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets
The description for Conservation Development Plan is made.	While it has not mentioned any conservation plans, it describes renewal concept projects.
Is for sustain while conservation purpose.	Is for sustain while conservation purpose.
Pays attention to socio-cultural structure.	Without taken into consideration the socio-cultural structure, physical plans are made.
It has collaborative planning perception.	The description of "collaboration" in 7 th article does not overlap with the collaboration concept in planning discipline and practices.
Creates substantial solutions in most instances.	Intends to create gentrification.
	Gives spontaneous implementation authority to administrations, which results making investors partners with property owners.
	Invalidates housing and ownership rights, which are written before No. 5366 Law.
Expropriation is done when needed.	Promotes expropriation.
	Without a plan, the firm and municipality can make agreements and then produce projects. Company executives make deals with property owners. If they are unable to agree, expropriation rises as a threat. Yet it is not possible to expropriate without a plan.
	Project-based intervention manner.

Table 1. Comparison of two laws

As understood from the table, No. 2863 Law provides a collaborative planning perception via taking into consideration the socio-cultural structure of the area and on site conservation of historic tissue. On the other hand, No. 5366 Law brings a number of justifications in order to demolish and rebuild dilapidated historic tissue. This law has not mention any conservation plan although it describes renewal concept projects. For that matter, the firms and municipalities can create projects without a plan. In short, within this law, project-based major physical interventions can be done via ignoring socio-economic structure to historical areas.

3 ANALYSING THE DIFFERENCES BETWEEN NO. 2863 LAW AND NO. 5366 LAW IN THE IMPLEMENTATION PROCESS WITHIN THE SCOPE OF ADJUDICATIONS

These two laws to understand which cases are the subject of the file of these two laws and to examine the decisions made regarding the case was examined two desicion of Council of State 6th Chamber. One of which is determined as a renewal area which is mentioned Ulus, Hacıbayram Mosque and Bent Runnel and Ankara Castle and Surroundings in Ankara's historical city center covered by Law No. 5366. Another decision is related to changing the degree of the natural site boundaries of Hill of Dragos and its surroundings.

3.1. ADJUDICATIONS OF ACCORDING TO NO. 5366 LAW

In order to understand the contradictions between these two laws in the implementation process with the scope of adjudications, two Supreme Court Decisions are examined. Supreme Court Decisions are related with the cases of implementation process of two renewal projects in Istanbul (Council of State 6th Chamber,2008).

A claim was filed to Council of State 6th Chamber for the cancellation of the decision numbered 935, which is for the urgent expropriation of the structure in Ankara Province, 19959 island with the number 8 parcel by Ankara Metropolitan Municipal Council. The area which is mentioned Ulus, Hacıbayram Mosque and Bent Runnel and Ankara Castle and Surroundings in Ankara's historical city center, is actually determined as a renewal area according to article 2 of the Law No. 5366 with with the decision of the Council of Ministers taken in 2005(Council of State 6th Chamber,2008).

According to the definition¹ of the renewal area (in article 4); in order to determine a renewal area, the area must be initially registered as a site area by Cultural and Natural Heritage Conservation Board and the same area has to be worn and started to lose its characteristics.

Under the light of these information, the case file is examined. According to the examination, it is founded that in this urgent expropriation decision, the boundaries of the area is not detailly specified. For this reason, an expert examination has been done. According to this examination it is stated that the boundaries of the area are indicated as X and Y coordinates due to the size of the area, these coordinates are not shown in the current maps and the boundaries of the conservation area and site area which is decided under the scope of Ankara Historical City Center are not signed. Therefore, the decision of the Council of Ministers on the determination of the boundaries of the renewal area is not in accordance with Law 5366(Council of State 6th Chamber,2008).

It is mentioned that in the proposal of the Renewal Area boundaries presented to the Council of Ministers, Ulus, Kale, Ankara old town tissue and archeological sites are are found. However, is determined that in the proposed sketch urban and archeological site areas and their conservation areas are not shown. Besides archeological areas cannot be accepted as renewal areas(Council of State 6th Chamber,2008).

In his example, firstly the renewal area is declared. Then in this renewal area, a conservation area is planned and afterwards approved by Ankara Cultural and Natural Heritage Conservation council. Thus, an area which have not been identified by Cultural and Natural Heritage Conservation council is declared as a renewal area.

According to Law No. 5366, in order to be able to detect a region as a renewal area, it is necessary to show that the region should contain site and conservation area, also it should be pointed out that the area is worn and about to lose its character. For this reason, it has been determined that the decision of the Council of Ministers is not in accordance with the Law No. 5366, since the decision of the renewal area is given without examining whether or not it carries the conditions stipulated by law. As a result, Council of State 6th Chamber cancelled the urgent expropriation desicion(Council of State 6th Chamber,2008).

3.2. ADJUDICATIONS OF ACCORDING TO NO. 2863 LAW

Another case filed to the Council of State 6th Chamber was investigated in accordance with the Law No. 2863 on the protection of cultural and natural property.In 1999 with the conservation decision numbered 513/5385 It has registered the forested area which of the upper part of hill of Dragos in Maltepe, Istanbul as 1 st degree of natural site and The zone is south-west of this area and the area along the coastal path south of Drogos Hill as 2 st degree of natural site and the area of enclosing both this areas as 3 st degree of natural site as shown in the scale of the 1/5000 plan borders. The case has been filed with the cancellation of this conservation desicion(Council of State 6th Chamber,2002).The report prepared by the Administrative Court after the investigation of the expert and viewing and documents in the case were evaluated together.

