Being part of the AFP and being a publicly-funded, albeit imperfect, arts centre implied progressive structural changes in the Escocesa. Firstly, the relationship between the Escocesa and ICUB changed. The latter, in order to justify its inclusion in the programme and the direct investment of public money began to be more demanding towards Escocesa especially in relation to its compliance towards public and cultural interests. Two of the demands were the most pressing: the realization of as many public activities as possible and the rotation of as many artists as possible, reducing the number of permanent artists in order to guarantee an open access of the centre to creative professionals. Secondly, the internal management changed. Artists involved in the management of the Escocesa, especially the president of the EMA association, were no longer able to carry out his/her art project. The management entailed such an amount of work that it could not be carried out during an artist's free time, but rather required a person to be contracted full-time. Thus, at the end of 2011, the association decided to hire a manager through a public call, dedicating a part of its budget to this new administrative role. Despite the fact that the manager was appointed by the same EMA association he was seen as a sort of representative of the public institution, since he strongly pushed for the Escocesa to satisfy the public and cultural interests. From 2011 onwards, the AFP was marked by a major cultural policy change. In this year municipal elections were won for the first time in Barcelona, by a conservative party, Convergence and Union. The new government set a new cultural agenda, also effecting the AFP design. The new guideline for the programme represented a shift towards a market-oriented cultural approach, whereby the Arts Factories had to be frontline arts centers in order to contribute to the city's cultural internationalization and professionalization (ICUB Report,

2011). In relation to the Escocesa, the ICUB became less tolerant of its precarious conditions because they did not allow the factory to achieve the new objectives. However, as the ICUB could not stand away the EMA until the renovation works had been done, while not having any intention of actually carrying them out, it began to put the artists under pressure, pushing for an internal collapse of the Escocesa by underfunding the project while over-demanding results.

During these years, public funds increased, reaching around 40.000 euros from 2013 onwards. Nevertheless, this contribution was still the lowest in comparison with other factories. This situation made all of Escocesa's artists feel discriminated against by the public administration and always in competition for funds with other factories. The underfunding also caused many social tensions among the same Escocesa artists. Since a part of the resources could finance art projects of both permanent and temporary residents, the result was that especially young, unsalable and low-income artists, for whom a little contribution meant a lot, were struggling for an extremely limited budget. Moreover, the underfunding also increased the tension among artists and workers. In order to be positively evaluated by the AFP and to receive more funds, the Escocesa had to maintain a high level of performance, but with inadequate resources, relying on overworking and the exploitation of both artists and the manager. In reality the reasons for all of these tensions are rooted in the protraction of the precarious condition created by the postponement of refurbishment works and the integration of the Escocesa into the AFP as an imperfect arts factory.

Due to the lack of realization of the works, the artists were paying for the effects of a non-compliance of the ICUB, which was implicitly recognized by the ICUB since the underfunding can be interpreted as an admission of non-compliance. This was also the reason why the relation of the permanent artists with the space changed. Since there was no prospect for the works to be carried out, the temporary privilege of permanent artists that were retaining a studio space far below the market standards was becoming more and more a consolidated privilege. This is why, no movement was developed among artists to press the ICUB to start the renovation works. Retaining the affordable studio space in such a central location of the city and benefitting from the public funds for their art projects was an extremely advantageous situation that none of the artists sought to change. The attempt to protect the privilege on spatial resource of permanent artists along with the tension in the struggle for the monetary resources among all artists caused the collapse of the Escocesa as it had been expected by the ICUB.

In September 2016, the artists of Escocesa decided to fire the manager. This decision was officially taken after a majority vote of the Assembly but it was heavily pushed for by a group of permanent artists, who saw him as a threat to their privilege on the space. The dismissal of the manager can be seen as the last desperate attempt by some artists to maintain their affordable studio space, by stopping the transformation of the Escocesa into a fully Arts Factory. However, this operation, far from achieving its objective, contributed to worsening the tension among artists and to legitimizing the ICUB's view of the factory, which played a leading role in its future transformation. At the moment, the Escocesa is in a transition period where the assembly presidency has changed, handed over to one of the artists who had good relations with the ICUB and in which the latter, despite its non-compliance, is leading a progressive transformation of the Escocesa to becoming a fully frontline Arts Factory: with many public arts activities and with the rotation of all of its artists. Being public property, and given the fact that the AFP was a consolidated programme of the ICUB, the artists no longer had any legitimacy to maintain their relations with space, especially in the re-valued, saturated space of the Pólenou.

DISCUSSION

Before the Escocesa became part of the AFP, it could be considered an Urban Commons as it was rather self-sufficient and self-governed. Moreover, the Escocesa, together with other creative factories of the Pólenou creative milieu, was contributing to producing the Common, that is, a more diverse, democratic and de-commodified arts production, free from market and political imperatives although the diversity, democratization and de-commodification were only partial because it could exclude all those more than unsalable, young and low-income artists. In this sense the logic of the Public could have compensated the logic of the Common, reducing its imperfection. However, the existence of the Escocesa Urban Commons and the Pólenou creative milieu depended on the City Council and private sector's lack of interests and investments in the area that undervalued land prices. Once the City Council and private sector's interest and investments increased, highly planned by the 22@, the days of both the Escocesa and the

Poblenou creative milieu were numbered. The result was that the autonomous creative factories disappeared from the Poblenou and moved to other under-valued postindustrial areas, such as the Hospitalet de Llobregat, where the same type of Urban Commons can currently be found and the same type of Common is produced. The Escocesa Urban Commons was saved only thanks to the intervention of the ICUB. The public ownership was the only guarantee to save the Escocesa at the cost of its inclusion in the Arts Factory Programme.

This AFP programme was born with the intention of producing, protecting and compensating the imperfection of the Common produced by the Escocesa and the Poblenou creative milieu, through the logic of the Public, by universally providing affordable creative spaces to arts professionals. However, in its operationalization it was neither able to produce and protect nor to compensate the imperfection of the Common. The ICUB didn't protect the Poblenou creative milieu and it saved the Escocesa only because of a lack of planning. The emergence of autonomous creative factories and the production of the same type of Common moved to more marginal areas and Escocesa could not be considered an Urban Commons anymore, since its management and sufficiency was no longer autonomous from state power and it was no longer producing the Common. Under the Public logic, the diverse, democratic and de-commodified arts production of the Escocesa and the Poblenou creative milieu had been distorted, confined within a spectrum of arts excellence and market imperatives. In other words, the AFP became the expression of the intertwined relation between the State and the Market, where the intervention of the State, despite with the logic of the Public should have protected, produced and compensated the imperfection of the Common was not able to do so. The current state of the Escocesa is the materialization of the degeneration of the conflictual relation between the Common and the Public. Certainly, the Public logic in the name of universality must guarantee open and democratic access to all. In this respect, the defense of the interest of permanent artists on the space represented the defense of the interest of a particular collective on a universal space. However, it is also the last desperate attempt of a group to defend that crucial social relation with the space and the memory of the production of the Common once possible, against the total disruption by State intervention and Market forces despite, in this case, the defense of the Common meant the closure of the group inside on its own privilege, inside the Urban Commons.

6 CONCLUSION

Surely the Commons can be a means to institute and constitute the Common. However, the theory of the Commons lacks an empirical approach that allows evaluating their emancipatory capacity. This paper aimed to bridge this gap by proposing a relational approach to the study of the Commons that reflects their relational nature. This methodology is applied to the analysis of a case study of Commons in the urban space of Barcelona. Through this approach is possible 1) to build the network of relations that made possible the Urban Commons; 2) to understand if the Urban Commons was producing the Common; 3) to analyse how a change in these relations impacts the Urban Commons and its emancipatory capacity. From the analysis of the case-study it emerged that the Urban Commons and the Common need the intervention of the State and the logic of the Public. The former because, under the pressure of the saturated space of the city, public property becomes the only salvation; and the latter because, the Urban Commons was producing an imperfect Common that needed to be compensated by the logic of the Public in order to guarantee universality and democratization. However, the intervention of the State, with the logic of the Public permeated by the logic of the Market, has led to a deterioration of both the Urban Commons and the Common, which can no longer be regarded as such. The paper concludes sustaining that the emancipatory capacity of the Urban Commons cannot rely only on the logic of the Common but needs also the logic of the Public. However, the latter, highly permeated by the logic of the Market, instead of protecting, producing and compensating the logic of the Common produced by the Urban Commons, often limits its emancipatory capacity.

1 ACCESS TO THE INTERNET IN MARGINALISED COMMUNITIES: THE RURBAN STANCE

Specially in the last two decades, the widespread of the internet has had profound impacts on howspace is organised and experienced, reinforcing the importance of Information and CommunicationTechnologies (ICTs) in its production. While enough attention is being paid to our cities, limited studies onthe impact of internet on the countryside reflect a neglect of specific demands and needs of the ruralpopulation, with the risk that the rural continues to play catch-up with the urban (Craig and Greenhill, 2005).

The prevalence of an urban approach is further explained by the blurring of urban-rural boundaries brought by an extended urbanisation (Brenner and Schmid, 2012; Monte-Mór, 2005).

The foundations of extended urbanisation discussion were laid by Henri Lefebvre in the 1970s, when he anticipated a complete urbanisation of the society that would lead to the “homogenization of space and the disappearance of diversity” (Lefebvre, 1989, p. 23), and culminated with the assertion that, if successful, the planetarisation of the urban would render the deconstruction of capitalism unviable (Lefebvre, 1989). As such, it would render the categories that conform bounded territories and their oppositions, such as city-countryside, inadequate to describe the pervasive encroachment of capitalism.

For Neil Brenner and Christian Schmid (2012, p. 12), “while the process of agglomeration remains essential to the production of this new worldwide topography, political-economic spaces can no longer be treated as if they were composed of discrete, distinct, and universal ‘types’ of settlement”. They challenge the “existence of a relatively stable, putatively ‘non-urban’ realm as a ‘constitutive outside’ for its epistemological and empirical operations” (Brenner & Schmid 2012, p. 13). Discussing the existence of a rural—transitional territories where urban and rural elements mingle and challenge one another—would be simply ineffective.

Questioning the authors’ position, Kate Shaw (2015, p. 591) underlines that “while the urban can indeed be framed theoretically, in some places it is also subject to a powerful demarcation between land inside and outside boundaries—arbitrarily drawn, socially constructed, but not at all theoretical—which produces profoundly different land valuations”. No matter how contentious the urban as a category might be, its practical effects are felt by those people whose inclusion is defined by a matter of location.

Thus, this paper embraces a yet unfinished process of extended urbanisation punctuated by places where a set of elements typical from the countryside have not been corroded or dissolved by the planetarisation of the urban. Being so, disregarding further qualifications of space means ignoring the specific socio-spatial arrangements that result from an uneven capitalist-framed urbanisation.

The specificities of the rural motivate a growing body of research to focus on the rural-urban interface (such as Buciega et al., 2009; Cimadevilla, 2010; Grazuleviciute-Vileniske and Vitkuvienė, 2012) with a critical view on how current social, spatial, cultural and economic changes are reshaping territories formerly labelled as rural (Pereiro and Prado, 2013). This paper addresses a gap in literature on the impact of the internet on rural communities’ socio-spatial practices by investigating the interaction between socio-spatial practices and the late introduction of the internet in three marginalised communities: Santo Antônio do Salto (Salto) and Noiva do Cordeiro (Noiva) in Brazil and Pendennis in the United Kingdom. Its main ambition was to find indications to whether internet could foster micropolitics, “a situational politics based on local knowledge and action” (Feenberg, 1995, p. 105), in subaltern groups subjected to both the domination of ‘the centre’ and the resulting capitalist social relations of production that stem from extended urbanisation.

2 FRAMING THE DISCUSSION ACCORDING TO LEFEBVRE’S SOCIAL LEVELS

Lefebvre suggested we discuss social levels—global, urban and the everyday—rather than scales, as they are a social extension of social relations, rather than a hierarchy of spatial relations (Lefebvre, 1991). The global level is the level of the institutions, and the most abstract one, i.e., the level of the capital markets and the politics of space. The urban level, or mixed, represents the built and unbuilt domain that mediates the global and the everyday, composed of institutional buildings and infrastructure in general. The everyday is the level of ‘inhabiting’, the lived experience, and also where the social relations of production are reproduced and power relations enacted. Indeed, the breadth of the social, political and socio-spatial impacts of the internet in the rural cannot be grasped by analysing encapsulated scales. The global permeates these communities, reinforcing and sustaining an international division of labour through an unequal access to information and deficient production of knowledge (Dantas, 2006), resulting in consumption of knowledge that comes from outside and the withering of local knowledges.

Furthermore, the widespread of corporate internet is contributing to the exponential expansion of the so called ‘gig economy’ with the proliferation of apps such as Uber, where workers submit themselves to highly exploitative labour conditions without being aware of the work relations disguised in the so-called

'sharing economy' (Rosenblat and Stark, 2016). Despite being a global phenomenon, the impact of the internet in work relations is deemed to be greater in the countries of the South, where regulation and labour protection are even more feeble. In these places, even when local arrangements lead to alternative social relations to those brewed under a capitalist mode of production and result in particular forms of socio-spatial organisation, there is no significant inside-out or bottom-up triggering effect.

In regards to ICT, the discrepancies in access observed in the urban suggest the strengthening and the emergence of socio-technological peripheries, geographical territories connected to centres in an asymmetrical relationship of technology and knowledge production and use. In countries such as Brazil, this was already denounced by Marcos Dantas (1986, par. 12): "for Third-World countries forced to integrate themselves internationally, the problems become even bigger, due to the dissipation of the so-called comparative advantages, resulting from the application of new technologies in the industrial processes and in the services." Nevertheless, peripheralisation is not exclusive to the Global South and East—always perceived as peripheral and therefore exogenous to the 'developed' nations—, but also happens in the Global North and West—regarded as advanced and the motor of technological development. Central countries are creating peripheries and divides within their own territories at an unforeseen pace.

Locally, this form of peripheralisation presents itself in accordance to existing socio-spatial processes and the ways in which ICTs are being introduced in the everyday. Major corporations successfully implement the consumer model (Feenberg, 2012), extracting as much surplus value as possible all over the world. But it is in the peripheries that this process becomes even more evident: internet provision driven by profit, and service is often poor with high costs.

On the articulation of the urban level with the everyday, technical infrastructure interacts with spatial infrastructure influencing socio-spatial practices. Understanding the technocratic, heteronomous, economically driven articulation of ICTs gives insight to the processes inherent to planetary urbanisation. As extended urbanisation encroaches the countryside, the everyday recurrences that characterised the idyllic rural are gradually becoming an unfinished urban project. There emerges a urban with the prevalence of a heteronomous order conflictive with reminiscences of moderate autonomous approach to the 'inhabiting'. As technology is introduced in the urban, conflicts that were already in place tend to be reinforced. Figure 1 shows the articulations between the different social levels with a focus on the everyday, based on an adapted version of Comparative Political Urban research method Denters and Karen Mossberger (2006).

For its richness, this paper will focus on the everyday, the most intimate social level, and, therefore essential for the reproduction of social relations of production:

Implicitly, it is accepted that daily life does not boil down to a sum of isolated acts: eating, drinking, dressing, sleeping, and so on, the sum total of consumer activities. Except when society is defined exclusively by consumption (something that is increasingly rare), there is an awareness that consideration of these isolated acts does not exhaust daily life, and that we must also attend to their context: the social relations within which they occur. Not only because each action taken separately results from a micro-decision, but because their sequence unfolds in a social space and time bound up with production. In other words, daily life, like language, contains manifest forms and deep structures that are implicit in its operations, yet concealed in and through them (Lefebvre, 2005, p. 2).

For Lefebvre (2000), the everyday prevails in the current mode of production, even superseding economics as the defining element of capitalism. "Daily life is key to hegemony and the reproduction of capitalism insofar as it is saturated by the routinized, repetitive, familiar daily practices that make up the everyday in all spheres of life: work, leisure, politics, language" (Kipfer, 2002, p. 132). The everyday holds the key to as much as the maintenance of the status quo as to disruptions in the mode of production that might lead to insurgency: "a revolution takes place when and only when, in such a society, people can no longer lead their everyday lives; so long as they can live their ordinary lives relations are constantly re-established" (Lefebvre, 2000, p. 32).

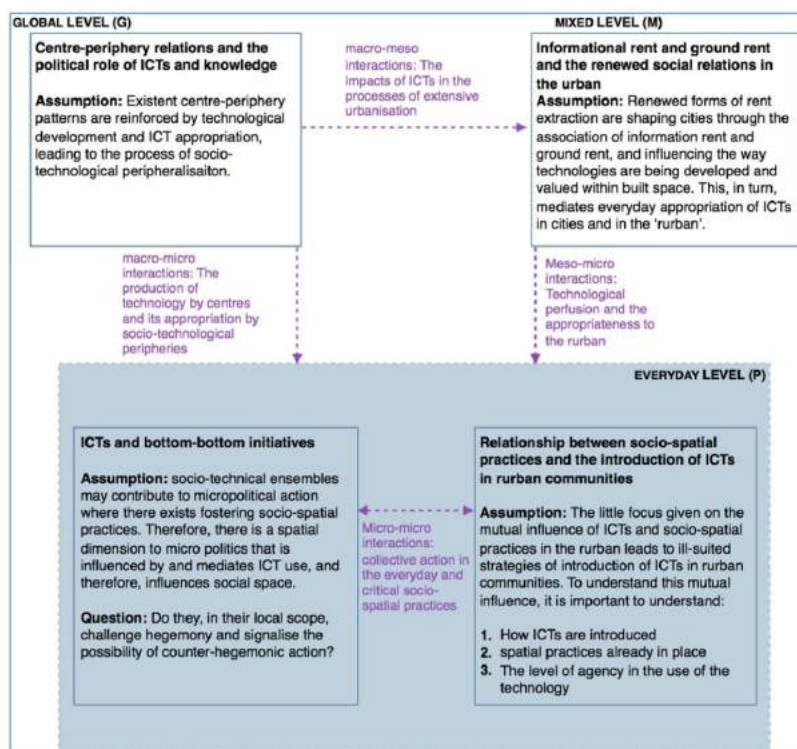

Figure 1: Articulation between the different social levels in regards to ICTs. The author, based on Denters and Mossberger (2006) comparative studies methodology.

Drawing from Lefebvre's theory, Marcelo Lopes de Souza (2011b) defines spatial practices as social practices dense of spatiality. In this paper, the use of socio-spatial practices, rather than just spatial, aims to highlight the social character of such practices. As social practices, they serve both heteronomy—coercion, domination, imposition—and autonomy—emancipation, self-determination and legitimate self-defence, with the prevalence of the former. According to Souza (2011a, pp. 23-24), "at the level of explicit power, it is guaranteed by the top-down or outside-inside imposition of the nomos, and at the level of 'implicit infra-power' (which refers to 'subliminal messages', the imaginary), by the weight of transcendence (extra-social sources and justifications of power) and by alienation". The result is an uneven and unavoidable sociospatial development that "[...] constitutes, simultaneously, a reflex, means and condition for the functioning and reproduction of the capitalist system" (Corrêa, 2007, p. 63).

The rurban evinces the necessity of the uneven spatial development for capitalism, specially underextended urbanisation. Rurban communities feel forced to enter the circuit of capital accumulation, and do so from a marginalised position. The exogenous introduction of urban elements in a previously exclusive rural fabric contributes to the alienation of the population leading to an outside-inside differentiation of the space.

Salto and Pendeen illustrate this process. The implementation of mining companies in both territories impelled a specific spatial configuration and the development of a roughly urbanised core to serve production purposes and industrial flux, hardly considering existing socio-spatial processes already in place. The economically driven division of space affected the social division of space and led to fragmentation. The resulting incongruous space became evident when the companies ended their activities locally.

3 SOCIO-SPATIAL PRACTICES AND INTERNET ACCESS IN THE RURBAN

Three rurban communities were studied during 2012-2016. The communities were approached as per information found on site and strategies developed according to preliminary assumptions of how

they implemented and use internet. The empirical research followed an Actor-Network methodology and the following analyses were based on a Marxian theoretical framework¹. In Salto, a series of non-structured interviews and map aided interviews were conducted, first with known inhabitants and then with a random sample defined according to the conglomerate method. In Noiva, information was collected through in-depth interviews with members of the community in four different occasions and previous works conducted by colleagues at UFMG. In Pendeen, information was collected in the framework of the research 'Digital Neighbourhoods', in the University of Plymouth. Questionnaires and unstructured group interviews took place during 'tea-and-cake' sessions, followed by further in-depth interviews.

3.1 TOP-DOWN ACCESS TO INTERNET IN SANTO ANTÔNIO DO SALTO AND PENDEEN

Salto is a Brazilian district of Ouro Preto, former gold capital of Minas Gerais in the 18th century. The lack of formal historical documents implies its peripherality since the gold mining era. Salto did not connect important places or developed strong commerce or agriculture. In the 1930s, starving and unemployed villagers saw the political decision to house an aluminium industry in Ouro Preto as crucial. The job offers attracted people from nearby and contributed to Salto's timid urban development. The arrival of the aluminium plant settled the population who, not starving anymore, did not have a clear reason for mobilisation, and since then the district is dependent on the private sector. The district lacks a socio-spatial organisation able to foster any collective action, contributing to the introspection of the inhabitants. The community gathers in religious festivities and the gastronomy festival, a local event managed by some of Salto's women. Most attempts of mobilisation come from the outside and have failed, such as the village tourism initiative, where locals could use their own infrastructure to welcome tourists, practice with positive response in other districts in the region. The only attempt of internet provision by the local government was frustrated as computers were stolen on the same day they arrived at an improvised telecentre. Currently, the service, specially mobile internet, is provided by private companies.

Pendeen is a 700-inhabitant former mining village established in 1846 in the Penwith peninsula in Cornwall, UK. It developed along the road that connected Trewellard and Higher Bojewyan, both small settlements existing since pre-historic times and still heavily rural. In the 18th century, the village became an important mining hub in the region. The steep increase in population led to the expansion of the village that became a highly self-sustainable parish on its own. The crisis in the mining industry and the closure of the two most important mining companies in the 1980s led to out-migration. The village retracted, leading to the shutdown of many of its shops and the consequent reduction in local employment. Currently, Pendeen is amongst the 25% more deprived and isolated areas in UK. The recent arrival of internet was the result of a massive European Union funded programme with British Telecom to provide superfast broadband to Cornwall. Owing to the highly technocratic nature of the programme, the service has not yet reached most of the population. An initiative of the local community centre and volunteers bridges the gap between infrastructure and local needs, by providing support and infrastructure for the population to benefit from the service independently from the program.

3.1.1 INTROVERTED SOCIO-SPATIAL ORGANISATION AND USE OF INTERNET IN SALTO

In Salto, the implementation of the mining industry in the region had a great impact on subsistence agriculture and led to a dependence on external produce, aggravated in the last years by the cash inflow of commuters and the implementation of Bolsa Família (a social welfare programme to counter extreme poverty in Brazil, in loose translation: family bursary) by the Federal government. Still, it is possible to observe the prevalence of a family economy, based on male productive labour and female reproductive labour and agriculture, that defines the community's everyday. The socio-spatial dynamics of Salto on weekdays prevail on the private sphere, largely dictated by the division of labour: reproductive labour is performed within the households and men are often out of the village for work. The recent change in employment dynamics caused by the shutdown of the local industry suggests a shift in the local economic

¹ The conflicts and possible reconciliation of both fields are dealt in Melgaço and Baltazar 'Anthropophagy In Planning: Building A Theory From The South Through An Association Of Actor-Network Theory And Historical Materialism' in this volume.

and social organisation, with women becoming the primary source of family financial support. For instance, younger generations of mothers rely on the elderly relatives to help raise their children.

Despite an everyday solidarity at the individual level typical from rural settlements, the introverted dynamics of the community and the absence of basic infrastructures (both social and spatial) contribute to a lack of collective engagement and action. It was often stated that problem of Salto is that “each one is for themselves”. As pointed, “what is missing here in Salto is difficult to get, because what is missing here is cooperation. Here you have, as they say, you know, you just have people to pull you back, right (sic)? Now, to help you, that is hard.” Another inhabitant believes that this lack of collective spirit is the elderly’s fault, and that Salto residents will only be united when “the old die” for the young to take the initiative. Nevertheless, several of the young people interviewed have no interest in taking an active role in the community, and are often motivated to leave the district.

Currently, broadband internet is available through local providers at low quality and high prices, costing the equivalent of a seventh of the minimum wage. Mobile internet, though also low-quality and expensive, is more disseminated as pay-as-you-go service with no long-term commitments and no need of computers. Locally, the way they use the internet reflects the way they use their scant public space and shows the overlapping of previously existing physical networks: the use is based on individual needs and is based on existing social and economic hierarchies. Once Facebook is prevalent, the population has much less access to alternative sources of information and knowledge-building tools, limiting the depth of use of the internet. Furthermore, there is little effort to share local knowledge. Some will use Facebook to advertise their economic activities, such as the quituteiras with the gastronomy festival and the local tourism agency. But still, most of the population do not know how to use other tools available online. More recently, WhatsApp is also being used for people to communicate, but again, it is mainly reproducing the networks they already had before. As it is, the internet fosters only a marginal improvement in the quality of life of Saltenses.

3.1.2 THE KEY ROLE OF THE CENTRE OF PENDEEN IN BROADENING INTERNET USE

Pendeen’s current socio-spatial processes also reflect the deprivation and isolation from the 1980’s crisis in the mining industry and the unbalance in the local economic triad: fishing and agriculture were heavily industrialised, and farmers could not adjust and compete. The lack of open spaces for everyday and spontaneous liveliness means that extracurricular activities are organised by volunteers, mostly in the Church and the local community centre—the Centre of Pendeen. These activities are essential for those inhabitants who cannot resort to external sources of leisure or knowledge building.

The Centre of Pendeen is the most recent example of how local community engagement leads to the improvement of local conditions. The community centre was implemented in the former Men’s Institute facilities, created in 1931 to alleviate the high unemployment in the region by providing social support and events. Since then, the centre has become a social and spatial local hub, where inhabitants have the opportunity to meet at social events, such as the farmer’s market, the cinema evening and the different clubs; and to seek advice and help, as the centre organises computer, CV writing and employability sessions run by volunteers. Nevertheless, the community has a track history addressing common issues collectively. Back in 1966, for example, the community raised funds for improvement works to the slipway and path at Boat Cove.

More recently, in 2014, together with St Just’s community, they devised a both online—through social networks and an online campaign—and face-to-face strategies to resist the government decision to reduce the opening hours of the library of St Just. They arranged to continuously borrow books as a symbolic gesture of the importance of the library for the community.

The centre has also an essential role in regards to internet availability. Even though internet was available much earlier, in 2013, superfast broadband was installed in the village as part of the pilot EU programme Superfast Cornwall. Nevertheless, the high costs for individual subscriptions and levels of ICT literacy it was virtually impossible for a large proportion of the population to access internet. The centre of Pendeen acts as an intermediary, not only subscribing to the service, but also by securing computer infrastructure and creating different courses, clubs and support sessions based on broadening the concept of access to effective use (Gurstein, 2003). With the interference of the Centre, Pendeen is now regarded as one of the

most successful examples of the Superfast Cornwall pilot. Volunteers advise and tutor the community catering for their individual needs and many people will use the internet to gather information and as a knowledge building tool, even if rudimentarily. Others will use internet, especially social media, to mobilise, as it was seen in the attempt to keep the library at Saint Just's open. Even if on the personal level some have decided to refrain from using the internet on a regular basis, they still see the changes brought by the infrastructure allied with a supporting place for its use.

Local ties have not changed drastically with the penetration of internet, as people still rely heavily on more traditional modes of communication, such as landlines or face-to-face encounters. Mobile technology and email exchanges have been embraced to solve everyday issues. A clearer change can be observed on networks at a broader scale. Software such as Skype have become part of the everyday of a large part of the population, allowing the expansion of social networks. The patchwork club is a good example of how internet access contributes to the expansion of localities. The group, formed in its majority by elderly women, keeps close ties to other clubs located in other countries, such as the USA. They use Facebook as a common platform and have regular meetings on Skype to exchange knowledge. Social media is also boosting local small businesses, such as the Lil's Fish and Chip shop, listed on tripadvisor.com. These examples highlight that internet is becoming an important instrument in the everyday of Pendeeners, but there have been no profound changes in the socio-economic structure of the community. Nevertheless, despite its collective appeal, the reach of the Centre's actions is still very limited, concentrating on the improvement of the quality of life of its inhabitants on an individual basis and not necessarily leading to any social change.

3.2 NOIVA DO CORDEIRO: SOCIAL DISRUPTION ENHANCED BY INTERNET ACCESS?

Noiva is a community in the fringes of Belo Vale, a 7.000 inhabitant city in Minas Gerais, Brazil. According to local accounts, the community started when, in the 19th century, newlywed Dona Senhorinha left her husband for Francisco Fernandes fleeing to the outskirts of a nearby village. Due to strictly catholic rules, the couple was excommunicated and raised their family in isolation, creating a strong bond among the family members. Fifty years later, their granddaughter Delina married an evangelical minister who founded a rigorous religion 'Noiva do Cordeiro', reinforcing local prejudice against the community. Harsh rules, which included daily prayers, constant fasting and public punishments led the community to extreme poverty. It was only in the 1990s, with the minister's death, that the community concerted to fight poverty. Its inhabitants have started to undergo a process of critical awareness (Demo, 1995) and questioned their own peripherality.

They have created traditions that bond the younger generations together but also reversed their isolation by attracting attention to their own cultural ties. The arrival of steady rural internet in 2011, through the federal programme GESAC, expanded and accelerated this opening up process, first allowing the community to improve the quality of life and then increasing the interface with capitalist activities, contributing to profound changes in local socio-spatial organisation.

Noiva has a peculiar social structure when compared to other small Brazilian rural communities. It results from an internal movement of rupture from local strict ruling based on religious grounds and a recent movement of openness by allowing and creating social interfaces with the outside. Both processes are leading to a systematic re-appropriation of local space. It started with a symbolic change: in the 1990s the church was transformed into a 'bar'—a space for celebration. The public space slowly transformed into an engagement arena, where common struggles could be addressed. Overhauled, space marked a shift on their perception of public contributing to a socio-spatial organisation based on a communitarian spirit that can be acted upon the space itself.

Despite perceiving leadership within the community networks (especially D. Delina, the matriarch and Rosalee, one of her daughters), they organise themselves non-hierarchically to assign the chores and the productive work. To avoid female out-migration, women ventured in productive activities for income, specially sewing: they started producing lingerie, first joining previously owned non-professional sewing machines. The factory started with no fixed working hours and they would interrupt production every cropping season, when everyone harvested for subsistence agriculture. Products were initially sold in Belo Vale, at craft fairs in Belo Horizonte and other cities and to visitors that go to the community. Formally, they created two associations that allow them to access public funds and legally sell what is

produced. Due to the group cohesion, Rosalee was elected city councilor, defending their rights and interests in the governmental sphere. Since the 2010s, the community ventured in medium-scale agriculture by first cultivating pepper and tangerine to supply the Redistribution Centre of Minas Gerais, and then diversifying production. Specific cultural activities were created to cultivate local bonding and create a common cultural identity, as well as to produce and share knowledge. These were later developed into Noiva do Cordeiro em Show, diverse professional cultural groups, including a Lady Gaga cover, their most successful number. From the 2000s onwards, they invested in regional networks to counter isolation. They shared their diverse cultural and educational activities with marginalised communities in the region, changing the negative perception. The foreign interest in the community lifestyle is explored in the form of 'social tourism', with clear implications in their socio-spatial organisation that is changed to please visitors, often conflictive with previous practices. ICTs, specially internet, have an important role in this change. If, at first, they were digital illiterate, in 2006 they became a reference in the region for establishing the first rural informatics lab (CIDEC) through a partnership between the local association, the Committee for Democratisation of Informatics and Vale Foundation. Rapidly they became known as rural pioneers. Internet was first available in CIDEC in 2008; and in 2011, a governmental project guaranteed broadband internet at no cost. It soon became an essential tool, used for research and knowledge building, as knowledge was essential for the community's turn: to disrupt radical religious beliefs; to overcome prejudice from neighbouring regions; to improve economy, with the search for references to the lingerie collections or inspiration for the artistic groups' performances; to reinforce the local lifestyle through courses for younger generations, games and theatre plays; and to learn and exercise their rights.

Regionally, CIDEC gave the villagers a voice in the region leading to a local inversion of power relations: Noiva acquired a centrality it never had. The importance of CIDEC faded away in the following years, as equipment aged and mobile internet was made possible through the acquisition of a mobile antenna.

Locally, they use mobile phones to talk to each other, rather than knock on doors. The pervasiveness of mobile internet is observed in the increasing importance of social media in the community, if compared to 2013, even surpassing the importance of information and knowledge (Fig. 2).

There are important implications to the pace of explosion to the outside: spectacularisation of the festiveness of their cultural; the loss in importance of bonds with nearby communities; and an increased interface with capitalist activities, observed in the importance given to tourism and the professionalisation and diversification of production, among others, as it can also be seen in the time comparison in Fig 1.

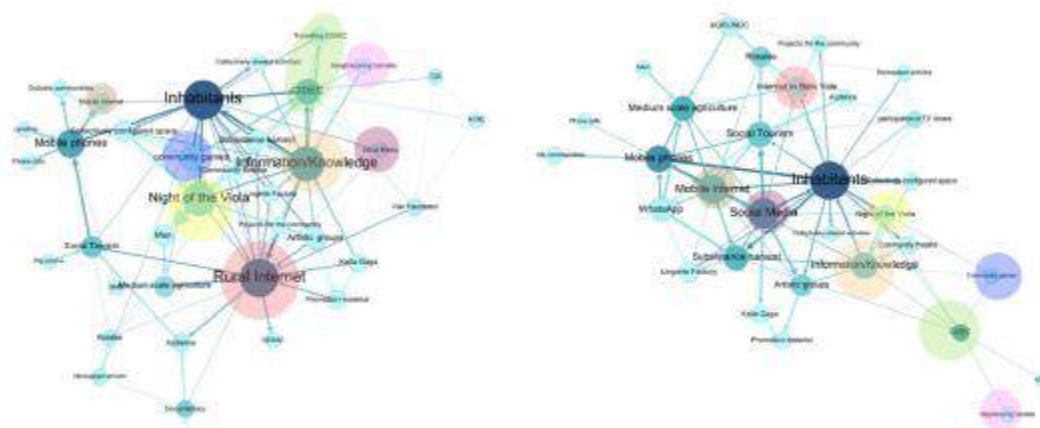

Figure 2: 2013-2014 and 2015-2016 networks of introduction of internet and some elements to be discussed, produced with the use of Gephi software. Source: the author, 2016

4 CAN INTERNET HELP COMMUNITIES CHALLENGE THEIR PERIPHERAL POSITION?

Socio-economic and geographical peripheries have been often neglected by Eurocentric simplified narratives that take the marginalised 'Other' for granted (Noxolo et al., 2012) by pinning centres as fixed points that emanate 'proper' knowledge. This macrological approach fails to account the 'micrological texture of power' (Spivak, 1988, p. 279) sealing the fate of the marginalised as eternal recipients of knowledge. While ICTs reinforce the macro centre-periphery conflict, as technological infrastructure is unevenly distributed in the globe, it confronts the stability of the centre-periphery dichotomy by allowing for "less contiguous modes of communication are subversive tools for organising new kinds of centrality and horizontal concentration" (Merrifield, 2013, pp. 40-41), time and place specific.

For Andrew Merrifield (2013, p. 42), centrality is no longer being at the centre, "[it] calls out for people and acts, for situations and practical relationships". It is never fixed and needs constant negotiation and mobilisation, reflecting the encounter of citizens. That is because centrality is not about fixation—not of people, situations or space. As much as it is related to social relations, it depends on how such relations are spatialised. This study points that communities that have weaker ties tend to reproduce the pattern in the physical and digital spaces they occupy. ICTs may afford centralities, but also further socio-technological peripheralisation, influenced by their implementation in the everyday and interaction with existing socio-challenging spatial practices. Associated with ICTs, space responds to change and acts onto people fostering or hindering action. And the way the internet is being introduced in the rural reinforces peripheralities by validating the exertion of power from the different social levels in the everyday: technology is produced in central countries and implemented top-down with little bottom-up active response, often leading to conforming uses of internet that contribute to the reproduction of the already existing oppressing conditions.

Of all three communities presented, Salto was the one showing the highest level of passive appropriation of the internet. There, the activities carried online reproduce the dullness of their everyday—"insofar as it is saturated by the routinized, repetitive, familiar daily practices that make up the everyday in all spheres of life: work, leisure, politics, language, family life, cultural production" (Kipfer, 2008, p. 199). The overall use of social media reveals a shallow exploitation of the internet that can be grasped by understanding the hegemonic construction of access and mirrors a hegemonic production of space. Thus, it is possible to observe that "media (institutions, technologies and representations) disembody social practices, while simultaneously making these practices and experiences dependent upon the media as such" (Jansson, 2010, p. 179). Despite its formal centre—where the Church, the square and small commerce are located—it has no centralities. Its longitudinal spatial configuration, reinforced by two spatial discontinuities—the river and the water channel—hinders action and contributes to the reproduction of political poverty, the inability of a given community and its individuals to mobilise in the various spheres of common and individual life (Demo, 1994). Despite also being a marginalised periphery, Pendeen has managed to develop a local centrality that extrapolates its limits with the implementation of the Centre of Pendeen, only possible because of the existing collective engagement in the village. The centre, in turn, stimulates this engagement through targeted actions that also contribute to marginal micropolitical action. By doing so, the community centre is actively contributing to the improvement of livelihoods in the region.

Initially, Noiva developed a local centrality by strengthening existing connections and investing in regional connections mediated by ICTs. D. Delina's house (now communarian) became also a centrality acting as a nodal point for decision-making and bonding. It became a centralised periphery regardless of its economic-geographical position, which no longer strongly defined who they were. Noiva benefited from being on the outskirts of capitalism: they developed their own conviviality rules and created interfaces with capitalist society when seen fit. With this arrangement, they were able to improve their living conditions without compromising their beliefs and social structure. In fact, its centrality was not connected to production capital, but to information and knowledge—their lifestyle was a valuable capital to be traded. Nevertheless, the unfolding of the community throughout the last five years leaves the question whether centrality is unassailable from centralisation. Noiva became a reference for the nearby communities, as it was provided with something unique—be it technology, knowledge or a social organisation that calls the attention of outsiders. That granted them a symbolic capital that, seen as such, became a source of power. Could Noiva be a new centre that feeds off from its peripheries? Recent developments suggest that no, because it is difficult to operate in the outskirts of capitalism without being swallowed by it. Looking from outside, it seems that they are willing to bypass the regional ties built over

the years (and even the central position they occupied) in favour of closer relationship to already established centres, such as Belo Horizonte or São Paulo. They seem unaware of the compromises that such a decision demands. Drastic changes in their working patterns are being followed by adaptations in their socio-spatial organisation, affecting their own everyday, and the long-lasting consequences of this shifts are still not clear.

5 INTERIM CONCLUSIONS

The three communities illustrate that appropriation of internet follow, generally, existing levels of peripheralisation and rarely contribute to a profound socio-spatial development. They also ascertain that, to envision change from within, communities need to produce fostering spaces for the internet to be better explored and for the stultifying tendency of the everyday to be overcome, towards micropolitics. But that is not enough. Salto and Pendeen suggest a conforming approach to the internet, which is not used to overcome peripherality as such, but as means to improve the quality of life with very limited production of local knowledge. Differently from Salto, though, Pendeen has a nodal point, the Centre of Pendeen, that works as a very local centrality and contributes to (moderate) collective mobilisation. In Noiva, the internet briefly was used as a tool to challenge peripherality, despite being a periphery. While they did not innovate internet use, the way it improved on the local production of knowledge impacted on their thinking, and, to a certain extent, questioned the mode of production. Their socio-spatial organisation, coupled with the internet allowed them to become a regional centrality. Still, the same internet increased the interface with capitalism and re-shaped part of the community, which, on its turn, offset its disruptive potential. Noiva underscores that even if the internet contributes to the furthering of previously existing socio-spatial autonomy, it may, over time, foster heteronomous and conflictive socio-spatial practices, illustrating a vicious circle where gains in autonomy allowed by effective use of the internet are further absorbed in the system because of the internet model. To conclude, the more ICTs become essential to the maintenance of capitalist structure, the less likely they will formally mediate social change. The way the internet privileges the consumer model shadows horizontal forms of solidarity, where alternative centralities that not based on structural dependency can be built among peripheries. We need to continue looking for bottom-bottom encounters that blossom with the use of internet (even if produced by the centre) and understand the socio-spatial practices at place. These might hold the key to new forms of micropolitics, and to the redefinition of centralities as envisioned by Lefebvre without relying on the relations established by the capitalist mode of production. Nevertheless, detecting the insurgent rural is a combination of patience and fortuity. Seeds might abruptly appear, and in the same intensity, be re-absorbed into the system.

ACKNOWLEDGEMENTS

This paper follows the PhD research "Socio-spatial practices in socio-technological peripheries: the case of rural communities in Brazil and in the UK" at the Universidade Federal de Minas Gerais funded by CAPES/REUNI scholarship. Part of the work was conducted on the framework of the researches "Museu Tempo" coordinated by Dr. Ana Paula Baltazar and "Digital Neighbourhoods" coordinated by Dr. Katharine Willis, to whom I must thank.

ID 1380 | SOCIO-SPATIAL JUSTICE: THE SOCIAL STRUGGLE FOR THE ACCESS TO BASIC RIGHTS SUCH AS HOUSING OR SUPPLIES IN SPAIN

Eva Álvarez de Andrés¹; José Miguel Fernandez-Güell¹

¹DUyOT-ETSAM-Universidad Politécnica de Madrid

eva.alvarez@upm.es

ABSTRACT: About one million and a half families live in Spain in self-built housing with an informal access to the supplies, to which more than 700,000 families have been added after being evicted from their homes after the crash of the real estate market in 2008. The response of Spanish local communities has been the emergence of a networked social movement called Plataforma de Afectados por la Hipoteca (PAH; the Spanish Mortgage Victims Group) that aims at building a sustainable future by claiming the right to housing and other rights like electricity supplies. This networked movement has been fueled by its ability to create a hybrid space between communication networks and occupied urban space in which face-to-face assemblies and protests take place. The modes to operate of the PAH have been replicated by other movements, and their logics have contributed to transforming institutions and their political agenda. In this work we want to show the impact of the economic recession on the access for communities and families to the basics rights as housing or the electricity supplies, as well as the dissemination of the PAH's logics to other actors as the way to address the challenge. In this paper we are willing to unpack the concept of hybrid space, developed by Manuel Castells and informed by the dynamics of the PAH and to other movements emerged by imitation of the PAH. We will also analyze the impact of the struggles of these movements in the transformation of the political agendas made by the new institutional spaces such as in Madrid or Barcelona. All of this will be done by a close look of the PAH and other movements, via participation in assemblies and the observation of other activities such as their use of social networks as well as by interviewing other actors and observing the new policies proposed in the medias regarding the right to housing or to electricity supply. Finally, we will discuss how networked urban social movements as PAH have the ability to create spaces of citizenship that challenge the taken-for-granted principles of capitalism, such as the powerful discourse about the primacy of property rights over the right to housing.

1 INTRODUCTION

According to Alguacil et al. (2013), it is estimated that 30,000 homeless live in Spain and one million and a half families inhabit in sub-standard housing. In addition to these situations, more than 700.000 foreclosures have been initiated since the financial crisis outbreak in 2008¹.

According to Alguacil et al. (2013:188) "there has been an abdication of the public responsibility regarding accessible housing by all the societal sectors, entrusting speculative markets for the satisfaction of the housing accessibility". The housing exclusion problem in Spain continues being a problem of lack of political will² to guarantee the right to housing, which is included in the Article 47 of the Spanish Constitution³.

In this context of absence of effective and comprehensive policies and practices implemented by public administrations, people unable to make effective their right to housing and their supporters have mobilized to generate alternatives that respond to the housing emergency in Spain.

² "We all know that the obstacles to those solutions are not technical but political. Political will is needed to address certain economic interests. No more "(Colau & Alemany, 2013: 29).

³ The Article 47 of the Spanish Constitution, expresses that: "All Spaniards have the right to a decent and adequate housing. The public authorities shall promote the necessary conditions and establish the appropriate standards to make this right effective, regulating the use of land in accordance with the general interest to prevent the speculation. The community will participate in the benefits accruing from the town-planning policies."

One response from the Spanish local communities has been the emergence of a networked anti-eviction social movement known as PAH, the Spanish Mortgage Victims Group (Plataforma de Afectados por la Hipoteca), to build a more sustainable future through the right to housing. Originally born in Barcelona in 2009, the PAH has successfully spread to over 160 cities and stopped 2045 evictions throughout the country (April 2017). The PAH social movement supports householders in their negotiations with banks to prevent evictions, and has succeeded in negotiating thousands of “payment by account”, restructuring of debts, and other solutions improving the conditions of the mortgage payers. The negotiations with the banks are always driven by the householder, advised by other mortgage victims within the PAH, which has resulted in the improvement of the financial literacy of mortgage payers, and hence in their empowerment. When negotiations do not succeed, PAH activists block the evictions, gathering people together by efficient use of social networks. Moreover, PAH provides help and shelter for evicted families, arranges for over 2500 people to rent some of the vacated houses for an affordable price (called the PAH social housing project). The PAH has also led a campaign to change the eviction laws and has succeeded in presenting a popular legislative initiative (ILP) with over 1.5 million signatures. In only four years (2009-2013) the PAH gained the trust of Spanish citizens, as 86% of Spanish citizens claim to share the demands made by this movement (Metroscopia/El Pais, 26/03/2013). This support has served to propose between 2015 and 2017 two new housing laws in Barcelona and Madrid.

This paper examines the ability of the PAH social movement to influence other movements and to regain the right to housing and prompt social and institutional change in Spain in the aftermath of the economic crisis. In the paper, the method followed for the research is presented firstly (Section 2). Secondly, we unfold the main factors that have triggered to this situation: the Spanish property model and the explosion of the housing bubble (Section 3), then we show how the PAH operates and influences other movements, and how these logics have contributed to transforming institutions and the political agenda (Section 4 and 5). Finally, conclusions are drawn (Section 6), showing how the actions and regulatory mechanisms promoted by government institutions in Spain have been characterized by the promotion of housing as a speculative asset serving the interests of the real estate sector, and not as a right of the majority of the society, and how the social network movements organized and with clear goals can fight to transform reality.

2 METHOD

This paper shows the social struggle aiming at making effective the right to housing (Harvey, 2012) and to basic supplies (water, energy, etc.) in Spain, through the analysis of different actions and mechanisms of regulation promoted by different actors that constitute blocks of power and counterpower (Foucault, 1998), as well as the role that hybrid space plays in that struggle (Castells, 2009 , 2012).

The research has been carried out using the case study method (Yin, 1994). Firstly, we analysed the main factors that have led to the current situation of housing emergency in Spain, and more specifically the influence of the Spanish property model and the explosion of the housing bubble in this situation (Section 3). Secondly, we studied how social network movements as PAH operate, that is: what their objectives are, what actions they carry out, with what resources they count and what their achievements are, as well as their capacity to transform reality and to be replicated by other movements (Sections 4 and 5).

Data collection and analysis comprised four stages: immersion (description); systematic data collection (classification); data processing (making connections); and drawing conclusions (producing and account) (Frediani, 2007). All of this will be done firstly by a close look of the PAH and another movement called Assembly of dignified housing for all people (ApT), via participation in assemblies and other activities during the last years, and by the observation of their use of social networks as well as by interviewing other actors and observing the news in the media regarding the right to housing or to electricity supply. Data also comes from texts, photos, and films produced by both social networks movements (e.g. Facebook, Twitter, blogs, YouTube, and websites)¹.

Our research strategy was pragmatic in that we combined methods (Silverman, 1993) in order to understand the struggle for the right to housing in Spain, and more specifically the actors involved (in particular, government institutions and social movements) and actions implemented as well as the

¹ Sources as: <http://afectadosporlahipoteca.com/> or <http://viviendadignatodos.blogspot.com.es/>

regulatory mechanisms imposed or promoted by each of them (Foucault, 1998). It is also pragmatic in that it is neither purely inductive nor purely deductive, but follows patterns of creative abduction (Schurz, 2008). Inspired by Strauss and Corbin (1990), our data collection, coding, and categorizing involved iterative moves between data sorting, coding, probing, and collecting until we could reconstruct the story of the struggle for the right to housing in Spain.

3 THE MAIN FACTORS THAT HAVE TRIGGERED TO THIS SITUATION: THE SPANISH PROPERTY MODEL AND THE EXPLOSION OF THE HOUSING BUBBLE

The situation of housing emergency that exists today in Spain is based on the implementation and development of a finance-property model that has its origin in the dictatorial regime of General Franco, which has persisted even with the current democratic constitution and remains an anomaly among the main members of the European Union. This model is characterized by:

The housing construction, almost exclusively based on the private property regime for those who can pay it at market price. In 1950, 90% of the Spanish population was living in the largest cities, as for example Madrid or Barcelona, where most of the housing was offered for rental. However, housing for rental currently represent only the 13.5% of the housing while the 78.9% are private properties inhabited by their owners¹. The changing model has its origin in the last decade of the Spanish dictatorship, which began to consider the property as a mechanism of social control. The Prime Minister of the Housing Ministry said in 1958: "The man, when is homeless, takes over the street ... We want a nation of homeowners, not proletarians" (José Luis Arrese quoted by Colau & Alemany, 2012:34). The credit flow by the end of the XXth century was the final input to this process.

This change has been driven by policies based on the tax relief for the purchase of new properties but not for the rental², the restrictions on the property rental market³, or by promoting the social housing construction destined to private ownership, and more specifically for households with an average income between 2,900 and 3,900 € / month, decreasing the production of social housing units destined to renting almost to extinction. While social rent housing represents between 20 and 30% of the housing in the European Unión, less than 2% is destined to social rental in Spain. Since 2000, the development of social housing has not achieved the 0.4%⁴.

The understanding of the housing and infrastructure construction as an investment based in speculation, rather than assets linked to the people needs. The model has encouraged an exponential growth of housing production that responds to speculation, instead of satisfying the real housing demand. It is estimated that 6.6 million homes (ODESC, 2013) were built in Spain between 1997 and 2007, maintaining the percentage of empty housing close to 13%⁵.

Deregulation of the land, the housing market and the credit. Urban development has focused on the application of the appropriate law for the mass production of housing and for the implementation of infrastructure. This process has culminated with a territorial law known as the "all building land", although

¹ Sources: Naredo 2012 and population and housing census 2011. Source: <http://www.ine.es/prensa/np824.pdf>. Last access: July 9, 2014.

² The average rental market in the EU-27 was 29.3% in 2010, while it did not reach the 17% in Spain. Source: Housing Statistics in the European Union, 2010 Income and Living Conditions. Eurostat.

³ The market has been characterized by a shortage of rental units, the absence of a minimum conditions for renting, the imposition of conditions difficult to fulfil (exorbitant prices, guarantees, open-ended contracts, etc.), discrimination for immigrants, indiscriminate increases of the rent every five years allowed by the law of urban tenants contracts, etc., "and in addition to all this, the proliferation of messages by the institutional authorities and the banking system about the rent as a form for wasting savings." (ODESC, 2013: 11).

⁴ Sources: data provided by The Ministry of Public Works, Ministry of Housing and the INE.

⁵ Source: <http://www.ine.es/prensa/np775.pdf>. Last access: July 9, 2014. According to the president of Provivienda, 2 of every 5 empty houses were built less than 10 years ago.

not only this law has failed to achieve the decrease of the housing prices, but also it has caused the prices to be tripled¹.

The over-indebtedness became the "only way" for most of the families to effect their right to housing. In the period (1997-2007) the population has been forced to go into debt "beyond the reasonable limits" which granted loans up to 120% above the appraised value. In this way, the debt amount turned from the 55% of the household disposable income, up to the 130% (from € 50,786 to € 149,007), and the average time for a mortgage has increased from 19 to 28 years, with the implications that all of this has on the living. (Colau & Alemany, 2012)

The use of the urban planning as a tool for the production of private property. The economic and financial efforts were aimed to develop new urban areas, leaving two main consequences: the progressive abandon of the city centres and urban sprawl; both unsustainable.

Generalize and systematize the corruption in the financial, political and real estate sectors. The implementation of the speculative model has been possible thanks to the close relationship between the housing-construction sector, the financial banking and the political power. The law of "all building land" decentralizes the responsibility on urban planning², promoting speculation and corruption, with democratic consequences for the traditional parties. "The list of cases where local authorities, construction companies and real estate companies work together are so common around the territory that could even be the subject of a monograph" (Alguacil et al.2013: 18). It is frequent to see operations of reclassification of parks and green areas in order to allow building in them, the allocation of public works with substantial cost overruns, the construction of "ghost" airports and neighbourhoods, etc.

All this has revealed that Spain had a structural problem of denial of access to the right to housing that was contemporary to the "real estate boom", both prior to the financial crisis. By the end of the 2006, following to a visit to Spain, the UN Special Rapporteur for the Right to Housing issued a report pointing out that the main housing problems in Spain were caused by the poor management of the public administration³. The report denounced the commercialization of the social housing programs. In the same line, the FEANSA 2008 report highlighted that 20% of the Spanish population was being excluded from the housing market.

In this context, the outbreak of the international financial crisis had hit Spain with devastating consequences. The rise of the interest rates and the interruption in the international credit flow, the construction sector reached the 70% of all the credit (ODESC, 2013), affected seriously to the real estate business, foundation of the "Spanish miracle". This sector accounted for up to the 30% of the GDP and 13% of the employment rate (Colau & Alemany (2012).

In a context of widespread indebtedness, the rise of unemployment, from 8% in 2007 to the 26.6% in 2013, has led to an increase in the difficulties of owners to comply with housing payments: "From 2008 until the present, the impossibility of paying the rent or mortgage has become a major issue for families" (ODESC, 2013: 13). Since 2008, over 700,000 foreclosures have left hundreds of thousands families on the street with a debt for life, condemning them to a social exclusion life.

However, the Achilles heel of the Spanish economy is not the default of the families, but of the real estate companies, the latter estimated to be 4 times higher than that of the families (a 21% of the housing debt corresponds to the families default and in a 79% to the real estate companies). A lot of money has been invested in "toxic assets" which are hard to place again in the market. However, the real estate companies are allowed mortgage releases while this possibility is forbidden for the families (Colau & Alemany, 2012 , 2013).

¹ Since the adoption of the law in 1998 and until the year 2006, the housing prices have been increased by 150%. In this period, the rate of land prices grew 8.7 times more than the CPI, and the construction price have been increased by 2.3 times.

² "With only 15% of government revenues, local governments were facing a very high percentage of public services. In times of massive construction, the differential between income and public spending was covered by urban planning resources. These incomes were considered as an ordinary income when in fact they were extraordinary. For that reason no provisions were made for a subsequent cycle or crisis" (Buron, 2012: 7). The real estate tax revenue reached in Madrid 50% of the city budget and in Valencia up to 60%. Source: Colau & Alemany (2012).

³ Source: A/HRC/7/16/Add.2, February 7, 2008.

After the outbreak of the financial crisis, the international "markets" also required the repayment of debts, by imposing the socialization of the losses and the implementation of "austerity" measures that have supposed the contraction of the public funds to sectors such as health and public education, social aids, etc., making the situation of individuals and families in risk of exclusion even tougher.

In this context, until February 2009, the public administrations continued denying vehemently the problems of paying the mortgage by the Spanish families. In this way the public administrations have continued largely directing their efforts to protect the interests of the large landowners rather than to ensure citizens' right to housing: "The goal declared for the Housing Plan was the solution of the problems of the developers, builders and financial institutions, instead of solving the housing problems of the population" (Alguacil et al, 2013:174). A bleeding example of this was the sale, in 2014 at a critical time of housing emergency, of 40% of the scarce stock of social housing for rental to investment funds (Vulture Funds) for a price 30% below the market value and without any requirement for the new "landlords" to rent their properties as social housing¹. Something that could be done by the municipal government of Madrid because the competences on housing policies are decentralized.

As Colau and Alemany explain, more than a financial crisis, we are facing a "scam circumscribed and protected by law" (Colau & Alemany, 2012:69) with devastating consequences for most of the population, with a poverty risk rate that has reached 20.4%². As the ATD Fourth World Movement said, it seems that "poverty is part of the system and has become a business"³. The fact that over 16% of the population are denied their right to an adequate housing⁴, while there are over 3.4 million empty homes⁵, is at least "a clear example of the failure of the liberal market, both in social and economic terms." (Alguacil et al 2013: 24). This unethical question urged to seek for alternative models.

As it has been explained, the Spanish public administrations have been characterized by the denial of the emergency housing status, generating a feel of guilt in the affected persons, by the lack of significant programs to promote effective access to an adequate housing, and by the application of social aid policies in absence of social housing policies.

Regarding the demands from families living in shelters: the direct expenditure for the public housing development has only accounted the 0.2% of GDP (Alguacil et al., 2013); furthermore, social housing programs have waned, representing a mere 2% of the global housing stock built in the last 35 years⁶. There are only 240,000 homes for satisfying the demand of more than 2 million people who live in inadequate housing.

Regarding the demands from People Affected by Mortgages (PAH): besides ignoring their situation, a new law for foreclosures was issued in 2007 and, although it was declared illegal by the Court of Justice of the European Union⁷, it has been implemented affecting more than 700,000 families, while more than 3.9 million homes remain uninhabited in Spain. The affected by mortgages prepared and presented a People's Legislative Initiative (ILP), but its presentation to the Congress found many obstacles and supporters of that process were almost criminalized (Colau & Alemany, 2013).

According to Alguacil et al. (2013. 188) "there has been an abdication of the public responsibility regarding accessible housing by all the societal sectors, entrusting speculative markets for the satisfaction of the housing accessibility." The housing exclusion problem in Spain continues being a problem of lack of political will to guarantee the right to housing, which is included in the Article 47 of the Spanish Constitution.

³ Source: Compromisos comunes (2012-2017): <http://atdcuartomundo.es/que-hacemos/>.

⁴ It is estimated that around 7.4 million people are denied somehow their right to housing in Spain. 0.4% would correspond to the homeless (30,000 people); a 28.1% living in inadequate housing conditions (more than 2 million people living in slums most of them gypsy and immigrant populations); a 18.4% have suffered or are in foreclosure process (over 1.3 million), and around the 53% are young people in housing demand (3.9 million young people living at home with their parents).

In this context of absence of effective and comprehensive policies and practices implemented by public administrations, people unable to make effective their right to housing and their supporters have mobilized to generate alternatives that respond to the housing emergency in Spain.

4 THE SPANISH MORTGAGE VICTIMS GROUP SOCIAL MOVEMENT

The PAH was established in 2009 in order to respond to the tragedy experienced by 700,000 families affected by foreclosure processes. It is driven by people linked to the fight for the right to housing, but most participants are people affected by foreclosure processes.

The PAH aims to reverse a model that has had devastating consequences in areas such as: the economic, environmental, political and social affairs, by a strong social mobilization. But in a short term the PAH must give specific and immediate solutions to a population threaten by the financial institutions, abandoned by the administration, and feeling guilty, anxious and depressed.

The first challenge for the PAH was to create a space of trust and mutual support where those being affected could speak and be heard, trying to release the feelings of guilt and to generate an empowerment process. The second challenge was to transform a problem perceived as individual by the affected into a collective problem with structural causes; and the third was to promote collective actions that could transform the reality and turn the impossible into possible.

To achieve its objectives, the PAH implements the following actions:

- The assemblies as a key instrument to create a space of trust that can be established as a mutual support network, in which those affected develop the necessary knowledge and skills to advice other families; a space where victims become fearless, learn to self-organize to act collectively, and to unleash the creative power of anger that turns into hope (Castells, 2009, 2012), in which those affected become active subjects of the change (Colau & Alemany, 2012, 2013) as the preamble of social change.
- Public denounce and campaigns. The collective advice is accompanied by other actions as public denunciation of the situation faced by those affected, so as to contribute to explain the causes of the problem, while responding to the urgent needs of those affected. The following campaigns are carried out:
 - o "This bank lies, scams and kicks out people from their home": The campaign is about pointing out the banks as direct responsible of the population's suffering. Contribute to balance the unequal negotiation and to manage the anger and helplessness of the people affected; as they lose their fear "to face Goliath"
 - o The retroactive "deed in lieu of foreclosure": an urgent regulation is demanded by the affected by mortgages. Basically, this consists of returning the property to the bank as a sufficient condition to pay the mortgage debt. The deed in lieu of foreclosure is considered as a minimum regulation that would permit the families to "start again", this proposal has and it has an extensive social support.
 - o The stop evictions: in a context of lack of solutions by the administration, an unfair regulatory framework¹ and a systematic violation of the affected's rights, the campaign "Stop Evictions" has become the best way to prevent evictions through demonstrations in situ. So far the PAH has paralysed 2045 evictions².

¹ The massive foreclosures and evictions for economic reasons of the Spanish government violate, inter alia, Articles 24 (about the effective judicial protection) and 47 (the right to housing) of the Spanish Constitution; Article 25 of the Universal Declaration of Human Rights; Article 11 of the International Covenant on Economic, Social and Cultural Rights (ICESCR), ratified by the Spanish government, and more specifically the General Comments of the UN Committee DESC Numbers 3 (obligations of the member states), 4 (the right to housing) and 7 (prevention of forced evictions)" (Colau & Alemany, 2012: 124).

² Source: [http://afectadosporlahipoteca.com/](http://afectadosporlahipototeca.com/) Last access: April 17, 2017.

- o PAH Social Work: without a stock of social housing, in a context where thousands of families were evicted, seeing how financial institutions kept collecting empty properties for speculation proposes results from an intolerable violence. The objective of the campaign "PAH Social Work " is threefold: firstly, it aims to recover the social function of the empty property, particularly those that are held by financial institutions result of foreclosures, to avoid the homelessness. Secondly, it exacerbates the pressure on financial institutions to accept the deed in lieu of foreclosure. And thirdly, it enforces the public administrations to adopt once and for all the necessary regulations to guarantee the right to housing. The PAH has managed the relocation of 2500 people¹. In addition, the pressures of the PAH have been able to force financial institutions such as the SAREB to give housing to the municipalities to offer them to the families at affordable rental prices.
- o The motions to the municipalities: in December 2010, the PAH organized a specific campaign targeting the municipalities. They proposed the creation of hybrid committees (with participation of the administration, PAH, neighbourhood associations, etc.), in order to solve and prevent the evictions, to ensure the resettlement and to alleviate the situation of those affected until the law proposal is approved. They also demanded, among other things, that social workers do not threaten the affected by mortgages with the loss of their children's custody, make a census of empty properties and persecute the anti-social use of properties, the suspension of the evictions and the cancellation of the illegitimate debts. Currently, more than 400 municipalities are supporting the deeds in lieu of foreclosure for the affected by mortgages, some of them governed by the strongest political parties, which reveal contradictions inside the parties (Colau & Alemany, 2013).
- o The Popular Legislative Initiative (ILP): in order to persuade the Spanish Parliament to apply the deed in lieu of foreclosure retroactively, the stop eviction and the promotion of the stock of social housing for rental, a Popular Legislative Initiative (ILP) was presented. For the PAH, a main aspect of this campaign was the social and political process. The ILP was a tool to visualize the problem, to make alliances and collaborations with associations and other groups, and to empathize with citizens. After two years of struggle, in February 2013 the Congress of Deputies admitted the processing of the ILP; however, a few months later the government approved the new law 1/2013 which did not include the deed in lieu of foreclosure, legalized unfair terms in mortgages and kept the forced evictions. In January 2017, the European Court of Justice fails once again in favour of the PAH. This judicial ruling opens the door to demanding the nullity of all foreclosure proceedings and evictions since 1995².
- o The PAH Housing Law: over almost 8 years, the actions of the PAH have shown that the vulnerability of the right to housing in Spain has been based on unfair laws that have been declared illegal by the European Court of Justice. "Far from solving the situation of the families, the Congress has been used to carry out measures to protect the banking and the electric, violating the Right to Housing collected in article 47 of the Spanish Constitution. It is time for the citizens' demands to finally come to Congress and be approved so that no family will ever live in the street".³

The PAH Housing Law arises in order to challenge the Government and force them to position themselves publicly in favor of citizenship and to legislate to protect and enforce Human Rights, and in particular the right to the housing and to the basic supplies. The PAH Housing Law develop measures to make effective the deed in lieu of foreclosure, the regulation of the rental market to make it affordable and stable, to stop the evictions, to promote a public park of social housing for which payments do not exceed the 30% of the families income, and finally the guarantee of basic supplies as water, electricity and gas by adjusting the prices according to the income of the families.

³ Source: <http://las5delapah.com/ley-vivienda-pah/> Last access: April 17, 2017.

For all this actions, the affected have been the PAH's main resource, but they have also been supported for many professionals (lawyers, urban planners, journalists, sociologists, etc.) that have been collaborate for free; and some research centres such as the DESC Observatory, social organizations, neighbourhood associations and 15-M assemblies. Furthermore, the PAH has promoted the networking with all the institutions who want to listen and support their efforts, such as unions, governments or political parties.

In relation to their economic resources, the PAH has offered its services for free, and its economic support have been based in donations from organizations and individuals. The PAH does not receive subsidies, grants, or any other funding. This approach is vital for the PAH, allowing to continue implementing their actions with complete independence from all the institutions.

The main achievement of PAH has been to show that reality is transformable "if we got organized and we kept on course, we could change things". (Colau & Alemany, 2013: 42).

- The PAH have succeeded to turn an individual problem in a collective problem. Those affected become active subjects of a change and join with others to perform useful actions and to make visible the structural causes of the problem. In this way, an alternative discourse is constructed apart from the official view. "This is not a crisis, it's a scam" (Colau & Alemany, 2013: 36) helping to change the collective perception.
- The PAH has accumulated victories and it has shown that the reality may be transformed. Hundreds of deeds in lieu of foreclosure have succeeded, and there have been thousands of evictions paralysed and families rehoused. It has achieved the administrations to be willing to act and financial institutions to negotiate.
- The PAH has gained legitimacy. Using the social networks and the media to spread their struggle; it had achieved to empathize with the majority's feelings "it has achieved the most difficult: to articulate a demand recognized by the 90% of the population" (Colau & Alemany, 2013: 94). It promotes dialogue and organizes and coordinates a network of professionals, social organizations, unions, etc., to fight for the right to housing. It has achieved to make all citizens aware and gain legitimacy "facing the discredit of rigid and coward institutions. The platforms have become a stable and consolidated reference." (Colau & Alemany, 2013: 56).
- The PAH had changed the politic agenda. In 2013, the ILP was accepted for processing; moreover, in 2014, their demands were incorporated as essential principles in the programs of the newly emerged political formations as Podemos, and in one way or another the housing exclusion becomes a crucial issue in the political program of other parties. Finally after 8 years of struggle, in 2017, the PAH has succeeded in having the European Court of Justice pronounce in its favor, which opens the door to demand the nullity of all foreclosure proceedings and the evictions carried out in Spain since 1995.

The PAH was born with the goal of being replicable both in their actions and in their ways of organizing. Currently it has over 214 nodes spread throughout the Spanish territory. The PAH has also become an international reference. In 2012, for example, an eviction was paralysed in Berlin, replicating the practices of the PAH. In 2014 the PAH proposals has led a "Grundtvig" project which aims to create a European school for the right to housing.

We can conclude by stating that PAH is highly replicable in a context of strong violation of the right to housing where a large part of the society is affected or empathizes with the victims and in a political context of a strong lost of trust in institutions unwilling to defend the rights of those they should represent.

5 A NEW SPANISH SOCIAL MOVEMENT CALLED: "HOUSING ASSEMBLY FOR ALL PEOPLE"

The Housing Assembly for All People was born in early 2015 and is promoted by the international movement against poverty ATD Fourth World, aiming to promote that those historically excluded from the right to housing such as people living in the streets, people occupying housing, slums dwellers, etc., can join the struggle led by those affected by Mortgage (PAH).

As the PAH in the long term, it seeks a change in the model, and in particular of those policies and mechanisms that generate injustice, of which the historically excluded are witnesses and experts. The Assembly joins the social mobilization of the PAH and adopts some of its logics as the creation of a hybrid space between communication networks and occupied urban space in which face-to-face assemblies and protests take place. In a short term, the Assembly must give specific and immediate support to a population historically abandoned, criminalized and persecuted by government institutions.

As the PAH, its main challenges were: to create a space of trust and mutual support where those affected could speak and be heard, trying to release the feelings of guilt and to generate an empowerment process; to transform a problem perceived as individual by the affected into a collective problem with structural causes; and to promote collective actions that could transform the reality and turn the impossible into possible. But the starting point was very different. The affected belong to social groups historically excluded and socially stigmatized which doubles the difficulty of their fight since, on the one hand, the mobilization of those affected will be more difficult, and on the other hand, the possibility of obtaining the support of the majority of the society that they do not see them or do not empathize with their struggles. Therefore, the Assembly intends, as a specific goal, to make visible the struggle of those living in extreme poverty, a struggle that has been witnessed for years by the ATD Fourth World movement (promoter of the Assembly), which has allowed to put this experience into dialogue with the current reality.

The Assembly focuses and develops its work in the municipality of Madrid, and, to achieve its objectives, the Assembly implements the following actions:

It establishes an assembly of affected and those who support them, in order to generate a space of trust in which those affected can share their struggles and seek alternatives for those living in situations of historical housing exclusion.

- The Assembly provides support and visibility to their struggles of the affected. The Assembly provides support to people in a situation of housing exclusion that approaching it and since two years ago it has been present in a slum core of the periphery of Madrid. In both cases the support has consisted in generating spaces of trust and mutual help, informing those affected of their rights, and giving visibility to their struggles through articles in the media and social networks as blogs, Facebook, etc. In short, it make sure that those affected are heard by those who decide on the problems that affect them, such as the legalization of a situation on a floor, or the development of a real-time process, etc.
- The Assembly has produced and disseminated a document called "the 5 commitments and guarantees". Work has been carried out on the analysis and production of key proposals to guarantee the right to housing to the most vulnerable people, including the proposals in this document. Later, this document has been presented by the affected and those who support them to the different political parties at both the local and regional level in Madrid, and has been presented to the Social Housing Agency (AVS), responsible of the processes of relocation and the award of social emergency housing.
- The Assembly is contributing to modify the laws and regulations that have excluded those affected historically. Together with the PAH, the Assembly has participated in the modification of the regulations of the AVS of the community of Madrid in order that the criteria for accessing social housing do not prevent historically excluded families from having the possibility to apply. As an example, in the regulation under review, a person occupying a house could not apply for a social housing. The Assembly is also currently participating in the campaign of the new housing law of the community of Madrid promoted by the PAH.

For all of this actions, the affected have been the main resource of the Assembly, but they have also been supported for many professionals (lawyers, urban planners, journalists, sociologists, etc.) ; and some researchers, other social organizations as the PAH. Furthermore, the Assembly has promoted the networking with all the institutions who want to listen and support their efforts, such as unions, governments or political parties.

In relation to their economic resources, the Assembly has offered its services for free, and its economic support have been based in donations from organizations and individuals. the Assembly does not receive

subsidies, grants, or any other funding. This approach is vital for the Assembly, allowing to continue implementing their actions with complete independence from all the institutions.

The main achievement of the Assembly has been to make visible the reality of historically excluded families, has proved that the combat against the extreme housing exclusion has to take into account the personal capabilities and resources of those living such situations and those supporting them. The struggle of the Assembly have been recognized by other housing movements in Spain, such as PAH. In addition, as the PAH, the Assembly has contributed to show that reality is transformable:

- The Assembly have succeeded to turn an individual problem in a collective problem. Those affected become active subjects of change and join others to perform useful actions and to make visible the structural causes of the problem, helping with its fight to change the collective perception.
- The Assembly has made it possible to create links between the historically excluded and other actors. In the first place, it has contributed to the fact that historically excluded families participate in a broader collective struggle in collaboration with other social movements such as the PAH. And secondly, it has contributed to make that the affected may be heard by technicians and decision makers responsible for housing regulations and policies that impact on them. And sometimes, as in the case of the neighbourhood of the Sabinas, they have succeeded to disseminated their claims by the media, which has forced local institutions to position themselves in favour of their demands.
- The Assembly contribute to transform the society and to modify the regulatory mechanisms that generate housing exclusion. The Assembly contribute to transform the society from the belief that "the real changes and future options need an active solidarity between those who have lived in very difficult circumstances and those who commit with them"¹. The Assembly has also contributed to modify the regulatory mechanisms that generate housing exclusion through their participation in both the campaign of the new housing law in Madrid as well as in the modification of housing regulations of the AVS.

We can conclude by stating that the main challenge for the Assembly is to mobilize the people affected, with the difficulty and risks that this entails for the people and communities that have been historically excluded, and to make the social majorities support the struggles of these for becoming part of the community, like the others, and that their rights become effective.

6 CONCLUSIONS

This paper shows the struggle to realize the right to housing (Lefebvre 1968; Harvey, 2012) and to basic supplies (water, energy, etc.) in Spain, through the analysis of the different actions and mechanisms of regulation promoted by different actors that constitute blocks of power and counterpower, that is, blocks with capacity to transform the reality, to produce new meaning and to exercise the power (Foucault, 1998). The article also shows the role that hybrid space plays in that struggle (Castells, 2009, 2012; Álvarez et al., 2015).

The article presents (Section 3) how the actions and regulatory mechanisms promoted by government institutions have been characterized by the promotion of housing as a speculative asset, serving the interests of the real estate sector and not as a right of the majority of the society.

Housing emergency resulting from the blatant violation of right in Spain has led civil society (Sections 4 and 5) to organize themselves to fight to make their rights effective. First, the PAH (a networked social movement) has succeeded in changing the collective imagination. Their actions (stopping of evictions, occupation of empty housing, ILP) have contributed to remove feelings of guilt in the families affected, and to point out to real generators of the problem. They have shown a lack of political will to tackle the challenge, and have shown that "¡Yes, they can! But they do not want to". Their struggle gained legitimacy and the support of a large majority of Spanish civil society, to the point of calling into question the legality

¹ Source: "Decent housing, a right for everyone." Document drafted by ATD Fourth World, Spain.

of the current regulatory mechanisms (Spanish mortgage law) that perpetuates the problem. After 8 years of struggle, in 2017, the PAH has succeeded in having the European Court of Justice pronounce in its favour, which opens the door to demand the nullity of all foreclosure proceedings and the evictions carried out in Spain since 1995. In summary, they have contributed to transforming institutions and their political agenda.

The PAH was born with the goal of being replicable both in their actions and in their ways of organizing. This has made possible the emergence of other groups such as The Assembly (Section 5), which takes advantage of the change in the collective imagination achieved thanks to the actions of the PAH to include in this struggle the families historically excluded from the right to housing.

This networked movements has been fueled by their ability to create a hybrid space between communication networks and occupied urban space in which face-to-face assemblies and protests take place. Finally, they have shown that a civil society organized and with clear goals can transform the reality and question principles were considered indisputable until now, such as the primacy of property rights over the right to housing.

ID 1391 | REINSTATING SOCIAL PRACTICES FOR SOCIAL INTEGRATION: EXPERIENCING THE BADARO- PINE FOREST AREA IN BEIRUT

Christine Mady¹

¹Notre Dame University-Louaize

christine.mady@gmail.com

ABSTRACT: This paper addresses how the reinstatement of everyday practices in urban public spaces could lead to social encounter and coexistence within unstable urban contexts, specifically those witnessing political instability and an influx of refugees. The context for this investigation is in Beirut, Lebanon with a focus on the area referred to as Badaro at the southern edge of the administrative boundary of the capital city. This area currently witnesses a juxtaposition between real estate development catering for market-led needs, and bottom up initiatives to generate rhythmic social practices that are affecting Badaro's within role in Beirut. The name Badaro is given to an area holding a street with the same name, which is bordered on one side by the Damascus Road, the capital's war time demarcation line, and on the other side by the pine forest that was the buffer area or no-man's land separating east from west during the fifteen years of war. Badaro was encapsulated in between, which meant the preservation of an urban fabric with pre-war architecture, and other features lending themselves to bottom up initiatives supporting social interaction and encounter, which were lacking following the war period. Examining Badaro's socio-spatial development is based on Lefebvre's approach to everyday social practice as well as the understanding of the role of collective memory in urban spaces in reference to Hebbert. The paper examines the spatial development of Badaro before the war, its dormant state during the civil war period between 1975 and 1989, and its recent reawakening after the rise of bottom up initiatives since 2005. Based on empirical data collected in 2015 and 2016, the conceptual framework linking everyday social practices and collective memories is used to trace the spatial and temporal diversities within this area and the contributions of initiatives to support coexistence among various social groups, in the absence of a planning strategy proposed by the municipality or the planning authorities. These initiatives seek to reinstate public spaces and everyday urban practices. In particular, the initiative for reopening the pine forest focuses on empowering citizens and raising awareness on the importance of public space in offering a healthy everyday urban life. The paper concludes by reflecting on the actions and results of some of these bottom up approaches in enabling the coexistence of diversity in a previously fragmented socio-spatial context.

1 INTRODUCTION

Among the diverse and equally important roles of public spaces in cities, is their role in meeting social needs, and in particular that of facilitating through encounter the integration of different users regardless of their backgrounds. Meeting social needs in situations of uncertainty requires an understanding of the context and its specificities through creative tools for the acquisition of information (Christensen, 1985). One such tool is enabled in public spaces, which is the formation of informal networks of communication (Hillier, 2000) that allow for the exchange of information among individuals and groups, enabling them to identify social needs, and search for opportunities to materialise them (Holston, 1995). This is particularly essential in unstable contexts.

Reflecting on population displacement as a highlight in the recent years in cities worldwide, in 2016, Habitat III in Quito emphasised the role of public spaces as conducive to coexistence, and the nurturing of shared values (UN Task Team, 2015). Among public spaces, streets persist through history and often link different layers of a city over time (Hebbert, 2005). Streets are representations of cities' characters and the urban life reflected in their past, present and potential future (UN Task Team, 2015). They are affected by instability and equally impact people's everyday practices, and activities. The density and duration of activities taking place in streets are indicators of their role of integration (Gehl, 1996). Under unstable situations, the density of activities decreases, perceptions and memories of a space become intertwined with feelings of insecurity, which could lead to avoiding the space (Khalaf, 1998). Reinstating everyday practices changes this perception of insecurity in a space, which is necessary in unstable contexts.

To explore this reconciliatory role of public spaces, this paper unfolds two key terms: everyday practices, and spaces of memory. The former relates to shared activities by people of different backgrounds, reflecting how people live and imprint space. The latter considers public spaces as mnemonic spaces charged with collective memories, but also as contributors to collective memories. The retrieval and reinstatement of the everyday as remembered by different coexisting groups, becomes a potential link to social integration in the present and possibly the future.

To demonstrate the role of public spaces in situations of instability, the past and present of the capital city Beirut-Lebanon is chosen as a context; a city long known for its ability to assimilate differences and influx of people (Khalaf and Kongstad, 1973). In particular, an area known as Badaro will be examined and presented in relation to Beirut's reconstructed city centre.

2 EVERYDAY PRACTICES IN URBAN CONTEXTS

In contrast to programmed events, everyday practices including “the right to stay inactive” (Kostof, 1992, p. 123), are shared and usually inclusive and tolerant to diversity and differences. They are a nexus to approach social integration. Everyday practices could be referred to as:

“those minuscule events, barely remarked at the time, on which posterity retrospectively confers the greatness of origins, ... there are those nonevents that are immediately charged with heavy symbolic meaning and that, at the moment of their occurrence, seem like anticipated commemorations of themselves.” (Nora, 1989, p. 22)

Practices are based on shared understandings of routine activities that are embodied in individuals. This shared understanding establishes a mutual relation between society and practices. (Schatzki et al., 2001). Social practices are “more persistent and more likely to structure other domains of thought and action when they constitute social relationships” (Swidler, 2001, p. 95). Social relationships among various groups could start in public spaces with their significance of enabling new social practices. Rather than repetition in itself, “the visible, public enactment of new patterns so that ‘everyone can see’ that everyone else has seen that things have changed” (Swidler, 2001, p. 96) leads to new practices. This relation between individuals with shared understanding, social practices and public spaces are intertwined (Madanipour, 2004). Shifting research from public space as object to research on these relations allows for establishing congruence between what is intended in the space and what is socially needed (Knierbein, 2015), especially in unstable contexts.

A relational perspective is used to understand practices and their spaces, based on the understanding that the nature of practices and their transformations are affected by and affect these ever changing spaces (Schatzki et al., 2001), which are closely knit to dynamic social, political, economic, and other factors (Knierbein, 2015).

In contrast to the relational perspective stand representations of space (Lefebvre, 1991), which fall into the danger of becoming abstract spaces, devoid of meaning (Knierbein, 2015) and disembodied. Public spaces delivered through the tools of design and planning are often out of pace with the users' changing identities due to population mobility or even displacement. Such spaces often carry the symptoms of neglect and deterioration (Madanipour, 2004). If there is no sense of attachment or emotional belonging, public spaces could be dominated by specific rather than all user groups and could easily be changed to other uses or simply stay neglected. Differences among user groups emerge in city spaces where multiplicities occur (Holston, 1995). In cases of political instability, and raised security alert, control often results in the “city's disintegrating public spaces and abandoned public sphere.” (Holston, 1995, p. 447) resulting in the loss of shared and transformative social practices. This disintegration is manifested in the erosion of public space by protective concrete elements and barbed wire (Németh and Hollander, 2010) that are a common sight in Beirut and other cities nowadays. Other forms of disintegration include closure, long-lasting effects of misuse, or even leaving these spaces on drawings without ever being executed and implemented as planned. The situation differs when there is a sense of attachment to space experientially: either mentally or physically.

On the one hand, mental experience includes the visual and the mnemonic, which act as anchors relating people to spaces imprinting them in their memory through language and names, “iconic elements,

soundscapes, graffiti, media contents" (Tornaghi, 2015, p. 30). Street names serve as a recall, (Hebbert, 2005) or "communal register" and "the safeguard of those continuities of culture and place that made us as street users vastly and substantively older than our age." (Kostof, 1992, p. 243 in Hebbert, 2005, p. 583) This dissipation of clues customises a space according to its local culture and society. It is this network of non-verbal communication, which informs people about the space, allowing them to interact with it.

On the other hand, and as explained earlier, physical experience related to spatial practices (Lefebvre, 1991) takes place in urban space, and defines the routine activities or practices of urban life including encounter, which supports the development of "social relations" (Knierbein, 2015, p. 42). Spatial practices occur in lived space over time, and are essential to healing schisms occurring in unstable contexts. The everyday traffic, buzzing and flow of people in streets are indications of 'balanced' life, as opposed to calm periods following a natural or manmade disaster, where city life comes to a halt. Restoring balance and practices pertaining to it become a shared objective among people. A balanced life in streets refers to: "the normality of street life [that] is a consolation during times of crisis – the impersonal flux of people and traffic 'calms and steadies us'." (Hebbert, 2005, p. 584)

This balance is related to rhythm, and familiarity where reinstatement means regaining the sense of security, promoting a sense of attachment, and reversing a stigma that could become associated with a space or locale (Madanipour, 2004). Rhythm facilitates appropriation through recurrence, yet allows for variations (Lefebvre, 2004). Disasters and conflicts cause changes, and yield instability, which annihilate contextual everyday urban life rhythms, disrupt them or completely alter them, affecting how people experience their cities. Thinking of public spaces relationally as practised space, the combination of non-verbal communication, memories, and social practices allows for exploring possibilities for social change (Holston, 1995), as social integration is one such change. When individuals are given the opportunity to participate in practices (Schatzki, 2001), the possibility for integration occurs, and in turn, antagonism towards the 'other' would diminish with opportunities of encounter in public spaces. In other words, conviviality is realised when individuals are: "... integrated (to varying degrees) into the ways of proceeding that characterize extant practices, where these matters are conserved and novelty and transformation take their start." (Schatzki et al., 2001, p. 21) The transformation of social practices through public spaces requires the consideration of three aspects over time "resources, spatial situations, and strategies" (Lefebvre, 1991, p. 356), which in this paper are related to streets as public spaces, shared everyday practices and collective memory as a strategy.

3 MEMORY AND URBAN SPACE

Everyday encounters in public spaces result in individuals sharing an urban space, which is the glue holding the urban fabric intact (Gehl, 1996). If such practices persist, they lead to embedded collective memories within these public spaces establishing mutual effects between memory and space (Hebbert, 2005). Through memory, spaces and people become intertwined, and associations within spaces help people recall activities and practices (Hebbert, 2005). This is related to memory's nature, which is a dynamic manifestation of "living societies" in constant change, "susceptible to being long dormant and periodically revived." (Nora, 1989, p. 8) Linking people to their present in contrast to history that represents the past.

What is of interest in public spaces is the collective memory, shared by individuals through socio-spatial interaction that allows for the transmission of shared values (Boyer, 1994). Collective memory is perpetuated by "... the living experience of a group or individual." (Boyer, 1994, p. 66) It supports this shared sense of belonging among individuals, so that "The less memory is experienced collectively, the more it will require individuals to undertake to become themselves memory individuals." (Nora, 1989, p. 16). The street as a public space becomes the "locus of collective memory":

"It can express group identity from above, through architectural order, monuments and symbols, commemorative sites, street names, civic spaces, and historic conservation; and it can express the accumulation of memories from below, through the physical and associative traces left by interweaving patterns of everyday life." (Hebbert, 2005, p. 592)

This view is used to examine how a street imbued with memories could support "maintaining, repairing and (sometimes) inventing an everyday public realm that will help its occupants to be ... 'older than their age'."

(Hebbert, 2005, p. 583) This brings us back to relational public spaces as opposed to representations of public spaces.