According to this; Hill of Dragos ,which is a special and potential value for the region in an urbanized area, is suitable for the definition of 1st degree natural site due to Hill of Dragos has a positive effect on silage and it needs to be purified from the constructions because its location and position in the topographic pattern and the sea-filling areas constructed by the human hand can not be evaluated as the 2st degree natural site and The part declared at the 3st degree natural site is constructed in large scale and

¹ The definition is given in the part, which is entitled as 2.1.1.Examination of regulation on the implementation of the law on conservation by renovation and use by revitalization of the deteriorated historical and cultural immovable property.

Evaluation of this constructed areas as site don't comply with the principles defined in the law. It was decided to canceled due to the fact that Registered of Immovables within the borders of Maltepe Municipality as 2st and 3st degree site don't compliance with the law. This decision has been appealed by the respondent administration and the intervening deputy. The conservation as a whole of Dragos Hill and its surroundings which is an important place in the landscape of Istanbul is a right decision in terms of conservation principles (Council of State 6th Chamber, 2002).

Decision based on the expert report, which is not based on sufficient examination by ignoring the fact that Removal of immediate environment from the boundaries of the site by the Administrative Court will be difficult to conservation, was not considered appropriate.

In accordance with paragraph (a) of Article 3 of the Law No. 2863 on Conservation of Cultural and Natural Poverty which is defined to refer to all assets on the ground, under the ground or under the water pertaining to geological periods, prehistoric periods until present time, that are of unique kind or require protection due to their characteristics and beauty (Council of State 6th Chamber, 2002).

According to Article 7 of the Coastal Law No. 3621 "Where public good necessitates and with the resolution of the application structure plan, lands can be acquired through filling and desiccation by considering the ecological features of seas, lakes and rivers" due to the fact that It is clear that these lands can not be qualified as natural assets above-mentioned (Council of State 6th Chamber, 2002).

For this reason, according to the decision which is subject to appeal no: E. 2002/1652 K. 2003/3386 T. 29.5.2003 of the Council of State 6th Chamber Part of 2st degree of the natural site area is approved and Part of 3st degree of the natural site area has not been approved. It opens the way for the reconstruction of a demolishing registered of structure.

These two adjudications will be evaluated; According to Law No. 5366, urgent expropriation is required to be made. So that, as mentioned in the regulation's article 24, these expropriated ownerships are marketable to third parties and this creates a situation against public interest. And in the other case a situation related to the Law No. 2863. By lowering the grade of the 1st degree natural site, It is requested that these areas be permitted to build. This issue is against this conservation. For this reason, the Council of State canceled the decisions in accordance with the laws.

4 CONCLUSION

The majority of Turkish cities have lack of upper scale plans; therefore, they are not ready for point projects. No. 5366 Law is completely a framework, which consist of only nine article and left to local municipalities. With this legislation, new conservation decisions are created peculiar to regions and the resell of expropriated areas after regulation became a current issue (Url-7).

Reviving desolated historic centres and traditional residential areas around them constitutes a very important problem. These areas are under a heavy migration pressure. The changes made in Conservation Law in 2004, socio-economic values, renewal and collaboration have started to be handled with conservation. Nevertheless, after almost 11 months from these changes with No. 5366 Law, conservation concept has been pushed into background. While planning is abolished, renewal at building scale and expropriation concepts are highlighted. By this way, No. 5366 Law, which breaks off the integrity of site areas and historical spaces, has become a debatable issue even before its implementation (Tekinbaş, 2008 and Url-7).

In this context, Historical Peninsula where this law has been first implemented has faced urban renewal projects, which ignore master plan.

Municipalities evaluated the opportunities which comes with No. 5366 Law in 2005 and they take serious steps for producing and implementing "renewal projects" under the name of "conservation projects". These projects is the Sulukule renewal project, which ignores the socio-cultural aspects of conservation and foresees the dislocation of Romany and culture living in Sulukule for more than a thousand years. New projects such for Balat is added day by day. Treating proprietary constructions in the areas which should

be protected within the scope of the law projecting “renewing” and trying to do it by overcoming the restrictions which make transformation difficult cause lots of problems(Dinçer,2008).

The most important problem is that focusing on physical interventions neglecting research about socio-cultural structure.The main problem in renewal projects for such as Tarlabası and Sulukule, which are the most important historical places of Istanbul is that, they do not have a plan. In an area that has lack of a conservation plan does not provide a planning hierarchy or planning process.

In no. 5366 law economic and especially social situations are ignored. Instead of boards, municipalities prepare Conservation Development Plan but organization of these plans delayed. When an application is performed without a plan, it creates wreckage. The expression of “Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable” results an incomprehensibility. Will it renew or conserve? (url-7).

Instead of conserving cultural assets in site areas via its complete historic, cultural and natural features, no. 5366 law foresees changes in property, social and physical renewal, usage of different user with different functions. As a result one can see that no. 5366 Law On Renovating, Conserving and Actively Using Dilapidated Historical and Cultural Immovable Assets considers no.2863 Law on the Conservation of Cultural and Natural Property as an obstacle and tries to surpass it.

1 THE METROPOLITAN AREAS IN BRASIL AND IN PORTUGAL

The process of industrialization in Portugal, if compared to the rest of Europe, occurred belatedly, coinciding with the same period in Brazil, in 1940, 1950, 1960. During this period a large number of people migrated from the countryside to the major cities in search of better living conditions, and settled in the territory, in a continuous process for decades.

The public authorities' actions were quite limited in these two countries. However, in Lisbon between 1935 and 1948, one third of the city was expropriated by initiative of Duarte Pacheco, then Minister of Public Works and Speaker of the House in Lisbon. The centralizing policies comprised a strong territorial intervention in a period of intense population growth, the city was endowed by planning instruments that allowed to tame urban expansion. In Portugal until 1965, the public administration took over exclusively the planning and production of urban land, acting with some urbanistic coherence.

This fact was not observed in Brazil, considering that the instruments of urban management were created after the enactment of the Federal Constitution in 1988, decades after the great immigration. Thus, the population that migrated from the hinterland into the Brazilian state capitals, for the most part settled in remote areas, far from any infrastructure, often occupying conservation or risky areas in the proximity of railways or next to flammable activities.

The growth of the industrial economy and urban lifestyle sought by the vast majority of the world's population produced a dense urban network, comprised of municipalities linked by economic interactions. In this context Brazil's Federal Government created, through Federal Act No. 14, of 08 June 1973, nine metropolitan regions in Brazil: Fortaleza, Recife, Belém, Salvador, Rio de Janeiro, Belo Horizonte, São Paulo, Curitiba and Porto Alegre. In Portugal, the metropolitan areas of Lisbon and Porto were created two decades later, through Act No 44 of 2 August 1991, amended in 2003 (Law 10/2003).

The survey was conducted in the Metropolitan Areas of Lisbon and Metropolitan Region of Fortaleza despite their different economic, social, cultural, environmental, and urbanistic conditions, these areas have some similarities and both are coastal and comprise an equivalent number of municipalities. Moreover, they are the most densely populated areas in each country.

1.1 THE METROPOLITAN REGION OF FORTALEZA

Fortaleza is a Brazilian municipality, capital of Ceará State, located in the Northeastern portion of the country. It is located on the Atlantic coast, with an average altitude of sixteen meters, with 34 km of beaches. Fortaleza has an area of 313.140 sq. km and an estimated population of 2 609 716 inhabitants in 2016, along with the highest demographic density among the capital cities of the country, with 8 334.0 inhabitants per sq. km. The climate is tropical, hot, with an average annual temperature of 26.5°C. According to IBGE (Brazil's Census Bureau), the metropolitan area of Fortaleza boasted a GDP of R\$ 80.4 billion in 2014 (corresponding to 8343€ per capita). This number has placed the Metropolitan Region of Fortaleza (RMF) as the third richest in the North-Northeast, behind Salvador and Recife - and the 11th in Brazil.

According to Ugeda Junior (2014), urbanization in Brazil occurred in an accelerated pace, even in the regions where the industrialization process was not so intense, as is the case in Brazil's northeastern

region, plagued by long periods with no rainfall, known as "droughts". In this region people are constantly migrating to the capital, in search of subsistence, which contributes to an increased population, as is the case of the city of Fortaleza.

In 1973, the city of Fortaleza, together with the municipalities of Caucaia, Maranguape, Pacatuba and Aquiraz constituted Fortaleza Metropolitan Area – RMF, with an overall population of approximately 1 million people. In 1991, RMF already had 2,292,524 inhabitants and in 2010 it exhibited a population of 3,615,767 residents. Currently it boasts four times the initial population, 4,019,213 inhabitants, of which 2,609,716 live in the city of Fortaleza, plus the eighteen municipalities that integrate RMF, known as the Great Fortaleza. It is currently the most populated area in northern and northeastern Brazil and ranks as the fourth largest metropolitan area in the country, and the 131th largest urban area in the world (Wikipedia).

Over the years one may observe that investments in urban mobility and the creation of new economic centers in the metropolitan area changed the economic and social dynamics, allowing for a greater balance in the relationships among the cities that make up RMF. The participation of the city of Fortaleza in the metropolitan area in 1970 was 82.75%, and in 2016 it dropped to 64.93%.

According to Souza (2015), the metropolis spread along with the process of industrial dispersal in neighboring municipalities of Fortaleza. First in the municipality of Maracanaú, following the creation of the Industrial District established in the late 1960s. As a consequence several housing complexes emerged, with the encouragement of housing policies, which corroborated the formation of a real estate metropolitan axis in tandem with the interests of the productive metropolitan axis.

The RMF municipalities are integrated by state and federal highways, which shape the road system, as the main transportation mode used by population in the municipalities. The metro line, completed in 2012, connects Fortaleza with only two of the cities that comprise RMF, Maranguape and Maracanaú, the largest cities after Fortaleza.

According to the Brazilian Census Bureau (IBGE 2010), water supply and sewerage networks in RMF, responded to 87.42% and 49.9% coverage, respectively in 2010, and since then there have been no substantial modifications in this scenario.