Hebbert (2005) indicates that one trend in memorialising cities is in fact exclusionist rather than collective, and focuses on the limitation of the preservation of a desired image rather than the lived everyday or as Boyer (1994, p. 54) states: "... these restored city streets and districts turned parts of the city into new visual spectacles and revitalized theatrical decors." These representations mask the users' perception of the space's reality, and without the social practices in these spaces, what is 'real' in the city gets lost (Boyer, 1994). These representations are solely based on the visual and pictorial rather than the experiential. Two contrasting approaches to reinstating public spaces in situations of instability are presented: the tabula rasa approach or selective urban renewal, both resulting in an urban story without a collective memory. Market-led development and its neglect of collective memory often introduces novelty while erasing the past and its extension in the present, and so:

"At a moment in history when urban renewal was destroying more of the city's historic patrimony than war and neglect had done, architectural ruins and ornamental styles held out a seductive and nostalgic allure." (Boyer, 1994, p. 54)

"Today our treatment of the city as an essential manifestation of life is determined not by the model of tabula rasa which modernism used to sacrifice existing substance and make way for the new, but by dialogue with the features of place and memory" (Burg, 1997, p. 19 in Hebbert, 2005, p. 591).

In a relational perspective this situation is avoided through considering architectural buildings as an assembly forming a street or a public space rather than as individual monuments (Hebbert, 2005), allowing for this porous mnemonic vessel to be imbued and to nurture the timeless everyday practices encapsulated in a past, transforming in the present, and reaching out to future generations (Hebbert, 2005; Nora, 1989).

Keeping collective memory alive becomes the strategy that enables public spaces to support encounter and shared social practices, which are required for social integration.

4 THE CASE OF BADARO IN BEIRUT

As explained in the previous section, lived spaces with everyday practices and collective memories establish a rhythm extending diverse users' experiences over time, and enabling a projection into the future. So what about the case of Beirut, whose public spaces have witnessed annihilation, closure, disembodiment, and remodelling due to instability?

The starting point is Beirut after the war period 1975-1989. The "fault line" (Holston, 1995, p. 444) marking differences in this case is the demarcation line that cut through Martyrs Square in the city centre and reached to the pine forest and Badaro at the southern edge of the administrative city (see Figure 1). Examining the relation of the two poles Badaro and the city centre, serves to explore the role of everyday practices in public spaces in reinstating encounter, once in a representation of space, and once in a relational space. First an overview explaining the development of Badaro within Beirut is presented prior to examining its current state. Within an urban planning framework, the following periods are marked: towards the end of the Ottoman Empire around 1900, the French Mandate period between 1920s and 1940s, and the golden period of the Lebanese Republic in the 1950s and 1960s, which was followed by the devastation of the war period between 1975 and 1989, then post-war reawakening.

Figure 1 – Location map of Badaro and the city centre

4.1 AN OVERVIEW OF BEIRUT'S DEVELOPMENT

Towards the end of the nineteenth century urban planning in Beirut was marked by the Ottoman emphasis on 'modernizing' Beirut (Hanssen, 1998; 2005), which at the time was confined to its medieval city walls, and Martyrs Square was extra-muros as well as Damascus Road (Davie, 2001) linking Beirut to the hinterland. Beyond the medieval city to the west and south, the peri-urban condition prevailed, characterised by evenly spread coarse and fine urban grain (Saliba, 1998), which was the case along Damascus Road (Debbas, 1986), with cemeteries marking the southern city edge. Following the fall of the Ottoman Empire, French urban planning proposals prevailed between the 1930s and 1960s. Among these proposals was the development of Martyrs Square in the image of the French culture with its cafes and cinema; the square was equally a hub for political, and social practices (Khalaf, 2006). Emanating from it, the formation of a geographically significant axis connecting agglomerations of French presence along Damascus Road- the main trade route for French commerce linking the port city to its hinterland. The agglomeration included the St. Joseph University established by the Jesuits in 1875 (Eddé, 2000), the French Embassy, the Pine residence next to the newly relocated hippodrome, military barracks and hospital, leading southward to the pine forest, which was traversed by a path linking the French quarters to their cemeteries. The Pine Forest dominated the southern limit of Beirut, with Damascus Road and Sidon Road traversing dense pine landscape as reflected in photographic documentation (Debbas, 1986: 160). Saliba's (1998) study of the growth patterns in Beirut, based on the 1932 Danger Plan by two French planners, marked merely rural presence in Badaro during that period, an area that was still marginal and of little urban planning concern, yet abutting the French quarters concentrated in that area.

In the period between 1958 and 1964 under President Fouad Chehab, urban planning was characterised by the modernist approach to planning under the influence of the French planner Ecochard, yet with an emphasis on the development and expansion of road networks (Salam, 1998; Tabet, 1996), the essential infrastructure for trade. Within a physical approach to planning, this emphasis on transportation infrastructure, and establishment of land exploitation zoning (Salam, 1998) disregarded the specificities and needs of each area within the city and its social practices. The state favoured entrepreneurial development as part of its free market economy, neglecting the significance of public spaces. This period was also characterised by regional turbulences resulting in the influx of people and investment from the neighbouring Arab countries (Khalaf and Kongstad, 1973). The bank secrecy policy in Lebanon attracted regional Arab investment to the country (Boudisseau, 1997; Davie, 2001; Davie M. F. 1991; Tabet, 1996), and Beirut witnessed a financial boom, accompanied by real estate development.

During this period, the city centre was predominantly commercial, expanding to the immediate surroundings, and requiring affordable urban land for residential development further out following topography and proximity to main roads (Tabet, 1998). To the east of the centre, the area of Ashrafieh was not attractive due to its steep topography. To the west and in the vicinity of the American University of Beirut established in 1866, Hamra Street in the area of Ras Beirut was developed with its commercial strip, cultural and leisure activities. To the south, the emerging middle class settled around Mazraa and

Moussaytbeh (Khalaf and Kongstad, 1973). In particular Badaro street developed next to Beirut's largest open green space, the pine forest with an area of 300000 m² (Shayya, 2010). In addition to the presence of pine trees, events, promenades, and music concerts entertained Beirut's residents, particularly those living in the forest's vicinity. This area acquired significant buildings by Lebanese modernist architects (Khalaf and Kongstad, 1973), among them and next to Badaro street the palace of justice constructed by the Lebanese architect Petro Trad in 1959 (Tabet, 1998). Thus, both areas: Hamra and Badaro played the role of 'transition zones' (Khalaf and Kongstad, 1973, p. 5) in relation to the city centre during this period and similarly after the war period.

4.2 THE SCHISM: WAR AND PUBLIC SPACE IN BEIRUT

Similar to the case of Berlin after the fall of its wall (Hebbert, 2005), the dissolution of the division of Beirut into east and west happened physically, but this border severing Beirut generated mental scars still evident to date (Bollens, 2012). Among the so-called war landmarks and associated meanings generated by the war (Khalaf, 1998), Beirut's demarcation line changed at least until the 1990s, how people referred to the eastern and western city parts (Fregonese, 2009; Yahya, 1993). The demarcation line remained as the 'communal register' even nowadays, 28 years after the declaration of the war's end. War disrupted city life, both Martyrs Square and Badaro lie in proximity to the demarcation line running along Damascus Street. The starting point of the demarcation line, Martyrs Square was sanitised of its context, which was completely demolished by bomb shells or bulldozers later during reconstruction. Although located east of the demarcation line, Badaro was encapsulated: to the west it abutted 'no-man's land' the pine forest, and despite its proximity Badaro lost its link to it due to military presence and closure; to the east Sami El Solh Avenue stretching between the Tayouneh roundabout to the south, and to the north the National Museum, and the east-west Abdallah Al Yafi Avenue, which defined the checkpoint with the 'west' at the Museum (Tabet, 1996). Badaro's residential buildings were deserted; scars of fighting across political groups are still evident on some building facades along Sami El Solh, and namely to the south towards the Tayouneh roundabout, where exposure of two neighbourhoods in conflict was maximized. The war not only burnt down the forest, but also resulted in post-war decisions to confine it within highways. Accessibility to the forest was limited, and its closure to the public for 40 years meant that it became a gap in the memory of the urbanites. Khalaf (1998) indicates how after the war, the Lebanese population got stuck between remembering and forgetting. The Beirutees were deprived of their heritage of the pine forest through the burning down and enclosure of this forest, which nevertheless survived in the form of their collective memories. The National Museum with the concrete casings protecting its contents was equally frozen in time until the late 1990s when it reopened.

Following the Taif Agreement in 1989, repopulating Beirut took place gradually and in seemingly selected areas. The vitality to Beirut, and its recreational and leisure activities emerged in specific areas after externalising them from community halls and the living rooms of private dwellings, the familiarity and safety of the known (Khalaf, 1998), to the sterilised shopping centres with their security control. These leisure activities started emerging in the previously 'demarcated' areas around 1994-1995 while the city centre was under reconstruction. These areas offered affordable rent, and spaces not polarised by the war. The displaced population from different parts of the country required time to come to their bearings. War-affected and even war-damaged residential properties were temporarily occupied by refugees. This image resurfaced with the Syrian refugees around 2015 occupying deserted constructions in Beirut. The 'transition zones' of the 1950s-1960s Hamra and Badaro, came back to life after 2005, with everyday practices slowly flowing back into them.

5 CURRENT STATE AND LESSONS LEARNED

This section explores the difference that everyday practices, and collective memory play in establishing and sustaining relational spaces for encounter within unstable urban contexts. Two approaches are considered: the tabula rasa approach with only selected conserved buildings as one approach, and the assembly of buildings, with punctual incisions within the streetscape as a second approach. In both cases, the street network remained as the constant in times of instability, once usurped from its memories, and once along with these memories.

Hillier and Hanson's (1984) emphasised the relation between morphology and social behaviour indicating that increased connectivity and integration in the street network is conducive to social practices. Similarly, the UN Habitat report considers the extent of street allocation and their intersections as indicators of the provision of public space that might be conducive to shared public practices (UN Task Team, 2015). This quantitative tool is used to compare the city centre and Badaro before the war with their current states. As a demonstration, within one square kilometre, the extent of streets, their intersections, and that of open spaces are calculated (see Table 1).

	1961		2016	
In 1 km ²	Badaro	City Centre	Badaro	City Centre
Area of building footprint in m ²	122108	50747	223689	256852
Percent roads	18.0%	33.5%	16.4%	28.2%
No. of Intersections	54	250	113	182
Open space	6.95%	0.75%	7.40%	1.47%

Table 1 – Example

While before the war the city centre had a significantly higher percentage of streets and intersections than Badaro, this difference decreased at present. Note that no new roads have been opened in Badaro, yet in the city centre, the urban fabric was modified according to the reconstruction plan adopted by the real estate company Solidere within a new parcellation plan. Regarding open spaces, Badaro's proximity to the hippodrome and pine forest makes the availability of open urban space higher than in the city centre (see Figures 2 and 3). This overview serves at least to indicate that the two areas differ in terms of their street networks spatially, as resources for public spaces, yet falls short of informing about the spatial practices and memories in these spaces. These are explored through considering the approaches to the two areas' revitalisation after the war.

Figure 2 – Figure ground plans of Badaro and the city centre based on a 1961 map

Figure 3 – Figure ground plans of Badaro and the city centre based on a 2016 map

5.1 THE CITY CENTRE

Solidere's reconstruction project for the city centre, or the Beirut Central District or BCD realised under the decree 117/91, had two facets. The first reflected the country's rise after the war, and the reinstatement of its governmental institutions, and its ability to regain its economic momentum within the region. The second introduced a business district, standing on land owned by shareholders, and reclaimed landfill, which in the absence of residents changed to a ghost town, were it not for some restaurants and commercial activities. What was a melting pot for Lebanese from all walks of life before the war became an exclusive terrain, not yet integrated in the minds of the population (Deeb and Harb, 2013). The calculated demolition of the urban fabric within the city centre, and eradication of its open spaces, leaving only few highly controlled spaces and edifices to be admired as objects in an open air museum, and replacement of everyday practices with events together resulted in the loss of the collective memory, and its replacement with kitsch and globalised trends (Khalaf, 1998). A disconnection with social practices and mnemonic spaces resulted from these representations of space. Even remaining streets were changed, the

peripheral ones widened into avenues, disconnecting the city centre from its immediate surroundings. The city centre was transformed, and uprooted from its past, despite Solidere's motto: 'Beirut an ancient city for the future'. Control and surveillance, physical barriers and the sense of heightened security together meant that some parts of the city centre were extracted from people's daily rhythms, and consequently from collective memory. With the progress of the reconstruction, life and recreation slowly crept into the city centre with the exception of areas protected by the military such as the Parliament. Following the assassination of the former prime minister Hariri in 2005 and consecutive demonstrations in the city centre, leisure activities started withering, and the pulse of recreation and leisure started spreading to the immediate vicinities to the east (Gemayze) and west (Clemenceau) again initially in the areas bordering the demarcation line, with former architecture lending itself to spaces of gathering and encounter. Then similar to the boom of the 1950s-1960s, a spill over effect took place after 2005 into Hamra and later Badaro, while demonstrations in the city centre prevailed and suffocated any leisure activities around 2014. This is when Badaro returned to the mental map of the population.

5.2 BADARO

With scarce documentation on Badaro, newspapers become a valuable reference on its activities in addition to site visits and observations conducted between 2015 and 2016. While in 2011 the newspapers reported street robberies and complaints by residents about feeling insecure at night, Badaro's media coverage switched to a different representation in 2014, marking its awakening (Iqlimos and Barrak, 2015; Maddox, 2014; Rahhal, 2014; Al Sahily, 2016; Yaghi, 2015). For example, the Arab Centre for Architecture ACA (<http://www.arab-architecture.org/>) started organising walks in Badaro, introducing visitors to the area's layers of architecture dating to the French mandate and Lebanese modernist periods. The encapsulated area allowed the recalling of events and participation in everyday practices. Badaro's sidewalks are conducive to a culture of street cafes and promenades. These routine activities enable encounter and the engagement of different people. The reuse of ground floor spaces transformed Badaro Street into a lively street hosting panoply of daytime and night time activities, in addition to occasional street festivals, enhancing the existing mixed-use character of the street.

Around 2014 Badaro became an attraction to investors with its location along Damascus Road. A hotel favoured by foreigners: Smallville, was constructed along this road, with a bicycle renting shop in its vicinity. Real estate development capitalised on living in a quiet and central area in Beirut while still enjoying the view or even the scent of pine trees. Apartments by contemporary Lebanese architects are located within gated buildings without dialogue with the street, unlike their modernist forbearers, the residential buildings integrated with the street through the treatment of the ground floor, the entrance, gardens, setbacks and pockets allowing for gathering spaces on a small scale.

In contrast to the market-led development, bottom up initiatives manifested through NGOs and social organisations that chose to locate their offices in Badaro such as zero waste act for recycling, and Kafa among others (<http://www.zerowasteact.com/>; <http://www.kafa.org.lb/>). These initiatives created rhythmic social practices such as addressing pressing social needs. A significant bottom up initiative is the activism of the NGO NAHNOO in raising awareness on the significance of public spaces, and negotiating with Beirut Municipality the reopening of the pine forest, which materialised in 2015 (<http://nahnoo.org/default.htm>; Executive Director at NAHNOO, personal interview, 12 July 2016). Different stimuli are present in Badaro to awaken and nurture collective memories. These include spontaneous uses of the same space differently by locals or refugees allowing for inclusion (sitting down on a green patch, using war-torn buildings as a shelter); minuscule events that enable sharing and participating in practices and routine activities; street names, sounds, and icons; and most importantly, the presence of the pine forest, and pine trees dispersed throughout Badaro's streets. In addition to the daily practices, periodically organised events including festivals such as food, Christmas markets, association of merchants of the area, invite people to reintroduce them to this deserted, frozen in time area. Note that celebrations, parades, group activities, public arts, staging public events, and festivals change the spatial experience (Madanipour, 2004), and enable new transformations of the streets.

Drawing on this overview from the two poles of the demarcation line, some lessons learned are drawn regarding three aspects: first, the public spaces- particularly streets- as resources; second, the social practices in those spaces; and third, collective memories, and their relation encounter and social integration.

First, the BCD with its reconstructed and regulated plan has provided the resource of space, yet dismantled the glue that binds the city centre together with its surroundings. The reconstructed plan introduced new configurations and representations of streets and other public spaces that are pleasant to observe, yet not necessarily able to engage people in shared practices. Badaro's continuity of the street network since the 1930s and persistence of the architecture marking different periods in the evolution of the city, provide the basis of public space as a resource for encounter. The reopening of the National Museum and the pine forest provide anchors for interaction within this area, gradually allowing Badaro to reconnect with its surroundings.

Second, with the efforts of Solidere and other shareholders, BCD's life is sustained through events attracting visitors from time to time. Yet the city centre as a so-called business district, remains sanitised of public facilities such as schools, hospitals, and to an extent residences. Under situations of instability, governmental buildings including the parliament still require surveillance and control, which limit the everyday use of the city centre. In contrast, Badaro's residents and property owners live in the area on a daily basis; activities related to the public facilities, services, and commercial activities in the area generate shared social practices; except next to military facilities, Badaro's control is through 'eyes on the street'. Through the practices taking place in the area both everyday ones and organised festivities, Badaro is slowly returning to people's mental map.

Third, reviving collective memory in Badaro is gradually occurring through the reopening of the pine forest, the National Museum, and practices such as the organised walks that provide knowledge on the area's history and urban fabric, highlighting the significance of the area's architecture to its urban character and people's practices. In the BCD, a 'dual identity' is forged, stuck between the current and what used to be (Khalaf, 1998), with a present not leaving any traces that link it to the past, and Martyrs Square being reduced to an event space during manifestations or a decorated 'kitsch' (Khalaf, 1998) during festivities, losing its everyday significance and central role in the city. Despite its apparent abundance of spaces as a resource, the BCD is limited in practised everyday spaces, and is reduced to an exclusionist area.

The three examined aspects that are conducive to transforming social practices are evident in the case of Badaro, where memory is still "borne by living societies" (Nora, 1989, p. 8), while stories of sporadic events linger in the BCD, experienced by selected users. In Badaro, this continuation of collective memories is evidenced by various minuscule activities that are slowly embedding themselves in the spaces and consequently their users, nesting in streets, ground floors or even war-affected buildings.

5.3 CONCLUSION

The possibility of having public spaces in unstable contexts as spaces for encounter and coexistence goes beyond the design and provision of the spaces. In particular, the focus should be on everyday social practices and collective memories in urban contexts, which are conducive to use equally by local authorities, and bottom up initiatives. The aim of reinstating streets as public spaces within unstable contexts is equivalent to allowing and even enabling streets to weave new collective memories that would knit the past to the present. This would allow for perpetuation despite population changes, facilitation of coexistence, and engulfing of differences, rather than lamenting spaces that are devoid of memories, and left without a sense of attachment. The case of Badaro and the pine forest served as one example of reinstating encounter gradually, despite the pressures of prevailing development trends and instability.

ID 1474 | TOWARDS CONSENSUS BETWEEN STAKEHOLDERS WITH CONFLICTING INTERESTS: EXPERIENCES FROM URBAN AREAS KALARANNA, TALLINN, AND MEZAPARK, RIGA

Viktorija Prilenska¹; Roode Liias¹; Katrin Paadam¹

¹Tallinn University of Technology

vprilenska@gmail.com ; roode.liias@ttu.ee ; katrin.paadam@gmail.com

ABSTRACT: The case studies examine the conflicts between local communities and developers during the design and adoption of detailed plans for urban areas Mezapark, Riga and Kalaranna, Tallinn. The conflicts are examined via a series of semi-structured interviews with the actors involved in the conflicts, the communities, developers, designers and municipality. Stakeholder opinions are complemented with expert opinions. The case studies aim to discover the causes of conflict during the design and adoption process. The conclusion is, the conflicts arise due to (1) mutual bias between the stakeholders, (2) inadequate engagement strategy and (3) the lack of flexibility and initiative in the actions of municipality.

KEYWORDS: case studies, civic involvement, conflict, Kalaranna, Mezapark, planning, public space

1 INTRODUCTION

Following the worldwide planning practice Latvian and Estonian legislation introduced the requirement for public display and discussion of urban plans. The corresponding regulations were included in the legislation in the end of 1990s. The actual activities, however, emerged in the end of the first decade of the 2000s. In the period 2008 to 2016 two plans attracted public attention, the plan of Mezapark, Riga, (2010- 2013), and of Kalaranna, Tallinn, 2003-2016. Both plans were dealt with the planning of public waterfront areas and caused significant public protests. The debate about these plans highlighted the growing public interest in shaping the city, the demand for greater public engagement in planning and the deficiency of existing civic involvement strategy, which encourages conflict instead of consensus.

The case studies explore the negotiations between resident communities, developers, designers and municipality during the design and adoption of the detailed plans. The negotiations are examined via a series of semi-structured interviews with the actors involved. Actor opinions are complemented with expert opinions. The themes, emerging from the interviews are complemented with the facts, derived from planning documents and the insights from the scientific research on participatory practices. The aim of the case study is to understand the drawbacks of current engagement strategies and to sketch possible solutions. The case studies are conducted in the framework of a broader research on civic engagement in planning in the Baltic countries, which aims to develop a locally viable methodology for public participation.

In the following section the authors briefly touch on key community engagement ideas and position the case studies and their context within research on participatory practices. Further on, the authors proceed with the research strategy, data collection and analysis technique. In the next section the authors introduce Mezapark and Kalaranna - the neighbourhoods in focus, and the planning legislation in Latvia and Estonia. The authors proceed with the findings of the research paired together with the discussion and make some connections to the scientific debate about participatory practices. The authors conclude highlighting the deficiencies of current civic engagement strategies and make suggestions for possible future improvements.

In the current article word sets public / citizen / civic and participation / involvement / engagement are used as synonyms.

2 THEORETICAL METHODOLOGICAL APPROACH

The discussion about the importance of civic involvement in planning was launched in 1960s by the classic essays of Davidoff (1965), Arnstein (1969) and Friedmann (1973). Davidoff and Friedmann advocated the need for co-planning with citizens, for citizens provide experiential knowledge of places, which are being planned, and are end users of places, resulting from plan implementation. Arnstein, in turn, classified citizen engagement into levels, by the degree of citizen influence on decision-making. Since 1960s participatory planning thought was advanced (Forester, 1987; Healey, 1995; Innes, 1998; Sager, 2012) and discussed (Huxley and Yiftachel, 2000; Hoch, 2007) resulting into the so-called "communicative turn" in planning (Healey, 1996). Currently, communicative planning idea gained support among civic leaders and firmly established itself in the planning practice (Faehnle and Tyrvaenen, 2013; Shipley and Utz, 2012). Indeed, civic engagement legitimates planning decisions and promotes public support of plans, thus, facilitating plan ratification and implementation (Sager, 2012; Irvin and Stansbury 2004). According to Irvin and Stansbury (2004, p. 56) the question, whether to involve the public or not, is outdated. Instead, the new question emerged, what strategy of civic engagement is best.

Throughout its existence public participation in planning was praised and criticised. The supporters of the idea claimed, that it leads to balanced (and hence better) policy solutions, encourages mutual learning, trust and consensus building, promotes civic empowerment (see eg., Hoch, 2007; Faehnle and Tyrvaenen, 2013; Innes, 1998; Irvin and Stansbury, 2004). The adversaries argued about the managed nature of participation, which results into limitations to certain interest groups and questions, inefficient resource expenditure, conflicts and frustration (see eg., Connely, 2006; Doorne, 1998; Huxley and Yiftachel, 2000; Irvin and Stansbury, 2004). Both parties have their evidence, as participation is context and implementation sensitive (Connely, 2006). The engagement strategy which is efficient in the society with established communities and long tradition of public involvement in municipal policy-making might be inadequate for the society with emerging communities and no experience of co-planning (Hoyle, 2000).

Furthermore, a wellintentionedparticipation strategy might fail if implemented poorly or partially (McGovern, 2013). The casesof Kalaranna and Mezapark, which are examined in the current research, point out the importance ofcontext and implementation in civic engagement practice.

The current research studies the public involvement in the design and adoption of plans forMezapark and Kalaranna neighbourhoods. For a 25-year history of Latvian and Estonian independence theseplans produced the most resonance in the planning field and, therefore, were chosen as research cases(personal communication with Riga and Tallinn planning department officers). They illustrated how theadvantages of participation can be nullified by the inappropriate participation strategy, leading to informinginstead of empowerment, mutual bias instead of trust and conflict instead of consensus. These plansprovoked outcry from local residents, resulting into long-lasting fierce debates between communities,developers, designers and municipalities. Although, the opponents finally managed to reach a (partial)consensus, all parties were unanimously dissatisfied with the process (personal communication withstakeholders).

The study takes a methodological stance (Creswell, 2007), as the authors started with general studyof the cases, adjusting the research questions and data collection techniques as new information wasdiscovered. Initially, the authors focused on the desired and actual outcomes of the dispute about the plans.As the research proceeded, the focus shifted towards the dispute process, how did it advance and why did itcause dissatisfaction. Indeed, a well-designed and smooth process is likely to lead to satisfactory outcomes.

Whereas, satisfactory outcomes in case of an ill-designed and ill-implemented process is a matter of chance(Christensen, 2015). As the focus shifted, the following research sub-questions emerged: (1) What were thedeficiencies of public involvement process in cases Mezapark and Kalaranna? (2) What are the desiredchanges to the public involvement process in the future? Both questions lead to the following main researchquestion: How does the planning system in Latvia and Estonia should be modified to meet the growingdemand for community engagement in planning?

Answering research questions the authors applied mixed research strategies. The opinionsconcerning the deficiencies of civic engagement process (sub-question 1) and the desired changes (subquestion2) were gathered via semi-structured interviews with actors involved in negotiations. The interviews were conducted with five actor groups: the citizens, developers, designers, planning department officers andexperts. The interviews were recorded in March - June 2016 and September - November 2016. Eightinterviews were conducted in Riga and six — in Tallinn. The interview length varied from 30 min to 2 hours.

Each interview was recorded, transcribed word in word and analysed with NVivo software. The intervieweeswere asked to comment on the participatory process, actors involved, conflict essence and resolution. Somecommunity activists presented their opinions in the media. These opinions were, also, included in the analysis.

The interviews and opinions were in three languages, Latvian, Russian and English, translated into English bythe authors. Analysing the interviews, the authors searched for common recurring themes and grouped them accordingly. In total, four themes, each containing two to five sub-themes, emerged. The themes are summarised in Table 1.

The opinions of the interviewees were verified against facts, derived from planning documents.Original graphic parts of both plans were examined. The original cover text for Mezapark plan (in Latvian)was reviewed. The text included building regulations for the planned area, citizen proposals and designercomments on these proposals. The cover text for Kalaranna plan (in English) was derived from thearchitectural competition task for the housing project in the area. The text briefly described the backgroundof the area, the vision and the competition task, which was developed following the building regulations.Additionally, the report describing the sequence of events during the planning process for Kalaranna wasexamined. The information about the cases available to the authors was unequal. For Mezapark there wasmore official factual information about the process and outcomes available to the authors. Resident opinionsabout the plan with designer comments were thoroughly documented. Furthermore, the quality of graphicand textual material for Mezapark was higher than for Kalaranna.

Themes, derived from the interviews, were complemented by the information from academic research sources on communicative planning theory, participation case studies and participation evaluation criteria. The research strategies are summarised in Table 2.

3 INTRODUCTION TO THE CONTEXT

3.1 PLANNING LEGISLATION

Process	Outcome	Planning system	
<ul style="list-style-type: none"> - mutual bias - absence of trust - absence of dialogue 	<ul style="list-style-type: none"> - Mezapark - dissatisfaction - Kalaranna - satisfaction 	deficiencies <ul style="list-style-type: none"> - late engagement - participation through protest - limitations (groups) - limitations (questions) - passive municipality 	desired changes <ul style="list-style-type: none"> - early engagement - flexibility - transparency - active municipality - research driven approach

3 INTRODUCTION TO THE CONTEXT

3.1 PLANNING LEGISLATION

Following international practices, planning legislation in Latvia and Estonia requires public consultation prior to adopting binding urban plans. Until 1991 Latvia and Estonia were parts of the Soviet Union, therefore the built environment was planned and developed by governmental institutions in the framework of planned economy and rational planning (Paadam, 2009). Since 1991, after the dissolution of the Soviet Union, Latvia and Estonia transferred to free market economy and market driven urban development. The transition was impetuous, thus, initially planning legislation was copied from other European countries and later modified to fit local conditions (personal communication with Riga and Tallinn municipality officers). Currently, urban development is regulated by relatively fresh documents: "Spatial development planning law" (Saema, 2011) and regulations Nr. 628 "Regulations about municipal spatial development planning documents" (Cabinet of Ministers, 2014) in Latvia and "Planning Act" (Riigikogu, 2015) in Estonia.

In their essence planning legislations of Latvia and Estonia are quite similar. Municipality manages its own spatial development by means of comprehensive (territorial) and detailed (local) plans. Comprehensive plan is a plan for the whole area of municipality. Detailed plan is a plan for a part of municipal area, which is more detailed, than the comprehensive one. Both plan types are binding and consist of graphic (maps) and textual (regulations) parts. Both plan types require a public display with a subsequent public discussion of a plan before sending it for approval to a municipal council. Public display is a time span of one month when any citizen can familiarise oneself with a plan and submit an opinion or a proposal about the plan. Public discussion is a meeting where citizen opinions and proposals are presented, evaluated, accepted or rejected. If an opinion or proposal is accepted, the plan is modified accordingly. If an opinion or a proposal is rejected, the legislation requires to give a rationale for that. In both countries the final decision, whether to accept or reject the plan, is taken by a municipal council.

As planning legislation is valid for all municipalities, from small settlements (~1 thsd. residents per ~185km², Baltinavas novads, Latvia, PMLP, 2016) to big cities (~700 thsd. residents per ~304km², Riga, Latvia, PMLP, 2016), it sets minimum requirements for public involvement. Large municipalities are free to organise additional participatory activities. "I think the municipalities should apply the practice [of complementary engagement activities to those, required by law]... at their own initiative. These [activities] could be as recommendations... and the municipality could apply them, if it wants...", says a planning department representative from Riga. A planning department representative from Tallinn supports the opinion: "For each municipality it is possible to work out their own methods... the aim of the law is not to be very precise... because there are so many different possibilities and so many different municipalities with their own resources".

3.2 MEZAPARK AND KALARANNA - THE NEIGHBOURHOODS IN FOCUS

Although, requirements for public involvement in development of urban plans was included in the planning legislation in late 1990s, actual participatory activities started to emerge around 2010s, when a debate about the plans for Mezapark and Kalaranna took place. According to municipal officers, interviewed for the case study, plans for Mezapark and Kalaranna had most public resonance compared to other plans. Both plans deal with waterfront public space accessibility issues.

Figure 1 - Left: map of Mezapark; right: Map of Kalaranna (Open Street Map, 2017) from the Old Town by the Lake Kisezers. The park area was included in the city area in 1904.

Forest areas, which constitute 80% of the park area, were shaped between 1920 and 1940, cultural and sports infrastructure was built in 1950-1965 and 2008-2011 (Grupa93, 2013; Rigas Mezi, 2017). Currently, Mezapark houses the zoo, Song and Dance Festival open air theatre, BMX track, obstacle park for children and adults, playgrounds for children, a beach, a small boat harbour and multiple cafes.

The park is a municipal property area and is managed by the governmental institution Rigas Mezi (Riga Forests). In 2010 Rigas Mezi commissioned the plan of the area to the planning office Grupa93. Due to legislation changes the plan had two public displays, in 2012 and 2013. It was approved in 2013 with minor modifications. Initially, key elements of the plan were (1) division into four functional areas — for passive recreation, active recreation, waterfront activities and cultural activities, (2) traffic organisation — separation of motor transport, pedestrians, cyclists, skaters and skiers, allocation of parking lots, (3) allocation of public utilities, including an amusement park, (4) a solid public waterfront promenade (Grupa93, 2013). In the debate about the plan there were three points the citizens protested against: (1) the construction of an amusement park, (2) forest transformation for allocation of public amenities, (3) the construction of a solid public waterfront, suitable for motor vehicle traffic.

Kalaranna (fig. 1, 2) is a ~7ha brownfield area located between the Northern edge of the Old Town and the sea. In the Soviet time the area was a shipyard for the Union of Fishermen and was not accessible to the public. After 1991 the area was privatised, industrial buildings deteriorated and demolished, and the

area became physically accessible to the public (Pro Kapital Eesti, 2016). Currently, the area houses a small yacht harbour, a fish market and an informal pop-up beach.

The area is a private property and belongs to a developer Pro Kapital Eesti, which bought the land in 2001, demolished the fence around the area and the industrial buildings. In 2003 Pro Kapital Eesti commissioned the plan of the area to an architecture office Nord Projekt. Due to public protests the plan had four public displays, in 2008, 2012, 2014 and 2015. It was approved in 2015 with major modifications. Initially, key elements of the plan were (1) a residential quarter with an underground parking accessible from the seaside, (2) an extended yacht harbour, (3) a solid public waterfront promenade (personal communication with a planner from Nord Projekt responsible for the project). In the discussion about the plan there were three main conflict points: (1) the design of the apartment blocks; (2) the access to the seaside; (3) the elimination of the pop-up sandy beach with a swimming place.

Plan for Mezapark and plan for Kalaranna have a number of similarities and differences. Both plans redesign a strategic space in the city. The size, history and function of the space are different. Both plans deal with waterfront design and accessibility issues. In case Mezapark the de facto private space was designated for public use, and in case Kalaranna the de facto public space was threatened to become inaccessible. Both were subjected to a substantial public critique, which led to changes in plans. In case Mezapark these changes were minor, but in case Kalaranna - major. Participatory process, however, was similar, and caused dissatisfaction among all stakeholders.

Figure 2 - Left: Mezapark waterfront; right: Kalaranna waterfront (authors)

4 FINDINGS AND DISCUSSION

4.1 OUTCOME

The citizens managed to achieve certain changes in the plans according to their preferences. In Mezapark the idea about the construction of an amusement park was rejected and the design of the waterfront was subjected to a competition. The waterfront was a contradictory issue, as there was no unified opinion about it among the citizen groups. Some residents wanted it to be solid, accessible for motor transport, while the others were advocating a soft, natural, vulnerable to water fluctuations. The competition allows for another round of debate for the waterfront design. "If we had a promenade, [Pavé Street residents] could use it [to access their properties]. They wouldn't need to go through the park. Cafe suppliers could, also... avoid entering the park", argues a developer representative, Riga. "Greece is an excellent example where due to solid waterfronts the link to the water doesn't exist... How many places there are in Riga where it is possible to walk with the kids along the natural water edge?... We won't be able to get a natural waterfront after building an artificial one!", says a community representative, Riga. Despite these accomplishments some residents refer to Mezapark plan as "a lost case", as two of three conflict issues, the forest transformation and the waterfront redevelopment, remained in the plan. Furthermore, the future design of the waterfront remains unclear. The developer, in turn, regrets, that the amusement park construction was rejected.

In Kalaranna the expansion of the harbour and the construction of the waterfront road were dismissed. The citizens, also, secured a 20 m wide motor traffic free public area along the seaside and a beach with a swimming place, resulting in 40% of the private area being in public use and managed by the municipality. The design of the buildings on the site was subjected to a design competition. Participation resulted into

more or less consensual planning solutions. Both conflicting parties, the developer and the community, were satisfied with the outcomes, and the plan was ratified. The developer was satisfied with the opportunity to start developing the area. A developer representative admits: “We came to the decision that [the conditions of the detailed plan] are acceptable for us... Because... the public areas... will increase... the value of the area”. The community, in turn, assured the public waterfront and the beach with a swimming place it was fighting for. A community representative says: “We had a... long and painful cooperation... and we... reached quite a good outcome for the public sea-side...”

Civic participation is often blamed for its managed nature and the lack of public influence on actual decisions (see ex., McGovern, 2013; Connely, 2006). Indeed, according to Latvian and Estonian legislation the final decision is taken by municipality. Municipal decision can override any proposal from other stakeholders, such as developers or citizens, and can be argued only in the court. In both cases to a larger or lesser degree residents managed to persuade the municipality and other stakeholders to modify the plans according to their suggestions. Thus, the voice of the residents was heard and their opinions were incorporated in the final plans. Furthermore, participation is criticised for its redundancy, as an individual planner and a group of stakeholders can arrive to the same conclusions, thus, making a collective decision superfluous (Faehnle & Tyrvaenen, 2013). However, in cases of Mezapark and Kalaranna, the changes in plans would be impossible without community input. Besides, the contributions from the citizens, arguably, improved the quality of plans, forcing the developer to preserve and strengthen local values.

4.2 PROCESS

Plan design and adoption process for Kalaranna and Mezapark was hampered by mutual bias and mistrust. Judging by the opinions, expressed in the interviews, developers, designers and, surprisingly, municipality represented a “pro development professional” group, while communities represents a “counterdevelopment laymen” group. Developers and municipality were sceptical about the competences of the residents and their ability to provide meaningful contributions. Designers abstained from expressing direct judgements. Developers and municipality claimed, the citizens evaluate plans superficially and subjectively.

“The public... pays attention to visual details not... entering into real topics” says developer representative. A planning department representative supports the opinion: “Usually the opinions of the citizens are subjective”. Furthermore, both parties repeatedly emphasise, that “[citizen opinions] should be evaluated by professionals”.

The facts derived from planning documents proved these bias to be unreasonable. Firstly, both communities had professionals among their members, lawyers (both), architects (Kalaranna) and spatial planners (Mezapark). Secondly, citizen feedback about the plans was precise and constructive. The designer of Mezapark plan received and documented 21 comments on 55 A4 pages. Three of these comments were letters from resident communities, containing 13, 18 and 19 points each. Four of these comments were letters from private persons containing 4, 6, 10 and 48 points each. Comments were well structured and well-argued. The residents supported their arguments with a community wide survey about the values of Mezapark, with response rate of 10%. Moreover, some comments pointed out mistakes and inaccuracies in planning documents, which were, later, corrected by the designer.

For Kalaranna plan a similar document providing information about the resident comments was not available. However, judging by the interviews with community representatives, the residents studied the plan thoroughly, highlighting controversial points. Furthermore, the community hired a professional consultancy to evaluate the plan, which revealed the deficiencies of the plan, including the mismatches between the plan and higher level planning documents (Lindmae, 2014).

The review of co-planning cases shows, the quality of citizen input is a common concern (Doorne, 1998; McGovern, 2013; Vayona, 2011). However, the experience from Kalaranna and Mezapark proves the irrelevancy of these concerns for the local context, as in both cases the citizens provided qualitative contributions. Besides, there is a positive trend in the quality of public input, as municipality representatives admit, that “[citizens] know more about... urban planning... and... [the share] of constructive criticism... is getting higher”.

Another recurring argument from developers and municipalities was the resistance of the community to any development, to change, and the tendency towards “no, I don’t like it” attitude. “[The community]... wish was just to prolong the process and to maintain the status quo”, says a developer representative. A planning department representative supports the opinion: “The residents don’t want any development”. However, community representatives clearly stated in the interviews, the residents resist proposed design solutions, rather than the development in general. The statement is supported by community actions. Mezapark community based on self-initiated resident survey produced a balanced development plan for the neighbourhood. Kalaranna residents, in turn, established a beach with self-made street furniture. A community representative from Tallinn emphasises: “What concerns [community name] fight... it has been about... the use of sea-side... the access to the sea-side... it has never been against the development”. These examples showcase the resistance towards top-down planning, rather than to change, and the demand for bottom-up approach.

The communities expressed mistrust in developers and designers, and, at the same time, were sceptical about the ability of municipalities to protect their interests. The citizens were struggling rigorously for precise wordings in the building regulations, which exclude any misinterpretation. They feared, that any uncertainty would be interpreted in favour of developer and referred to these uncertainties as developers “tricks”, which conceal developers true intentions. “In professional language [the designer] can put it in a way, that no one pays attention... and it gets through”, says a community representative from Riga. A community representative from Tallinn supports the opinion: “[The developer and the city] haven’t agreed that... this [area] is in public use. Legal... agreements behind it... the contracts... everything was missing”.

The mismatches in the plans and plan complexity only contributed to the residents concerns. In case of Mezapark the designer prepared infographics summarising main features of the plan. Original documents, building regulations, maps, street sections, cover text, etc., were available at municipal website. However, some residents claimed, the infographics provided limited information and, thus, were (intentionally?) misleading. “The construction of an amusement park is not reflected in the infographics, thus residents get a corrupted impression of the essence of the plan”, says a community representative, Riga. In case Kalaranna the residents, on the contrary, blamed the developer and designer for the absence of infographics as the original plans were unreadable. “Detailed plan is like absurdly complex... in public display the drawing of the plan was... I don’t know... 10 meters long /laughs/... And they expect that on computer screen you will understand everything!” admits a community representative, Tallinn.

Developers and designers, in turn, were disappointed by community mistrust. Developer representative points out, “the quality of the land owners who want to establish a new detail plan... has increased substantially compared to... 10-15 years ago”, and, currently, the developers are interested in a large picture, because “the profit comes if the property is good and if the surroundings are good, if the public spaces are good, if the accessibility is good...”. The designers support the argument, stating, that, indeed, there were “a few cases where... let say, there was something in the project, which no one paid attention to... and when the project was realised... it didn’t meet the expectations... But it happened unintentionally”. Developers and designers unanimously agree, it was difficult to overcome the mistrust and to prove, the plans are designed according to the planning legislation and there is no hidden agenda.

Examining the public display process, becomes obvious clear, that “there was a discussion, but there was no dialogue” (designer representative, Riga). Conflicting parties took defensive positions and, thus, were unwilling to accept opponents concerns and arguments. Inness & Booher (1999) confirm, the inability to understand the position of the opponent is a common disease of many co-planning initiatives. Therefore for the co-planning projects to be successful it is important to start with building mutual respect and trust.

4.3 PLANNING SYSTEM

Although the initial interview setup did not include questions about the planning system, many respondents commented on it. Arguably, these were the deficiencies of the planning system, that exacerbated the conflicts. As a community representative puts it: “The planning system should be, also, changed!”

4.3.1 ENGAGEMENT FRAMEWORK

A crucial issue which is rarely discussed, is when to involve citizens in planning process and what questions to ask. In both cases residents were invited to participate in the end of the process to comment on final design solutions. For Mezapark there was, also, a working group, which discussed design solutions during the design process. However, the working group had a limited public access. In fact, the only option citizens were left with, was either to approve, or criticise final solutions, without the opportunity to participate in the development of solutions. "The only way that you can participate is through protests, and this is fundamentally wrong", says a community representative. "The question is how seriously people take it, how many and how often participate... many times [public displays] happen when... in some sense it's too late already", admits an expert.

Other stakeholders and experts point out, the citizens have been involved in the beginning of planning process, preferably, in setting the agenda for the plan and doing the preliminary research. A developer representative admits: "It would be good to find a way to involve different parties already in the beginning". A planning department representative supports the opinion, saying: "We encourage planners and land owners... to start with... the involvement of community before it's legally necessary...".

A common argument in favour of community engagement states, that participation increases public support of plans, thus, leading to successful adoption and implementation (see ex. Irvin & Stansbury, 2004; McGovern, 2013). The examples of Kalaranna and Mezapark illustrate, if the community is involved in the final phases of plan design and if engagement is limited to approval or rejections of final solutions, then participation is likely to lead to conflicts.

4.3.2 REPRESENTATIVENESS

Citizens involved into the discussion of plans were limited to local communities. Mezapark residents were represented by Mezapark development community and the residents of Pavu Street. Members of the community and Pavu Street residents live mainly in detached houses in the neighbourhoods bordering the planned area.