Fortaleza Metropolitan Area, currently with three times the original number of municipalities, has been losing institutional strength, until it was completely excluded from the plans of the State of Ceará, which operates with specific and unarticulated projects. There are no regional land use plans, and out of the nineteen municipalities that integrate Fortaleza Metropolitan Area, there are still four municipalities with no Master Land Use Plans.

The Metropolis Statute, approved by Federal Act No. 13,089, of 12 January 2015, establishes general guidelines for planning, management and implementation of public initiatives of common interest in metropolitan areas and in urban agglomerations created by the States. It also establishes the obligation to draw up and approve within 3 (three) years, the integrated urban development plan for metropolitan areas or urban agglomerations that were created until the date of entry into force of the law, through complementary state law, incurring the penalty of administrative improbity the governor who fails to take the necessary measures.

1.2 THE METROPOLITAN AREA OF LISBON

Lisbon Metropolitan Area (LMA) is equivalent to 3,015 sq. Km, has a maximum altitude of 528m, and an annual average temperature ranging between the maximum of 21,3° C to 13,1° C. The Metropolitan Area of Lisbon is home for the centres of decision of the country's economy, with a GDP of 64,010 million euros, 22.8 thousand euros per capita, representing roughly 37% of the national GDP and employing approximately 1,316 thousand people (29% of employment in the country), expressing an apparent labour productivity 1.3 times higher than that of the country as a whole (Lisbon, 2016).

Since the 20th century, LMA has been a continuous growth of the population in the country having nowadays more than a quarter of the country population (15% in 1940, 22.4% in 1970, 28.1% in 2011). The population value recorded in 1981 was the highest achieved by the city of Lisbon. In the 1980s, with

the intensification of metropolization, coupled with a stagnation of housing supply in Lisbon, the capital loses about 18% of its population to neighbouring municipalities. In the 1990s the situation remained, despite an increase in housing supply, and Lisbon lost more than 15% of the population, confirming a trend of population loss (REOT - LISBOA).

The rising price of real estate in Lisbon, as LMA expanded in the periphery, reinforced the migration to more affordable suburban land and housing. On the other hand, Lisbon has gradually lost population and is currently stabilized in the 550,000 inhabitants.

Lisbon is the traditional and symbolic centre of the LMA, which is the motor of the region's economy. The city daily sees the number of its users increasing from 547,000 to 925,000 people, a result of the commuting movements of home and work. Home-school. The number of people entering the city daily corresponds to 425,747 and the number of people leaving the city daily is 47,521, resulting in a balance of 378,226 people entering Lisbon (LISBON, 2016).

Lisbon and its metropolitan area have a very wide and modern transport network. The various modes of transportation, and their infrastructure, are arranged so as to substantially reduce automobile traffic in the metropolitan area, especially in its centre area. Circulation in the city of Lisbon is fast and efficient, for users within the city and people coming from the outskirts. The subway, trains and vehicles on light rail are the most important public transport.

Two bridges connect the city to the south bank of the Tejo river: Ponte 25 de Abril that connects Lisbon to Almada, inaugurated in 1966. And Ponte Vasco da Gama, with a length of 17.2 km,[4] the longest bridge in Europe and the fifth longest bridge in the world, which connects the Eastern area and Sacavém to Montijo (Wikipedia).

In LMA the population served with systems for collection and drainage of wastewater reaches around 91%, while the population served by the treatment systems is roughly 75%. According to INE, in the municipalities of Amadora, Cascais, Oeiras and Lisbon, the rate of coverage, both for the collection and drainage systems, as for wastewater treatment plants is 100 %. In the counties with lower service coverage for collection, disposal and treatment, the infrastructure is being completed in order to meet the current needs for wastewater treatment. (CCDR LVT, 2009).

The Regional Territorial Plan for Lisbon Metropolitan Area was prepared in 2002 by Central Government. The intermunicipal plan it is not mandatory however, all the municipalities that integrate LMA have Master Land Use Plans since 1992, and some have already been revised after 10 years. Only few of them have their Status Reports on Spatial Planning – REOT - finished.

2 URBAN AND ENVIRONMENTAL PLANNING AND MANAGEMENT

The urban policy envisaged in the Constitution of the Federative Republic of Brazil, regulated by the City Statute, as well as the Regional Planning and Urban Policy envisaged by the Constitution of the Republic of Portugal, and regulated by the Basic Law of Public Policy, Spatial Planning and Urbanism, granted extensive powers to municipalities to promote the adequate land use, establishing guidelines that govern the use of urban property for the collective good, the safety and well-being of citizens, as well as the environmental balance throughout the territory.

In both countries, the control over urban development does not involve the possession of the land by the public authority. When it comes to occupancy of land, a limited natural resource, we are faced with the issue of the distribution of this important commodity, which happens in a very disproportionate way, particularly in Brazil, since the private sector becomes the main actor responsible for the transformation and production of urban land.

During a period of about 30 years, the Portuguese cities had an urban growth similar to that of Brazil, in which the private sector is charged with the production of urban land, and with the subdivision operations and the construction of infrastructure, causing a dysfunctional growth, guided by operations that do not comply with any development plan. This finding resulted in significant alterations in urban planning in Portugal.

2.1 PLANNING AND MANAGEMENT IN FORTALEZA

In Brazil, out of the instruments provided by the City Statute, the Master Plan is the basic tool for city planning and urban management, through an urban policy integrated with the city planning system. The multi-year plan, the budget guidelines act and the municipal budget law should be guided by the fundamental principles, general objectives and strategic priorities contained in the Master Plan.

The Master Plan for the Municipality of Fortaleza (PDP), Law No 62 of 02 February 2009, sets out the principles and objectives of urban policy, guidelines and strategic actions. To comply with the guidelines for regional planning, the territory was subdivided into Urban Macro zoning and Environmental Protection. The city of Fortaleza is considered as 100% urban, excluding the demarcations of Macrozone of Environmental Protection, intended for the conservation of ecosystems and natural resources, subdividing into zones according to:

I - the environmental systems consisting of the water network, the waterfront, mountain vegetation, remnants of vegetation, mangrove forests, riparian forests, dunes and permanent preservation areas;

II - the morphological and typological characteristics of the built environment;

III - the systems of environmental sanitation, installed and planned;

IV - the mobility system;

V - the areas of trade, services and industry;

VI - public areas, green and leisure areas;

VII - the urban infrastructure and public facilities;

VIII - the areas intended for housing."

In the quest for the attainment of the objectives, the PDP defines differentiated urban parameters for each of these areas, to be followed by the owners for new subdivisions, uses and land occupancy, and these procedures must still meet other requirements. For example, we have the parameters for the Preferential Occupancy-2, ZOP-2, which is characterized by partial availability of infrastructure and urban services and areas with limited availability of density; and the intensification of land occupancy.

"Art. 85 - parameters⁴ of Zop 2 are:

4The utilization index is one that, multiplied by the area of the land, results in the computable construction area.

I – Basic utilization index :2.0;

II- maximum utilization index :3.0;

III - minimal utilization index :0.2;

IV - permeability rate:30%;

V - occupancy rate:60%;

VI - occupancy rate of subsoil:60%;

VII - Edification Maximum Height: 72m;

VIII – Plot minimum area size: 125m ;

IX - Minimum Front Size: 5m;

X - Plot Minimum depth: 25m."

In turn, the public managers should make use of the instruments for plan implementation, established by the City Statute to which the urban property must comply with its social function. Thus, Fortaleza Master Plan makes use of these instruments in accordance with the objectives proposed for each of the specific areas.

"Art. 86 - The following instruments shall be applied in the area of preferential occupancy 2 (ZOP 2):

I – Compulsory subdivision, construction and utilization;

II – Progressive IPTU (property tax);

III - Expropriation upon payment by public debt securities;

IV- Right of pre-emption;

V - Right to surface;

VI - Granting right to build;

VII - Transfer of the right to build;

VIII - Urban operation in consortium;

IX - Real estate consortium;

*X - Neighbourhood impact study (EIV);
XI - Environmental study (EA);
XII -Special Area of Social Interest (ZEIS);
XIII - Instruments of land regularization."*

According to Muniz (2006), Brazilian cities are experiencing the abandonment of strategic planning. The urgency to heal the daily problems replaces the medium and long term planning. Another reason for abandoning strategic planning is the concern of the municipality annually to prepare its budget in order to guarantee funds from the federal and state government, as well as external financing for the execution of its projects, which are, in most cases, punctual projects.

The Statute of Cities, Master Plans and other urban legislation are instrumental that require a policy that implements and manages them. The absence of policies and the way to manage cities with a short-term vision render urban planning instruments inefficient, demonstrating extreme resistance in the acceptance by the public power that uses them in extreme cases to make feasible punctual projects.

The process of land use and occupancy starts with the licensing of the land subdivision (Land Subdivision processes), the procedure of dividing the land into legally independent units, with their own individuality, for purposes of edification, and can be done by subdivision and dismemberment. All subdivisions, should be integrated into the existing urban structure by connecting with the existing road system and the networks of public services, both existing and planned.

The quantification of areas to be donated to the municipality of Fortaleza, must comply with Law No. 5532/81, Codes of Works and Postures of the municipality, which sets out a total of 45% regardless of the activity and of zoning area in which the property is inserted, of which 20% will be intended for the street network, 15% for open areas (plazas, parks, gardens), 5% for institutional areas, and 5% for the land fund (housing of social interest), the latter may be donated at a different location.

In Fortaleza, the parceling of land has no relation with density, and is limited to an indication of the plots, the blocks, the road system and the areas to be donated to the state. In this stage, it should exclusively be informed the type of predominant use the subdivision is intended to; it is not necessary to submit any building design. The entrepreneur will carry out the approved subdivision and will be charged with the costs and construction of the entire infrastructure (except sewage treatment), but will not contribute for their maintenance. Finally, each plot in the approved subdivision is registered and notarized.

When the subdivision is duly registered, the entrepreneur will, in due time, assign use and occupancy of the property, and will define the activity and its size, provided that it adapts to the road system in which it is inserted and meets urban parameters for the area. It is common to have plot merging, approved normally with a minimum area, for the implementation of large-scale projects. It should be noted that once the project is approved and the building is erected, at any time a new use and occupancy may be approved, provided that the activity adequates to the road system, and meets the urban parameters.