In the discussion of Kalaranna plan initially local residents were engaged as individuals. Since 2012 the case was overtaken by an official local resident community Telliskivi Selts, which managed to engage approximately 4000 local residents (counted by signatures to protect the sea-side).

Despite the significance of both areas for entire cities, city wide public was not involved. In case Mezapark the designer and the developer both point out that the absence of alternative resident groups was a significant drawback of a participatory process. According to them, resident preferences differ depending on their housing location and conditions.

"...There are two resident groups. Those residents, who live in detached houses in Mezapark neighbourhood, which was historically planned as a garden city... who established the Mezapark development fellowship. The second group are those, who live in apartment blocks at Ostas Street. This group hasn't established any community... And the opinions of these two groups are quite different... This group [who lives in detached houses] regards... the park as a continuation of their private property. They want it calm and quiet, without people... Without development, without events, without anything. And the other group, who lives in apartment blocks, sharing a few square meters with children, for them [Mezapark] is very important. For the sport infrastructure is important, places for walking are important. They want playgrounds for children, sport infrastructure for children. The opportunity to visit events... The place where they could enjoy nature... For many Riga residents [infrastructure is important]. In Riga there are little places, with the opportunity to have a walk in the forest, with paths, lighting, catering and recreational places" (developer representative, Riga) As a designer representative points out "the challenge is to communicate not only with the group, which is directly affected [by the plan] and which is against, but communicate with the beneficiaries, with the silent mass, which is much larger, who sees the benefit".

Low participation rates and strategies for involving passive groups is a topical question in the current research on participation practices (see ex., Brown & Kyttä, 2014; Thiel & Frohlich, 2017). Donders et al. (2014) support the arguments of municipality officers, emphasising, that the residents, who are usually engaged, are not representative of the community. Therefore, as Nienhuis & van Dijk (2011) argue, it is necessary to introduce strategies, aiming at involving the passive citizens to balance the opinions of active ones. In cases of Mezapark and Kalaranna, despite the fact, that most stakeholders mentioned the need for engaging “the silent majority”, no activities, beyond those, required by the legislation, were conducted to encourage them to participate.

4.3.3 ROLE OF MUNICIPALITY

Municipality officers recurrently argued, that the active minority, who participates in public displays and discussions, often follows their vested interests. “I often encounter the cases, where [the residents] think about their own benefits, rather than about public interest”, says a planning department representative from Riga. A planning department representative from Tallinn supports the opinion: “If we go deeply into the arguments very often it is not in the interest of the wider audience, but in the interest of someone in the community”. Municipalities, in turn, represent public interests. “A municipality is an institution which represents the society, pro-society”, says a planning department representative from Riga. A planning department representative from Tallinn supports the opinion: “A [municipality] represents the public interest more often than these community groups...”.

Although municipal officers are, partially, right, their arguments cannot be considered sound. The residents cannot be blamed for pursuing their agenda as the task of residents is the advocacy of their “selfish” interests. The task of municipality, in turn, is to balance various “selfish” interests, the interests of various resident groups, of land owners, of developers, of entrepreneurs, etc., to find the best possible solution, which would satisfy all parties. Furthermore, the task of municipality is to ensure, that these various interests are represented during the discussion. The more interests are present, the closer the common opinion is to “public interest”. “Public interest consists of various interests... at the end of the day the city have to decide... what stays on the table... But it... depends on what do you want to get... do you want to get more cars or do you want to get more pedestrians?... I’m talking about... the end result philosophically... Who sets the aim? The big aim?... The City?” says an expert from Tallinn.

The stakeholders blamed the municipalities for taking passive positions. Residents unanimously criticised municipality for showing no initiative in mediating the conflicts. “[The municipality] could have helped us with in the planning process... let’s meet... let’s... find out a solution... do something extra, than what is required by the planning law. But they didn’t show any initiative”, says a community representative, Tallinn. Furthermore, residents repeatedly expressed the concern, that the municipality is not exercising its “legal rights”, “legal power” to steer the development of the city towards equilibrium, where the interests of the stakeholders are balanced, and towards sustainable environment. “The task of the municipality to design a sustainable city, where the interests of [residents and developers] are aligned... Developers and residents need good environment. The developer can request to build a nuclear plant... And the city should say, why there can’t be a nuclear plant next to the kindergarten”, says a community representative, Riga. The developers, in turn, urged the city to define the priorities and take the decisions fast, as the circumstances for development change rapidly together with economic situation. “The City, in my opinion, should have taken clearer decisions faster... than they took”, says a developer representative. The criticism of the municipality is common for local context, whereas in the English literature on participatory practices it is, currently, rare. Speaking of the role of the planner, Forester (1987) emphasised, that the planners often have to manage conflicting situations between various parties, therefore negotiation and mediation skills are essential. Shipley & Utz (2012) support the argument, stating that the task of the planner (or the administrator) to balance different interests and to ensure the fairness of process and outcomes for all stakeholders. Thus, planners are in a difficult position, as their task is to navigate through conflicting interests and, furthermore, to address political agenda of elected representatives. Local municipalities are just entering the field of communicative planning and, thus, have little experience managing such complex situations. It is natural, that currently municipal response is late or showing less initiative than expected. Hopefully, the situation will improve in the future, as municipalities gain more experience, learn and embrace their role and legal power.

4.3.4 ROLE OF RESEARCH

Although, not mentioned directly, the residents and the municipality touched upon the role of research in planning. Talking about resident engagement, the respondents from Tallinn repeatedly expressed the desire to map the values of the residents prior to developing plans. “We would like to map... what are the values that people who live in Tallinn see in Tallinn. And if we start by mapping these... values... the masterplan... would develop these values further or reinforce them”, says a planning department representative, Tallinn. Indeed, supporters of civic engagement idea emphasise, that citizens are the end users of the space, thus, it is important to acknowledge their values, preferences and space usage patterns. In other words, it is essential to gather experiential information which complements the knowledge base for planning, and, thus leads to more balanced and sustainable solutions (Faehnle & Tyrvaenen, 2013; Brown & Kyttä, 2014). Furthermore, the respondents emphasise the importance of asking meaningful questions to the citizens. “It depends on the planning document type and on the area, on the [decision type]... and what kind of information for this certain planning document it is possible to get from the residents”, says planning department representative, Riga. As participation is a resource consuming activity, prior to engaging residents, it is essential to acknowledge, what information is necessary for the plan, what information the citizens are able to provide, what is the best way to get this information, and how this information is going to be integrated into the plan. In other words, it is necessary to design an efficient, clear, yet flexible, engagement strategy.

5 CONCLUSIONS

Despite certain deficiencies, the cases Mezapark and Kalaranna sketch a positive participatory trend in planning. The concerns about the inability of citizens to provide meaningful input proved to be unreasonable. Citizens proved their competence by providing well-argued critique of plans and by presenting their own, alternative, visions of the areas in focus. Developers, in turn, developed the capacity to make trade-offs to meet civic demands. Municipalities, however, fulfilled their tasks partially. On the one hand, they were inclined to prioritise public interests over private interests, which is a positive trend. On the other, their performance as conflict mediators was rather poor. Furthermore, the participatory strategy failed to meet current demands for community empowerment and inclusive sustainable city with well-balanced public-private interests.

There are the following deficiencies in the planning strategy. Late involvement, in the final stage of planning process is likely to lead to conflicts, as the only way for the public to participate is by challenging planning solutions. Thus, other stakeholders get a misleading impression of public resistance to change and development. Though, in reality, the public resists top-down planning solutions, which were developed without their participation and which often ignore public values. Fortunately, the interviewees mentioned the need for public engagement in the beginning of the planning process. The respondents emphasised the importance of acknowledging public values before the planning process, to reinforce and develop these values further. Furthermore, there is a clear demand for more inclusive planning process, for co-developing planning solutions together, instead of forcing top-down solutions.

Partial representativeness, limited to directly affected parties allows municipality officials and designers to speculate, that the citizens are following selfish interests instead of representing the public opinion. The argument is unsound, as every party, including community groups and developers, are advocating their vested interests. The more parties are engaged, the more balanced is the voice of the residents, and the closer it is to the public interest. Certainly, it is hardly feasible, nor necessary, to involve all resident groups to public discussion of each and every detailed plan, but in case of detailed plans for city significance areas, the opinions of both directly and indirectly affected parties have to be acknowledged.

Passive position of municipality to a certain extent contributed to an inefficient negotiation process between the conflicting parties. Conflicting parties did not empathise with the opinion of the opposition, holding to their initial biased positions. Thus, a discussion without dialogue emerged. In this case an active intervention of the municipality was necessary, serving as a mediator in the discussion, and encouraging the conflicting parties to develop a shared understanding of the issue and find consensual solutions. The municipality clearly needs to develop a toolkit to deal with conflicts in planning. Probably the competences of municipal planning officers have to be extended beyond planning, to negotiation and mediation.

To sum up current participatory approach is lacking an essential step — participation strategy design. Firstly, it should be acknowledged, which parties are directly and indirectly affected by a plan, what information they can provide, what information is essential for the plan and how it can be integrated into the plan. Then, participation strategy has to be designed to collect this information. Based on this information, planning solutions have to be developed and discussed. Thus, participation shifts from the political to a research field, being inquiry driven.

ID 1486 | FROM KNOWLEDGE OF THE TERRITORY TO THE SPATIAL PLANNING CULTURE

Paula Raquel Ferreira¹

¹CICS.NOVA/UNL - Faculdade de Ciências Sociais e Humanas da Universidade Nova de Lisboa

paularaquel9@gmail.com

ABSTRACT: Consolidating the paradigm of territorial governance (with civil society increasingly and more actively participating in spatial planning) with the assumptions of sustainable governance comes up against the lack of robust knowledge of the territory and a civic spatial planning culture, both from civil society as well as political and technical decision-makers. In this context, it is proposed as a starting question how it is possible to develop a greater awareness on the territory and a robust civic spatial planning culture for both in these new “actors” and the political and technical decision-makers so they see it as a common good and a scarce resource, ensuring its sustainable development. Underlying this question is another of no less importance: what is the role of school education, more specifically the Geography discipline of secondary school, in the processes of collective learning about the territory and spatial planning culture? After the theoretical study of the concept of territory, spatial planning and territorial planning culture, these are confronted with a representative sample of civil society through questionnaires applied to: - Secondary school students (who have not yet intervened in the reconfiguration of the territory), with or without frequency in the Geography discipline (in order to verify to what extent the geography, of this level of education, provides a better knowledge of the aforementioned concepts); - Parents/guardians, representative of the adult population, who have already intervened, consciously or unconsciously, in territorial reconfiguration, but who do not have direct responsibilities in spatial planning.

KEYWORDS: territory, spatial planning e spatial planning culture

1 OPERATION

With the purpose of assessing the knowledge that the civil society has of the territory, spatial planning and spatial planning culture concepts, two questionnaires were conceived and were applied to two universes of

analysis: school population, without intervention in the territory, and citizens, who may have already intervened in the territory (parents guardians).

The questionnaires are based on the theoretical basis, presenting three sets of affirmations identified as the territory concept (first group), spatial planning (second group) and the spatial planning culture (third group), that allow the understanding the organization of the questionnaire as a whole. Before each affirmation, the respondent chooses between "totally disagree" (1) and "totally agree" (6). It also includes option 7 that corresponds to "I do not know". The decision of the respondents is decisive to know the territorial culture of each of the universes of analysis.

It should be noted that the difference between the questionnaire of the students and that of the parents guardians is based on the reduction of affirmations in each thematic group (table 1).

Theme	Territory		Spatial planning		Spatial planning culture	
	Students	Parents guardians	Students	Parents guardians	Students	Parents guardians
Affirmations number	28	18	8	6	20	15

Table 1 – Affirmations number by theme. Source: Sample - Own survey (fieldwork conducted in 2016)

The selected sample focuses on secondary schools located in the cities of Viseu and Aveiro. The choice of these municipalities, belonging to the NUTS II Center, is based on the fact that, i) according to the PNPT, both are part of the Leiria-Coimbra-Aveiro-Viseu strategic polygon with the potential to contribute to a competitive, integrated economy and open; ii) are the two NUTS II municipalities with positive demographic trends between 2001 and 2011, and ii) have a resident population in 2011 (77 463 and 99 593, respectively).

Of the 358 questionnaires applied to the school population and parents guardians, 190 were considered valid, in the case of the first universe, and 138 in the second one (53.1% of the predicted sample, in the case of the first, and 38.5%, in the case of the second).

2 THE CIVIL SOCIETY VS TERRITORIAL CULTURES

2.1 "TERRITORY" COMPONENT

In the last decades, "territory" has become an important mechanism of political and social intervention, but the divergences (and ambiguities) in the intrinsic uses and meanings, make it a polysemic term.

In order to deepen and improve the concept in both samples, we propose affirmations about the multiple perspectives of the territory concept - such a) as physical support, b) as a political-administrative space, c) resources source (territorial asset/ scarce resource and common good), d) as living space and e) as a system.

In order to know the territory conceptual perspectives prevailing in civil society - the school population (without intervention in the territory) and adults (parents guardians), two criteria were used:

- a group of ten affirmations - top ten - which obtained the highest percentage values (agreement or disagreement) and, in this case, reflect a position of agreement with the conceptual perspectives presented;
- the frequency with which, in this top ten, the affirmations associated with each of the conceptual perspectives of territory arise;

It is concluded that the three groups - students with or without Geography and parents guardians - present themselves with different positions between the territory conception (table 2).

Position	Students with Geography		Students without Geography		Parents guardians	
	%	Conceptual perspective	%	Conceptual perspective	%	Conceptual perspective
1*	96,8	Physical support	84,4	Resources source	94,9	Political-administrative space
2*	91,5	Political-administrative space	84,0	Living space	92,8	Source of resources
3*	91,5	Living space	81,3	Political-administrative space	92,8	Political-administrative space
4*	90,4	Political-administrative space	82,3	Living space	92,8	Living space
5*	89,4	Political-administrative space	80,2	Physical support	90,6	System
6*	88,3	Political-administrative space	79,2	Political-administrative space	90,6	Resources source
7*	88,3	Resources source	78,9	Living space	90,6	Resources source
8*	88,2	System	78,1	Political-administrative space	88,4	Physical support
9*	86,0	System	78,1	Resources source	88,4	Living space
10*	84,0	Living space	77,9	System	87,0	Living space

Table 2 - Territorial conceptual perspective, by priority. Top ten affirmations (first criterion)
Source: Sample - Own survey (fieldwork conducted in 2016)

But there are points in common.

- Considering that the territory perspective as a physical support has more relevance for the group of students with geography (taking into account the first criterion), it do not stand out in the three universes, when the second criterion of analysis is taken into account.
- In all three groups, the traditional territory conception as political-administrative space is still very much rooted when one thinks of territory.
- For students without Geography and parents guardians, although the territory view as a resources source (territorial asset/ scarce resource and common good) is more recent than systemic view, it is with the latter that both groups show to be less familiar.

In the case of the students with the Geography, and in a first analysis - by order of appearance in the top ten - it is evident that the territory perspective as physical support is the one closest to them (table 2).

But, with a more detailed analysis, these students reveal affinities, mainly, with the territory view that conceives it as a political-administrative space. In a less prominent place, they also conceive it as a lived space.

Both the conceptual perspective that regards the territory as a resources source and the one that sees it as a system are at the same level of importance because, taking into account the first criterion, is the first that stands out in relation to the second, but if the analysis is extended to the second criterion in which the roles are reversed (figure 1).

Figure 1 – Territory perspectives of top ten frequency (second criterion)
Source: Sample - Own survey (fieldwork conducted in 2016)

The territory view as a political-administrative space continues to be taken into great consideration, however, the influence of the postmodernist paradigm is undeniable, insofar as it is confirmed by these students, the territory conception as an identity Individual and collective support, anchored in a social space and a lived space, placing this perspective in the third position (taking into account the two criteria). As for students who do not have the Geography discipline, the options are different relatively to the previous group.

Taking into the top ten account, the territorial perspective that presents itself as the first choice is the one that regards the territory as a resources source. This trend is confirmed by the other analysis criteria (table 2).

The following are the perspectives that have the greatest consensus and which conceive it as a political-administrative space and as a lived space. However, administrative decentralization and the fact that there is not always an explicit administrative territory delimitation, makes this conceptual approach insufficient so, in order of choice, these students prefer the second.

This is reflected, on the one hand, in the exclusion of the affirmations associated with the concept of property, and on the other, in the approximation to the territory perspective as a lived space, an approximation that can be understood as an extension of the reference and valuation of the territory intangible heritage, mentioned in the affirmation that obtained the highest percentage value - "The territory is both a material heritage (land, forest, etc.) and an intangible heritage (language, culture, etc.)."

Regarding the territory vision as a lived space, it should be pointed out that it presents itself in a relevant position in relation to what it regards as political-administrative space, which shows that these students are close to the thinking line of the postmodern paradigm, whose space is conceived as influenced by individual and collective (social) experiences.

About the territory conceptual perspective as physical support, even if it is close to them, it does not have the importance that reached in the first group of students to be placed in a more modest position.

Although the conceptual territory perspectives as a resources source and as lived space are the ones that have more adhesion by the parents guardians, since they are ones that hold the highest frequency of affirmations in the top ten, which considers it as political-administrative space also has a prominent place (table 2 and figure 1), since it is this vision of territory that reaches the highest value on the part of these respondents.

As for the territory vision as physical support, it's here too, as in the group of students who does not attend Geography, it is little valued. The traditional territory conception as a political-administrative space is still quite ingrained.

2.2 "SPATIAL PLANNING" COMPONENT

The spatial planning was the exclusive domain of researchers, technicians and policy makers but, today, it is spreading to common sense, imposed by the Central Administration, by the guidelines of the European Community or disseminated by the media.

But does civil society use it with content?

Considering several authors and legal documents, it is intended to identify, in the two samples, common points in the conception and functions attribution to the term spatial planning, resulting in the knowledge that with what spatial planning perspective - land use planning and spatial planning - civil society identifies itself.

What is spatial planning? What is it for? Who is responsible for its preparation/ application?

These are the questions underlying the affirmations presented in the second part of the questionnaire in order to know what the students of the secondary education (eleventh year) and de parents guardians understand by the term spatial planning and what it implies.

According to the options taken, one intends to know under what perspective - land use planning or spatial planning - each of the two groups of students and parents guardians think about spatial planning, that is, with which they are more familiar and which is still far from universal, when it comes to spatial planning.

Although distinct, the affirmations in the questionnaire, belonging to the two sub-themes later, are analysed according to the same criteria: by the options of both groups of students and parents guardians - of agreement or disagreement - one realizes if they approach the of land use planning or spatial planning perspective.

Analysing the students' options, both groups assume spatial planning as "public policy", "defender of the public interest". However, in view of it as public function, while the Geography students and parents guardians assumes it, without any doubt, the group that does not have the discipline shows some ambiguity in their choices.

As for the second aspect all groups take less defined positions.

According to the criteria mentioned above, in terms of the spatial planning functions and the identification of those responsible for their elaboration and application, it is verified that there is a clear approximation to the spatial planning perspective of the three groups.

Two approaches are safeguarded from the perspective of land use planning.

The first, is when it is verified that in most of the students (with and without Geography) and the parents guardians, there is a strong propensity to consider that spatial planning has the regulating function of the space use and occupation. Here, there is still an influence of the modern paradigm and consequent technorational territory vision, which lasts until the present day.

	Affirmations		
	Students with Geography	Students without Geography	Parents guardians
<i>Land use planning</i>	2	1	1
<i>Spatial planning</i>	4	5	4
Total	6	6	5¹

Table 3 - Spatial planning perspectives – Land use planning and spatial planning by affirmations frequency¹

The other exception is when the behaviour of the two students group is analysed, with respect to the responsibilities attribution of those who elaborate/ apply it, where there is an approximation to land use planning, but in an unclear way, since the percentages are very close between agreement and disagreement (1.0% in the case of the students with the frequency of geography and 4.3% in the case of the other students group).

These two exceptions are a reflection of the stubbornness of the modern paradigm in keeping to the surface of the change "revolt waters" and consequent techno-rational territory vision, based on the rationalism of scientific knowledge.

At the level of spatial planning policies, the transition from land use planning to spatial planning is slow, witnessing even today the coexistence of the two territorial policies.

But if these exceptions may obscure the clarity of the analysis, since they demonstrate that there is still a strong tendency to "place" spatial planning from the perspective of land-use planning, it is clear that the three universes of analysis visibly identify with spatial planning vision (table 3). Following the presented and in conclusion, the generality of three groups considers spatial planning: as an integrating and global factor and as a rational utilization territory factor, with the underlying intention of developing it in a sustainable manner, making it competitive (valuing existing resources), safeguarding the quality of life of the population.

¹ The difference between the questionnaire of the students and that of the parents guardians is based on the reduction of affirmations in each thematic group

Here, there is a government assumptions appreciation based on the sustainability paradigm, which presupposes the allocation of the best territory use, through a reflection on the capacity to resources use without compromising the futures generations.

2.3 "SPATIAL PLANNING CULTURE" COMPONENT

In view of the analysis of the various various spatial planning systems from land use planning to spatial planning, it is concluded that the spatial planning culture goes far beyond the characteristics of structures, instruments and procedures.

In this way, territorial planning practices can not "turn their backs" to other factors such as values, political traditions, representations about planning actions and competencies, governance structures, etc., producing different contexts regardless of the planner will.

This theme follows the previous one. If they sometimes seem to interfere, the pretension of their existence reflects the desire to know if the students and the parents guardian assimilate a new culture of spatial planning.

The answer to this purpose is based on the analysis of the affirmations grouped in the three subgroups entitled "role of the State in spatial planning", "criteria for spatial planning legitimizing" and "activities of the technicians/ planners".

	Affirmations		
	Students with Geography	Students without Geography	Parents guardians
<i>Land use planning</i>	1	1	1
<i>Spatial planning</i>	11	11	9
Total	12	12	10¹

Table 4 - Spatial planning cultures by affirmations frequency¹
Source: Sample - Own survey (fieldwork conducted in 2016)

Above all, it emphasizes, at once, the hegemony of the State, who persists in maintaining its ascendancy, intrinsic in common sense. This is confirmed by the approach of the three groups against this matter. However, other choices show that for them the spatial planning goes beyond the influence of the Administration, demonstrating that they are receptive to a strategic, integrated and visionary territorial planning.

Here, the consideration of spatial planning as public policy is reaffirmed by all groups, since they recognize in the State and entities within their jurisdiction, the legal competence to make decisions within the spatial planning.

The State is recognized as an authority, that it can use in its favour, not with authoritarianism, but as a reference, model, facilitator in the new forms of collaborative territorial planning, increasingly participated by other agents within its jurisdiction.

The techno-rational question is not neglected, since here also, the majority of the students of both student's groups and parents guardians, consider that the knowledge and technical contribution is essential in the territorial planning policies.

Observing the students' behaviour (with or not frequency of the Geography discipline), and the parents guardians, in general, do not observe significant differences, since all consider the State as legal support in the territorial planning policies production and implementation, confirming the general trend already observed, when the conception of spatial planning is accepted as public policy.

Noting the options of the two student's groups and parents guardians, in relation to the question "what are the objectives of spatial planning?", It is concluded that, here too, they are clearly next to the spatial planning

¹ The difference between the questionnaire of the students and that of the parents guardians is based on the reduction of affirmations in each thematic group

perspective, with coherence between the positions taken, with regard to the previous theme and the present theme.

The spatial planning conception, as an integrating factor, is reinforced, insofar as it is viewed in an interdisciplinary and integrated perspective, reflecting the perceptions and meanings of space, philosophies and planning traditions, cultural rules, norms, traditions and values, that is, the cultural contexts.

Manifestly, cultural diversity leaves the field of social sciences to assert itself as an essential element in territorial policies.

This influence is clear (even for those who persist in ignoring it), inherent to the territory interpretation and policies of spatial planning execution, by the decision makers/ technicians, with direct consequence on how the territory is ordered.

This fact had already been revealed in the first theme - Territory - where it was observed an approach to the concept of territory as a lived space, as a support of individual and collective identity, with more emphasis in the group of students without the discipline of geography and in parents guardians.

The sustainability paradigm is well present in all universes, when we speak about spatial planning. In other words, taking into account the political decision-makers and planning technicians actions, there is reinforcement of the concepts defended in the previous theme, agreeing that those territorial policies responsible should view spatial planning as an integrating factor, rational territory use factor, promoter of a balanced development, at different speeds, but do not forget that this territory is a scarce resource.

But the choices are not limited to the defence of sustainable environmental development. In order to achieve this balanced and sustained development, a prospective vision is required which, if it does not predict future transformations, can attenuate them.

As far as stakeholders are concerned, all agree that the participation of this is essential in spatial planning. It is confirmed here, that the two groups of students and the parents guardians view spatial planning based on shared responsibility.

2.4 THE GEOGRAPHY DISCIPLINE AS A DIFFERENTIATING FACTOR

Will the Geography discipline be a differentiating factor in the quality of the response between the groups of students (with or without Geography)?

When we observe the results, the conclusion is that there is no difference between two students' groups.

However, it is a conclusion little consolidated because:

- i) If one looks at the agreement and disagreement percentages, it is verified that difference between these two options is very close when we talk about the second group (without Geography). This means that these students have not solid positions about the subjects in analysis.

As subject's matter become more complex and less used in common discourse, this difference, between agreement and disagreement, becomes even more insignificant.

This situation is aggravated when the affirmations are related to the themes – spatial planning and spatial planning culture.

Figure 2 – “I do not know” percentages, in the three themes – Territory, spatial planning and spatial planning culture
Source: Sample - Own survey (fieldwork conducted in 2016)

- ii) On the other hand, the option “I do not know” (7), reaches higher percentages in the group without Geography, demonstrating once again that these students show less firmness in their positions than students with geography (figure 2), and which is also aggravated when faced with the spatial planning and spatial planning culture subjects (18,8% e 21,2%, respectively), while the other group of students registers percentages of 1,6% e 4,6%, respectively.
- iii) With the Mann Witney Statistic Test, there is statistical evidence that Geography influences the ability to respond, because it is the students, who do not have the discipline, that assume to do not know what option to take before the affirmation presented. This situation is especially evident in the last two thematic groups - spatial planning and spatial planning culture.

Another inference could be gotten. In the present study, there has been an approximation between the positions of the students without Geography and the parents guardians, mainly regarding the conceptual perspectives of the territory.

From here we can draw two inferences.

- i) Both, only had Geography in the 3rd Cycle of the Basic Education (more specifically in the students' case), or geography is "so far" from their lives that they are few curriculum content that they remember.
- ii) In comparing the "I do not know" option percentage values, in these two groups, it turns out that parents are more determined in their choices (figure 2). This could be justified by the transition from a representative democracy to a participatory democracy with the consequent need of a present State, but facilitator of the dialogue and moderator in the negotiations between the stakeholders (Where can these parents guardians be).

3 CONCLUSION

The group with Geography is more affirmative in their positions, which proves they know better the issues in analysis than the other students group. This fact demonstrates that the Secondary School Geography Programme contributes to a better understanding of these subjects. The political-administrative space territory perspective is yet consolidating in all students and parents guardians. But, the students with geography are closer to this territory concept than the others, which means that Geography discipline accentuates this concept of territory all over the School Programme, because it spoke about Portugal as a Nation and as a European member, and, consequently, about territory policies, which are often based on administrative boundaries. At the same time, this perspective is familiar for the students without Geography and for the parents guardians, which, as already mentioned, is associated with the traditional territory conception, in which the other group of students is no exception.

With more or less determination, in most of the subjects dealt with on spatial planning issues, all identify with the spatial planning perspective.

ID 1522 | SPACES FOR LOCAL WELFARE. HOW PLANNERS CAN CONTRIBUTE TO MAKE SOCIAL SERVICES MORE INCLUSIVE

Massimo Bricocoli¹; Benedetta Marani¹; Stefania Sabatinelli¹

¹DASTU, Politecnico di Milano

massimo.bricocoli@polimi.it ; benedetta.marani@polimi.it

1 INTRODUCTION

1.1 THE FRAMEWORK: INTEGRATION, ACTIVATION, LOCALIZATION

The combined effect of economic reorganization processes, the increasing precariousness in the job market and the shrinking of the national welfare systems, have progressively eroded traditional social protection measures and exacerbated the traits of social fragility in many European cities. The long phase of economic recession is linked both to the general worsening of the economic conditions of large parts of the population, and to the austerity policies and the drastic reduction of public expenditure on welfare. Devolution processes have played a significant role in reshaping the European welfare systems, underlining the relevance of the local dimension in the welfare policies and in the structure of social inequalities. The consequences are even more evident at the local scale, where local governments are facing the need of more adequate and effective welfare measures and policies with scarcer resources¹. Moreover, the ageing of the population, increasing migrations flows, the more frequent mobility of the individuals and the impoverishment of many families have generated new heterogeneous needs, mining the traditional welfare systems and the administrative treatment of the needs. Meanwhile, the number of actors involved in the governance of social policies has increased, highlighting at the same time the potential of innovation and the limits in responding to these new challenges (Bricocoli, Sabatinelli, 2016). This new panorama seems to orient the social policies towards three interrelated criteria: integration, activation, localization. These aspects, variously articulated, are addressing the social policies toward the interactions of different sectors (public, private, third sector) and subjects (social housing, new fee-paying or shared services, light forms of assistance and care, private company welfare services, etc.), promoting the autonomy of the recipients and the resources that can be activated at the local level (Kazepov, 2010). In addition, a renovated attention to the spatial dimension of social services and its generative power (Bifulco, Vitale 2003; de Leonardis, 2003), mainly referred to the territorial contexts in their material and tangible sense, often inspires and orientates ideas and resources for innovative projects (Bricocoli, Sabatinelli, 2016).

This contribution aims at analysing the contents and the outcomes of an experimentation led by the Municipality of Milan and currently under completion. The project deals with the reorganization of the access to social services in the city, with a particular focus on the home-based services. In this context, the Municipality is the leader of a partnership of 16 actors that includes the Department of Architecture and Urban Studies, affiliation of the authors of this contribution, who have been directly involved in the design and implementation of the project.

1.2 WEMI: A KEY PROJECT IN THE PANORAMA OF THE REFORM OF WELFARE POLICIES

The welfare system in the city of Milan is organized in different sectors; competences, responsibilities and resources are strictly divided between Departments, Sectors and Central Directions. The social services and policies' provision has been traditionally organised in pillars on a category-based system, rigid and separated in its articulation. According to this structure, each category – which represents a sociodemographic profile or a specific need (e.g. the elderly, adults in difficulty, disabled, etc.) - corresponds to specialized municipal offices with distinct staff and targeting particular needs. This organizational model, quite common in local governments across the Country, has been put under

¹ The National Fund for Social Policies has reduced from 1,884 billion euros in 2004 to 344,17 billion in 2013, a reduction of the 80%. Since 2007 the financial resources of the Italian municipalities have decreased of almost 15,8 billion euros. (Anci Lombardia, 2015).

discussion and, starting from 2012, the Milano city government has been implementing a significant reform. A main objective of the reform was to better face the tensions between the new social needs, expressed or still unveiled, and the provided answers, often inadequate or inappropriate. This re-organisation has been developed thanks to the Welfare Development Plan of the city of Milan (i.e. Piano di sviluppo del welfare della città di Milano), a strategic instrument introduced by the Department of Social Policies¹ starting from 2011. Based on an extensive analysis of current and perspective sociodemographic trends and on the composition of public expenditure for social care and services, the document draws provisions and strategic orientations for the development of local welfare policies. Along with the implementation of the plan, the Central Direction for Social Policies has modified the category-based system, substituting the existing sectors with three new transversal areas, that correspond to the different articulation of the action of social services: residential, territorial and home-based (in Italian *Residenzialità*, *Territorialità*, *Domiciliarità*) (Ghetti, Dodi, 2014). The system has been structured in two different levels: a first level dedicated to basic and preliminary access, aimed at reaching out and welcome all the citizens who express a need into the different locations spread in the city, without any restriction of category; a second level where, if necessary, entitled citizens could be addressed and benefit from more specialized services and structures. (Bricocoli, Palazzo, Sabatinelli, 2016).

Within this reorganization process, in 2015 the Municipality of Milan was the project leader (in partnership of 16 partners including public, private and social enterprises and two university departments), of the project *Welfare di Tutti* (i.e. Welfare for all), which was successfully submitted to a competitive call - *Welfare in azione* (i.e. Welfare in Action) - promoted by a Bank Foundation (Fondazione Cariplo) funding innovative community based projects. The project, named *WeMi* (acronym for Welfare-Milan and We-Milan), aims at overcoming the fragmentation of local welfare and at innovating the responses to a more diverse demands and needs, that still struggle to be represented and satisfied by the existing canals. Within the field of providing home-based services, *WeMi* is structured in different actions, developed in parallel by various working groups, heterogeneous in terms of professional backgrounds and competences.

A general objective of the project is to favour and support an access to welfare services by a wide range of citizens, including those who may be wealthy (and therefore not entitled to social assistance) but still bearing difficulties and expressing needs. With the goal of improving accessibility to the of home-based services which are provided by public and non profit organisations under the head of the City, two main projects have been conceived. An online platform (wemi.milano.it), which gathers the offer of home-based services provided by 58 cooperatives and associations and certified by the Municipality of Milan has been designed and implemented. Moreover, the project introduced the idea that new approach and reorganisation as well as a better accessibility to welfare services needed symbolic and concrete artefacts that witnessed the attempt of redefining the interaction between welfare services and the citizens. Three *WeMi* spaces (i.e. *SpaziWeMi*), located in different districts of the city (Municipio 8, Municipio 6, Municipio 5) were designed and organised with the aim of experimenting new solutions in the physical and organisational setting of social services. *WeMi* spaces are places where citizens are welcomed and oriented in the access to the services on the website, listened and supported in finding answers and solutions to their needs and where a specific emphasis is put on the promotion of new forms of shared services that could allow reducing costs through the aggregation of the demand. Laboratories for the creation of condominium-based, corporate and scholastic welfare services, have been developed in specific places (schools, condominiums, offices) with the purpose of better understanding emerging needs within the daily life of citizens.

The authors have been directly involved² in the different phases and actions of the project, with a particular reference to the conception and design of the *WeMi* Spaces; this has allowed a close observation of the intertwining between organizational change and the spatial organisation (at the urban and architectural scale) of local welfare services and has encouraged further reflections on the creation of more inclusive welfare policies.

¹ In 2016, with the elections of the new Mayor, the Department has been named "Department of Social Policies, Health and Rights and the mandate confirmed to Pierfrancesco Majorino.

² The working group of the Department of Architecture and Urban Studies has involved Massimo Bricocoli and Stefania Sabatinelli (coordinators), Benedetta Marani, Lorenzo Consalez and Francesco Curci, who collaborated to a first phase of the works.

2 THE SPACE FOR SERVICES

2.1 A STARTING POINT: WHICH SPACES AND PLACES FOR WELFARE?

The topic of welfare services and urban public equipment is a central dimension within the history and the development of the urban planning practice. The Italian normative introducing urban planning standards, which played a key role in the whole planning discipline and in the design of welfare spaces, is about to celebrate the 50th anniversary. While the role of the space in the design, production and provision of social services is a topic of fundamental relevance, it is rather under-investigated by urban planning research (Pomilio, 2009; Munarin e Tosi, 2012; Caravaggi e Imbroglini, 2016). The physical features of the services, in terms of geographical collocation and accessibility, the dispositions of functions and activities (setting) and the furniture (artifacts) are essential elements in the generative power of an organization (Gagliardi, 1990; Bricocoli, 2003; Bifulco, de Leonardi, 2003;). This aspect is even more relevant in the context of the welfare reform introduced by the Municipality of Milan. The new Milanese welfare model brings along the idea of an extension of welfare services: both from the “bottom”, involving the most in need subjects that struggle to access the traditional services and structures, and from the “top”, addressing those citizens who are not entitled to social assistance but ask for care and express social needs. Therefore, the topic of the access, in a metaphoric and material sense, represents a key issue. In this direction, the project Welfare di Tutti laid the basis for a new reflection on the dimension of the virtual access (the web platform to access the services) and of the physical access, through the creation of the WeMi Spaces. During the spring 2015, a working group coordinated by Massimo Bricocoli and Stefania Sabatinelli organized the training course “Spaces and Places for Welfare”. The course, addressed to the operators that would be involved in the project, has been structured to deepen and exchange knowledge on the relations between the services, social work and the spatial dimension. Starting from the concrete reference to practices and programmes¹, through the presentation of different contributions and explorations brought by the participants, a variety of spaces for services and the material contexts of welfare have been observed and analysed. From these confrontations, a critical panorama has emerged: most of the spaces for welfare appear inappropriate for their physical or functional features, unattractive for their neglected aesthetic, often located in structures owned by the Municipality, Third Sector cooperatives or Religious Institutions. These spaces contribute to increase the stigmatization of social services (and of their recipients), underlining their category-based access. Through examples and references to Italian and European contexts, the course has investigated different ways of rethinking the spaces for welfare both in terms of content (which functions and setting) and in terms of form (which furniture and artefacts). From this experience, in Autumn 2015, a laboratory of collective design was born to define the activities of the future WeMi Spaces and their spatial solutions.

¹ Some meaningful images of this experience will be presented during the AESOP Conference

2.2 THE WEMI SPACES

WeMi SanGottardo, WeMi Capuana, WeMi Trivulzio represent the spaces of the new Milanese welfare. The first, located in Corso San Gottardo 41, a central neighbourhood of the city, is a hybrid space in which the social operators work alongside a literary café. The second is located in a small square in the peripheric Quarto Oggiaro public housing estate and is an extension of an already existing office of third sector services. The third space is coexisting with “CuraMi”, an existing service dedicated to the research and the offer of caregivers located in Pio Albergo Trivulzio, a historic institution in the field of elderly assistance. These spaces, chosen for their representativeness or for the attractiveness of the location, are dedicated to the offer of social services, to the concrete meeting with the citizens and to the access to the home-based services provided by third sector bodies certified by the Municipality (Bricocoli, Sabatinelli, 2016).

WeMi SanGottardo is certainly the most emblematic case. As mentioned before, it is located in a former shop on a main commercial street located in an historic neighbourhood of the city, becoming increasingly attractive for students and young workers. Inside this space, the social cooperative BarAcca, dealing with the job reinsertion of people with mental disease, manages a literary café that coexists with the activity of the social services. Four social workers employed by different local cooperatives collaborate with a social assistant from the Municipality and with a junior academic researcher and manage the service four hours a day, in shifts.

The space of WeMi San_Gottardo was designed by the studio Consalez Rossi Associates Architects in order to emphasize the double identity of bar and welfare service, through the creation of two distinct but communicating spaces (Figure 2,3,4). The choice of this distribution derives from two different factors: from the one hand the social operators expressed the need of an intimate room for the weekly meeting of the team or for the private talks with the citizens; from the other, the urban planning rules required a distinct calculation of the square metres dedicated to the commercial activity and to the social services. In fact, the configuration of such hybrid space had no previous reference in the land use regulation of the city and required a very intensive work with the department for urban planning that resulted in a pioneering solution, creating a precedent for further experimentations in Milan and in other cities. Another purpose of the design was to make the double identity of the WeMi space visible from the outside: the double showcase facing the street (Figure 1), allows a wide but distinct view on both the bar and the welfare service. This aspect has been emphasized also by the contribution of the Department of Communication Design of Politecnico di Milano that is among the 16 partners of the project and that is responsible for the communication and the image of the project. Elementary geometries and bright colours were chosen to grasp the attention of who is passing through, while an interactive wall encourages the clients of the bar to deepen the knowledge of the project. These graphic tools are likewise repeated in all the WeMi spaces, even if adapting to their own physical features.

Figure 5 – Activities inside the space WeMi San Gottardo
Source: authors' archive, 2017

Figure 6 – Activities inside the space WeMi San Gottardo
Source: Authors' archive, 2017

The other two spaces are developed through the insertion of WeMi inside other already existent and consolidated realities. WeMi Capuana is located inside Spazio Agorà, a multifunctional centre active since the 90's in via Luigi Capuana, in Quarto Oggiaro (Municipio 8), a large neighbourhood characterized by a strong concentration of public housing and the presence of many fragile families. This space mostly provides services oriented to scholastic and parental support, with the help of the local cooperatives and associations and within the activities of Save the Children. Through the participation to WeMi, Agorà challenged itself in experimenting new ways of co-production and co-participation of services with those families who decide to shift from recipients to providers of the answers to their needs. Compared to WeMi San Gottardo, whose research of the location and design of the space required a strong process of concertation between the different actors of the project, WeMi Capuana is a reconfiguration of an already existent space. In particular, the project consisted in the redefinition of the reception desk and of the small adjacent office, with the purpose of making a more welcoming "first access". Similar considerations can be done for the third case, WeMi Trivulzio, located in the offices of the social cooperative Eureka. As in WeMi Capuana, the organization didn't provide a proper architectural project but a reorganization of the interiors and of the colours of an existing office.

3 A FIRST EXPERIMENTATION: CHALLENGES AND PERSPECTIVES

Even if it is premature to address the results and the outcomes of Welfare di Tutti on the long run, it is anyway relevant to underline some outstanding features of the project. As far as the process is concerned, the experience of cooperation and concertation between the municipality and the third sector bodies and other actors has been extraordinary, both in the creation of the online platform and in the design and definition of the new spaces of welfare. The governance asset in which the provision of services results from the action of a multitude of actors (public and private) led by the Municipality is made visible. While this overcomes the risk of pure externalization it also implies a proactive orientation of social services, that literally gained a showcase on the street, as a response to a diffused and consolidated reality

of inaccessible, unattractive and badly maintained offices. The WeMi spaces, in fact, are not only “showcases” for the homebased services but are developing into places of loose aggregation for citizens, where to express needs, set new relationships and create new solutions and services. The space in Corso San Gottardo, thanks to the presence of the bar and the strong influence of the managing social cooperative, has taken its first steps in this direction, becoming a major gathering point for most of the initiatives organized in the neighbourhood.

A beautiful, functional and welcoming space it's not only attractive for the citizens, that could reconsider the quality of the offer of public services, but also very meaningful for social workers, who are more willing to face the new challenges and to rethink their role and position in the community. Two are the main solicitations that seem relevant in perspective, with particular focus at the crossroads between welfare and urban planning policies: 1) the project has represented a precedent in the urban planning law, where the hybridization of the commercial and social uses have required a special agreement allowing further experimentations; 2) the Municipality of Milan is going to update and revise the Plan for Services (i.e. Piano dei Servizi) inside the more general local plan (Piano di Governo del Territorio). In the same period the procedures to develop the new Welfare Development Plan (i.e. Piano di Sviluppo del Welfare) would start. The experimentation of the WeMi project constitutes an important reference to challenge the possibility of integrating two different planning perspectives, until now operating in separate and dissociated ways. It is therefore evident that the extension and the possibility to repeat this innovative experience in the field of social policies is strictly bounded to the capacity of urban planning to receive and elaborate its solicitations, both to orient new policies based on diverse needs, and to provide the city with new and diverse places in which the local welfare is present and accessible.

4 ACKNOWLEDGEMENTS

We would like to thank the 16 different partners involved in the project Welfare di Tutti for their contribution in understanding how the innovation on local welfare is challenging the role and the competences of the urban planning project. In particular, we would like to thank the coordinator of the project Doc. Cosimo Palazzo, his staff in the Municipality of Milan and the colleagues of the Department of Design of the Politecnico di Milano, coordinated by Valeria Bucchetti.

ID 1545 | SOCIAL PERSPECTIVES OF URBAN REGENERATION ON NEIGHBOURHOOD-SCALE: THE CASE OF SPANISH QUARTERS IN NAPLES

Lorenzo De Vidovich¹

¹Milan Polytechnic

l.devidovich@gmail.com ; lorenzoraimondo.devidovich@polimi.it

1 INTRODUCTION

Social cohesion became a key issue for the European urban policies, supported by programmes aimed to the regeneration of deprived areas through a participatory approach (Fioretti, 2015). The social issue was definitely introduced into the debate about urban regeneration in the first half of 1990s, also because during the previous two decades, several urban areas across Europe experienced economic, social and environmental disadvantages (Wacquant, 2008; Cremaschi and Eckardt, 2011; et. al.). Within the urban regeneration policies and strategic planning cultural framework of the 1990s, «stakeholders involvements and civic participation in the public decision-making were often introduced by local governments as policy tools, through which to guide the urban transformation processes» (Saporito, 2016: 8). The trend was to convert participatory practices from episodic experiences to ordinary institutionalized practices in order to set up inclusive practices and collaborative tables among the complex network of stakeholders. Within this framework, the urban regeneration of those deprived urban areas looks at the social cohesion, in order to generate not only physical and urban transformations, but also to produce well-being, working on the improvement of local milieu and local resources, deterred by social exclusion processes that cross a vulnerable neighbourhood. The attention to the participatory and inclusive practices paved the way for a combined policy framework between urban renewal and social cohesion, where the urban regeneration process can be defined through an area-based approach focused on the social issues, looking at the local welfare system (Andreotti et. al, 2012; Bifulco, 2015), that can be developed in order to generate well-being. According to these assumptions, the paper grounds its reflection on the implementation of the well-known European Community Initiative called URBAN (1st edition, 1994-1999) in a particular vulnerable urban area of Naples: the Spanish Quarters (in Italy known as Quartieri Spagnoli). According to the focal points of the Programme, URBAN at Spanish Quarters was aimed to regenerate a particular deprived urban area, located in the historical city centre. Although URBAN did not generate the expected results, its main strengths, in line with a local welfare approach (based on the combination of place-based and people-based initiatives), provides findings for a social perspective of urban regeneration on the micro neighbourhood-scale. According to these assumptions, the paper looks for the answers to the following research questions: how can we look at the social aspects of the urban regeneration process in a deprived neighbourhood? How important is the role of local milieu in this regeneration process? How the urban planners can work to include citizens' in an urban regeneration process? In this respect, the case of URBAN implementation on Spanish Quarters in Naples – an experience concluded two decades ago – provides some indications. The theoretical framework is an analytical bridge between the capability approach (Sen, 1992) and the territorialisation of local welfare policies (Kazepov, 2009; Clarke, 2008; Bifulco, 2015, 2016, 2017). The third chapter introduces URBAN Community Initiative, and the rest of the

paper analyses its implementation at Spanish Quarters of Naples. The conclusions illustrate the main findings for further perspectives, which had already taken place in Napoli over the past decades.

The paper presents the outcomes of a qualitative fieldwork based on ethnographic observations and narrative interviews to some privileged actors involved in the Programme: professors Giovanni Laino, planner of URBAN at Naples, and Daniela Lepore, who contributed to the paper with an expert counsel, Immacolata Voltura, a local operator during the implementation of the Programme, and Daria Esposito, a social operator proficient in assistance programmes for NEETs. The paper does not evaluate the whole URBAN CI at European level, but it is more focused on the area-based planning on Spanish Quarters at Naples, analysed from a sociological viewpoint.

2 THEORETICAL FRAMEWORK

Following the participatory framework outlined during the 1990s, the 2014-2020 period of European policy-making has put the urban dimension at the centre of Cohesion Policy system, in an interwoven relationship with environmental, economic, cultural and social issues. A core point of the 2014-2020 agenda is the integration, seen as a keyword for the EU's Urban Agenda policies in order to cope with the urban deprivations and disadvantages emerged during the last three decades. It is not by chance that since the 1980s public policies in Europe have undergone «an increasing process of territorialisation, which has mainly concerned two intertwined phenomena: the territorial reorganization of public powers and the tendency to take the territory as the reference point for policies and interventions» (Bifulco, 2016: 628). The focus on the territory stimulated new approaches to tackle the high concentration of social, environmental and economic problems of certain urban areas. Since the first half of 1990s, European Union has started to promote communitarian initiatives dedicated to disadvantaged urban areas, «pursuing an integrated approach that takes account of all dimensions of urban life»¹, and looks at the regeneration of disadvantaged urban areas together with measures to combat social exclusion and to upgrade the quality of environments. A hybridization process has increasingly taken shape, and «in the 1990s and 2000s, policies to improve social cohesion and economic integration were complemented by physical restructuring and tenure conversion» (Uitermark, 2014: 1424).

This process is based on local welfare (Hall, 1993; Andreotti, et. al., 2012; Andreotti and Mingione, 2014; Bifulco, 2015, 2017; et. al.) and it implies «the discovery of the territory as a dynamic entity that is active and under construction» (Governa and Salone, 2004: 797), where to stimulate citizens' participation and inter-institutional relationships, working on the neighbourhood-scale of urban regeneration. This perspective takes into account citizens' needs, understanding and identifying the most critical problems that afflict a specific urban area, considering the voice² of its inhabitants. Hirschman (1970) identifies the voice-option as «a general outcry addressed to anybody willing to pay attention and listen to» (Hirschman, 1970: 13), trying to change the already existent practices. The voice-option is a dimension of the capabilities (Sen, 1992, et. al.) that activates citizens' agency, providing their positive freedom to choose. In the light of this paper the capability for voice (Sen, 1992, Bonvin and Farvaque, 2006) of inhabitants plays a role in the urban regeneration processes oriented to social inclusion. According to this perspective, the local welfare approach gives a fundamental role to the territory, seen as the best field to enhance the inhabitants' capabilities in the regeneration projects and processes. A local welfare system looks for the possible resources that can be activated for the renewal of an urban area within a combined empowerment of places and people. The core principle of this combination is that the policy for places must not be divided from those for people, but nevertheless, for several years these policy fields remained apart from each other, and the urban issue overwhelmed the social one (Donzelot, 2008). To overcome this distinction, the need of an integrated approach has arisen in order to promote «the action on the territorial scope as a leverage to rearrange what public policies treated separately in the past» (Bifulco and de Leonardi, 2006), assuming the urban areas as a resource and setting for the public action within an area-based perspective (Parkinson, 1998). This theoretical configuration between the capability approach and the territorialisation

¹ Source: http://ec.europa.eu/regional_policy/archive/urban2/urban/initiative/src/frame1.htm

² The term voice is used here in the Amartya Sen's perspective, as an instrument to carry out the positive freedom to choice and to do. Indeed, the capability for voice represents a fundamental key analytic of the local welfare approach (see Bifulco and Mozzana, 2011).

of welfare, introduces the case study which, where the importance of local actions and a strong relationship with the local milieu are enhanced. Before presenting the Neapolitan case, the paper introduces the analytical framework of the whole URBAN Community Initiative.

3 URBAN: AN OVERVIEW

URBAN Community Initiative (CI) was a European programme aimed to address «the economic, social and environmental disadvantage faced by neighbourhoods across the EU» (Carpenter, 2006: 2146). Two main assumptions influenced the Programme: on the one hand, the necessity to overcome both the housing growth and infrastructural policies, on the other hand, the intention to continue the successful urban requalification policies on neighbourhood-scale realised from the second half of 1980s, particularly in Central and Northern Europe. The initiative was destined to certain vulnerable urban areas where problems of poverty, unemployment and social exclusion were concentrated. The aim was to provide a spatial, social and economic revitalization of those areas through the involvement of local actors, on the one hand, and a learning-by-doing approach from the public administrations, on the other hand. The Programme was articulated in two editions (1994-1999; 2000-2006) and defined by five macro-objectives: (1) social cohesion, (2) economic competitiveness, (3) sustainable development, (4) promotion of equal opportunities and (5) integration of immigrants. The European Commission emphasized the role of the cities as territorial scope to set the social exclusion problems in a relationship with the urban renewal; 118 European cities were involved, of which sixteen Italians in the first edition and ten in the second one. A communitarian approach was designed «to address urban deprivation through an integrated approach to the problems faced by run-down neighbourhoods, using a partnership approach that involved local authorities and target communities to design and implement the programme» (Carpenter, 2006: 2148). Due to the heterogeneity of its objectives, the Programme was divided into five Objectives (Misura in Italian) (CEC, 1994):

1. Support of the already existent local businesses and encouragement for new activities
2. Promotion of employability among local populations
3. Support of new services and enhancement of those already existent
4. Urban spaces renovation and re-functioning of transport systems and accessibility
5. Involvement of local actors in communication and information about the on-going projects.

In the Italian context, the Programme was aimed to promote horizontal inter-institutional integration, and to overcome a sectorial and fragmented approach to the urban problems (Bricocoli, 2007) and «the interventions on the physical space was predominant» (Laino, 1999: 71). The first edition started an experimentation that yielded positive outcomes, both on the target areas and on the administrations that have rearranged themselves in an unprecedented ways (Palermo, in Balducci, 2001: 11). The contents of URBAN affected at the same time the physical city and the social city (Palermo, 2002). Moreover, the targeted areas – divided into four categories (see Table 1) – were different from one another, also in the Italian case¹.

Type of neighbourhood – URBAN I st Edition (1994-1999)	Number	Percentage %
<i>Peripheral urban area:</i> districts in the edge of urban areas, with public housing estates from 1960s to 1970s	44	37
<i>Inner city:</i> the core of the city, characterised by abandoned industrial buildings, dilapidated housing and a neglected environment	37	32
<i>Historical city centre:</i> areas with historical architecture and the potential to develop cultural heritage	23	19
<i>Mixed:</i> areas which combines the above characteristics	14	12
Total	118	100

Table 1 - Type of neighbourhood targeted by URBAN
Source: Carpenter (2006)

Although the inclusion of citizens was an important keyword of the programme, several experts (see Chorianopoulos, 2002; Carpenter, 2006) state that the community involvement was not

¹ Three main target-areas in Italy: Historical city centres (such as Spanish Quarters at Naples; Cosenza and Lecce), marginal peripheries (Syracuse, Reggio Calabria and Cagliari), and industrial areas in crisis (such as Genoa and Venice).

completely realised. The heterogeneity of the local contexts together with the stringent European guidelines affected the Programme, creating a conflict with the need of an error-friendly approach, i.e. the ability to re-arrange a re-define the practices during the planning activity (see Laino, 1999).

About the financing, a total of 900 million euros of EU investment was allocated, although European Commission has spent only 720 million euros by June 2003. The expenditure was divided as follows: 38% for physical and environmental regeneration, 32% for entrepreneurship activities, 23% for the social inclusion projects, 6% to technical and IT assistance, and 2% for «other types of initiatives», strictly related to the particularities of each city (Carpenter, 2006). About Naples, the European URBAN Commission identified two areas: Rione Sanità and Spanish Quarters.

4 CASE STUDY: URBAN AT SPANISH QUARTERS, A QUALITATIVE EXPOST EVALUATION

4.1 THE SPANISH QUARTERS AREA

Spanish Quarters (SQ) is a district located in a sloping area between Via Toledo and the hill of Certosa di San Martino, in Naples' historical centre. Its urban structure is «a dense gridiron founded during the Spanish domination (15th century) [...] unaltered over the centuries» (Lieto, 2013: 148). Figure 1 - Identification and boundaries of Spanish Quarters.

Legend. Blue area: historical Spanish Quarters; Orange area: large Spanish Quarters area.
Source: author's construction with Open street map based on REVES data (2015).

Traditionally, «SQ is the area bounded by via Toledo to the east, Augusteo-Ponzano axis to the south, corso Vittorio Emanuele to the western side, and the axis Saint Pasquale-Concezione a Montecalvario, to the north» (REVES, 2015; see the blue area in Figure 1). Some of the local actors of the third sector identify a wider area with similar cultural identities from Chiaia at South to Montesanto at North (see the orange area in Figure 1). The area has 14.000 inhabitants. Viceroy Don Pedro from Toledo built the area in 1536, during a period of demographic increase.

Since their birth, Spanish Quarters has been considered an enclave separated from the rest of the city, despite its central position. Therefore, the area remained isolated from the urban dynamics and exposed to the criminal organisations. Since 20th century the neighbourhood has turned into a front door of Naples for heterogeneous social classes, from middle-classes to immigrants until new bourgeoisie (see Laino, 2001, 2012)¹.

¹ Spanish Quarters populations (Laino, 2001, 2012): eduardiani (simple middle class in rented accommodation), vivariani (vulnerable families exposed to poverty and social exclusion), low-middle working class (usually public servants), new immigrants (not only foreigners), and new bourgeoisie (the latest, new owners of renovated apartments).

The area is characterized by an historical handcraft tradition: a report done in 2008 (S.I.Re.Na) catalogued 209 basements (bassi), of which 76 used for craft activities and 82 for commercial activities. Previously, in 1998, an Infocamere census counted 350 craft activities. This means that services sector substituted handcraft activities over the past years (see REVES, 2015). Since 1980s Spanish Quarters became a laboratory of continuous planning between several uncertainties, due to three main features (Pirozzi and Rossi-Doria, 2010): social exclusion and poverty of some families, high presence of early school leaving, and the political instability of public institutions.

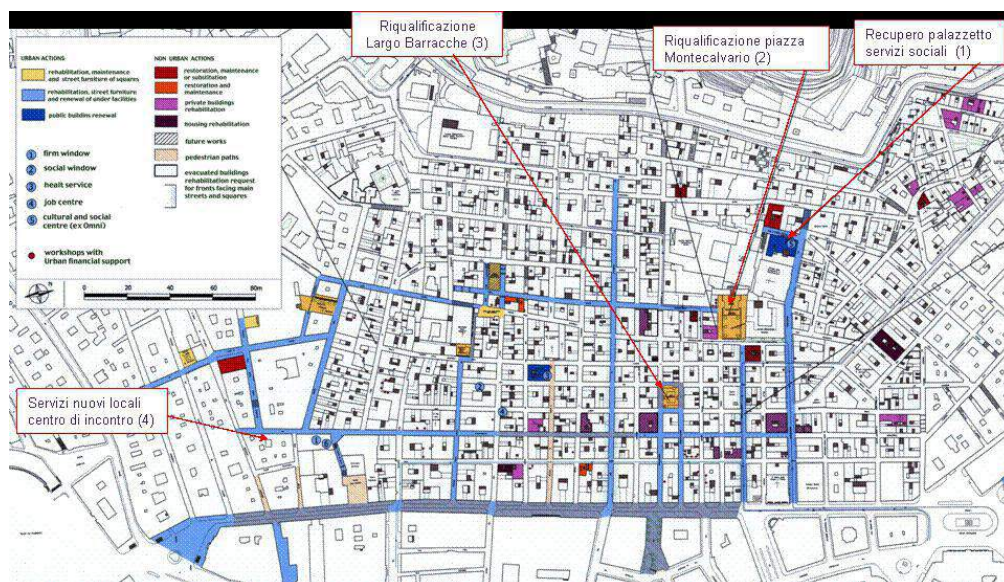

Figure 2 - URBAN implementation at Spanish Quarters.
Legend: 1. Palazzetto URBAN; 2. Regeneration of piazza Montecalvario; 3. Regeneration of Largo Barracche; 4. New social services centre. Source: Laino (2012), REVES (2015)

During the 1990s the area turned into a construction site for place-based policies sustained by the Europeanization, during a phase of progressive local welfare, which represented the peak of a policy cycle not reproduced in the following years (Giovanni Laino, Interview, 20 October 2015). URBAN was an element of that important planning phase, it proposed some important spatial renewal to the area (see Figure 2), and produced heterogeneous outcomes.

4.2 URBAN AT SPANISH QUARTERS

URBAN CI at Naples was planned for the encouragement of local small-scale craft activities and the promotion of educational initiatives as area-based socio-health services, taking care the inhabitants' participation through a double-binded pathway: one related to social dimension, the other oriented to the regeneration of open public spaces (see Laino, 2012). On SQ, URBAN was influenced by Regie di Quartiere (Laino, 2002, 2012): a group of associations which act as local agency¹, promoting partnerships among municipalities, public housing operators and inhabitants' associations, and characterised by a strong territorial connotation and a pluralistic approach to the local economy. Here, the URBAN planning was much closer to the social policy field, in order to build relationships among local actors and public administrations. Indeed, the organisational structure was flexible and semi-informal (Lepore, 2002), whereas an intense partnership was designed as a guarantee of effectiveness, regarding the Measures 1 and 2 (support to local craft activities), and as a chance of empowerment, concerning the social activities of the fifth Measure (ibidem). Table 2 finds the main features of URBAN implementation at SQ (for a more detailed overview, see Lepore, 2002; REVES, 2015).

¹ Bonvin and Rosenstein, 2012 define the local agency as organisations that work for the inclusion and the activation of local population's *capability for voice*.

URBAN – SPANISH QUARTERS	
Programme	URBAN CI (I) 1994-1999
Sources of funding	Naples Municipality through EU funds
Financing	€ 693.214
Period of activity	1997-2001
Responsible of the implementation	Naples Municipality; delegation to the Alderman of social policy
Other stakeholders	Spanish Quarters Associations
Objectives 1-2: socio-economic	Support to local activities – support to education, formation, local employment, social services
Objectives 3: infrastructures - environment	Renovation of buildings dedicated to social services; Urban renewal
Objectives 4 -5: <i>weak-willed</i> (Lepore, 2002)	Seminars for maintenance and safety; Implementation and spreading of outcomes among inhabitants

Table 2 - Info about URBAN at Spanish Quarters of Naples
Source: author's construction based on REVES data (2015)

At SQ, URBAN paid more attention to the enhancement of the existing resources, «seen as ties with logical and formal rules repeatable or further improved through a good design» (Lepore, 2002: 156). The improvement of endogenous resources of the area was an idea by Professor Giovanni Laino, the planner of the Neapolitan URBAN experience:

The planner – Giovanni Laino – stimulated an intelligent thinking to the simple project of gentrification to attract trivial craft activities on the pretext of spreading new local enterprises, as happened in Cosenza or Salerno. However, in these two cities, the historical city centres have been emptied. On the contrary, here at SQ the idea was not to import craftsmen, but to reinforce the existing economies. Thus, through this idea the Objective 1 brought the best outcomes. (Daniela Lepore, Interview, 18 November 2015)

Despite the numerous initiatives and projects implemented by URBAN at SQ (see Figure 2, paragraph 4.1) only the first two Objectives brought the expected result, according to a locally based process. The support of local craft activities began in 1996 with a detailed research-action task aimed to an empirical census of local productive activities. Doctor Immacolata Voltura – who worked for the data-collection tasks – explained this census activity to me in an interview. Four local operators, two from SQ and two from Rione Sanità, three economists and an architect, composed the multidisciplinary team set up for the census, also to foster the integration between heterogeneous fields. The SQ area has been empirically examined street by street, with the aim to offer a complete overview of the economic situation, even reporting those activities which were not present in the Infocamere lists (provided by the Camera di Commercio), used as a preliminary document. Once concluded the empirical on-field census, planners promoted the renewal of craft workplaces through a call for financial aid and a contract notice for craftsmen. Meanwhile, a safety problem emerged in the area: the conformity with regulation 46/1990¹ obliged the provision of a new lighting rig to the streets of SQ that lead to via Toledo. Therefore, the need to secure the workplaces has prompted the former Alderman for Dignity – Maria Fortuna Incostante – to ask for the involvement of building supervisors and security experts in the renovation of craft activities. In this way, the renewal of workplaces was accompanied by an empirical evaluation of working conditions and security standards. Within six months, 148 renovation projects were successfully approved² and then finalised thanks to the EU funding and the credit institution Artigianacassa, which provided money for those craftsmen who could not guarantee 10% of the total expenditure, as requested by the Programme's guidelines. Alongside this research-action census activity, an initiative called sportello-impresa was developed «to create relationships of trust between URBAN administrative structure and the potential recipients» (Lepore, 2002: 75). This street-level office has been a great device to facilitate the relationship between the URBAN operators and the local craftsmen in the renovation project:

At the beginning, there was scepticism between the citizens. Once we obtained the sportello-impresa, we achieved more credibility and the inhabitants' understood the

¹ L. 3 March 1990, n. 46: Norme per la sicurezza degli impianti (Standard for the safety of installations)

² Immacolata Voltura, Interview (18 November 2015), see also Lepore (2002)

importance of the Programme. We were present on the area as “co-active” operators. (Immacolata Voltura, Interview, 17 November 2015)

The Spanish Quarters Association (SQA), lead by Professor Giovanni Laino and Anna Stanco, played an important role in the implementation of the socio-economic Objectives (1 and 2), promoting local actions strongly rooted with the urban area, thanks to a strong network. The close connection with the local context, channelled by the sportelli-impresa, had a positive impact on the calls for financial aids, which were ad hoc drawn up for QS. Sportelli-impresa together with the job centre was the main strength of the socio-economic Measure 2.

The job centres were temporary desks to help the inhabitants to find small jobs or training activities. The implementation of these devices has been possible thanks to SQA and its relationship with the area and its inhabitants. The micro-scale of the implementation of Objective 1 (renovation of craft activities) and 2 (sportelli-impresa and job centres) made possible a renewal of the area from the labour market side. For Measure 1, the voice of craftsmen has been stimulated by the street-level census, and the recipients of the renewal acts played an active role. Nevertheless, the support-services developed by Objective 2 declined over time, turning into an interim experience that did not generate a long-term planning to maintain a local welfare system (see Andreotti et. al., 2012; Bifulco, 2015, 2016) in SQ area:

URBAN at Naples was only an interlude concluded without a continuation in the following years. The whole programme not stimulated the start of a new welfare phase. Today, the only local welfare structures in the area are those of SQA planning. (Daniela Lepore, Interview, 18 November 2015)

This comment enables to introduce the weaknesses of URBAN at SQ that shows the reasons why is possible to state a missed territorialisation process. The URBAN framework and guidelines were successfully applied for Objective 1 and – partially – Objective 2. However, Objective 3 (infrastructures and environment, i.e. urban renewal) and 4-5 (safety and citizens' participation) reveal a lack of locally based planning, thus the results are incomplete – in the case of Objective 3 – or even non-existent.

4.3 A MISSED TERRITORIALISATION

The main differences between the first Objectives and the others can be found in the governance field. The renewal of craft activities was supported by a well-structured policy-making, where the Municipality (thanks to the Alderman Maria Fortuna Incostante) and the planners (led by Giovanni Laino) worked together. On the contrary, for the Measure 3 (infrastructures and environment) proposed urban renewal interventions with non-linear governance (Lepore, 2002b). Almost twenty years later, the aims of an urban requalification oriented to «caring of places», have not been realised.

The case of ex-OMNI building is an example of this inefficiency. In 1997 Antonio Bassolino – the former mayor of Naples – glimpsed a more dynamic period for SQ, thus he decided to expand the URBAN planning adding Palazzetto URBAN at the ex-OMNI building, an abandoned kindergarten acquired with URBAN funds and then transformed into a multifunctional structure with aggregating duties and service to citizens. It was opened in 1998 and its utilisation has still constantly increased: from 13.546 accesses in 2006 to 21.474 in 2009 (Cherubino, Pierce, 2011, in REVES, 2015). 12.151 entrances during the first months of 2010 were encouraging. However, in June 2010, the municipality of Naples decided to change the current structure into an accommodation service for evacuated families due to building collapses, cleaning out the previous social service activity.

The closing of Palazzetto URBAN was a watershed. The Palazzetto had become a reference point of the area, but its transformation in an accommodation area for displaced families demonstrated the institutional lack of interest to maintain Palazzetto URBAN, because actually other spaces were available for that emergency. (Daria Esposito, Interview, 14 October 2015)

In the governance of Objective 3 the municipality started the planning of social service and then it began to take over more and more spaces where to place not so innovative services, such as the police headquarter or the health service desk, that were already

existing. Afterwards, it also transformed the Palazzetto URBAN, deleting an innovative and inclusive street-level service. Moreover, the Objectives 4 and 5, dedicated to social inclusion and citizens' participation, were not implemented at all. The attention on Naples was more on the other Objectives, but in Objective 3, for instance, a lot of money was not spent, hence some architects decided to include the pedestrianisation of via Toledo in URBAN planning. Actually, it was not a specific project for Spanish Quarters and it brought some traffic problems to the historical area, temporarily solved by a local bus. (Daniela Lepore, Interview, 18 November 2015)¹

The pedestrianisation of Via Toledo was an ex-post side project desired more by the Municipality rather than by inhabitants. «It was planned with a loophole to bypass the spending efforts and underline the hidden aspects of the Programme» (Lepore, 2002b: 164), but in practice it overlapped the communitarian approach of URBAN with simple restyling aims. The more visible urban renewal project also had unexpected results. A demonstration is the renovation of Largo Barracche, an area previously dedicated to illegal traffics.

At the beginning, URBAN proposed the placement of a soccer field, but the consultation with inhabitants opted for a playground area dedicated to kids. Just one year after the requalification, the area returned to a state of abandonment (see Figure 3).

The renewal of Largo Barracche has gone wrong. Once the playground was built, the area has been damaged; the bench were burned due to unknown reasons, but I suppose it has something to do with organized crime. For the basement located under the square, a community centre with inclusive duties was designed, but it has never been realised. (Daniela Lepore, Interview, 18 November 2015)

Figure 3. Evolution of Largo Barracche: before, 1 month after and 1 year after URBAN.
Source: kind concession by Professor Daniela Lepore

Today, Largo Barracche comes as a square without any service, facilities or community centres (see Figure 4). The playground has never been renovated and the basement is empty since 2011. A significant European Programme did not completely develop an area-based planning due to a weak relationship with the local milieu in the governance of urban renewal projects, and the significant experience of Palazzetto URBAN was not reproduced elsewhere in SQ area. A territorialisation process did not completely take place.

Figure 4. Largo Barracche, October 2015. Source: author's photo

¹ For further details about the side-project of via Toledo, see Lepore (2002c), Approfondimento. Il Progetto sponda Via Toledo, in L'attivazione e l'uso dei progetti sponda a Napoli

Piazza Montecalvario, unlike Largo Barracche, has been completely transformed. During the 1980s, the square was used as a car-parking area without any criteria, then repaved and pedestrianized through URBAN. Shortly after, the square was vandalized, and a requalification project was completed in 2013 thanks to the opening of a subway exit (stop Toledo), which gave a new face to one of the biggest square of Spanish Quarters. Moreover, Istituto Paisiello, the most important educational institute of the area, is located there, and it was the recipient of a PON 2007-2013, financed by European Social Funds. However, after this important renewal, Largo Montecalvario has not changed (see Figure 5). Overall, the implementation of URBAN at SQ was focused on a normalization of the area (Lepore, 2002), aimed to reconstruct the urban open spaces, to turn abandoned buildings into areas for social scopes, and to renovate public facilities (street lighting, traffic signs and public transports). However, in a framework characterized by both integration and Europeanization of the local practices, URBAN at SQ did not affect¹ the territorialisation process. A complete integration of social and urban issues within the local rescaling of welfare policies did not take place, except for those projects developed with the help of Spanish Quarters Association.

Figure 5. Largo Montecalvario, October 2015. Source: author's photo

URBAN at Spanish Quarters did not bring the expected results and twenty years later it can be identified as an important European planning disappeared into a simply useful but uneven requalification. The important opportunity of activating a new kind of planning influenced by URBAN practices was not exploited. The success of Measure 1 was due to a great understanding of specific characters of SQ area, made possible by the network of relationship built by SQA during several years, since the 1970s. In the European URBAN framework, Spanish Quarters Association has been able to catch its important economic resources, put into practice the URBAN guidelines where was possible. SQA played an important role in stimulating the participation of local-level groups in the implementation of the Programme. Indeed, «the inclusion of local authorities in partnership mechanisms with economic and social bodies as an essential was viewed as essential for tackling urban deprivation» (CEC, 1998: 6). This inclusive relationship was built just for the renovation of craft activities, but more generally, the regeneration of the area has been more urban than social, hence the combined regeneration of place and people did not happen, providing only short-term effects. The absence of long-term effects is due to the inability of local administrations to pursue an area-based planning and to learn from the approach proposed by URBAN. In Naples, as stated by professor Lepore, a new phase of integrated policy did not begin, and when the former mayor Antonio Bassolino moved to Regional government, followed by Alderman Maria Fortuna Incostante, a gap in Naples municipality was not filled, and the local welfare remained a weak topic in the urban agenda of the Municipality.

A territorialisation of social policies has partially taken place with URBAN CI. If we look at an integrated approach to the local areas, this happened in Naples on a small-scale. The Objective 1 triggered some labour activities reinvigorating their productivity. Today, new pathways for local approaches on local scale should be proposed by the

¹ PON 2007-2013 was a National Programme to renovate school buildings, financed through ESF (European Social Funds) and the European Regional Development Fund. A second 2014-2020 phase is established.

governmental institutions, but this has never happened, and SQA has been left alone in the local welfare planning for SQ. (Immacolata Voltura, Interview, 17 November 2015)

SQA is still the main local agency of the area, it launched an area-based social planning long time before URBAN, juggling among several uncertainties, due to three contextual factors: (1) the extent of premature social exclusion of NEET, (2) the absence of a vocational way out from compulsory education, and (3) the unreliability of local institutional administrations, unable to consolidate the existing good practices over time (Pirozzi and Rossi Doria, 2010). This pluralistic approach for urban regeneration implies «a research-action process [...] of designing and implementation of social spaces for regeneration, that can take years to occur, in a pathway not free of setbacks and re-definitions» (Laino, 1999: 79). This process did not precede the implementation of URBAN at Naples, except for Measure 1. Although the Programme was based on partnership principle (CEC, 1999), at Naples it put into practice a downgrading of local resources due to «an opposition to recognize and strengthen the already existing local actors» (Lepore, 2002: 164). This lack of local engagement was observed also for other URBAN implementations (see Carpenter, 2006: 2155).

5 CONCLUSION

The specificities of URBAN CI at SQ outline a framework where the territorialisation of local welfare was just partially developed, and the principles that drove the Programme were not fully applied, except for Objective 1, where the voice of craftsmen has been included in planning activity. This last part of the paper aims to identify the social perspectives of urban regeneration, in the light of the theoretical framework and the analysis of URBAN experience at SQ. The outcomes of the renovation of craft activities provide us a recommendation: to strengthen the social inclusion of inhabitants in planning projects designed to their neighbourhood, the role of a local agency which manages the relationship between the local milieu and the institutional programme is fundamental. In the governance of a programme like URBAN, focused on social cohesion within urban regeneration, local actors determine the effectiveness of the results. The lack experienced by Objectives 3, 4 and 5 shows that the focus on social cohesion is weak if not sustained by a strong knowledge of the specificities of each local context. As we saw for the renovation of Largo Barracche and Piazza Montecalvario, a European Programme is able to develop a top-down planning, even if it is focused on a communitarian approach. The rigidity of timeline and guideline of URBAN has met with the peculiarities of SQ, affecting the bottom-up aims. Therefore, it is important to look at the urban regeneration of deprived areas with a less naïve conceptualization. «Frequently, there is a research-action phase, characterized by the dissemination of opportunities, the ideation and implementation of requalification of social spaces, in a process that can take a long time, not without risks and possible mistakes» (Laino, 1999: 79). Except for Objective 1, this kind of process did not take place at the Neapolitan URBAN and the experts noticed «an opposition to acknowledge the existent local networks» (Lepore, 2002: 164), therefore the importance of social aspects was particularly limited. What was missed in URBAN at SQ was a shared definition of the main general aims and constraints. On the contrary, the governance of the programme preferred to work towards procedures instead of towards aims, i.e. without a more flexible policy-making adapted to the particularities of the neighbourhood. This approach, for instance, took place in the transformation of Largo Barracche, where the voice of some inhabitants pushed for the construction of a playground instead of a soccer field. Unfortunately, the following planning did not proceed on the same way.

The theoretical framework of the paper identifies the territorialisation of welfare (see Kazepov, 2009; Bifulco, 2015, 2017; et al.) as the best field for area-based initiatives where to include the capability for voice (Sen, 1992) of inhabitants, but this frame has to be supported by a practice of adaptation to the local context, characterized by two features: on one hand, it needs a dancer planner, i.e. a «professional requirement for designing and planning urban regeneration among different re-elaborations, experimentations, negotiations and redefinition of the problems» (Laino, 1999: 96), opened to error-friendly practices and able to keep the attention more on the objectives of the programme than on the procedures of the planning activities. On the other hand, the adaptation on neighbourhoods' peculiarities needs a reflective practice (Schön, 1993) to cope with the agency of the inhabitants, that is not a precondition but the outcome of a training path which takes into account all the environmental characteristics of the area, the spoken communications of the inhabitants (Pirozzi and Rossi-Doria, 2010) and the local milieu where to stimulate capabilities in a pluralistic planning framework. Not by chance, «the participation of local-level interest-groups in all the phases of the programme» (CEC, 1998, in Chorianopoulos, 2002: 714), was a key

novel aspect of URBAN, viewed as essential «for tackling urban deprivation and promoting economic competitiveness» (ibidem). At SQ, the only Objective 1 and 2 experienced this approach, whereas the other Objectives were not enough focused on the local-level groups, indeed, the urban deprivation has been tackled just with physical projects that ended with the conclusion of URBAN. A reflexive practice was not developed for the entire URBAN, and the local administration did not reproduce the potentialities of the Programme in other subsequent initiatives. On the contrary, SQA (Spanish Quarter Association) has been able to develop a reflexive practice in the regeneration process of SQ, thanks to strong ties between its planner Giovanni Laino and the local milieu of SQ. It is not by chance that since late 1970s SQA produced several innovative projects aimed to strengthen the endogenous resources of SQ's inhabitants. This NGO association acts as a local agency for the co-production of social policies «taking into account local expertise and knowledge, as well as local circumstances [...] promoting a reflexive and situated view of public action» (Bonvin, Rosenstein, 2012: 75). Local agencies here are identified as important devices to promote a kind of planning like that proposed for URBAN.

The main weaknesses of URBAN implementation at SQ, i.e. a missed territorialisation of welfare which only produced a physical restructuring on the one hand, and the lack of a learning-by-doing approach in a reflexive way, on the other hand, fits with the limitations noticed also for the whole URBAN planning at European level. Indeed, the importance of more precise conceptualisation of urban governance differences in the EU policy-making process became increasingly apparent (Chorianopulos, 2002). URBAN at Naples confirms that area-based approach is useful policy tool to cope with urban deprivation, when applied in city policy framework that work in the same direction and aimed to concretely generate social inclusion and social cohesion through an on-going process. Area-based policies need support from local administrations and a deep knowledge of urban deprivations, to be most effective. This support and this knowledge were more in the hand of Spanish Quarters Association instead of Naples Municipality.

URBAN has contributed to demonstrating how is possible to create the conditions to improve wellbeing in deprived urban areas through an area-based planning. But it appears that the key to tackling deep-rooted disadvantage in urban neighbourhoods lies in complementary macro policies that address the structural causes of poverty and disadvantage. It is through a combination of macro and micro policies that those facing deprivation in Europe's most disadvantaged neighbourhoods have the greatest chance of moving out of poverty (Carpenter, 2006). Atkinson (2000), in the same way, argues that area-based initiatives need a support by wider policies (on the economy, employment, social protection)—in other words, place-based policies need to be integrated with people-based policies.

In Spanish Quarters, URBAN has been a significant European Programme that brought physical improvement to the area, but it yielded concrete outcomes only for the Objective 1, where Spanish Quarters Association played an important role for the social cohesion aims. In addition, the local administration did not plan other initiatives or projects based on URBAN framework. SQA continued, sometimes alone, the planning activity to deal with urban deprivation of SQ through participative processes aimed to social cohesion. Its long experience (see Laino, 2012, 2015) paved the way for new projects of social innovation within SQ area, developed from the third sector. The social perspectives of urban regeneration define an integrated approach between the physical renovations and the in-depth relationship with local environment, on one hand, and between European and local administration on the other hand, for a well-structured participatory governance, where the local institutions are informed about the patterns of deprivation of the fragile areas. Without these forms of integration, social cohesion and participation remain simple assumptions just added in the urban regeneration discourse, but not developed in planning activity.

ID 1587 | LEVELS AND SCOPE OF PARTICIPATED PROJECTS: CASE STUDIES IN THE PORTUGUESE CONTEXT

Pedro Mendes¹; Susana Gaivoto²

¹ISCTE-IUL; ²A3Astudio

pm.arq@pm.mail.pt ; info@a3studio.com

ABSTRACT: In Portugal, there has been a growing concern, in recent years, about the participation of citizens in architectural and political decisions. The ineffectiveness of the traditional processes of participation of the democratic system proves incapable of responding to the contemporary problems of the citizens. In parallel it has been seen in recent years the deepening of the economic and financial crisis of 2007/2008, which, in Portugal, led to a sharp rise in the levels of unemployment in the architecture market. The lack of commissioning of building projects and plans, that had previously generated work, led to new concepts and approaches in particular in newly formed architects. On the one hand, there have been numerous collectives of architects motivated by issues related to political intervention and dynamics of social and territorial innovation. On the other hand, political decision-makers implemented new participatory instruments to support decision, such as Orçamento Participativo (Participatory Budget). This program has been implemented widely among municipalities in Portugal. Citizens' participation in project decisions is a recurring theme in the 1960s and 1970s, which reappears with a new configuration at the beginning of the XXI century. These days are marked by years of economic crisis and the universe of facilitated circulation of information in a wide network system accessed by a large number of citizens. However, some questions arise concerning the levels and scope of participation. Since a conventional project involves a certain level of involvement of decision-makers, architects and users (Carlo, 2010), two questions arise: how can we now achieve a higher level of participation and involvement of stakeholders (citizens, Architects, policy-makers) in the project? How can we achieve a real bottom-up procedure, in which context problems find the best formal solution (Alexander, 1964), during a process implemented in most cases by groups of architects outside the community of citizens for whom they work? Starting from a reflection on SAAL, a housing program promoted by the Central Government in the post-revolution period of April 1974, research is carried out through the assessment of the participation level (Arnstein, 1969) of referred participated

projects. From a different typology, two Municipal programs with relevance at regional scale - OP Cascais and BIP ZIP Lisbon - are analyzed. The study of two exploratory case studies - Casa do Vapor (Almada, Portugal) and "Building Together" (Guimarães, Portugal) - and an investigatory proposal - "City Mosaic Collective" project (Mendes et al., 2017a) – complete the selection. "City Mosaic Collective", which I am a founder member, aims to achieve a higher level of participation, "Partnership" (Arnstein, 1969). The research points to conclude that even for the cases studied that do not reach the highest level of participation (partnership), the initiatives reveal valid potential for their evolution.

KEYWORDS: Participated project; Partnership; Cova do Vapor; Building Together; City Mosaic Collective.

1 INTRODUCTION

The recent financial crisis has underlined the failures of a system of intervention in the public spaces dependent on political power and public investment (Bourdin, 2011). In recent years Portugal witnessed a general reduction in resources available for public works. Following a government commissioned demand, University do Minho conducted a study about municipal investment reduction. The level of municipal investment dropped 74% from 2001 to 2014. During this period the largest investment fall occurred before the Portuguese adjustment program of the troika. Between 2010 and 2014 the lowering of investments situated on 39%, but in absolute terms the reduction was sharper in previous years, starting at the beginning of the decade (Esteves, 2015). The aftereffect repercussions of divestment rely on the lack of commissioning of building projects and plans, which had previously generated work. This situation has led to a sharp rise in unemployment in the area of architectural design. In consequence the largest group most affected demonstrates great availability to explore new paths related to the universe of architecture. New concepts and approaches arise, in particular in newly formed architects. Numerous collectives of architects motivated by issues related to political intervention and dynamics of social and territorial innovation.

The reduction on the available budget has direct repercussions in promoting public works and maintenance of the public space. This fact leads to situations of stagnation and degradation of environmental quality of public space. On the other hand we are witnessing a growing civic consciousness about the limitations of local government capacity to respond to the needs and problems that arise in day-to-day citizen life. This awareness is associated with the economic crisis and the dissociation between citizens and the political power. The difficulties of communication and interaction between citizens and political power are accentuated by the ineffectiveness of planning instruments set. At the basis of this problem there is a representation deficit. Citizens do not identify with their decision-makers and decision-makers are unable to establish effective means of sharing or communicating their decisions. From the holistic design of the map that connects the economic situation and their consequences, the instituted political power, stakeholders, the citizen and the architectural designers, several questions arise about a recent growing participation phenomenon: We face a wide and complex range of issues. In order to focus, this paper investigates on how to achieve a higher level of participation and involvement of stakeholders (citizens, Architects, policy-makers) in the project and how to reach a real bottom-up procedure, in which context problems find the best formal solution (Alexander, 1964). To reach this goal the approach is made analyzing three types of programs involved in participative projects: First SAAL, a program promoted by the Central Government national wide scale. Secondly two municipal programs with relevance at regional scale (OP Cascais and BIP ZIP Lisbon). Thirdly two small scale implemented initiatives (Cova do Vapor and Building Together) and an investigatory proposal (City Mosaic Collective) that aims a higher level of participation.

2. AUTHORITARIAN METHODOLOGY

Before addressing the analysis of case study, it is relevant to go through the methodological process commonly used for the realization of an architectural, in the universe of public entities. We face a participated process, characterized by a reduced participation level, with a reduced variety of agents. This methodology is classified, according to Giancarlo de Carlo, as authoritarian (Carlo, 2010). Design process is defined through different phases of development and implementation of an architectural project. The architectural project is understood, in this article, through a wide scope of view. Urban and built elements, the city structure and its buildings are inseparable universes and part of the whole which is the

city (Rossi, 1977). "An Architecture of the Participation". is the article title of Giancarlo de Carlo (Perspecta: Yale Journal, in 1980). The article approaches the different phases and procedures of project methodology. In a simple and clear perspective the project methodology is addressed on the distinction between an authoritarian planning and a participative approach. According to Carlo (2010), the project methodology is defined in three main phases. The first phase is focused on the problem definition. The second corresponds to the development of the project, and the third relates to the evaluation of results.

The authoritarian methodology is characterized by a rigid sequence of the different phases. The articulation between the different stages is reduced and at the end of the second phase (design) the project is mostly completed. This type of approach is commonly used in the development of architectural projects. It is characterized by being carried out in separate phases in which the results of each phase little interfere with each other. On the other hand the design process is highly centralized in the design phase of the project. The designer, the political power and their technicians assume the central role and monopolize the decision process. This way aesthetic and use issues are taken for granted and imposed to a wider group of citizens. In a certain way the users and the use associated to the project end up having a reduced influence on the final result (Carlo, 2010). It is a level 3 (Informing) of tokenism (Arnstein, 1969). Citizens are just informed of the result. The decision-making is kept in the sphere of the political power and the designers. It is an authoritarian approach, centered on the design process of the project, focusing on policy-makers (Carlo, 2010) and designers.