Figure 1 shows the current scenario of a city portion inserted in Preferential Occupancy 1, proposed in the draft bill to be one of the Special Areas of Urban and social and Economic Dynamics - ZEDUS, which aims to introduce and/or intensify social and economic activities. This area is characterized by the availability of infrastructure and urban services and by the presence of buildings, not used or underused; and the intensification and acceleration of land use and occupancy. The scenario was devised using CityEngine software, with database of the city of Fortaleza.

The constructions, in their majority, represented in the color blue, are residential units with 1 to 2 floors. The buildings in yellow, are intended for commercial use, in general small stores. The color magenta depicts the public facilities, which are university, churches, hospitals, schools.

Figure 1 – Existing scenario

A simulation was performed, using the maximum urbanistic levels, given the rules of urban planning, in which only the public buildings have been preserved. The plots for small dwelling units and stores were unified, to allow for large-scale housing projects, with heights ranging from forty-eight (48) meters to seventy two (72) meters, complying with the setbacks of ten (10) meters mandated by the legislation for this activity. As a result, we have a large concentration of residential buildings a common feature in the neighbourhoods of the city that have been the object of urban development. In this area, the groundwater level averages a 2.00m depth, thus there should be a lowering of the water table in this whole area.

Figure 2 - Simulation

The large-scale initiatives illustrated in Figure 2, must be environmental licensing, in accordance with the environmental legislation Law nº 208, dated July, 15, 2015. The law classifies the works according to its size and its impact, and considers the conditions of the terrain, including the level of groundwater and the urban area in which it is inserted. For each type of work there are specific procedures for environmental licensing that are linked and have priority over urbanistic permits.

Environmental licensing is one of the instruments of the National Environmental Policy, Law no. 6,938, dated August 31, 1981, which allows the public to intervene preventively in carrying out works, plans and activities that could endanger the environment, requiring the prediction of potential damage and the

creation of conditions to minimize them, when unavoidable. It is, therefore, an instrument of preventive control, which can be accompanied both by the public and by society.

2.2 PLANNING AND MANAGEMENT IN LISBON

The establishment of a democratic regime in 1974 and the creation of the Local Authority after the enactment of the new Portuguese Constitution in 1976 was followed by a difficult period of legislation changes and planning practices at the local level. In the early 1980s it was obvious that the issue of clandestine occupancy and illegal urbanization had become a problem. It was clear that the legal system of production of dwellings at LMA was not coping with the influx of migrants from the hinterland and the former colonies, for whom urban growth was dysfunctional.

Only after the integration of Portugal to the European Economic Community (EEC) in 1986, in which a new law (DL69/90) mandated the municipalities to draw up Master Plans (PDM), a period of effective planning control, construction and urbanization supervision began. That Act was a milestone in Portugal, since it established that, for the municipalities to enter into contracts and programs with the government, with access to European funds for the implementation of infrastructure and facilities, they should have their Master Plan approved by the local planning authority.

After the new instruments were in place, one may observe the intervention of public administration, with the supervision and control of regulatory compliance with planning regulations for licensing. The city administration began enforcing the laws and regulations dictated by the plans. In general, besides these efforts in conducting the process, citizen participation was very limited.

The new Law of Bases of Public Policy, Planning, and Urban Development - LBOTU defines the system of land use through land classification and dedication. Land dedication determines the use a given development is targeted for, and the distinction between rural and urban land use. Rural land is the one which, by their recognized vocation is destined for agricultural use, farming, forestry, conservation, enhancement and exploitation of natural resources, geological resources, or energy resources, as well as the land intended to become natural spaces, cultural, tourism, recreation and leisure activities or protection from risks, even if it is has infrastructure. Urban land is the area that is already fully or partially developed or built and, as such, has to have a territorial master plan for urban development.

Land dedication defines the content of exploitation by reference to the development potential of the area. The area of the Municipality of Lisbon, considers the degree of urbanization of land and the degree of morphological or typological consolidation, featuring the following categories: consolidated spaces and spaces to consolidate.

According to PDML (the Master Land Use Plan for Lisbon), land dedication is carried out through an integration of the following land categories, depending on the predominant use, mapped on the plan for dedication of urban space: central and residential spaces; areas for economic activities; green spaces; areas of special use for equipment; areas of special use for infrastructure; spaces of special use on the river waterfront.

In the Municipality of Lisbon, the Mayor's Office is charged with urban planning and urban licensing. Urban planning includes the implementation of the Municipal Master Plan, Urbanization Plan and the Detailed Plan, the latter may be by initiative of the public or private sectors and should produce regular reports.

The State, the Autonomous Regions and local authorities may acquire or dispose of real estate property to pursue the purposes of public policy. Among the plans implementation instruments envisioned in LBPSOTU, we have: the right of preference, right to surface, demolition, expropriation, and forced sale.

The operations of subdivisions may be carried out by public or private initiative. For the purposes of legalizing existing buildings, the operations of conversion of the Urban Areas of Illegal Origin (AUGI) will be a municipal initiative, or any modification of a subdivision licence issued prior to PDML entry into force. A Municipal Regulation approving the System of Incentives for Urban Operations with Municipal Interest is expected to pass in the future.