It is now relevant to detail each stage of the authoritarian methodology. The problem definition phase starts with the order of the project and the subsequent data collection about the context (Alexander, 1977). At this stage the proceedings fall into an intuitive and non-systematic approach of gathering information. The selection of data and the definition of problems is strongly centered on the designer and policy makers' options. The defined goals are taken for granted and the possibility of an expanded discussion with the users is excluded. The issue subject to be discussed is centered on the costs of the operation, technique and aesthetics aspects. The prospect of future users is rarely considered or subjugated to the interests of political power or the designer's idea.

The stage of project design development runs since the presentation of the first intervention proposals to the conclusion of the project construction. Throughout this period the project is regarded as an absolute entity that responds to the principles set out by the designer (technician) and the public developer. The scope for changes is scarce. In case of inadequacy minor changes are introduced or in extreme cases the solution can be rejected and replaced by another proposal. If the promoter accepts the project, the work will be executed and delivered to their users. Sometimes the users who will use the space are different from those that initiated the project process. However the project keeps unchanged. The users have a small share of influence in the drafting of the project and in the final solution to be built. The knowledge potential of all the involved actors in the process is not fully explored.

The third phase focuses on the evaluation. Most often corresponds to a greatly neglected moment. The final work tends to be considered and evaluated exclusively from the aesthetic point of view. The subjective dimension overrides the rational and objective approach. The objective issues accessed focus mainly on financial aspects related to the cost of the work. The overvaluation of the aesthetic and financial components leads to a deterministic perspective. The process as an integrated whole is neglected. The end result is not the result of a broad outlook process, but rather an isolated case that responds to the will of political power and the designer intentions. This corresponds to Giancarlo di Carlo (2010) definition of authoritarian planning.

3. A PIONEER EXPERIENCE FROM THE SEVENTY'S - SAAL

Following the April 1974 revolution, the democratic regime faced the challenge to build a new social, economic and cultural structure. The heritage from the authoritarian regime registers a lack of housing of about 500 000 dwelling. In order to face this problem Nuno Portas, the Secretary of State for Housing and Urban Planning (Ministry of Social Equipment and the Environment, and of Internal Administration of the 1st Provisional Government) decided, in August 1974, to create SAAL - Serviço Ambulatório de Apoio Local (Ambulatory Support to Local Residents). The population target belongs to a social and cultural disqualified sector that inhabited in very precarious and poor conditions.

Before addressing the SAAL program a previous participated project experience has to be mentioned: the project to Associação de Inquilinos Lisbonense (Association of Tenants Lisbonense) led by the Atelier of Nuno Teotónio Pereira with Bartolomeu Costa Cabral. The architectural design developed, from the mid-fifties, involved the participation of the future users. The operation of 100 dwellings developed typologies from T1 to T5. (Bandeirinha, 2007). In parallel, with the objective to replicate the experience, an exhibition was organized. The widespread event exhibited drawings, models and a prototype, in real size of one house. After the visit to the model house, the visitors were asked to fill an inquiry. The inquiry asked about the general impression about the house, as well as more specific issues concerning materials, spatial relations, compartment location, etc. The impact among the media and architects community was significant, but the results from the inquiry were not properly compiled. The character of SAAL pointed to the direct involvement of the future users in the search of solutions regarding the land, infrastructures, technical assistance and financing. The program basis considered the direct involvement of the users and their representatives on a process of deep engagement in planning, and construction of their neighborhood and houses. This process was shared with teams of architects and technicians, social workers, and students. During two years (1974 – 1976) 170 projects for over 2 259 houses were on process. This process involved 41 665 families (Conselho Nacional do SAAL, 1976).

SAAL objectives centered on the empowerment of citizens through the support of the government and technical skills of the involved technicians. We are on the higher levels of the “Ladder of citizen participation” (Arnstein, 1969) where decision and work have a shared relation (Wates, 2014). Although in October 1976 the new constitutional government ended the program, under the argument that self-organized teams and neighborhood representatives surpassed the limits of defined objectives of the program. Somehow the new government considered that SAAL was being used for political intervention and not for solving local house and neighborhood problems.

4. OP CASCAIS

Considering the municipality of Cascais where participative processes have been successfully implemented it turns out that the number of voting citizens for local elections has consecutively decreased from 2009 on. In the other direction the figures for abstention show an increase tendency (Pordata, 2015). Looking for solutions to fill the gap of citizen involvement in decisions about the planning of public spaces, local authorities launched initiatives such as the OP - Orçamento Participado (Participatory Budget). Referring to the case of the Municipality of Cascais, the focus is placed on the idea of strengthening the participation of citizens in the definition of budget priorities. The total budget available for the program is Eur 1,5 million/year to be applied in projects that do not exceed 300 000,00 euros. The case of OP Cascais, the number of presented proposals (from 2011 to 2015) totalizes 891. The winner projects are 65, selected with a total of 160 740 votes, that reach the investment of 11 000 620,00 euros (Cascais, 2015a). Implemented proposals embrace interventions on public space, schools and rehabilitation of buildings.

This instrument, which has been spread by various municipalities in Portugal (In Loco, 2017), aims to create a proximity scale and stimulate civic participation of citizen. It represents an attempt to overcome the problems of communication and involvement of citizen in local governance decisions. The process comprises a collection of proposals presented by citizens to a municipal working committee. The municipality multidisciplinary committee legitimates and selects the proposals to be submitted to popular vote. The voting process is held by mobile phone application, a large range access technology. Citizens are consulted on the solution to be implemented, but the development of the project rests under the domain of political power. We are facing what Arnstein (1969) classifies as tokenism. Citizens are heard and informed but do not have the power to ensure that their prospect will be fully answered. The level of participation is on the 3rd and 4th level, which corresponds to Informing and Consultation respectively. These levels of participation do not introduce significant changes on the status quo. The participatory process is focused on the consultation of the existing problems and informing of the selected proposals to be implemented. Still, development of architectural design decisions still under the control of the local authority. However the popular involvement on the Participatory Budget of Cascais is significant. In 2014 the number of voters for the project proposal selection reached 41 005 votes (Pincha, 2015). Looking at the 2013 municipal election (Cascais, 2015b) there were 65 546 voters of a total of 172 537 registered voters. Considering that the political coalition elected (PPD-PSD / CDS- PP) had 26 455 votes, there is a larger number of voters (plus 14 550) on the Participatory Budget process.

5 BIP ZIP CM LISBOA

Created by the municipality of Lisbon in 2011, Bip/Zip Lisboa (Lisboa, (2017a) is a public policy instrument and an outcome of the Local Housing Programme. This programme aims to recalibrate the public politics on housing, “not focussing only on municipal housing estate but to expand its scope to the whole city, especially in order to include vulnerable areas and neighbourhoods” (Lisboa, 2017b). - Final report PLH, March 2012). Once these vulnerable territories were identified, a map was created – Bip/Zip map - (Lisboa, 2017c). in which 67 territories in the city, with an estimated population of 141,126 residents, are pointed as Priority Intervention Zones and Priority Intervention Neighbourhoods. Each project developed for the improvement of these areas can be financed up to €50 000 and from a minimum of € 5000. In order to add a social dimension to the approach to these territories and to contribute to a wider territorial cohesion of the city, the Bip/Zip Programme supports strategies and actions specifically shaped for these territories. Projects must be local based, created by partnerships, which can bring together the local authority, citizen organizations, informal groups and other local-based stakeholders, which somehow relate to the territory and to its critical issues. This is a way of enhancing local resources and existing knowledge about critical situations, stimulating at the same time, new dynamics and a policy of greater proximity, with the aim of improving the habitability of these places.

The program takes place through a cycle of 7 phases: 1. Preparation; 2. Communication and Empowerment; 3. Application submission; 4. Application Approval; 5. Signature of the protocol; 6. Execution of projects; 7. Evaluation of the program (Lisboa, 2017d). Without exhaustive description of each phase, we will focus on some aspects, in order to describe the level of participation promoted by this programme:

- During phase 2, the programme is publicized and workshops are developed so that, in addition to training potential partners, their network for action increases in their territories.
- The application process includes the presentation of a diagnostic of the territory, a strategy for intervention and its activities, all prepared by the local partnership. In the diagnostic phase, prepared by the partnership and using its diverse knowledge of the territory, the more community elements are heard and engaged, the more valued the application can be.
- From here, the partnership develops a strategy that consists on a set of activities that respond to a greater and a few specific goals, within the themes already predefined by the program itself, for they are structuring for the main goal of territorial cohesion – the themes can go from improving the neighbourhood image, to inclusion and prevention and public space. Nevertheless, there is a considerable degree of freedom for the construction of the proposals.
- The selection of the winning applications is made by an external jury although takes into consideration the level of participation of the project.
- The funding is handed to the sponsoring entities that are part of the partnership; they manage it and materialize the projects in an independent way - although they have to submit reports.
- The evaluation of the application and subsequent monitoring consider several indicators that present the number of involved partners, the number of people in the community to whom the actions / interventions are intended.
- Whatever the amount attributed to each project, its sustainability must be guaranteed for a year or two depending on the amount attributed, ensuring that the dynamics created remain in the territory, as well as its materialization.

The first edition had 77 proposals, with a foreseen cost of 2,5 million euros, far above the available budget. For the 34 intervention territories, 33 projects, from 31 promoters and 53 partner organizations, were selected to complete 50 interventions, totalling 1,249,843.48 € (2011 and 1st quarter 2012. (Lisboa, 2017b) In 2016, 122 applicants were admitted, the requested amount was 5,248,564.00 € and a total of 1,606, 806 € was allocated to 42 selected projects. This involved 186 entities (52 promoters and 134 partners) that will promote about 250 interventions in 53 territories (Lisboa, 2017e).

From 2012 to 2016, a total of 591 applications were presented and 199 were supported. From parishes (local government) to civil society organizations, the bip/zip partnerships network has 528 partners. One can conclude that, in Bip/Zip it's a tool to impulse and activate action and partnerships. From the development of the application, to the signature of the protocol and to the implementation of the actions, although under a monitoring process, there is a great deal of autonomy in decision making and action by the partnership. There is also autonomy in managing the funding that goes directly to the partnership and it's predicted that its capacity for action goes beyond the time subject to funding.

If we consider the participation matrix of Nick Wates (2014), which evaluates the level of community involvement in the various phases of the project, we can say that despite being a programme promoted by the municipality and started jointly between local government and community, unleashes a process of great community control - self-help - in the remaining phases of planning, implementation and maintenance. One can conclude that this programme is designed to be on the higher levels of the “Ladder of citizen participation” (Arnstein, 1969).

6 CASA DO VAPOR / BUILDING TOGETHER

The two following case studies – Casa do Vapor and “Building Together” - integrate an initiative of Capital Europeia da Cultura - Guimarães 2012 (European Capital of Culture – Guimarães 2012). Both are characterized by their ephemeral character. Another common characteristic is their local micro scale type of intervention.

Curator's Lab was the kick off program for a sequence of experiments characterized by interventions in the field of art and architecture. The initiative integrated in Capital Europeia da Cultura - Guimarães 2012 (European Capital of Culture – Guimarães 2012), occurred at the disused ASA Factory, located 2 km away from Guimarães.

The transdisciplinary collective Ezyzt was invited to lead the public workshop “Building together”, a three weeks collective residency. Around 30 art and architecture students, along with others participants, were involved on the construction of the facilities for the residency: a shelter (with kitchen and sleeping areas), working, meeting and living areas combined with public social spaces. As for the dynamic element of the proposal, an auditorium was built using wood elements and constructive system. During the construction process local community was invited to participate. A survey to the population, some of them former workers from the factory, established the connection with the local community. Construir Juntos (Build Together) was the symbolic name given to the fanzine published by the Lab editorial. Its contents registered the process and the evolution of the project. Through this document the reuse potential and future dynamic of the ASA factory was enlarged. During the workshop the idea of reusing the wood elements of the auditorium configured a desire to be developed in a future collaborative project. (Braga, 2017). The reuse of the wood elements of the auditorium of the former ASA factory (“Building Together”) provided the material support for the project at Casa do Vapor. Another link to the previous project is the leading team - Ezyzt (Ezyzt, 2017)/Constructlab - and their foundational principles: concept and construction merge in specific site action. This approach stands as a contemporary alternative to the authoritarian methodology. Casa do Vapor (Steam house) is inserted at Cova do Vapor (Steam Cove), a small informal neighborhood located in the estuary of Tejo river, 20 km south of Lisbon. Its origins go back to the twenties of XX century, with a spontaneous small fisherman village. Due to its privileged location several threats to its existence occurred. The first in the forties, the second around the post-revolutionary period (after 1974) and the latest dating from 2002. The existing small village is mostly organized by 350 self-built houses occupied by around 200 inhabitants (Ramòs, 2013).

The enterprise is grounded on the analysis of the community expectations and it aims to respond with a material proposal to local needs. The intervention aspirations are based on social issues and points to create a gathering point between the local community and the exterior (Catarina Ferreira). The program implementation - artistic residency, surf school, a common kitchen, a concert venue, an open-air cinema – supported by Cova do Vapor Residents Association, was built around the idea of creating a centrality, where people can meet and develop leisure and cultural activities (Ramòs, 2013). Another significant fact allowed the project to be accomplished: the financial and legal support provided by the Almada Municipality. Casa do Vapor was built with the wood from the workshop at Guimarães Capital da Cultura: Construir Juntos. Although the organizing and financial process came mainly from outside the neighborhood, local community and local associations were involved. Most of the volunteers involved came from outside the community. Nevertheless some residents involvement occurred. In this case the level of participation is somewhere in between “informing” and a “partnership” (Arnstein, 1969) level.

Ended the time period of the legal permit for the construction, Casa do Vapor was dismantled and the existing public library installed at the facilities of Associação de Moradores da Cova do Vapor (AMCV)

7 CITY MOSAIC COLLECTIVE

Reacting to a liberal urbanism which has characterized the last three decades with a lack of place for a scientific approach, multiplication of actors and power holders, generating too complex, unclear and incomprehensible operations and languages (Bourdin, 2010). “City Mosaic Collective”, which I am a founder member, aims to establish an operative methodology to be implemented. This methodology responds to the current Portuguese context where economic resources are scarce. It aims to answer to local needs and contribute to citizen empowerment through participated projects of streets public space valorization (Fig.1). The process is to be triggered by local and dynamic citizens, associations, municipalities, companies, entrepreneurs, and other institutions. Through a collective architectural design project and IT it is possible to implicate design and IT experts, policy-makers, private and public interests on the support of meaningful social and participative process. Through this form of collaboration it is possible to achieve improvements in the better living on the streets and reach meaningful social changes (Manzini, 2015).

In contrast with the exposed conventional, authoritarian methodology of project, “City Mosaic Collective” (Mendes et al., 2017), proposes the overlap between a conventional architectural design methodology with a participatory process (Bourdin, 2011; Slocum, 2003) and IT knowledge. The intersection of these two components pretends to establish an operative methodology of intervention in the public space. It seeks to establish the foundations of simple and direct instruments to communicate and implement in specific cases. Issues such as programming, architectural design and implementation (Quaroni, 1977) apply and overlap to a bottom-up approach (Mendes et al., 2014). The proposed methodology develops a blend between a conventional architectural design methodology and a participatory process and IT knowledge. The proposed strategy is based on the conventional architectural design phases – analysis, architectural design proposal and implementation on building site - and tools – free-hand sketches, plans, sections, detail and axonometric drawings. The working methodology establishes a systematic perspective for each project. Each project is case-sensitive to a particular context, time and space scale.

Figure 1 – “City Mosaic Collective” methodology.

The project target aims to enhance community quality of participation along with the improvement of public space living. In parallel, individual and group civic awareness will be reinforced by City Mosaic Collective tool. The implementation process will be developed with a flexible pattern and will go through various steps (Fig 1). From the detecting and reporting of a challenge/problem, using a mobile phone or with direct contact, the data will be analyzed and organized through a Web site. Afterwards the solutions are developed with citizen, decision makers and stakeholders. Through a participated process, full of advances and setbacks (Alexander, 1964), the final solution will be implemented. All the agents will be involved in a dynamic and positive process (Mendes et al., 2017b).

8 CONCLUSIONS

With the exception of SAAL, the programs analyzed have been developed in the last 10 years. This is a relatively short period for a definitive evaluation to be made. However it is possible to draw some conclusions namely concerning the levels and scope of participation. The SAAL program was

developed during about two years. However, it is the proposal with a high degree of participation, between partnership and self-help (Wates, 2014). Despite its short duration, it is a national and international reference. The purpose of the program centered on the empowerment of citizens through the support of the government and technical skills of the involved technicians. Its implementation was decisive in the housing offer for disadvantaged populations. Due to the program scale the projects and construction did not stop with the end of the program. This led to future housing initiatives for disadvantaged classes being developed along with the completion of the works begun.

For the two municipal programs - OP Cascais and BIP ZIP Lisbon – we face different levels of participation. Concerning the OP Cascais, citizens are consulted on the solution to be implemented, but the development of the project rests under the domain of political power. Citizens are heard and informed but do not have the power to ensure that their prospect will be fully answered. The level of participation is on the 3rd and 4th level, which corresponds to “Informing” and “Consultation” respectively. The participatory process is focused on the consultation of the existing problems and informing of the selected proposals to be implemented. Still, development of architectural design decisions still under the control of the local authority.

We are facing what Arnstein (1969) classifies as tokenism and on the level of “Consultation”, according to Nick Wates (2014). On the other hand BIP/Zip can be placed on a higher level of participation, once it works as a facilitator tool to impulse and activate action and partnerships. From the development of the application, to the signature of the protocol and to the implementation of the actions, there is a great deal of autonomy in decision making and action by the partnership. There is also autonomy in managing the funding that goes directly to the partnership and it's predicted that its capacity for action goes beyond the time subject to funding. According to the participation matrix of Nick Wates (2014), which evaluates the level of community involvement in the various phases of the project, it is possible to allege that despite being a programme promoted by the municipality and started jointly between local government and community, unleashes a process of great community control - self-help - in the remaining phases of planning, implementation and maintenance. It is possible to conclude that this programme is designed to be on the higher levels of the “Ladder of citizen participation” (Arnstein, 1969).

“Building together” workshop should be placed on the specificity of the event. It was an ephemeral event, focused on the experimentation between art and architecture to intervene on an disused factory. The intervention involved a restricted number of direct participants, although the population was called to participate. In a straight sense the level of participation is not high, situated around tokenism Arnstein (1969) and “Information” Nick Wates (2014). Nevertheless the objective to draw the attention, of a local population, to the potential asset of the disused factory was accomplished.

Casa do Vapor is a case where most of the resources came mainly from outside the neighborhood. The majority of the work and decisions was done by volunteers from outside the community. Even though the local community and local associations were involved. In this case the level of participation is somewhere, in an ambiguous position, between “informing” and a “partnership” (Nick Wates (2014) (Arnstein, 1969) level.

City Mosaic Collective has also to be seen on its specificity as an investigatory methodology. It aims to enhance a high participation level, reaching the level of “partnership” (Nick Wates (2014) (Arnstein, 1969). Although it lacks confirmation with concrete processes and experiences. So far the collective has been struggling with difficulties in finding local structures of organized citizens. In the same direction has faced difficulties in financing proposals and implementations outside the systems of organized power. The complexity and effectiveness of design project of public spaces requires a high level of integration of disciplinary insights, stakeholders, political representatives and citizen perspectives combined and developed through time constraints and location conditions. Therefore, more effective decision support methodologies and programs, which are able to improve citizen participation on the construction of a better fit between the context and the designed form are needed.

The research points to conclude that even for the cases studied that do not reach the highest levels of participation (partnership), the initiatives reveal valid potential for their evolution.

ID 1628 | URBAN REGENERATION PROCESS AS AN ASSET TO RISE ACTIVE CITIZENSHIP: THE HUMAN CITIES EXPERIENCE WITH USING PHOTOSTORIES AS A TRIGGER

Matej Niksic¹; Biba Tominc¹; Nina Gorsic¹

¹Urban Planning Institute of the Republic of Slovenia

matej.niksic@uirs.si ; biba.tominc@uirs.si ; nina.gorsic@uirs.si

ABSTRACT: While the rapidly developing world is facing a rapid urban growth, these processes have been in a fullswing much earlier in the s. c. western world. Many of the western cities thus face a need for a redevelopmentand regeneration of the already aged-up urban quarters constructed in the periods of their fast growth. Typical examples are the modernist urban neighbourhoods built in the decades after WWII which offered newstandards of living when constructed, but need renewal and up-gradings to cope with the needs andexpectations of contemporary urban population that is much more individualised in its life-styles. The paperputs light on the new approach to participatory urban regeneration process that is developed around revealingresidents' perceptions of their living environments through crowdsourced analytical photography and attacheddescriptions. The approach was developed in Ljubljana, Slovenia, as an experimentation programme of theEuropean Human Cities project running from 2014-2018 in eleven European countries. The project aims toencourage and enable civil society across Europe to actively contribute to urban regeneration of livingenvironments in participatory way.

1 INTRODUCTION

Many European cities that grew very quickly after the second world war face a big need for urbanregeneration nowadays. This does not apply only to some historic parts of the cities or the abandoned industrialareas, but more and more also to the large housing estates that were built to accommodate new working forcein the times of post-war redevelopment of the cities in 1950-1970 period. In many parts of Europe these areasare in a big need for the improvement of the rise of material standard of living in order to be competitive andin line with the expectations of the contemporary urban dwellers. It seems that the advancement of technicalsolutions and development of smart technologies successfully addresses these issues.

However, as an urban anthropologist Lisa Redfield Peattie (1998) argued, for our happiness creativeactivity, empathy and other values of community are of equal or even bigger importance than material standardof living. Her knowledge is created through numerous peace actions about urban planning that seeks socialchange by including all interests and groups in the planning processes. This reminds of the importance to understand the community's experience with its living environments. In order to do so, revealing people'sperceptions of their living environments is essential (Sarason, 1974 and 1986, Chavis and Pretty, 1999).This can be partly addressed by research of the shared values that residents of urban environmentshave in common. Knowing these values is important for setting up common visions for the future of localenvironments. Once the collective values of a local community are identified they can backbone the bottomupaction plans of community improvements with the active participation and involvement of the inhabitants.Shared visions for future developments are especially important in the field of urban public spacesas these are the common spaces aimed to address the needs of people of all walks of life. The new approachesto participatory redesign of public space are in the focus of a European project Human Cities that is runningunder Creative Europe program in eleven cities from 2014 to 2018. Its main aim is to test new approaches tourban regeneration by participatory improvements. Project partners are

proposing and testing new tools to make participation in urban regeneration operational through public space (re)design.

One of the project teams is based in Ljubljana, the mid-sized city of about 280.000 inhabitants with a number of aged-up large scale housing estates that need comprehensive approach to urban renewal (City of Ljubljana, 2014; RRA LUR, 2013). The team is experimenting with the new approaches to reveal inhabitants' values in relation to their living environments. As one's perception of space is a subject to a constant change, revealing the values of the users of urban space proves to be a theoretical and practical challenge (Walter, 1988, Thwaites and Simkins, 2007). The following topics are highlighted in the research:

- How to reveal the common values of the local community related to their living environments?
- Shall established methodologies (interviewing, perceptual mapping, cognitive mapping, etc.) be upgraded/combined with new technologies and social networking media? What is the general usefulness and real value of information technologies and crowd sourcing in revealing people's attitudes towards their living environments?
- How to track changes in the value systems and how to integrate them in the urban regeneration process? What kind of urban design solutions are robust enough to stand the changing nature of value systems over time?
- Is a more and more atomized society an appropriate playground for linking the design of living environment to the value systems of its users? Does a growing individualization mean that the common denominators will get harder and harder to be identified?

These complex issues have been addressed in the Human Cities project in different ways. This paper will focus on one single approach that aims to develop an innovative tool based on the usage of the new technologies and applications in our daily lives. It is based on the new forms of communication used in contemporary society where photography and short texts play an important role. The next chapter dips into some selected theoretical approaches in this field.

2 THE IMAGE AND ITS CAPTION – THEORETICAL BACKGROUND

Photography is composed of images and descriptions which form semiotic codes. This forms a multimodal message where images and captions are in an interaction and develop their relation to form a sign. The interpretation of a sign depends on both the creator and the reader of a sign and is strongly culturally conditioned (Barthes, 1977, Kress and van Leeuwen, 2006). The goal of visual communication is not only the communication of the message but also the exchange of the meaning. Mitchell (2009) argues that the act of reading does not only refer to the reading of text, but also of everything that surrounds us, including the signs and phenomenon, therefore the receiver of the message can be called the reader.

When the image and the word meet in the multimodal message, the reading approach is different compared to the classical reading. The reader has to set up the meaning. This process depends on reader's experiences and knowledge, trust into the source of the message and the influence of social environment. Eco (1979) introduced a term »ideal reader« to stress that the reader is the one that concludes the process of passing (in this case artist's) message to the others – the reader is called ideal as he/she is awakened and aware of existence of numerous interpretations of the image.

The image and the word are included in a dynamic process, and represent two different ways of visual communication - non-verbal and verbal. A combination of both represents one of the most powerful communication strategies (Kress, 2004, Lester, 2006). The image is an effective way to transfer knowledge and information. The image attracts the eye of the reader and arouses his curiosity (Nikšič, 2008). Muhovič (1998) points out that the images facilitate the flow between empiricism and theory and increase flexibility when operating with the experience. Using imagery encourages the reader to think and communicate, and makes him motivated to take a different view. The advantage and communicative power of the image is in the fact that one can use it on a small area to display a large amount of information that would, if expressed in words, require much more space. The images show data at several levels, from a wide view to the fine detail. To decode the meaning of the image does not require knowledge of writing and understanding of language as it applies to the text, but requires knowledge of visual language and symbolism. The image can easily be detected, while decoding is less straightforward as it can lead to different interpretations, which is especially true for the images without captions.

Therefore, the image is often accompanied by the text in the form of captions. The reasons for this are varied. It could be that the image is very ambiguous and vague so its contents can not be clearly defined. The word can more accurately and clearly explain the content of the image. Captions are essential if we want to make the reader clearly understand the message. Sometimes it is enough to decode the image by a couple of words only, but even if few they are indispensable.

This intimate relationship between the image and the text was intensively explored by Barthes (1977) who argues that we rarely see the image without a caption, even if it is only for the subtitle that denotes very basic information such as time and location. For Barthes the importance of the image is always associated with text and depending on it as images on themselves are too polysemic and too open to different interpretations. In his opinion, we need words that determine the image of a definitive meaning. The text accompanying an image can assist in narrowing the wide spectrum of possible interpretations. To explore the city's image, it is important to note the work of Kevin Lynch too. His urban analytics contributed a methodological innovation that brings the senses a step closer in the understanding and enjoyment of a city. Lynch (1960) has pointed out that the view of the city, no matter how uneventful the city itself might be, represents a special pleasure. The dynamic parts of the city, especially its users, are just as important as are the built structures of the city. Lynch also believed in the ability and the power of the users of urban space to participate in shaping their living environments. He believed that perceptual studies can support and enrich the design of urban space.

3 REVEALING SHARED VALUES OF LOCAL RESIDENTS THROUGH PHOTOGRAPHY AND ADJOINING TEXT

To go beyond planning practices in the urban territories, the Human Cities partner cities are specifically enhancing unplanned activities within a frame of 13 shared values that have been identified by the project consortium as relevant. Table 1 lists them and indicates the definitions of these s.c. Human Cities Shared Values (HCSV) as they were revealed through the review of more than 170 civil initiatives reclaiming public spaces across Europe (see the Human Cities web archive for more information: <http://humancities.eu/casestudies/>).

Shared Value	Description
Empathy	The ability to understand and share the feelings of others, despite different backgrounds and life experiences. Empathy creates a bond between individuals that ends up becoming part of their shared identity.
Wellbeing	A state of feeling healthy and happy. It is a contribution to society through knowledge, culture, design, music, ecology, healthy food or the renovation of public spaces. The main goal of wellbeing is to improve living conditions so that people can achieve better physical and mental health.
Sustainability	Sustainability is about meeting the needs of today's population without compromising those of future generations. It includes environmental, social and economic aspects.
Intimacy	The possibility of feeling a sense of closeness with people, objects or places.
Conviviality	Live together, share ideas, activities, discussions... Create a common spirit, a sense of belonging, around which people can gather and find joy.
Mobility	The capacity to make citizens leave their private spaces and join the public one.
Accessibility	Being open to everyone and easily reachable. It has both geographic and social meaning.
Imagination	Mentally creating images, ideas, concepts, and the like. Imagination is the main provider of solutions to our daily problems, and of dreams for the society to come.
Leisure	Free time, away from the demands of work or duty, when one can rest, take ease, and enjoy hobbies or sports.
Aesthetics	A visual attribute aiming at beauty, creativity and innovation, which provides an identity to a place.
Sensoriality	The mobilisation of a person's senses, whether hearing, seeing, tasting, smelling or touching.
Solidarity	Solidarity is a unity of people sharing the same interests in order to help each other.
Respect	Respect is showing due regard to people's lives, opinions, wishes and rights. It implies there are no barriers or stereotypes that come between us.

Table 1 - Human Cities Shared Values

The relevancy and interpretations of these values from the side of the inhabitants were investigated through different activities and tools. One of them is newly developed tool called Photostory of our neighbourhood. In a broader sense this is a photo contest in a form of a participatory on-line album of photos and their captions which offers an insight into today's state of the art of living environments as seen and interpreted by the inhabitants themselves. The album is created by residents and visitors of urban neighbourhoods themselves and aims to reveal the neighbourhoods and their life through the eyes of all of us who live or occasionally spend time there. The tool has three main missions:

1. it invites residents to start observing and thinking of their local environments, their assets and problems, and thus become more conscious of the characteristics of the living space they inhabit
2. it reveals peoples' perceptions and interpretations of living environments to urban planners who often lack this layer of information and thus do not include it in regeneration strategies
3. in a long term, it aims to evoke inhabitants' readiness to take an active role in one or another form in participatory urban regeneration processes which take place in their living environments.

It is largely based on the public contribution of combined graphical materials and their captions. Any registered visitor to the web page can submit up to 10 photos with captions. After uploading the image and its caption to the web portal the author must also link it to the Human Cities shared values that seem appropriate to the image and its caption, as well as classify it into one of the pre-defined categories.

The categories were set up by the project team to remind the residents of some important aspects of common life in urban environments. They were described in a form of lead questions to awake one's thinking of the important aspects of life in an urban neighbourhood as shown in Figure 1.

Most pleasant place in my neighbourhood
We usually spend a major part of our time in our neighbourhood, therefore its arrangements importantly influence the quality of our life. Which are the spaces in the neighbourhood that I like, I find interesting and like to spend time in? What makes them pleasant? Activities and people that spend time there, street furniture, presence of natural elements, maybe the light and colours or details on surrounding buildings? Try to show the places of your neighbourhood that you find pleasant, and explain what makes them attractive, through the photo and its subtitle.
Professions in my neighbourhood
Good neighbourhoods are not merely sleeping spaces, but places where different activities and programs take place which cater the inhabitants of the neighbourhood and the city. The baker at the end of the street, the shop-seller in a local shop, the driver of a bus stopping in the neighbourhood, the local greens care-taker etc. are only few more visible professions which importantly contribute to the quality of life in a neighbourhood.
At the same time, there are many other professions which are more hidden to our eyes – people with different skills, abilities and knowledge. Present their activities through a photo and its subtitle.
My neighbour
Fast rhythm of life and new ways of communication supported by new communication technologies are changing and often weaken the contacts between people living in the same space. With the help of a photography and its subtitle catch moments showing that social beings inhabit neighbourhoods that despite changed ways of life still gather, support and help each other. Street play, chatting on a bench in a local park or ringing neighbour's door when running out of flour when baking biscuits are examples of activities that join people in a neighbourhood. Photos with subtitles in this category shall show that in vivid neighbourhoods

reside people, who make neighbours and not complete strangers to each other.
Borders of my neighbourhood
Until where reaches my neighbourhood? What is its border and what defines it? Is it physically, functionally or symbolically defined? Borders may sometimes be clear and exact, sometimes blurred and fluid. Getting to know the borders is welcome for someone to be able to overreach them. Or strengthen the distinctive identity of space within. Present the borders of your neighbourhood with a help of photography and its subtitle.
Shared values in my neighbourhood
Which are the shared values among inhabitants of my neighbourhood? Which ideals unite us as a community? How are they reflected in space? And can they be a basis for common action of inhabitants in the endeavours to improve the living conditions in a neighbourhood? The values are an immaterial category, nevertheless often reflected in the physical, real environment. In this category, we are collecting the photos which will show the state of the art of the neighbourhoods reflecting the values of their inhabitants.

Table 2: Five categories of Photostory of our neighbourhood.

Photostory is »written« by the residents themselves and thus reveals their own notions of their living environments, as well as their personal values in relation to these environments. This allows an insight into the values that are shared among local residents. These shared values can become an important step stone in preparing shared visions of urban regeneration and future development of local environments which would be adopted by residents and thus more likely implemented with their active participation and contribution.

The next chapter reports the results of the first launch of the Photostory of our neighbourhood in 2016, it mainly focuses on the shared values that were exposed during the contest. It explains how this kind of storytelling can be used in rising active citizenship in urban regeneration processes.

4 THE RESULTS OF FIRST LAUNCH OF PHOTOSTORY

The Photostory of our neighbourhood was launched in autumn 2016 and promoted via news channels of UIRS and affiliated partners, Museum of architecture and design (MAO) and local civil initiative Skupaj na ploščad! among others. It was a parallel activity to an exhibition held at MAO which presented the legacy of neighbourhoods built in socialist times. This exhibition represented a good momentum and opportunity to encourage the inhabitants to rethink the questions of planning, maintenance and quality of living in urban neighbourhoods.

The activity was organised as a competition. The main prize was the exhibition of the winning photos and their captions at the travelling Human Cities exhibition as well as print in a form of a postcard. To select the winners, the international jury was set up, which selected 5 winning photos in each category, so 25 altogether.

There were 172 entries received to the call (see some examples in Figures 1 -5). As 10 of them were submitted without all relevant information (caption or attached shared values), 162 entries were taken into account and analysed.

The analyses were approached from two different angles:

1. The most/least often indicated shared values no matter its position on the first, second or third place
2. The most/least often indicated shared values within the range (within the values that were named on the first place, second place etc.)

These analyses were done for all the materials that were submitted to the call. To compare the participants' and jury's point of view, the same analyses were then done once more for the 25 winning images and their captions.

The most often mentioned value (taking into account any ranking – first, second or third place) was wellbeing (60x) followed by leisure (48x) and then aesthetics (44x), conviviality (43x) and imagination (42x). The ranking of other categories was as follows: empathy (36x), intimacy (33x), sensoriality (33x), sustainability (32x), respect (30x), accessibility (25x), mobility (20x) and solidarity (10x).

When we look at the number of recalls within each of the five competition categories, the results are a bit different.

In the category Most pleasant place in my neighbourhood wellbeing (27x) and leisure (23x) were indicated most often, followed by aesthetics and sustainability (23x). The least often indicated values were mobility (1x), solidarity (2x) and accessibility (4x). In the category Professions in my neighbourhood, the most often indicated shared values were sustainability (9x), conviviality (8x) and respect (8x), while intimacy was indicated most rarely (2x). In the category My neighbour none of the shared values is standing out, they have all been indicated more or less for the same number of times. Solidarity was the only shared value that did not get any vote. In the category Borders of my neighbourhood two most often indicated shared values were aesthetics (18x) and sensoriality (17x). Solidarity was again the least often mentioned value (1x). While in the category Shared values leisure (15x) and wellbeing (12x) were indicated most often, and the least often aesthetics (1x), sensoriality (2x) and solidarity (4x).

When taking into account the importance of each value to the participant (first, second or third place on the list of three values that describe the submitted photo best), it gets clear that in all categories well-being is the strongest one (53x), followed by empathy (35x) and sustainability (25x). Four shared values have never been indicated as most important ones (never named at the first place): leisure, respect, sensoriality and solidarity. The values most often named at the second place are conviviality (27x), aesthetics (18x) and imagination (17x). While at the third-place leisure (36x), respect (30x) and sensoriality (26x).

To make a comparison we did the same analyses for the 25 winning photos chosen by a jury. The strongest value (taking into account any ranking – first, second or third place) was conviviality (13x), followed by leisure (9x), while solidarity ended up last (1x).

Once more, when we look at the number of recalls within each of the five competition categories, the results are a bit different.

In the category Most pleasant place in my neighbourhood most often accessibility, intimacy, conviviality and leisure were indicated (all of them 3x). In the category Professions in my neighbourhood, the most often indicated shared values were wellbeing, conviviality and respect (all of them 3x). In the category My neighbour mobility is stepping out (6x). In the category Borders of my neighbourhood the most often indicated shared values were wellbeing (3x), followed by intimacy, sustainability, accessibility and imagination (2x). While in the category Shared values conviviality was most often (4x).

When taking into account the importance of each value to the participant (first, second or third place on the list of three values that describe the submitted photo best), the jury's results differ from the participants'.

In all categories wellbeing is the strongest one (9x), followed by sustainability and conviviality (5x). The value most often named at the second place is conviviality (8x), while at the third-place leisure (7x). These two values (most often named at the second and third place) coincide with the original indications from the participants.

Figure 1 – Photo submitted to category The nicest place of my neighbourhood by Urška Podgrajšek: In a small corner at the edge of the neighbourhood there is a secret place, where the whole community gathers, from mothers with babies to competitive youths, and grandmothers who observe their growing grandchildren with an unseen pride. (attached shared values: conviviality, imagination, leisure)

Figure 2 - Photo submitted to category Professions in my neighbourhood by Lea Piškur: A small centre for the elderly was opened in our neighbourhood not so long ago, meant for socializing, exercise and other activities. The lady in the photo has just been sweeping autumn leaves in front of the entrance. (attached shared values: wellbeing, leisure, respect)

Figure 3 - Photo submitted to category My neighbour by Maruša Račić: Balcony tales, 2015 (attached shared values: conviviality, imagination, aesthetics)

Figure 4 – Photo submitted to category Borders of my neighbourhood by Tisa Neža Herlec: The border of my city is the horizon, when I exceed this - the sky becomes the limit. (attached shared values: wellbeing, accessibility, imagination)

Figure 5 - Photo submitted to category Shared values of my neighbourhood by Tisa Neža Herlec: With my childhood friend, we are but shadows, just memories in the neighbourhood where we were growing up. We return sometimes and recall our memories. (attached shared values: conviviality, imagination, leisure)

5. PHOTOSTORY AS A TOOL TO ENCOURAGE PARTICIPATION IN URBAN REGENERATION

The urban renewal process has to be undertaken in a participatory way nowadays, therefore theregeneration strategies shall be built around the values shared by local inhabitants and different stakeholders, such as NGOs, and local businesses. There is a need to reflect on the distinctive social and cultural values expressed in public space, resulting in the finding that place attachments and identification with places are differently experienced and encountered by individuals. The main obstacle is being the neoliberal drift that, by spreading individual and strictly private interests, is excluding instances of more vulnerable and disadvantaged groups.

The good respond to the call Photostory of our neighbourhood within Human Cities experimentation indicates that residents are ready to contribute to the urban regeneration processes in new, previously not seen ways. The approach following the new social media repertoire of sharing graphic materials and short textual descriptions seems an approach that residents can embrace. Urban planning professions shall build on such good examples and develop new well-structured tools to encourage truly participatory involvement of local residents and their notions in regeneration processes. Such tools must not stay at the level of commonly spread social media practices, but shall be adjusted to the numerous and specific demands in the complex process of urban regeneration within planning system. At the same time they have to stay simple and straightforward to use in order not to discourage the potential users.

One question that stays open is the integration of data gathered in these new innovative ways into the existing planning procedures. As the cities are getting more dynamic, the traditional master plans are getting less appropriate to manage the (re)urbanisation processes and must be upgraded with new tools. However, even if some new tools and approaches are already existing, their integration in the official planning procedures is lagging behind and this issue must be addressed more thoroughly in the future.

The Human Cities experiment with a Photostory also shows how subjective the spatial perception is and how it changes through times and reflects the spirit of the current social reality. The 2016 experiment revealed that values such as well-being, leisure, aesthetics and conviviality are currently the ones that are most strongly shared among local residents, while some others, such as e. g. solidarity, that were much stressed in the previous socio-economic framework of socialism, are much lower on the ranking lists. These results remind the professionals that they shall not assume they can guess residents' notions about their living environments in any sense.

The Photostory also opened a number of completely new perspectives of positive aspects of living in suburban neighbourhoods even if they are rather aged up. These new perspectives of the neighbourhoods cannot only help strengthening their identity and rise self-esteem of the residents, but also represent new opportunities to develop new niches in the local economy, e. g. in tourist sector by spreading the tourists' flows from central attractions to more hidden ones that would not be recognised without the expertise of local residents. This approach represents a new window of opportunities for less attractive areas in the cities that are usually losing in the global race for getting attention of potential visitors and investors.

1 INTRODUCTION

1.1 BACKGROUND

In the conditions of ever growing urbanization and continuous societal transformations as well as the increasing prominence of the sustainability agenda the issue of urban quality is subject to prior consideration worldwide (Brenner and Schmid, 2015). As acknowledged by Healey (1997), it is difficult to avoid the impact of economic restructuring on the landscape and social and economic life of many cities which were used to grow within certain economic structure and also supported by the state. In many post-socialist countries the issue is even more pressing due to existing urban decay as a result of major institutional transformations, economic crisis and political discrepancies. In particular, the collapse of the socialist system in these countries was followed by a number of economic, social and legal reforms, due to which the land and property ownership in most of the countries has been transferred from public to private sector. However, in most cases the state transferred to private hands not only the ownership to the property but also the problems related to the quality of that property as well as the responsibility for its further maintenance. The issue has a specific importance with regard to multi-unit housing since the latter occupies the largest share of urban fabric in many countries worldwide, and in majority of post-socialist countries in particular.

If considering that the most fundamental idea of sustainable development determined in the World Commission on Environment and Development (WCED) Report is “development which meets the needs of the present without compromising the ability of future generations to meet their own needs” (WCED 1987), yet, building deterioration will inevitably result in higher economic loss, more environmental waste and poorer social living conditions, in other words in decrease of urban quality.

Alterman (2010) claims that the issue regarding sustainable legal-financial mechanisms to ensure the long-term maintenance of condominium buildings has received very limited attention so far. She points out several factors that make multi-owned tower buildings particularly vulnerable to deterioration and decreased property values, e.g. that they are more complex and therefore create higher maintenance costs and less possibilities of structural modifications, which causes a greater risk for a diminished relative value and faster deterioration, that large investments are needed for large scale repair, upgrading and renovation, and that because the costs are not consistent over time makes it more difficult to find a mechanism for financing the long-term maintenance.

In many former socialist countries uncertainty in private and common ownership parts within residential urban space as well as imperfect management schemes resulted in gradual depreciation of common parts of apartment buildings and surrounding land, which has led to decline of urban quality.