In 1998, the Law of Bases of Public Policy, Planning, and Urban Development - LBPOU (Law 48/98, 11 August) introduced the principle of fairness in planning policy and urban development. In this context, equalization appears as a goal to distribute the benefits and costs of the plans among the owners and private promoters and local public administration. Decree 380/99, as Legal Regime of the instruments of Urban Management - RJGT regulates the equalization and specifies the rights and duties with respect to plan implementation.

In the operations of subdivision, the land surface is intended for private use, and should comply with the rules for consolidated areas and areas being consolidated, which are specific to the Central and Residential Areas, and to the Areas of Economic Activities defined by law. The area is measured in sq. m., susceptible of construction, excluding those that will be transferred to municipal ownership, such as infrastructure, roads, green spaces, and areas of collective use. The donated areas are related to the built areas, therefore at this stage the architectural projects and building specifications must also be submitted for approval.

Land transfer to the municipalities for social facilities (due in the case of private subdivision projects), must comply with rules inscribed in each Municipal Land Use Master Plan or should follow what is prescribed in a general regulation that imposes approximately a quantity of land of 63sq.m. per dwelling for open and green spaces and other public facilities.

In the Master Land Use Plan of the Municipality of Lisbon, the Art. 88 says:

"1 - The parameters for measuring the areas to be transferred to municipal domain, for green spaces and collective use, in an area not covered by the detailed plan or per unit of execution that implement the equalisation mechanisms, are listed in the following table:

	Area to yield per 100 m ² area of floor
Consolidated spaces, urban polarities (POLU) and areas of economic activities to consolidate	30sq.m
Spaces to consolidate	30sq.m

Table 1 - Land transfer - Lisbon

However, among the 18 municipalities of LMA, there are a great variety of values for that parameter which is related, in part, with different land needs for social facilities and also with some competitiveness between municipalities struggling to attract investment.

Once approved the subdivision, it may be subjected to alterations, as long as they do not change the project's original concept. This ensures that the donated public areas are proportional to the density, ensuring the maintenance of the characteristics of the surrounding areas of the property, minimizing real estate speculation.

In Lisbon, the urban plans and programs are subject to an environmental assessment, in compliance with European Union policy 2001/42/EC. The preparation of an environmental assessment at the planning and programming levels ensures that environmental impacts are taken into account during the preparation of a plan or program and before its approval, thus contributing to the adoption of innovative and more effective and sustainable solutions, and control measures to prevent or reduce significant negative environmental impacts arising from the implementation of the plan or program (Decree-Law no. 232/2007).

According to Verocai (2002), since 1985, the European Union obliges all member countries to adopt and incorporate general standards of environmental impact assessment into their legislation. The goal was to solve a problem of competitiveness: the economy of some countries benefiting from environmental requirements that are less stringent than others. Until then, Portugal did not include environmental assessment procedures in the country's legislation.

The planning and environmental licensing is under the responsibility of the Portuguese Environmental Agency, which since 1985 is under the influence of the directives of the European Union, which took environmental management to a scale that was higher than urban management. The Municipal Land Use

Master Plans, the Urban Development Plans and the Detailed Plans are now subject to environmental assessment, thus ensuring the operations of subdivisions.

3 RESULTS

Planning and urban management in Fortaleza presents a flexible model of city, allowing changes in the use and occupancy at any time, after subdivisions occurred.. The small dwelling units make room for large projects, whenever there is an upgrade of an area due to infrastructure works, for example, which increases the buildings' value making them vulnerable to real estate speculation.

The lack of a demand for a definition of buildings in housing developments, makes this type of transaction a simple procedure, favouring a rapid growth of the city's urban mesh, including the areas devoid of sanitation infrastructure. In Fortaleza and in its metropolitan area, the lack of such infrastructure produces serious environmental impacts. Wastewater does not receive adequate treatment in places where there is no public collection and often they are discharged in lakes or rivers, thus polluting the environment. In poor areas, wastewater accumulates next to the housing units, and cause disease outbreaks and contaminate the resident population.

The public areas transferred at the time of the subdivision of land operations in Fortaleza and Lisbon under different rules, let's look at their application in an area of 10 Hectares:

Figure 3 - Different quantities of land dedication which is required for the approval of the development by the local planning authority

Figure 3 illustrates a subdivision in Fortaleza. The remaining area is 55% and the area to be transferred to the municipality is 45%, where "a" corresponds to 5% of Land Fund, "b" corresponds to 15% of Green Areas, "c" corresponds to 5% of Institutional Area and "d" represents 20% of Road Network.

Plates B and C of Figure 3 illustrate an area to be subdivided in LMA (considering the rules of the general law) in areas with high density (about 80 dwellings/Hect) and low density (3 dwellings/Hect), respectively, in which the areas to be transferred are proportional to the built area, being 35 sq.m/120sq.m for Social Facilities 28m2/120m2 for Green Spaces. In drawing B, the areas assigned "e" and "f" are 52.5%, with the remaining area of 47.5%. In drawing C, the areas "g" and "h" totalling 5%, and the remaining area are equivalent to 95%.