Armenia presents certain specificity with this regard. Major transformations in the country took place mainly from the late 1980s and beginning of 1990s associated with the collapse of the soviet planned system and commence of movement towards capitalism.

This recent history of Armenia has its implication when considering the role that property management features might have on countering urban decline. In particular, due to immature institutional framework as well as lack of property management schemes and limited public resources, the first decade after the collapse of the soviet system in the country can be characterized by an underdeveloped real estate market and a rapid deterioration of the urban neighbourhoods, including housing and other property.

As a result of privatization almost all real estate property belonging to the state both in urban and rural areas was transferred into private ownership of the users/dwellers¹. With regard to apartment buildings the residents of apartments became owners thereof; however, the right to common property within the apartment buildings as well as to the land attached to the buildings remained uncontrolled due to lack of supportive legislation. The uncertainty between public-private ownership rights had its negative impact on most of the urban neighbourhoods throughout the territory of Armenia, and especially in Yerevan. In many cases the common use properties in the urban neighbourhoods, including within apartment buildings have been left to their own fate and were subject to volunteer intervention by the residents. Also, due to imperfect regulation of management and maintenance of apartment buildings and lack of urban and property management in practice the buildings started to deteriorate rapidly thus lowering the quality of urban space.

Notwithstanding the appearance of neoliberal movement in urban development of Yerevan, as well as a number of state-supported projects on management and maintenance of apartment buildings, the quality of urban space has been suffering intensively and continuously up to now. Hence the declining quality of urban space in Yerevan can be represented in two main directions: 1) low quality and unplanned new developments mostly in the centre of the city paralleled with 2) lack of maintenance and management of existing housing and real property stock, inherited from the Soviet period.

The methodology that is proposed within the framework of on-going research project envisages the development of tools through using collaborative management schemes in order to enhance citizen (residents) participation and integration of private investments in urban renewal projects, in particular regarding residential and mixed-use urban spaces, thus minimizing the share of public funding. In this paper the authors will discuss one of such approaches, which is the condominium management, as well as the prerequisites for successful application of such approaches, namely the enhancement of value-added by the project to each participant.

In the conditions of scarce public resources the promotion of private property-based investment projects may become a sound solution in regenerating urban residential spaces and in overcoming urban decay. Such projects shall become successful if applying a collaborative approach through public-private partnership models where the enhancement of value added to the project shall serve as a main tool.

Thus the current paper will discuss the role of “value-added” and “participatory approach” in improving the quality of urban space and illustrate it through a case study analysis.

1.2 AIM AND METHOD

The aim of the current discussion is to disseminate the observations achieved while conducting research on the theme “Property-based urban management models and urban decay in post-socialist transitional societies”. For the purpose of discussion, the urban space is composed of private and public space within boundaries that correspond to a specific problem-area; the urban space is envisaged as mixed-use, though at this stage we have in mind mostly the residential use. The quality of urban space is explored through selected literature review with the aim of finding an adequate list of indicators for the purpose of the research (Annex 1). The participatory approach we intend to explore for the improvement of the quality of urban residential space is based on the idea of management of common property and so we resort to the discussion of the condominium management approach as a settled example of common property management. The land attached to apartment buildings is included in the common property to be managed since the former is taken as an indelible part of the latter. The pivot-concept for launching the participatory approach is the value-added to property by the urban renewal project for the defined urban space. A purposeful concept of value-added is therefore introduced, based on theoretical discussion and

¹ In fact, 96% of the republic's housing stock was privatized by 2000 (HfH Armenia, 2010).

illustrated through a case-study based on an analytical approach. The data used for the calculations is provided by stakeholders acting in the urban development field in Armenia as well as collected through several surveys previously conducted in the field. The aim of the case study presentation is more illustrative at the current stage rather than comprehensive and is subject to further elaboration within the framework of the on-going research project.

2 THEORETICAL FRAMEWORK

2.1 QUALITY OF URBAN RESIDENTIAL SPACE

Historically, in British planning debate the discussion of the impacts of development has been closely linked to the question of betterment, or in other words to the improvement of urban quality (Healey et al. 1995).

If considering the quality of urban space with regard to urban design and architectural issues the definition of the concept is provided through more specific features within the framework of the Bristol Accord. Among these features are included: (1) “Sense of place – a place with a positive ‘feeling’ for people and local distinctiveness” (2) “Appropriate size, scale, density, design and layout, including mixed-use development, that complement the distinctive local character of the community” (3) “High quality, mixed-use, durable, flexible and adaptable buildings, using materials which minimise negative environmental impacts”. The Commission for Architecture and Built Environment CABE (established in 1999 by the first mandate of Tony Blair’s Labour Government) has provided a broad range of publications to clarify what is meant by a Well Designed and Built city or project. The assessment tool used by the CABE is the Design Review, based on the principle that “Good design is fit for purpose, sustainable, efficient, coherent, flexible, responsive to context, good-looking and a clear expression of the requirements of the brief”. A valuable attempt has been made in UK to combine expert assessments with the opinions of stakeholders (end users, investors, developers, building managers, neighbourhood associations, etc.), which is the Design Quality Indicators (DQI) - “a method of evaluating the design and construction of new buildings and the refurbishment of existing buildings” (Borghi, 2010).

The concept of urban quality is differently explored by Insch and Florek (2008). The authors tried to illustrate the interrelation of the value, quality and expectations of residents with regard to place satisfaction. In their discussion on place satisfaction in the case of the city’s residents they claim on a direct link between the quality of life and the quality of place or environment where people live (Insch and Florek, 2008). According to the authors, research in the field of human ecology and sociology more closely examines the interactions of humans and their environments and in the case of cities focuses on the neighbourhood as a place to live. In addition, they state that from the aspects of psychology and marketing measures the neighbourhood satisfaction contains objective neighbourhood characteristics, such as level of urbanism (city, urban, suburban, and rural), socio-economic status, income, population density etc., and subjective mental constructions of the neighbourhood, including such qualities as social environment (neighbours), noise, traffic, neighbourhood maintenance, safety and security, convenience for shopping, etc. Through referencing La Gory (1985) the authors mention that subjective assessments of the physical and social context of the neighbourhood significantly influence their satisfaction, whereas objective contextual variables, related to satisfaction, showed little causal impact (Insch and Florek, 2008).

Some indicators of the quality of urban space are considered as an important factor also for attracting future investments. According to Sarău (2015), in order to be a strong competitor in attracting investments, a place must demonstrate convincingly that their city residents enjoy a higher level of well-being and satisfaction than the competitive places.

According to Insch and Florek (2008) when considering the urban space as the city itself or a larger compound of the city, important factors taken into account include the welfare and satisfaction, employment, infrastructure, transport network, education and learning and development opportunities. Therefore, achieving a high level of satisfaction of residents should be an objective of places. Furthermore, they argue that the ultimate goal of the places is not financial success but the welfare and satisfaction of their residents. The authors prove their argument by referencing Guhathakurta and Stimson (2007, cited by Insch and Florek, 2008) as: “after the decline in quality of life crosses a threshold, growth may slow down or even become negative”. This statement proves the very distinct relation of urbanism with the

economic growth of the country, thus proving the actuality of the selected research problem and the methods to approach it.

Song and Knaap (2007) offer a quantitative classification of neighbourhood type, through identifying relevant attributes of physical form and computing indicators of those attributes, such as street pattern, plot density, land-use mix, accessibility, transportation infrastructure and open spaces, based on parcel-level Geographic Information System (GIS) data. Factor analysis is then used to derive generalized dimensions of neighbourhood character based on the raw attribute data.

Quite a different approach to the quality of urban space is introduced by Cilliers et al. (2014), who argue again that the urban space is valuable due to people attached to it and that the old spaces which have story behind them and thus are characterized by their identity, can be much more valuable than the new developments. This idea supports the intention of the on-going research project to improve the urban space quality through redevelopment and through adding value to the urban space instead of complete demolition and rebuild.

2.2 CONDOMINIUM MANAGEMENT AS A PARTICIPATORY APPROACH IN IMPROVING URBAN SPACE QUALITY

The discussion of condominium-based management models shall be based on exploration of the concepts: 'condominium', 'common ownership' and 'management of apartment buildings'.

Condominium (apartment ownership) can be considered as a form of three-dimensional (3D) property right. It includes the use of a three-dimensionally delimited part of a building. Condominium is a common and wide-spread form of 3D property utilization and exists all over the world in e.g. Australia, Canada and South America (van der Merwe 1994; Paulsson 2007). Discussing an example of Vancouver, Harris (2011) reflects on the capacity of condominium as a certain form of residential property ownership and its contribution to the transformation of the urban landscape. According to Lippert and Steckle (2016) the inner governance of condominiums profoundly matters for understanding urban governance and life but has so far been neglected in urban studies.

There are two main forms of condominium, namely the condominium ownership type, or the dualistic form, and the condominium user right type, or the monistic form (Paulsson 2007). In the condominium ownership type each apartment owner owns the certain private space he or she occupies, and the common parts of the building and surrounding land usually are owned jointly by all the owners of the building. This type can be found, for example, in most of the former Soviet countries, including Armenia, and was recently also introduced in Sweden (Paulsson 2007; Paulsson 2013). The condominium user right, on the other hand, is a type where the apartment occupants jointly own the entire building and surrounding land together, including private and the common parts, but the share of the property each owner has, gives the right to occupy a specific private space in the building. This type exists, for instance, in the Netherlands (Paulsson 2007).

There are also more indirect forms of condominium where a legal person stands between the resident and the property as the formal owner (Nordisk Ministerråd 1997). The legal person could be e.g. a co-operative, an association or a limited company, such as a tenant-ownership form in Sweden (Lilleholt et al. 2002) or a limited company system for apartment ownership (also called stock cooperative or share-block scheme) in Finland (Falkenbach et al. (eds), 2009).

Within the condominium scheme each private owner has got a share of the common property of the building and surrounding land and other facilities that the private owners own or control in common. This share can be based on e.g. equality, relative size or relative value of each private space, or a combination of such. The ownership fraction can determine the responsibility each owner has for the costs of management of the building and association, as well as for maintaining and repairing the common parts of the property (Grigoryan, Paulsson, 2017).

The land that exists below and around the apartment building is usually included in the common property. This land becomes common property if the building is not surrounded by municipal or state land. In those cases easements are granted for the owners to use the land for access to their building, such as roads or

pavements (Rabenhorst 2001). However, in former socialist countries this may cause difficulties. When buildings and surrounding land went from public to private ownership, how much land to include was fixed to the “footprint” of the building, i.e. the land under it, which creates difficulties for the apartment owners as to getting a right to use the surrounding land. Solutions that are applied are to include the land just under the building, or including the land to one meter around the building as well, although it might still be unclear to whom the land beyond this belongs. Another solution has been to let the municipality keep the ownership of the land and to grant long term user rights to the association, by which the owners will be responsible for maintaining the land (Rabenhorst 2001). In Armenia, for instance, this type of solution was applied to the existing (inherited from Soviet period) privatized housing stock, (RA Government Decree No 1855-N dated 30.11.2006). If more than one condominium building would like to use the land between the buildings, the owners in these buildings will jointly have to decide how to use and manage this land.

When studying condominium internationally, there are several factors that seem to have created problems and that can be considered as important for creating a successful and lasting system for apartment ownership (Paulsson 2007). Thus, a factor that seems to create problems is management, which in general is important when dealing with individuals sharing the same resources (Ostrom 1990). A structured and efficient organisation for management is crucial for the commons and the community of owners to function properly, as well as for financial institutions with an interest in the property. This becomes more difficult when a large number of co-owners are involved, where there is also a need for enforcement mechanisms to promote cooperation and efforts from the co-owners (Tracht 2000).

The above discussed condominium management practices provide viable schemes for management and maintenance of common interest properties, and although used for management of common ownership within apartment buildings, they can successfully serve as basis for management of urban spaces within the city neighbourhoods.

2.3 VALUE-ADDED IN URBAN RENEWAL PROJECT

Based on conceptualization of the value by CABE (2006) provided below in Table 1, it is obvious that the benefits of identifying a linkage between better urban design and enhanced economic value, as well as social and environmental value, are potentially significant. The research conducted by Carmona et al. (2002) provides analysis of key stakeholders in urban design and their detailed views on the importance of a good urban design for the value added.

Based on this research, the authors state that the positive results which might flow from being able to demonstrate the positive effects of well-designed spaces are potentially large (Carmona et al., 2002). They further claim that through illustration of the value added as a result of better urban design, or assessing its costs and benefits, is part of the effort to link design quality to the decision-making logic of private sector development interests. From the other side there is a need to develop an understanding of how the public sector can modify the institutional incentives and barriers and the regulatory context in which decisions about design are made (Carmona et al., 2002, p.146).

Type of value	What does it mean?	How it is measured?
Exchange value	The building as a commodity to be traded, whose commercial value is measured by the price that the market is willing to pay. For the owner, this is the book value, for the developer the return on capital and profitability. Also covers issues such as ease of letting and disposability.	Book value Return on capital Rental Yield
Use value	Contribution of a building to organisational outcomes: productivity, profitability, competitiveness and repeat business, and arises from a working environment that is safe in use, that promotes staff health, well-being and job satisfaction, that encourages flexible working, teamwork and communication, and enhances recruitment and retention while reducing absenteeism.	Measures associated with occupant such as satisfaction, motivation, teamwork. Measures of productivity and profitability, such as healthcare recovery rates, retail footfall, educational exam results, occupant satisfaction.
Image value	Contribution of the development to corporate identity, prestige, vision and reputation, demonstrating commitment to design excellence or to innovation, to openness, or as part of a brand image.	Public relations opportunities Brand awareness and prestige The recognition and 'wow' factors.
Social value	Developments that make connections between people, creating or enhancing opportunities for positive social interaction, reinforcing social identity and civic pride, encouraging social inclusion and contributing towards to improved social health,	Place making Sense of community, civic pride and neighbourly behaviour Reduced crime and vandalism.
	prosperity, morale, goodwill, neighbourly behaviour, safety and security, while reducing vandalism and crime.	
Environmental value	The added value arising from a concern for intergenerational equity, the protection of biodiversity and the precautionary principle in relation to consumption of finite resources and climate change. The principles include adaptability and/or flexibility, robustness and low maintenance, and the application of a whole life cost approach. The immediate benefits are to local health and pollution.	Environmental impact Whole-life value Ecological footprint.
Cultural value	Culture makes us what we are. This is a measure of a development's contribution to the rich tapestry of a town or city, how it relates to its location and context, and also to broader patterns of historical development and a sense of place. Cultural value may include consideration of highly intangible issues like symbolism, inspiration and aesthetics.	Critical opinions and reviews Professional press coverage Lay press coverage.

Table 1. Types of property value (Source: Value handbook, CABE, 2006)

According to the case studies made by the authors in UK, it is obvious, that notwithstanding various barriers (certain commercial pressures, decisions that are often made by the bodies far removed from their impact on the ground), through demonstrating the positive, even if potential, return from the better urban design, the positive change in private investment as well as public institutional decisions shall emerge. In addition, a demonstration that better urban design adds value might provide a powerful incentive to overcome many of the barriers that together hold back a general improvement in urban quality (Carmona et al., 2002). However, it might be taken into account that at the same time other institutional, investment, social and cultural barriers still remain challenging and of course not all the stakeholders will change their approach and persuasions during rather long period.

Based on various motivations and perceptions of different stakeholders of urban design projects, Carmona et al. (2002) divided them into two main groups: with public interests and with private interests, provided that the community interests may relate to both groups (Table 2.).

According to a number of researchers, in this process the key concern is not with an absolute measurement of value but with the processes through which stakeholders change their perception of the value.

Based on six different case studies on requalification of urban spaces conducted in UK the authors claim that “indeed from the perspective of key stakeholders better urban design adds value and does so in economic, social and environmental terms. In addition, the results indicated that almost all stakeholders see for themselves the value added by the project. In particular, in case of everyday users, the latter benefit from the economic advantages of successful regeneration, including access to a better-quality environment and an enhanced range of amenities and facilities.

Stakeholders with private interests	Stakeholders with public interests
Landowners	Planning authorities
Funders (short-term)	Highways authorities
Developers	Fire and emergency services, police authorities
Design professionals	Building control
Investors (long-term)	
Management agents	
Occupiers	
Local communities	

Table 2. Main stakeholders of urban design project (Source: Carmona et al., 2002)

Based on the conducted analysis it can be also mentioned that it is not necessary to make huge investments in order to add value to the project. Instead, according to Carmona et al. (2002, p. 165) “...better urban design can then be used as an important sales pitch to differentiate products with modest, but fundamental, improvements in urban design, such as better external linkages, more ‘life-giving’ uses, and configuration of buildings to face public spaces”.

ILLUSTRATION OF THE VALUE ADDED IN THE URBAN DEVELOPMENT PROJECTS

Following the research focus we intend to suggest a model which, based on the power of the private ownership and collaborative management will improve the quality of urban space by adding value in both social and economic context. The social, cultural as well as environmental contexts of value and value added in urban development project have been reflected previously. Under this section we are going to highlight that the involvement of private owners in an urban area upgrading has to go through evidencing that a significant part of the net benefits of the intervention will be allocated to them. Thus the composition of enhanced economic value of the urban intervention project is going to be revealed hereunder. Based on valuation theorists the property shall have development potential once an element of latent value can be released by the expenditure of capital upon it (Ratcliffe et al. 2004). Generally this may arise through different types of intervention, including development of a plain site according to approved urban plan, or redevelopment through demolition and replacement of existing buildings or even through upgrading the quality of existing buildings and/or urban space. In other words the financially balanced nature of urban planning projects shall be explored through value added by the intervention. The calculation of the ex-ante value added is considered as an important instrument for various property-based approaches in urban management, namely the public-private partnerships (PPP), land readjustment schemes (like the “perequação” tool in Portugal) and even condominium-based management models. In this context the value added can be interpreted as planning gains, which principally differ from planning obligations, since the latter are non-negotiable compulsory contributions of real estate developer to the public domain required by the profile of the specific development business. Whereas the planning gains are the outcome of a voluntary negotiation between the public and private parties, through which a share of the developer’s normal business margin is given up in favor of the local community or private property owners.

It is quite important for the urban development project to potentially contain this share of added value, since it has to be the part of the global value derived from the urban development project that is not assigned to costs and to the minimum business margin the developer requires. This share or the so called “shareable value” is indeed the value added of the urban project. We must however acknowledge that the minimum business margin the developer might be willing to accept may not correspond to the normal business margin regarding his other previous real estate developments. This is the core concern for revision of the urban intervention project and negotiating on higher expected returns.

Thus the enhanced economic value of the urban project, including the “shareable value” will be possible to calculate through urban development valuation, whereas for the mentioned purpose the residual method

shall be applied (Ratcliffe et al. 2004). The conventional approach to a residual valuation is based upon the following simple equation:

$$\text{Gross development value} - (\text{costs} + \text{profit}) = \text{residual value}$$

The assumption is therefore that the value added is the difference between the expected value (i.e., some future value expectation but without knowing if, when and how that expectation would be fulfilled) and the “value of the set of properties included in the urban development project once the urban design is defined” (i.e., in their present condition but with the development potential settled). The expected value has to be discounted for time period and uncertainty (considering the discount rate). Thus, taking into consideration the above equation the value added in the urban intervention project will be determined as follows:

$EV - TC - FC - BM - RV$, whereas

EV - value of the properties generated by the settled urban design

TC - total costs required to achieve the urban layout that corresponds to the new properties

FC - financial costs

BM - developer's business margin

RV - value of the set of initial properties

These subtractions take place within the methodological framework that allows for the determination of the Net Present Value (NPV) and Internal Rate of Return (IRR).

The above presented theoretical approach will be applied to a previously selected residential urban space in one of the neighborhoods of Yerevan, Armenia and will be illustrated in the following section.

3 CASE STUDY OBJECT IN YEREVAN

A mixed-use urban space within an urban neighbourhood in Yerevan (Figure 1) shall serve as a sample for illustration of the improved quality of urban space and enhancement of value-added for the residents and project stakeholders.

Figure 1. Illustration of present plan of the urban space according to property types and ownership types (the scheme is developed by the authors based on data provided in www.e-cadastre.am)

Total area of case study object is 4.77 ha. Total area of private property (lots) in the case study object is 2.61 ha. The area can be described as a residential urban space in the big centre of Yerevan which includes:

- Single family houses (0.5 ha)
- Apartment blocks inherited from Soviet period (1.4 ha)
- Newly built apartment building of Post-Soviet period (0.1 ha)
- Construction site conserved for indefinite period (0.03 ha)
- Public road in a poor condition (0.72 ha)

The quality of urban space is low (based on indicators provided in the Annex 1), however the market value of the properties in the area is rather high (due to land value), thus potentially, the property owners of the area can be interested in improvement of urban space quality in the area. In order to substantiate the

potential increase in property value for the case study urban space, a newly developed area in close proximity to the case study object (however located in the land zone with less market value) occupied with mixed-use (residential-commercial) buildings has been analysed and compared with the case study object. Based on this analysis the main comparative qualities of the newly developed area include:

- Considerable share of public and green space within urban space (about 27%),
- Developed infrastructure, including roads,
- New and fresh look of the buildings,
- Existence of underground parking zone
- Well-organized management and maintenance of the urban space.

Considering these qualities the average market value of residential space in both areas vary as follows:

Case study object¹

- EUR 600/sq m (apartments in the buildings from Soviet period)
- EUR 800/sq m (apartments in the buildings from Post-Soviet period)

Comparative object²

- EUR 1150/sq m (apartments in the newly built multi-unit buildings)

Based on the comparative analysis the newly proposed urban plan aimed to improvement of the quality of urban space and increase of the value of properties for the case study object is illustrated below (Figure 2.):

Figure 2. Illustration of proposed plan of the urban space according to property types (the scheme is developed by the authors based on data provided in www.e-cadastre.am)

According to this plan and to data analysis, the value of existing properties will increase even in the case where only public space improvements and parking zone are implemented in the studied urban space. Thus, based on the calculations made according to the above stated formula of value-added, the value of the properties in the case study object will increase as follows:

- EUR 812/sq m for the apartments in the buildings from Soviet period
- EUR 1150/sq m (apartments in the buildings from Post-Soviet period)

Therefore, considering the total new value of existing properties (EUR 104,419,459) and by subtracting the discounted (8%) costs of property to be purchased for implementing new development (EUR 13,898,318) and the costs for land development³ (10,733,449) as well as the developer's margin, the value added by proposed urban renewal project is estimated about EUR 2,608,092.

However, it is worth mentioning that achievement of proposed quality improvement requires responsive and collaborative approach of residents of this urban space. Furthermore, in order to maintain the quality achieved by the proposed urban plan the case study urban space has to be duly managed and maintained which supposes additional constant expenses by residents. Thus sharing costs through condominium

¹ Source: www.akcern.am, www.cadastre.am

² Source: official inquiry by the authors from "ERAZ" residential complex

³ Official data provided by "Avetisyan Construction" developer company, www.avetisyanconstruction.am

management schemes could probably provide a quite effective solution for the raised issues thereby approaching the model of closed condominiums or gated communities.

4 CONCLUSION

While the above reflection on certain concepts was conducted within a wider framework, including various social, economic, environmental and cultural aspects, however it obviously proves the importance and requirement of consideration of the value added in each urban development project. Also, it may be definitely stated that, for successful improvement of urban space quality, the collaborative approach is required particularly with integration of residents and everyday users of the urban space.

The conducted survey proved that the concept of value added in each specific urban development project has an important role for all the project stakeholders, as well as for successful urban development at a larger scale. This statement facilitates much to use the value-added as a tool for implementation of urban regeneration projects through integration of and cooperation with various stakeholders.

Hence, further research proposed in the field of urban management with the focus on improvement of urban quality is aimed to enhance the role of value-added in urban regeneration projects mostly in residential areas. The allocation of value-added among property owners is proposed to be introduced through a land/property readjustment (“perequação” in Portugal) algorithm, which is assumed to be of use if it is adapted to the specificities of private property ownership, particularly through co-operation schemes once value enhancing features are evidenced to the property owners.

ANNEX 1

URBAN SPACE QUALITY INDICATORS

1. Monotype and non-degraded façade of the building, including:
 - Construction and exterior
 - Condition of balconies
 - Condition of windows
 - Condition of general entrance(s) of the building
2. Apartment buildings with proper roof and rainwater removal facilities
3. Public space provided for general socializing of residents, including playground for children, green space surrounding the building, corresponding to urban planning norms
4. Proper condition of internal road providing access to the main street or highway
5. Minimal distance from the nearest public transportation station
6. Proper lightening of the urban space
7. Proper and timely garbage removal
8. There is a territory adjacent to the building which corresponds to the urban planning norms for proper functioning of the building and its maintenance
9. Car parking established in proximity to residential buildings and corresponding to urban planning norms
10. Proper isolation of the half-built construction existing in the neighbourhood and the term of construction conservation

naggilafrota@gmail.com ; urbcla@gmail.com

1 INSURGENT CITIZENSHIP

The understanding of citizenship runs through the centuries and changes as civilizations change. Greeks and Romans of antiquity already questioned the relationship between State and Nation (Miraftab, 2012), shaping the bases for a structuring of what is now understood as Social Contract. This concept, created at the end of the seventeenth century, emerged in the period of transition from the medieval regime to the modern democratic regime, from the replacement of social control exercised by feudal kings and lords, by a society in which its citizens abdicate their individual freedoms in exchange for representation and equal treatment before the law. These new relations of the individual with society presuppose that the State grants and guarantees rights from the consensus of the Nation that makes it legitimate, in contrast, affiliated citizens agree with a set of duties and obligations (Miraftab, 2012).

The modern concept of citizenship encompasses the rights, expectations, and responsibilities associated with belonging to a political community framed by the Nation-State (Miraftab, 2012). The State is not able to guarantee the minimum rights to citizens in an unequal way, therefore, a differentiated treatment between citizens is perceived. The pressure on the part of the population that is more dependent on services and public policies provokes questions and increases the perception about the condition of citizens living on the margins of society, who are deprived of fundamental rights, such as housing, transport, education and health. This imbalance in the representation of different social groups makes evident the crisis in the modern model of citizenship.

To reinforce this point of view, Castells (2013) emphasizes that society is formed by power relations and those who have it build institutions according to their interests. It is only through counterpower that the excluded actors challenge the norm installed in the institutions of society with the intention of questioning their values. This claim contributes to the construction of a new model of citizenship, which Holston (2008) named as an insurgent citizenship based on the citizen as an active agent that creates new ways of achieving their rights that go against the practices of differentiated citizenship. Holston (2008) uses the term "differentiated" to describe Brazilian citizenship, in which citizens, even though they identify themselves as belonging to the same nation are not able to materialize their rights given current power relations. A process of manipulating the legal system is clearly expressed in the phrase "for friends, everything; for enemies, the law".

In this context, the potential of urban planning as a tool of spatial planning of the State that directly affects the daily life of society is highlighted. Planning can be and it is considered a mediator between the needs and demands of the various agents in contemporary cities. Souza (2013) highlights several typologies of traditional urban planning that have some characteristics in common, such as technocracy, the distance from reality and popular pseudo-participation. Thus, we understand that social participation strategies are innovative instruments in the face of the traditional planning methodology, insofar as it is admitted that the State serves diverse interests and elaborates a specific space for collective interests. However, these environments are rigid and limit popular participation to one-on-one consultations, making the previously established Social Contract fragile since many citizens do not have their rights guaranteed. Recognizing the limits of participation in the decision-making, it is necessary direct actions by citizens. Recognizing this limitation, Miraftab (2012) introduces the concepts of invited spaces and invented spaces. In this way the invented spaces become an unforeseen mechanism to reinforce the State's responsibility to comply with the Social Contract. The inefficiency of the invited spaces, represented by participatory planning, demonstrates that a parcel of society is not considered in decision-making process of city. It promotes the emergence of a new model of urban planning, which Miraftab (2012) named as urban insurgent planning. It highlights the following characteristics:

- Direct action undertaken by a marginalized group as opposed to an established order that does not favor collectivity;
- Creation of an autonomous and non-institutional space for discussion;
- Claims of specific interests and values that were not met by the state and by the hegemonic powers.

This new extent of urban planning has emerged in several countries in recent years through manifestations, occupations of public spaces and other forms of expression of the discontent of the population with the current order. Among the main examples are the occupation of Tahir Square in Tunisia and Occupy Wall Street in New York, the first being the pioneer and the trigger for the other demonstrations, and the second being the most representative in terms of questioning the neoliberal regime adopted by one of the greatest economic powers in the world. Understanding the influence of this worldwide movement, our objective here is to analyze an insurgent action that occurred in the Brazilian context from the point of view of its main characteristics, identifying the actors involved and the main current norm challenged, and its impact on institutions that have the power of decision. To this end, the Ocupe o Cocó movement was chosen because it was a manifestation that occurred simultaneously to the “Jornadas de Junho” in 2013 in Brazil. It constituted a camping on the place where some trees were cut within a protected area to give place to a road overpass. The camping was a measure of protection and visibility of the impact of the road work. The participants of this direct action of protest aimed at defending the community by demanding the protection of diffuse rights to environment and urban mobility. Initially a theoretical discussion about the construction of insurgent citizenship in Brazil will be made, using two movements as landmarks: (1) urban social movements of the re-democratization period that succeeded in the institutionalization of their demands through the approval of the federal bill name Estatuto da Cidade in 2001; and (2) the “Passe Livre” movement, whose influence exploded in June 2013 in a series of street protest in all major Brazilian cities that became known as “Jornadas de Junho”. Next, we turn to the scale of the city of Fortaleza and the history that involves the Movimento Ocupe o Cocó in Fortaleza and its unfolding years after the end of the occupation is presented. Finally, an analysis is made based on the theoretical concepts initially presented in the attempt to perceive the reach of the movement and its impact on the norms and public institutions in force.

1.1 INSURGENT CITIZENSHIP IN BRAZIL

The construction of Brazilian society is defined by several waves of insurgencies interrupted during periods of suspension of the democratic regime. According to Sader (1988 apud Barroso, 2013) during the period of the military dictatorship, between 1964 and 1985, the housing social movements were gradually extinguished and those left over were subordinated to the government under a clientelist and patrimonialist relationship.

In the mid-1970s, some movements supported by the Catholic Church began to reorganize throughout Brazil. Da Paz (1993 apud Barroso, 2013) highlighted the União dos Movimentos de Moradia de São Paulo e do Interior (Union of Housing Movements of São Paulo and Interior, UMM-SP) as one of the country's main social movements in this period. The UMM-SP defended the struggle for housing and for serviced land and worked through land occupations and public buildings, manifestations, marches and negotiations with the government. In addition, the internal organization of the UMM-SP was characterized by merging traditional instruments of mobilization of the population with instruments of direct participation, besides having fixed and renewable leaderships recognized in plenary sessions and enjoying regional autonomy guided by general principles.

In 1987 and 1988, the number of land occupations for housing purposes increased considerably, and at that time the Movimento Nacional de Reforma Urbana (National Urban Reform Movement, MNRU) was founded with the aim of bringing together movements and entities to discuss and include the issue of elaboration of the new Federal Constitution. Based on this articulation, the chapter on Urban Policy inserted in the Constitution of 1988 was elaborated and, later, the Estatuto da Cidade (Statute of the City) was enacted (Barroso, 2013).

The Estatuto da Cidade provides new mechanisms of popular participation for public power, so in the 2000s an effort was made on the part of the State to create institutional environments capable of promoting dialogue with the population, among them conferences, councils and public audiences.

From 2005 to 2015 Brazil has experienced a period of economic growth, accompanied by a real increase in the minimum wage, higher employment rates and policies for housing financing particularly through the Minha Casa, Minha Vida (My House, My Life) Program (Freitas & Pequeno, 2015). This scenario of improvement in access to means of consumption and the rise of a political group linked to the grassroots movements of Urban Reform caused many social movements to settle in institutional spaces (Maricato, 2014). In addition, the institutional channels of popular participation are dominated by groups linked to the real estate market or to the public power, so in many situations these spaces of discussion have become inefficient.

These processes of accommodation and institutionalization of housing movements in Brazil were accompanied by political, social and economic transformations at the international level, which brought about a new format for the social movements that claim the Right to the City. From the second decade of the twenty-first century a series of protests around the world with a strong popular adhesion occurred, such as the Arab Spring and Occupy Wall Street. Although varied, there were common patterns to this new generation of movements, such as dissatisfaction with the world economic crisis and the crisis of representative democracy. In general, the protesters claimed greater participation in political decisions than voting (Castells, 2013). Most of these actions were followed by physical occupation of a public space or building in order to increase the visibility of the movement and create new spaces of dialogue analogous to the concept of invented spaces.

In Brazil, the climax of this international conjuncture occurred in June 2013, a period known as the Jornadas de Junho (June Days). If compared with the movements pre-Estatuto da Cidade, it is observed that both have insurgent characteristics. However, the most recent mobilizations have no clear claim, since their struggle is broader: they fought for a fairer city in several aspects, such as mobility, housing and the environment. Another difference is the organizational structure, the most recent movements do not have easily identifiable leaders and are organized in a horizontal way, without direct influence of political parties, which are often deemed undesirable (Brasil and Cavalcanti, 2015). Other characteristics of these new movements are the dense and complex social diversity of the participants and the use of social media to amplify their mobilization (Alves, 2012).

The trigger for Brazilian new wave of protests in 2013 was the increase in public transportation tariffs in São Paulo. O "Movimento Passe Livre" organized, consecutive marches with the blockade of traffic of automobiles on Avenida Paulista, which echoed throughout the country through social networks, and influenced protests in 388 cities in Brazil, among them Fortaleza (Estadão, 2013).

2 INSURGENCES IN FORTALEZA: OCUPE O COCÓ

Fortaleza is one of the densest metropolises in Brazil, with around 77 hab/ha (IBGE, 2010), and has a history of disorderly urban growth, marked by spatial and social fragmentation. This process culminated in a growing problem involving the environmental issue, as well as the consolidation of a clear social inequality pattern, which is often evident within the geographic territory of the city.

The Fortaleza Environmental Inventory (Inventário Ambiental de Fortaleza), published in 2011, quantified about 786 hectares of free green areas, parks and plazas, representing only 2.35% of the total area of the city (Moscoso, Lavor, 2011). In 2007, Fortaleza had 3m² of green area per inhabitant, while the minimum recommended by the World Health Organization is 12m² (Rocha, Lima, 2009). Nevertheless this theme historically occupies only a secondary place in the agenda of the public managers of the city.

The existence of areas with landscape and recreational potential has always been a demand of the organized movements of neighborhoods and representative entities. Nottingham (2006, apud Costa, 2014) makes a historical recovery and points out that the environmental movement of Fortaleza arose around 1976 with the creation of the Sociedade Cearense de Defesa da Cultura e do Meio Ambiente (Ceará Society for Defense of Culture and Environment, Socema) that had as guidelines the preservation of the Cocó River, and later gave rise to the Fórum da Sociedade Civil Cearense sobre Meio Ambiente e Desenvolvimento (Forum of the Civil Cearense Society on Environment and Development). In addition, Costa (2014) lists 18 other entities related to the struggle for green areas of the city in the period 1972 and 2012.

The sequence of events described below aims to characterize the process of negotiating the delimitation of the Cocó Park, between State and civil society, highlighting the main developments and the insurgent character of this action. The information came from two main sources, (1) a 2015 academic piece about the episode (Brasil and Cavalcanti, 2015) and (2) a video published by “FrenteCocó”¹. It was also complemented by document analysis and participant observation on diverse¹ episodes by the authors.

Figure 1 - Aerial view of the green area extension. Photo taken by Fernando Travessoni, accessed at: <http://diariodonordeste.verdesmares.com.br/cadernos/cidade/parque-do-coco-deve-ser-oficializado-com-1-050-ha-1.1531156>.

As a direct consequence of worldwide and national protests, the same strategy of occupation of public spaces mentioned before was observed in Fortaleza. The most representative movement denominated “Occupy the Cocó” consisted in a reaction to highway project that compromised a stretch of green area of the greater park of the city, the Park of Cocó. Although there is no official delimitation that protects this area, it is undeniable its environmental value, since it is home to one of the main rivers of the city, the Cocó River, and has two conservation units already demarcated in its vicinity, the Natural Municipal Park of Sabiaguaba’s Dunes (Parque Natural Municipal das Dunas da Sabiaguaba) and the Sabiaguaba Environmental Protection Area (Área de Proteção Ambiental da Sabiaguaba).

Besides the environmental impacts, the construction of the highway overpass has also provoked controversy around the theme of urban mobility. As part of the TRANSFOR (Fortaleza Urban Transport Program), developed by the City of Fortaleza, which aimed at the implementation of exclusive bus lines and requalification of roads, a project of a viaduct complex was elaborated that caused the deforestation of a stretch of the green space. This project was intended to relieve the intersection of Engenheiro Santana Júnior and Antônio Sales avenues and made no mention of preservation or use of the Park in activities of low environmental impact, nor did it favor non-motorized modes of travel, such as pedestrian and bikes², his priority was the execution of the viaduct as a great public work (Brasil and Cavalcanti, 2015). The project was elaborated in 2003 when an Environment Impact Assessment (EIA/RIMA) was elaborated and approved by state agencies. Yet, 10 year later the work that was being constructed was significantly different from the design proposal of the Impact assessment, and this was one of the main reasons for the several embargos on the work (EIA/RIMA is out of date - O Povo, 2013). It is worth mentioning that the EIA/RIMA elaboration body consists of an invited space of participation of civil society on the decision making process of the city, as it is seen as an instrument for the democratization of information. However, what is perceived is that both the EIA/RIMA of the 2003 project and the 2013 did not foster a participatory process through discussions with the population, but were conducted only to abide to a provision regarded as a bureaucratic legal requirement. As soon as the news of the project was broadcast by the mainstream media, there was resistance to the proposal accompanied by the creation of the hashtag #viadutonão (no viaduct) in social networks by groups that were against the investment. Public hearings were taken by the municipal power (ou state?) in order to initiate a dialogue with the population. Despite the questionings, the City Hall advanced with the works and overthrew 74 trees. On June 16, 2013, the work was stopped by

² According to Law 12.587/2012, which establishes the guidelines for National Urban Mobility Policy, urban mobility systems should treat pedestrians, non-motorized vehicles and public transport as priorities in order to promote universal accessibility.

the Public Patrimony Department, which alleged that the land was Federal Government property, and city hall had no permit to use that land. At that moment, demonstrators setup camp in the deforested area (Brasil and Cavalcanti, 2015). The camper have said that the occupation was the only form of preventing another tree-cutting episode, as the first was undertaken during the night in order to avoid protests (Pinheiro, 2014).

The articulation and dissemination of activities was consolidated by social networks, a strategy that added more support to the occupation, both from other social movements and from isolated individuals. Pinheiro, (2014) says that although all participants of Ocupe o Cocó had in common the goal of defending the Park, people were very different in their conceptions of social model. It had people of various ages, sexual orientations, creeds, ethnicities, races, from the various areas of knowledge that went from the popular to the academic. On the other hand, there were opposing reactions to the protests, which were positioned in favor of the viaducts through the hashtag #viadutosim (Brasil and Cavalcanti, 2015). Openly elitist, the counter movement arose in response to the questioning of the privileges of the elite in the face of collective yearnings. These two movements are representatives of the two citizens who live in the country, the insurgent and the differentiated. For Holston (2008) the confrontation between them creates an inherently unstable and dangerous space of citizenship in contemporary Brazil.

In parallel to the occupation, on July 17, a contest of ideas occurred to suggest alternatives to the City Hall project and reinforce the technical arguments against the construction of the viaducts. A total of 10 proposals were elaborated that had principles regarding environmental maintenance and preservation, pedestrian, cyclist and public transport prioritization. The proposals were presented in the occupation and also to the City Hall, who claimed the alternative proposals were not feasible because they were not concrete proposals (Brasil and Cavalcanti, 2015).

Figure 2 - First page of the file with the ten proposals. File at: https://issuu.com/cacauufc/docs/caderno____concurso_de_alternativa.

Figure 3 - Call to open meeting about the viaduct project, organized by the population itself. Accessed at: <https://www.facebook.com/groups/DireitosUrbanosFortal/>

Another articulation front of the population that strengthens the character of the OccupyCocó insurgency beyond the occupation itself was the creation of an online platform called DireitosUrbanos Fortaleza (Fortaleza Urban Rights), which aimed to discuss urban issues in search of a fairer city and democracy. This initiative can be considered an invented space as it aims to fill a gap about a space for discussion and from it radiates various actions and proposals formulated by civil society. At dawn on Aug. 7, after xx days of camping, the city guard invaded the camp in an action without legal and truculent authorization, using non-lethal weapons, expelled the occupants. The Shock Battalion and the Military Police Cavalry were ordered to avoid any attempt to reoccupy. Days later, demonstrators won the right to re-occupy in justice, and this time the occupation was done in an artistic and symbolic way. After a court decision, the works were released and protesters continued to press for the delimitation of the Park by other communication channels (Brasil and Cavalcanti, 2015). Once again, the insurgency actions extrapolate the occupation period and take place in other places in a more lasting way.

A important development of Ocupe o Cocó movement was the creation of the CocóForum , on January 20, 2015, as an initiative of the Federal Public Ministry. This is a multidisciplinary¹ discussion space made up of scientists, researchers, technicians, lawyers, members of municipal and state public authorities and representatives of civil construction (Federal Public Prosecutor's Office, Ceará State Attorney's Office, 2015).

After a series of debates, the Forum presented a proposal that was constituted in a Unit of Conservation of Integral Protection of 1,435 hectares that was delivered to the State Government on August 26, 2015. The governor created through Decree No. 31,741 of 2015, a multidisciplinary group among state, municipal and federal agencies that met behind closed doors and organized the physical demarcation of the park, still in 2015 (Frente Cocó, 2016). In April 2016, this group linked to the government issued a new proposal for the delimitation of the park called Official Proposal. The Cocó Forum in possession of the Official Proposal organized a counter-proposal enumerating divergences of the Official Proposal. The Official Proposal, differing from the Cocó Forum Proposal, delimited an area of 1,050 hectares, that is, there was a reduction of almost 400 hectares outside the protection area of the Cocó Park. The justification for the exclusion of this area was the scarcity of public resources for expropriations. Aqui cabe a figura com a official proposal e a counter proposal.

¹ The Cocó Forum was created with the objective of adding efforts for the implementation and, above all, preservation of the Cocó Ecological Park, the Federal Public Ministry in Ceará (MPF/CE) proposed, in a public manifesto published on January 20, 2015, the implantation of a permanent forum for the implementation of the Cocó Ecological Park, the so-called "Cocó Forum. Through weekly meetings, the forum brings together about 20 entities with the objective of supporting the Government of the State of Ceará in the decision-making process that has as its objective the establishment of a model of environmental management capable of providing the ecosystems that make up the Cocó region with effective and definitive protection, integrating these areas with the environmental, cultural, social and economic patrimony of the city of Fortaleza and the state of Ceará". (Retrieved from <http://www.prce.mpf.mp.br/conteudo/forum-coco/forum-coco>)

In search of a configuration that harmonized the governmental, forum and community demands, the Cocó Forum made a second counter-proposal suggesting that several areas be included again in the Park. As an alternative to the high cost of expropriations, the Government suggested combining Ecological Interest Area and Environmental Protection Area (ZPA), which would maintain ownership of the land for the owner, but would prevent deforestation (Cocó Front, 2016). Due to the lack of an official commitment of the City of Fortaleza that is made visible by the absence of the Secretary of Urbanism and Environment in the public hearing held on the Cocó Park, the tendency is that ZPAs will not be created after the regulation of the Park (Cocó Front, 2016).