Land donations in Fortaleza are equal to those of Lisbon, when they occur in areas of high density; however in Fortaleza the utilization index in some areas can reach a value 3.0, which means that it can be built three times the land area, while in Lisbon, the utilization index does not exceed the value of 1,5. Thus, the areas granted in Fortaleza are undersized when compared to those in Lisbon, especially when the neighbourhoods increase in value and go through subsequent changes of use in buildings.

In Lisbon, the availability of infrastructure in the municipality, the unchanged density and characteristics of buildings in areas already built, the predictability of density in other areas favour a more accurate urban planning. The plans and programs are subjected to environmental assessments, which safeguards the operations of subdivisions, and it is not necessary to issue an individual environmental license to each building.

The urban planning, carried out in a 1:20,000 scale in Brazil, does not distinguish natural characteristics of the terrain, when making the definition of urban and zoning parameters. In turn, the lack of a definition of activities, their size, building typology and urban form, in the Land Subdivision Processes hamper the environmental assessments and make extremely difficult any planning tentative to control / guide or influence a more general and comprehensive urban form. Environmental licensing is done separately for each large size development, not allowing for an integrated larger scale view, which is essential for the analysis of environmental impacts. Lowering the waterbed in a plot may not cause consequences, but on a larger area it may cause irreparable environmental impacts, as well as damage in surrounding buildings, as is the case of Fortaleza, in which public services, such as hospitals and universities are in place.

As a result of the transformation in regions that have experienced real estate appreciation in Fortaleza, one may observe a large concentration of residential buildings, shaping a common scenario in the neighbourhoods of the city, once the adequacy of activities is related to street classification. The 10-meter setback requirement for these large-scale developments creates private leisure facilities and reduces the need for the use of public spaces, resulting in a loss of identity of the region and decreased community interaction.

In Lisbon, the buildings are approved in tandem with the operations of subdivisions and are under the responsibility of the developer, therefore the areas to be subdivided become smaller than in the city of Fortaleza. The smaller the area of urban intervention the greater the accuracy of planning and distribution of public areas and the best is the management of these areas.

The planning models of the municipalities that comprise the metropolitan areas have similar urban planning systems and environmental issues as those of the capital cities, following national guidelines. The legal and licensing procedures are similar in Lisbon and Fortaleza, thus exacerbating the urban problems, and causing environmental damage in an even larger scale.

4 CONCLUSIONS

Lisbon metropolitan area and the metropolitan area of Fortaleza present historical, economic, social, environmental, and geographic differences related to the integration with their municipalities, but the comparison of these two areas allowed for an understanding that enhancing the integrated urban planning and environmental management will result in a more balanced relationship between the cities that integrate those areas.

The low investment made in Fortaleza Metropolitan area reflected quickly in the reduction of the participation of Fortaleza in its metropolitan area, with a trend to a slight drop in population growth in the metropolis. In Lisbon, the population is currently stabilized, which in turn intensified the economic and housing activities in the neighbouring municipalities, thus demonstrating how Portugal responded to the great immigration caused by industrialization, which occurred in the same period in the two countries; Portugal is ahead in planning and urban management when compared to Brazil.

There are great cultural differences despite their common origin, in Brazil cities are recent and seem to have a stronger liberal attitude in terms of urban control, perhaps due to US proximity and cultural influence which makes a low preoccupation to the control of urban form. Moreover there are the very high migration flows, from the rural interior to cities and consequently, the difficulty to control land use and respond to the social needs of affordable housing producing it very quickly, in short periods of time, by local authorities or private entrepreneurs.

In view of those findings, we sought to deepen our research in the city of Fortaleza, where the lack of an integrated urban and environmental planning brings conflicts in the administration of the territory, by means of licensing, supervision and control. The territory of Fortaleza, which is a result of so many

subdivisions could bring down the scale of urban planning and prioritize interventions in areas where there is a greater trend for transformation and urban development.

The Master Plan of the Municipality of Fortaleza envisions the creation of Special Areas of Urbanistic and Socioeconomic Dynamics - ZEDUS, through a delimitation of portions of the territory for

the deployment and intensification of social and economic activities taking the local diversity into account, and pursuing the principle of sustainability.

The Master Plan recognizes the ZEDUS as areas with potential for the deployment of plans and strategic projects of socioenvironmental development. Therefore an opportunity for an integrated planning, in which the public authority can use the instruments for land management provided by the legislation, that is, expropriation, the environmental impact studies; instruments of land regularization; right of pre-emption; right to surface; urban operation in consortium; real estate consortium; granting the right to build.

The research will proceed with experiments in SIG3S, using software of Geographical Information Systems, including Arcgis, and urban simulation, Esri CityEngineTM, software for three-dimensional modelling expertise in urban environments, by means of survey data, on-site observations, technical studies and research in areas proposed by the administration to become ZEDUS.

The use of the GIS3D appears in this case as an important planning tool, allowing from an expert point of view:

- Improve the rules of construction and urban development defined in the plan, through simulation and its technical validation of its 3D impacts in the urban form;
- Improve the integration of these rules with environmental rules, which often involve restrictions on land use or construction;

And from the public participation point of view:

- Improve people awareness of the 3D effect of the proposed urban and environmental rules, allowing their comparison and verification with the current occupation (licensing) that is taking place.