The struggle to delimit and establish a Conservation Unit in the Cocó Park has been going on for more than 30 years, but only with the occupation made against the construction of the viaducts, the agenda has surfaced as an urgency of Fortaleza.

3 FINAL CONSIDERATIONS

Urban policies of both Government of the State of Ceará and the Municipality of Fortaleza, have clearly not been able to meet diffuse collective interests, such as the guarantee of urban mobility and environmental preservation. In this sense we can affirm that there was a breaking of the Social Contract. State actions on the territory primarily serve the demands of social groups with greater power and political influence, such as the civil construction industry and middle-class car owners. Faced with this context, disadvantaged groups are insurgent through practices considered illegal, such as occupation of the green area and obstruction of the progress of public works. These actions provoked a change in the way of managing the territory, being incorporated or neutralized by the urban public policies.

We can consider the Occupy Cocó initiative as an instance of insurgent planning practice, the encampment and the contest of ideas are direct actions carried out by part of the population that has their right to the environment urban mobility threatened. This same group opposed an established order that does not favor the collectivity, that is, it opposes the construction of a viaduct complex that threatens a portion of the green area important to the city. In addition, this action was able to create autonomous spaces of discussion, the first of them inside the camp, and later in the social networks. The main agenda of these created spaces of participation becomes the delimitation of the Cocó Park, a specific agenda that was not attended by the hegemonic powers and by the State.

The Occupy Cocó provoked other developments in the urban planning of the city that prove the power of this type of action, such as resumption of the discussion about delimitation of the Cocó Park, forgotten by many years. Although the road work was executed as originally planned, the protests forced an increase in the dialogue of marginalized groups with the City Hall. After the protests, other urban conflicts were also mediated through direct action such as the re-design of Praça Portugal, which was announced in 2015, has undergone several changes in an attempt to meet demands of civil society; and the painting of the Ana Bilhar Street cycle lane, organized by the collective Massa Crítica, which was later incorporated by official bicycle lane system.

Figure 8 - Viaducts in operation after construction. Photo accessed at: http://tribunadoceara.uol.com.br/noticias/cotidiano-2/manifestantes-relembra-momentos-de-luta-dois-anos-apos-ocupacao-do-coco/attachment/dsc_8396/.

Although relevant, it is important to emphasize that this movement was led by organized groups that do not represent the active peripheral militancy in the city, especially with regard to the problem of homelessness. With a population that possesses strong political capital, the contested interventions were inserted in an economically privileged area of the city, fact that granted greater media visibility to the movement. The Occupy Cocó represents a specific group of the urban society, which are not predominant in the history of insurgent movements in Brazil, but which are not predominant in the insurgent movements observed in Brazil. Therefore, we can affirm that Occupy Cocó contributed in the development of an insurgent citizenship that is consolidated through the popular control of the alterations of public spaces proposed by the State.

The struggle of the Occupy Cocó protesters was not only against the trees - cutting and the preservation of the park, but for the fundamental right to actively participate in decisions about the city. The strong mobilization demonstrates the questioning power of the population of Fortaleza, refused projects that do not dialogue with the collective demands. The eighty-four days of occupation ended violently, amidst bombs, raids and wounded, but left a deep mark on the mobilization consciousness of those who accompanied the movement. Ramon Cavalcante, one of the occupants, gave us the following statement about the Ocupe o Cocó experience:

In the year that we learned to set a limit, even if it was for twenty cents, we decided to fight for almost 80 trees. But it was not just the 80 trees, of course, there were so many others and it was to establish a limit for this city project that, systematically, destroyed the Cocó. And it was an incredible dispute, however much the press, the government, and the elite, in general, tried to discredit the movement, the trees, the occupiers. The creation of alternative proposals, the deliberations for the (still not conquered) demarcation of the Park. It was a huge learning about the right to the city, about collective construction, institutional dispute, fight and police cowardice. There were two violent evacuations conducted by the municipal guard. And a defeat, because the viaducts were built, the trees were overturned. But it was a defeat, delayed, conquering day by day and an enormous strengthening of struggle, achievements in the people that we meet again in several other disputes, in Alto da Paz, Vila das Artes, Vila Vicentina, wherever.

The Occupy Cocó can be considered as insurgent urban planning instance because it is a direct action of occupation that demands a quality urban space, a greater attention for the urban mobility in the scope of the pedestrians, cyclists and collective transport and questions the *modus operandi* of urban public policies that privilege specific groups to the detriment of the community.

ID 1725 | PARTICIPATORY PLANNING: THE ROLE OF NGOS IN NEIGHBOURHOOD REGENERATION IN RIGA

Sandra Treija¹; Uģis Bratuškins¹

¹Riga Technical University

sandra.treija@rtu.lv ; ugis.bratuskins@rtu.lv

ABSTRACT: In the last decades urban regeneration has become an important part of urban policy. Availability of financial opportunities were the engine of change in the approach to the revitalization of many urban sites. At the same time even if the number of projects concerning development of new infrastructure, both social and technical, increased, they didn't always lead to the improvement of the quality of life. The participatory approach involves the wide range of stakeholders in the common process of planning. One of the ways of cooperation at the level of neighborhoods, is a work with active neighborhood residents, not only regularly informing them about the ongoing projects, but also to enable them to express their views and vision. Neighbourhood organizations are the mobilized section of a human group (the neighbourhood) which is underpinned by a local support network. The nature of these bonds of solidarity is a factor that determines the potential of local organizations for action and for their inclusion in any kind of democratic process. Riga, the capital of Latvia, has 58 neighborhoods, and more than ten of them have their own neighborhood associations and activist groups in social sites that are actively and constructively defend their neighborhood citizens. The paper examines the main fields of public activity and identifies the main challenges in cooperation process between different stakeholders involved in urban regeneration.

1 PARTICIPATORY APPROACH IN URBAN REGENERATION

Urban regeneration is a way to reorganise and upgrade existing places rather than planning new urbanisation (Puppim de Oliveira and Balaban, 2013). Factors underlying the adoption of urban regeneration policies and projects include pressures from major short- or long-term economic problems, deindustrialisation, demographic changes, underinvestment, infrastructural obsolescence, structural or cyclical employment issues, political disenfranchisement, ethnic or social tensions, physical deterioration, and physical changes to urban areas. Typically, urban regeneration actions involve economic, social and physical/ environmental improvement measures in the areas under intervention. Urban regeneration at its most basic contributes towards the implementation of sustainable development through the 'recycling' of land and buildings, reducing demolition waste and new construction materials, as well as reducing demand for peripheral urban growth and facilitating intensification and compactness of existing urban areas (Turcu, 2012).

Over the years, the participation of residents has become an indispensable instrument to facilitate a sustainable "bottom-up" implementation of neighbourhood regeneration initiatives. Participatory processes are expected to contribute to identifying the needs of the people, to empowering local groups, integrating local knowledge systems in the design and planning, reinforcing a learning process and to ensuring political support. The list of possible objectives to achieve with these participatory processes (such as generating ideas, identifying attitudes, disseminating information, reviewing and implementing design proposals) can differ at every place and time. Once the objectives of community participation are stated, it then becomes clear that participation is perceived according to the type of issue and the people involved (Sanoff, 2005).

In Eastern Europe, participatory planning is mandatory and it is regulated by the planning legislation. However, due to the relatively little experience in participatory planning, its implementation has become a major challenge. Community-driven initiatives and NGO-led actions can bring together the different actors involved in urban regeneration processes. These activities include problems of practical implementation of public participation and access to justice pillars. The pressure by short term political and economic interests could leave out public participation and reduce transparency. Public participation is often perceived more just as an additional procedure and not as an opportunity. Quality of communication between the various interested persons in the urban regeneration projects is a crucial issue since the people involved need to understand the importance of each stage of development, in a way that they can easily recognise. Thus, a developer, planner or any other specialist coordinating the public participation process should be a communicator, and communicate in a manner which not only is professional, but also readable and understandable to the recipient. Communication should be diversified and with this said can occur in various forms, for example, the modelling of the development versions.

2 LOCAL COMMUNITIES FOR BETTER NEIGHBOURHOODS

Participatory actions in the neighbourhood regeneration are of special importance because they strengthen community spirit and consequently intensify community-driven initiatives. The engagement of inhabitants can significantly increase the efficiency of planning proposals and facilitate other viewpoints that are normally not considered in a formal planning process. If sustainable development is a main objective, then it should include participatory processes to organise and manage the continued demand for effective solutions to neighbourhood regeneration (Laws et al., 2004).

In urban regeneration, self-organization means that the urban actors are enabled to contribute to the shaping of their places by themselves; it is not simply to give them a voice, but to enable them to take responsibility and action for their places, by their own contributions, in bottom-up grassroots processes (Boonstra, 2011).

Nevertheless, the extent, the outcomes, and the methodologies with which urban self-organization can be managed are largely debated (Bond and Thompson-Fawcett, 2007; Innes and Booher, 2004.) In this context, the neighborhood level, which sits between the city and the building levels, appears to be particularly interesting in operational terms. It is well suited to experimenting with the specific practices aimed at improving the urban environment. This allows to look at the urban reality at a scale that is large enough to address themes that clearly exceed the scale of a single building, while remaining small

enough to examine concrete actions. By addressing targeted issues, this type of approach can result in innovative solutions through the application of certain technological developments as well as through the redefinition of the processes of governance and participation. The neighborhood is situated exactly at the crossroads between the art of constructing buildings and the art of managing a city, two areas of action in which the various stakeholders are proceeding independently from each other. While the neighborhood does not necessarily exist on a legal level, it is still an important operational meeting point between the public and private sectors.

The neighbourhood regeneration of individual small-scale projects, where inhabitants can participate not only in planning but also in the implementation process, contributes to the formation of a sense of belonging and identity, creating conditions for further participation of people in building management processes. In small-scale settings, people have a better perception of the problems and are more involved in their solution. Smaller projects require fewer resources and can be carried out in a shorter time-frame and the outcomes can be quickly perceived. Besides, these interventions can serve as a springboard for public participation in large-scale projects, and promote the confidence in the participation of urban regeneration processes. The barriers to effective participation of people from stressed communities in partnerships with government and business include: relative lack of capacity and resources; low levels of interest and risk of activist burn-out; worries about community 'representativeness'; need for long-term commitment; differences in organizational cultures (different modes of working and behavioural expectations).

3 INTRODUCING THE NEIGHBOURHOOD CONCEPT IN RIGA

The capital city of Latvia, Riga, is currently facing a new challenge: how to prepare a new city development plan that would be sustainable, that would satisfy all the interested parties, and that would solve the most urgent urban design problems, that is, de-urbanization, polarized economic growth, increased pollution, conversion of brownfields into greenfields, maintenance of historical sites and buildings, insufficient funding for fulfillment of public needs, and so forth (Barvika et al., 2015).

City Development Department of Riga City Council describes the concept of neighbourhood as a residential environment of suitable size with its own service, identity and character, arising from the construction type, physical borders, landscape and togetherness of residents. One of the main reasons for the idea of neighbourhoods is efforts to improve the planning of city development and life quality of citizens. Currently data on each neighbourhood of the city – Bolderaja, Bierini, Mezaparks, Purvciems etc. are collected in total for 58 neighbourhoods. These neighbourhoods are not planned as administrative units, but the collected information on neighbourhoods will serve as a precondition for development of investment policy. The main topics are relating to urban planning, statistics and community engagement. The main goal of neighborhood development is to create the conditions for sustainable socio - economic and spatial policy in the Riga. This approach will contribute to the strengthening of the identity of residential neighborhoods, residents' awareness of belonging to their neighborhood, support of territorial balance and improve the living environment.

In order to activate the neighborhood movements as one of the ways of inhabitant self-organization, a series of support tools have been created during the last decade in Riga. The main emphasis in idea competitions organized by the neighborhood associations is on the local community interests and inhabitant problem solving with mutual residents and municipality cooperation. Municipal co-financing is available for the organization of neighborhood forums, community integration activities, cultural activities, as well as for the surrounding environment improvement. A website www.apkaimes.lv collects information on neighborhood development opportunities and activities in neighborhoods, public participation and involved opportunities to operate at the level of neighborhoods, as well as local authorities and non-governmental organizations in the process of strengthening neighborhoods.

4 NGO ACTIVITIES IN RIGA NEIGHBOURHOODS

About 1/3 of the neighbourhoods in Riga have created their neighbourhood associations - NGOs. Observing the neighbourhood character and activity, a link can be found between the scale and activity-

although most of inhabitants of Riga (60%) live in large-scale residential areas, the cooperation of residents in these neighbourhoods is weak, almost nowhere any neighbourhood associations and other activity movements have been established. Conversely, in small, often marginalized neighbourhoods with a historical identity people are much more interested in neighbourhood regeneration and development. Summarizing the data from the sources who finance the neighbourhood initiatives, the different websites and other sources of information we can conclude the main fields of activities.

FIELDS OF ACTIVITIES	NEIGHBORHOOD ASSOCIATIONS
Strengthening affiliation to community	Čiekurkalns, Grīziņkalns, Sarkandaugava, Maskavas forštate, Trīsciems, Vecāķi, Bolderāja
Preservation of cultural heritage	Čiekurkalns, Mežaparks, Vecāķi, Āgenskalns, Bolderāja
Improving quality and accessibility of education	Mežaparks
Social integration of community	Grīziņkalns, Sarkandaugava, Maskavas forštate, Bolderāja
Environmental protection	Sarkandaugava, Mežaparks, Trīsciems, Bolderāja, Mangalsala
Strengthening of local identity	Čiekurkalns, Grīziņkalns, Vecāķi, Bolderāja, Miera iela
Activation of local enterprises	Čiekurkalns, Miera iela
Participation in urban planning process	Mežaparks, Dārziņi, Āgenskalns, Mežaparks, Bolderāja, Mangalsala
Regeneration of public space	Čiekurkalns, Grīziņkalns, Sarkandaugava, Mežaparks, Maskavas forštate, Vecāķi, Āgenskalns, Bolderāja, Mangalsala

Table.1 Fields of activities in Riga neighborhoods

Activities of neighborhood associations are specified by several factors: the neighborhoods location: for the neighborhoods near the River Daugava or lakes the main objective is environmental protection; the neighborhoods history: historical neighborhoods strengthen community identity with protection of cultural heritage etc. Specific problems such as school closures will serve as strong promoter for public participation. Activities regarding the urban planning are the leading causes of many communities' initiatives. Rail Baltica, relocation of sea port terminals and other major development which could bring any risk to quality of life in the neighborhoods, have been important motivators for consolidation of the population. However, the most common field for every neighborhood is regeneration of public space.

5 PUBLIC SPACE: A PLATFORM FOR CO-CREATION

A readily accessible public open space is a centre of public activities which may affect the everyday life of people and development of the entire neighbourhood (Rapoport 1985). The public open space is beyond the control of individuals, it is an element linking the private living spaces of inhabitants and it is used for different functional and symbolic purposes (Madanipour 2003). Public open space in the residential environment is the main platform for socialisation as well as an essential component of a dwelling, "an extension" of the personal living space into outer world (Belanger 2007). The quality of public space, in terms of respect for rights of assembly and expression, is the most important long-run parameter shaping civil society organization, strength and capacity to act. In this dimension there is a striking variation of conditions across the post-communist space as well as significant changes over time. Once residents begin to think of themselves as content and platform co-creators and as active players who can not only react to design proposals and planning initiatives, but also devise their own, it becomes possible to develop tactical approaches based on small scale local interventions where weak constituencies can even take a leadership role, and which can spark catalytic processes at a large scale, as in the urban acupuncture approach (Iaconesi & Persico, 2014; Landry, 2005). The public dimension of such space is another key resource to harness the full potential of inclusive participation, in that it gives visibility and social salience to

practices that, however relevant and transformational, could be overlooked or even misunderstood by some constituencies (Sharp, Pollock, & Paddison, 2005). It is, quite differently, turning public space into a co-creation arena where the very fact of being a resident sets the conditions to become part of the design process. In practice, co-design approaches vary greatly from being close to consultation and information gathering to facilitating people in generating their own ideas and solutions.

The positive co-creation and self-organization synergies result in a grassroots process of local information and knowledge, aimed at improving places and driven by actors' lived experiences. Co-creation methodologies aim to enable people, laypersons as well as experts, with a very broad range of knowledge and know-how to have a creative contribution to the design processes (Sanders, 2002). The European Design Leadership Board defines co-design as "a community centred methodology that designers use to enable people who will be served by a design outcome to participate in designing solutions to their problems" (Thomson et al, 2012). Co-creative processes are the outcome of a shift in urban design; they move from experts towards giving actors the capability to directly contribute their experience (Sanders and Stappers, 2008).

Figure 1. Case study neighbourhoods in Riga context

CASE 1. REGENERATION OF A SQUARE IN SARKANDAUGAVA

Sarkandaugava is a historical industrial district, located in the northern part of Riga, with 18 095 inhabitants.

According to a survey conducted in 2013, 34 % of Sarkandaugava population would be willing to participate in the activities linked with courtyard or other public open space improvement, 26% would be willing to engage in their neighborhood clean-up. Answering the question "which territories should be targeted first in the cleanups" the respondents most often mentioned apartment house surroundings and courtyards (34%) and the railway surroundings (22%).

Sarkandaugava neighbourhood association has been active since 2013. Association aims to promote the development of the Sarkandaugava neighborhood and to improve inhabitant life quality. They are representing the interests of Sarkandaugava residents in Riga municipal institutions, also being a communication tool for the exchange of ideas between the active Sarkandaugava neighborhood residents as well as promoting neighborhood residents responsibility for their surrounding environment and encouraging mutual tolerance. The Association is one of the most active neighbourhood associations in Riga, with activities related to environmental issues - industrial pollution reduction, mitigation of negative impacts of the port and also different cultural activities.

One of the most successful projects in Sarkandaugava is Alekša Square regeneration. Till 2013 Alekša Square was abandoned, polluted and degraded place next to the district's main street. In 2012 an initiative "Labas vietasTALKA» created series of events, in which neighborhood residents together would create

ideas to improve a specific location in their district. Alekša square was chosen to be the location for improvement and development. The action started in 2014 with several clean-ups including different activities for shifting the square's visual appearance, functionality and liveability respecting the identity of the neighbourhood.

Figure 2. Regenerated Alekša square in Sarkandaugava neighborhood

CASE 2. DEVELOPMENT OF A PLAYGROUND IN ČIEKURKALNS

Čiekurkalns is a historical industrial district with 7 794 inhabitants. According to a survey conducted in 2013, 40 % of Čiekurkalns population would be willing to participate in the activities linked with courtyard or other public open space improvement, 35% would be ready to participate in the restoration of the residential buildings visual appearance. Answering the question "which territories should be targeted first in the clean-ups" the respondents most often mentioned apartment house surroundings and courtyards (47%) and also the sidewalks and streets (22%). Čiekurkalns Neighbourhood Association is active since 2014. Association's mission is to target Čiekurkalns neighborhood development. The activities are mainly related to the revitalization of the neighborhood identity by organizing various events for the inhabitants. Significant

activity was the TEC historic buildings protection. One of the most striking projects has been Čiekurkalns playground creation. Before this project there was no place in the neighbourhood for children to spend their free time actively. In 2015 for this purpose a fundraising campaign was launched. In 2016 this initiative was noticed and implemented by the Riga City Council.

Figure 3. Development of a playground in Čiekurkalns

CASE 3. REGENERATION OF A COURTYARD IN MASKAVAS FORŠTATE

Maskavas Forštate is a neighbourhood adjacent to the Riga city centre with 27 155 inhabitants (Census, 2011). An important factor in the development of the Maskavas Forštate has been the multiplicity of nationalities and religions of inhabitants that in the course of time populated this neighborhood. More than half of the inhabitants of Maskavas Forštate (59%) are willing to participate in activities linked with courtyard or other public open space improvement. Answering the question "which territories should be targeted first in the clean-ups" the respondents most often mentioned apartment house surroundings (35%), as well as streets, sidewalks and all courtyards (23%). The Maskavas Forštate neighbourhood association was founded in 2011 to unite the society and to activate the educational, social, health, cultural, integration and environmental spheres. The association actively participates in environmental management, social and cultural projects. In cooperation with the other active associations and movements project "Sun courtyard" was developed. During the "Big clean-up" children's playground was upgraded and improved, new greenery planted, new benches and different decorative installations installed. The project partners were the Riga Technical university students and professional landscape architects. The project was funded by Rīga 2014 foundation.

Figure 4. Regenerated courtyard in Maskavas Forštate

6. CONCLUSIONS

Public participation in neighborhood regeneration relates with a number of advantages: communities have a fresh perspective, and can be seen often issues new kinds; community involvement helps deliver programs that better target local needs; as a result, projects are acceptable to the local community. Still, there are plenty of challenges in cooperation process between different stakeholders involved in urban regeneration. On the one hand, there is considerable activity of the marginalized communities that require a hearing and respecting of their opinion in the development and planning processes. On the other hand, in many cases, public participation is a decorative and is accepted unless it does not interfere with financially significant development projects.

Public participation in neighbourhood level needs different types of public participation, at different stages and with different levels of involvement. The public also have an opportunity to exercise its responsibilities when the ideas are put into practice, and even afterwards, when they are inhabiting the spaces. An optimal participation process would be one which engages the people in the definition of the problem, seeking the solutions, and collaborating in the realisation of the proposals.

ID 1756 | LOCAL PLANNING INSTRUMENTS - IF ONLY WE KNEW HOW TO PLAY

Paula Grant¹; Matt Grant²

¹University of Queensland; ²University of Southern Queensland
paula.grant@uq.edu.au

ABSTRACT: We know little about how the implementation of planning instruments are communicated to the members of the community by the planning profession in terms of complexity of language and process, power relationships and how this impacts upon an individual's ability to engage as an active citizen in the development assessment process. In order to create more value for community engagement in the development assessment process, we need to better understand how local planning instruments are perceived by members of a community in terms of ease of navigation, interpretation and application to development proposals. It is particularly in the role of community as submitters to a development application that these perceptions may be best explored as it is an opportunity for non-planners to interact with planning instruments perhaps for the first time. This paper will discuss the type and nature of submissions made by non-planners to development applications within two case studies and identify barriers to non-planners effectively participating in planning discussions and decision-making about development applications. The research will undertake data collection and content analysis of six (6) submissions from each case against development proposals within a regional city context. The content analysis will aim to match the de-identified public submissions with what the planning profession considers valid urban and regional planning grounds expressed in local statutory planning instruments. This will help to ascertain the submitters' effectiveness in understanding and applying the local planning instrument to the site specific issue that has ignited the active citizenship response. The paper will seek to answer questions about what is the engagement framework within which submitters can participate in planning, how are planning schemes navigated, applied and interpreted by non-planners lodging submissions to proposed development and what knowledge and skills do community members need to participate in the development assessment process as submitters ?

1 INTRODUCTION

In order to build trust many local governments and Local Government Acts are based on values and codes of conduct that include transparency and accountability. This is no less important for the planning profession if it is to be seen as legitimate, open, honest and fair in the way it communicates issues around development proposals and development assessment.

In Queensland the Statutory Instruments Act 1992 (Queensland, 1992) defines the meaning of an Instrument and identifies that a local government planning scheme is a statutory document prepared under the planning act applicable at the time.

The Integrated Planning Act and Sustainable Planning Act provides for community consultation relating to development proposals in Queensland. It transfers appeal rights in the Planning and Environment Court to those submitters that have made properly made submissions within a required timeframe.

2 CONTEXT

Two case studies have been selected for this research. The cases are based in a regional city in Queensland, Australia with a population of 165 000 people. The first case is referred to as Maridhadi and the second is referred to as McDonalds. The cases were selected using the criteria that the development applications were to have been decided by the Local Government between 2009 and 2013, they must have drawn more than ten submissions following public notification, they must have drawn media attention and they must have involved a development that had been approved and one that had been refused. This comparative case study approach seeks to determine if the submissions made to the development application are considered to contain knowledge with validity and therefore are material matters to consider in development decision-making.

Maridhadi was an impact (not preferred) assessable application for a secondary school (educational establishment) located in a residential neighborhood proposing reuse of a heritage listed building on the edge of the Great Dividing Range escarpment. A group calling themselves CASE Citizens Against School Establishment secured the assistance of a planning consultancy to write a submission against the proposal and this submission formed the basis of the 74% pro-forma submissions received against the proposal. Twelve different pro-forma letters are evident in the total number of submissions. 681 submissions were received over two advertising periods against the proposal. 25% of these were from people living outside of Toowoomba. There were 32 not properly made submissions. There were also 212 submissions received in support of the proposal. The Council overturned the assessment managers recommendation in this instance and refused this application.

McDonalds was an impact (not preferred) assessable application for a number of café/restaurants and supermarket in a Residential Mixed Housing zone. Thirty two submissions were received opposing the proposal of which 31 were properly made under the legislation. Six of the properly made submissions took the form of a petition. The assessment manager provided responses to the submissions and also sought responses to the submissions from the applicant's consultancy team. There is clear evidence of knowledge validity testing in the submissions and the "experts" responses. The Council approved this application.

Both of these cases were heard in the Queensland Planning and Environment Court and both matters were dismissed. In the case of Maridhadi the applicant appealed the decision and the proposal did not proceed. In the case of McDonalds the submitters appealed the decision and the proposal was built and is operating today.

3 APPROACH

The research method used for this paper involved content analysis, using nVivo software, of both the planning officers reports to the Local Government and twelve (12) of the submissions received from submitters during the public notification period. Content analysis has also been conducted on various media and social media publications and posts.

The content analysis of the planning officer reports adopted a process to create categories or codes of words and phrases within the text used by Weston and Weston in previous research with some additional codes added for emotive submissions (Weston & Weston, 2012). The codes should then be able to be replicated.

The research also used a readability tool to analyse the complexity of text within the planning officer reports and assign it a rating equivalent to schooling age. The Gunning Fog Readability Index will be used to measure reading difficulty rather than reading ease. The Gunning Fog Index counts words and divides by the number of sentences to find an average sentence length. Rather than counting syllables, as compared to Flesch's Reading Ease and Human Interest Formula, Gunning's method counts the number of long words with three or more syllables. All proper nouns, verbs in which the third syllable is an -ed or -es and compound words made from two short words like workable are excluded. To apply the formula the author will use Readability-Score software programmes that take the average sentence length and add it to the number of long words per 100 words and then multiply the total by 0.4. The resulting score is roughly equivalent to the grade level of difficulty. A score of 12 for example indicates that an average high-school senior should be able to read the material. In practice, no general-audience newspaper or magazine would rate above 12 on the Gunning Fog Index. Time magazine rates 11, Readers Digest scores about 5 and comic books score 6 (Readable.IO, 2017).

To overcome some of the limitations identified in the literature with computerised readability indices the Readable IO software takes an average across the material to use several different readability formulas. This enabled a range of readability scores to be produced providing more confidence in the results. Other determinants outside the scope of this paper may include legibility, motivation of the reader, learnability of the text, usability, relationship among words, sentences and sentence parts and the level of abstraction of the reader by the material (Hiebert, 2011).

The submissions were subject to analysis that involved a coding approach to determine if submissions were made about material planning matters referred to in the local planning instrument or if they were not relevant to the tool against which the applications could be assessed. This has led to discussion in the conclusions part of this research in regard to questions about the validity of knowledge and particularly what non planners need to know in order to be able to enter the field of contestation as it relates to decision making on development applications (McClymont, 2011).

4 READABILITY AND TRUST

Even local government elected officials with experience in discussing and deciding on planning matters can find themselves at a disadvantage when reading through planning documents. During a recent meeting at a Council within the case study area in Australia a discussion regarding the adoption of amendments that would see a transfer of authority over development assessments was met with confusion. (Backhouse, 2017)

Calls for a 'layman's reference' to help elected officials (without planning qualifications) understand the policy changes were made by one Councillor who stated he would have to 'take a leap of faith' that the proposed change would be in line with previous decisions. Throughout the exchange the technical expert in the meeting – the manager of the council's development assessment branch – advised that a more detailed report could result in 'hundreds of pages being produced that might not result in the document being any clearer.' Despite the misgivings aired by the elected officials the Council endorsed the motion and the amendment was recorded (Backhouse, 2017).

This paper primarily looks at how accessible planning documents are to members of the general public, and given the difficulties described above it is not hard to form an opinion that even those non-town planners who work in government may still occasionally have trouble discerning meaning.

To this end, when considering this it should be noted the various employment streams involved in the drafting of a planning report. Town planners obviously are involved in the process and provide the bulk of the content, however other specialisations within the local government structure play key roles; legal experts, for example, provide guidance on interpretations of the relevant Act and on more specific matters as required, environmental specialists may be called on to provide data used to recommend certain courses of action and politicians themselves may call for adjustments to aspects of a report.

Each actor in the process of delivering a planning report uses language and knowledge specific to their particular field, and in the course of doing so provide further depths of encoding that members of the general public need to navigate, to interpret and to understand before being able to respond. All of this is

completed in what Tait (2012) notes as a 'contested societal activity, characterized by fractious processes and disputed outcomes.' The use of complex language in the form of jargon and industry-specific terms can make, to the layman, the reading of a planning report an arduous process (Tait, 2012).

If anyone is free to make a submission and thus become an actor in the progress of a development application, and the language of the supporting documents create a barrier to effective communication and subsequent understanding does it 'create opportunities for mistrustful relationships to emerge, as groups with different interests cannot always come to a compromise' as Tait (2012) suggests? Interestingly, Goldthorpe (1982) noted a greater level of trust between professionals and society in the past 'emanating in part from social respect for the specialist knowledge and expertise of the former.' In the modern interconnected world perhaps Rydin's statement that 'knowledge now has a variety of sources and takes a variety of different forms' is truer than ever. (Goldthorpe, 1982) Rydin, 2007)

With greater access than ever before in human history to a global repository of knowledge, albeit unregulated, the modern person is able to seek information faster and, increasingly, from more locations as the use of mobile handheld devices increases. Pre-Internet stakeholders in a certain scenario would seek information from subject matter experts and would, usually, trust that advice to be accurate. The plethora of information available online today makes it difficult for individuals to not search for answers before consulting with a subject matter expert, so much so the wider medical profession is credited with coining the term 'Webchondriac' to describe patients who enter a consultation with their own diagnosis, courtesy of any number of professional and amateur medical websites (Austin, 2014). The sheer volume of information available on the Web, including University-level lectures and presentations, means that virtually anyone can access information similar to that used in a recognised degree course but with the significant difference that this information is not placed within a pedagogy of a considered structure of learning with formal assessment criteria thereby earning the participant a qualification. In short, the Internet lays the world of information at our feet, but not necessarily the ability to adeptly use it in a professional context.

This brings the argument neatly back to the question of trust; what is it and why is it crucial to the relationship between town planners and the public they serve? The second part of that question is simple – without trust there is no comprehension, no receipt of offered information let alone action taken on it. At the core of comprehension are three factors – accessibility, readability and trust.

Accessibility is accomplished through standardised procedures according to local law. In the case study area it is a requirement that information pertaining to town plans as well as development applications are made public for consideration by all stakeholders. Readability refers to level of education required by an individual to read and comprehend a document. Professional report writing styles typically, and in the case of town planning reports almost always, require a high level of education to understand and apply various terms and wider concepts. Underpinning readability is trust – perhaps defined as 'one party's willingness to be vulnerable to another party based on the belief that the other party is (a) competent, (b) open, (c) concerned, and (d) reliable.' (Mishra, 1996) The need for this trust to be evident and true is highlighted by the many number of stakeholders in a typical round of submissions to a development application, and of the differing roles of submitter, applicant, facilitator, technical expert and politician, amongst others. In the post-modern approach to planning Rydin (2007) notes the planner takes on a number of roles where, for example, 'a community report on the experience of living in a village will be different to an expert assessment of the quality of life or natural capital in that village.'

Rydin (2007) further outlines the need for engagement forums 'engaging expert with expert, lay perspective with lay perspective and lay and expert perspectives in examination of each others' claims' in a process that effectively initiates discussion, acknowledges differences and defines essential facts as part of a decision-making cycle, and without trust this cycle cannot be completed. In terms of this paper we looked at two particular development applications and the subsequent submissions in terms of readability and barriers to comprehension (Rydin, 2007).

Tennoy & others (2015) identify five different types of knowledge necessary in planning:

1. Expert knowledge including the theoretical, empirical and methodological
2. Knowledge of project/objectives
3. Knowledge of context, including lay knowledge;
4. Process knowledge includes knowing about laws, regulations and procedures of planning and

5. Other kinds of knowledge (Tennoy, Hansson, Lissandrello, & Naess, 2015)

Rydin (2007) goes further to identify a typology of knowledge claims in planning. These include current state, predicted state, societal process, planning process, outcomes state, planning –societal interaction and normative knowledge. Planning is by its very nature a normative process (Rydin, 2007). For the purpose of this paper we will focus on both typologies identifying process knowledge and planning process as important knowledge types and knowledge claims. This type of knowledge is fundamental to learning how to play the local planning instrument and all of the associated and hidden processes that go with that instrument in a field of contestation relating to development decision.

4 RESULTS AND ANALYSIS

4.1 CODING

This paper adapts the coding developed by Weston & Weston (2012) to reflect the aspects of language within written documents that are unclear or appear coded (Weston & Weston, 2012). They provide us with examples of exclusionary language. The codes used in the nVivo software against the two case study planning reports and six submissions from each case are as listed in Table 1.

Description	Code Name	Code
Reference to a type of application, legislation or policy without an explanation of what that reference means or where an explanation can be found.	Unknown application	UNAP
Use of an abbreviation/acronym without explaining its meaning within two pages of its use.	Unknown abbreviation	UNAB
Use of encoded terminology without explaining its meaning.	Encoded terminology	ENTE
Use of unexplained encoded information without referring to the location of the key/code book when one is provided.	No key reference	NOKE
Use of terminology or phrases only used by those familiar with the fields of planning and transport without an explanation for others.	Planning terminology	PLTE
Use of terminology or phrases only used by those familiar with the fields of urban design and architecture without explanation for others.	Design terminology	DETE
Reference specifically directed at committee or council members.	Council exclusivity	COEX
Third party comments rejected without explanation.	Unknown comments	UNCO
Third party comments	Unanswered comments	UNAC
provided but not commented on.		(Weston & Weston, 2012)
Third party comments that relate to the local planning instrument.	Material Planning Comments	MACO
Third party comments that do not relate to the local planning instrument.	Non-material Comments	NOCO
Emotive comments that do not relate to planning matters.	Emotional Comments	EMCO

Table 1 – Content Analysis Coding

The results from the coding are included in Tables 2 and 3 below in both hits and a percentage of the total.

Codes	UNAP	UNAB	ENTE	NOKE	PLTE	DETE	COEX	UNAC
Total number of hits	32	13	5	11	53	6	11	0
Percent of total hits	24%	10%	4%	8%	41%	5%	8%	0

Table 2 – 2 Planning Reports Results by Code

Codes	MACO	UNCO	EMCO
Total number of hits	17	25	12
Percent of total hits	31%	46%	22%

Table 3 – 12 Submissions Results by Code

The first issue to note is that overwhelmingly the results point to a significant use of Planning Terminology making up 41% of all coded material. An example of PLTE is the location of a residential use on an arterial road is undesirable due to amenity issues. These terms are often used and understood by professional planners not however by those with lay as opposed to expert knowledge. The concept of establishment of need or amenity impacts is not defined categorically in legislation nor in the planning instrument itself. Indeed one submitter went to the Macquarie Dictionary to try and understand the concept.

EXISTING AND CURRENT AMENITY OF STREET

I am concerned about the impacts on the amenity of the area.

- a) Amenity is defined in the Australian Macquarie Dictionary as "features, facilities or services of a district, etc, which make for a comfortable and pleasant life".

How will this development impact upon our street?
Will it change our current residential character? YES!

Figure 1 PLTE Example

The second issue to note is that 24% of coding relates to UNAP or an unknown application. Most of this coding refers to terms or actions that are contained within the legislation or approach to performance based planning. A UNAP example is referring to a proposal as Impact (not preferred) and a Material Change of Use with no reference to the planning legislation and the process knowledge that is inherent in those terms. Another example is reference to a concurrence agency without any explanation of the referral stages within the development assessment process.

- This combined application - Impact (Not Preferred) – seeks approval for:
- a Material Change of Use for Food Outlet (Café/Restaurant) 240m², Food Outlet (Convenience Restaurant) 1,106.1m², Shop 193m², and Supermarket 237.5m²; and
 - Operational Works for Advertising Signs (2 x Pole Signs).

Figure 2 UNAP Example

4.2 READABILITY SCORES

Using the Readability IO software available online the two assessment manager planning reports were given an average score relating to the conclusion and recommendation of those reports (Readable.IO, 2017). The findings are represented in the figures below.

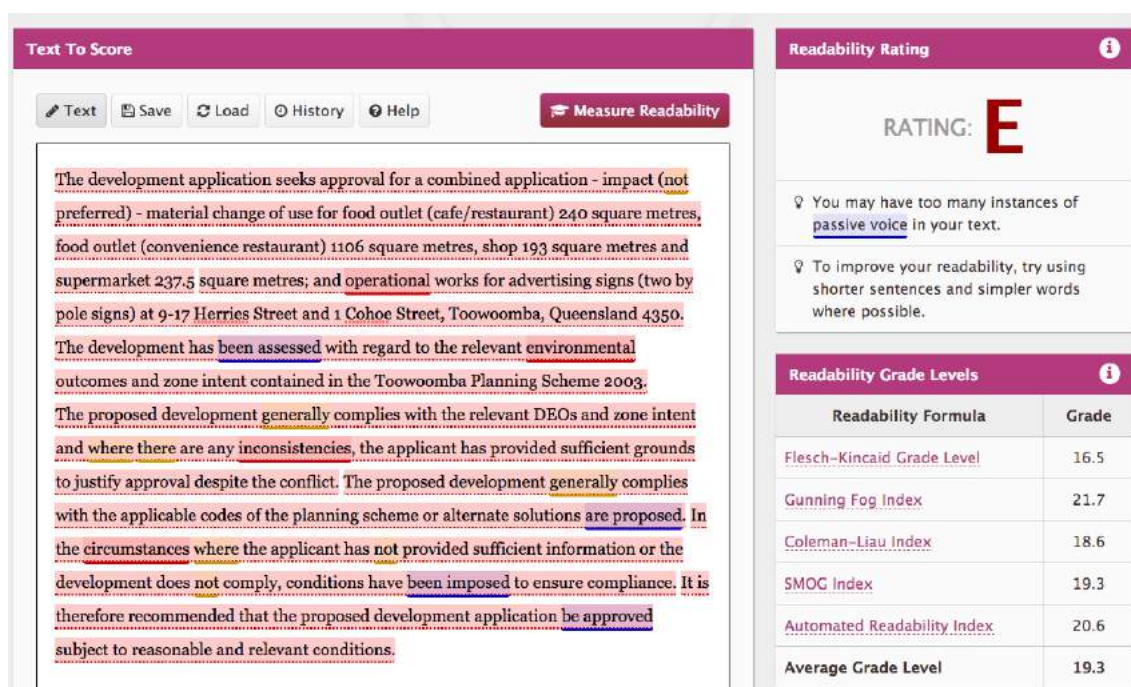

Figure 3 Readability Score Average McDonalds

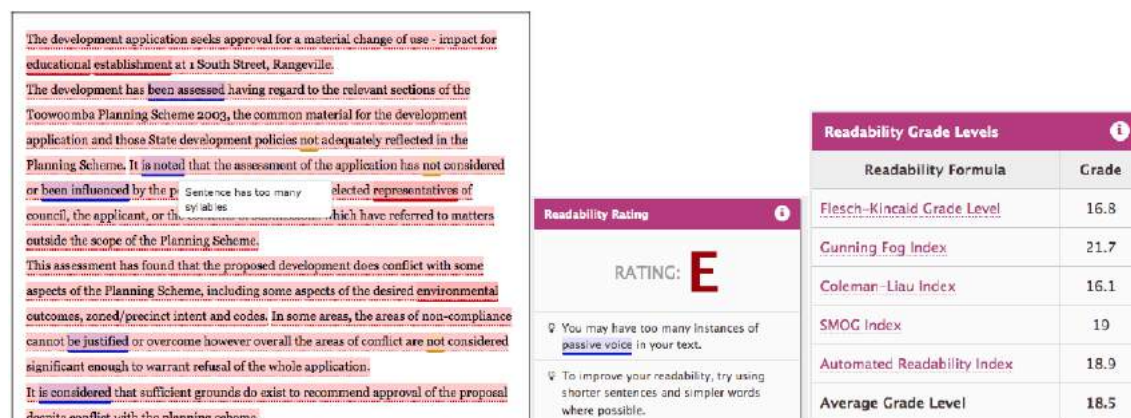

Figure 4 Readability Score Average Maridhadi

Both planning reports have been scored as an "E" rating according to the Readable.IO software. This represents an averaged readability grade level of 18.5 for the Maridhadi report and 19.3 for the McDonalds report. The scores demonstrate complexity in the planning reports. This exclusivity in communication is clear when the score requires a post graduate qualification and 79% of the case study population has no more than a Year 12 educational qualification (ABS, 2017).

5 DISCUSSION

Many of the submitters were able to identify material grounds for their submission e.g, intent of the zone, demonstration of need and impact on amenity. The barrier for the submitters appears to be translating that into evidence. This lack of evidence and indeed an ability to interpret the application of that to proposals e.g. the intent of the zone particularly seemed to relate to an absence of expert knowledge or understanding of the performance based planning system upon which the legislation is based. This points to a lack of process knowledge and expert knowledge. Most of the indignation and mistrust came from an assumption that zoning meant certainty in terms of land use. Indeed the performance based system aims

for flexibility over certainty and this appeared to be an important expert and process knowledge gap when the submitters were trying to grapple with what appeared to be inconsistent with the intent for the locality (Tennoy, Hansson, Lissandrello, & Naess, 2015).

There are a number of examples where submitters have clearly done a great deal of research to try to place this development proposal within the context of the legislation and the planning system in which it is situated:

I understand from my research that according to the Sustainable Planning Act 2009 (SPA) a 'materials change of use' is defined as:

- The start of a new use of premises;
- The re-establishment on the premises of a use that has been abandoned, or
- A materials change in the intensity or scale of the use of the premises.

It would appear to me that this proposed development is seeking a material change in the intensity and scale of the use of the land proposed where this entire development will occur.

Figure 5 UNAP Example

The connection between seeing zoning as certainty and the feelings of loss of trust within a performance based planning system is evidenced in the extract from a submission below:

I cannot countenance the council allowing such an intrusive development which is clearly contrary to the town plan. The community's trust in the council will be severely eroded should this development proceed. It would in effect render the town plan and associated zonings meaningless and the council itself ineffective as a guardian of people's rights.

Figure 6 Intent of the Zone and Trust Example

In addition to the complexity of language, process and context properly made submissions must be made within the statutory timeframe. This means that submitters have only a compressed amount of time in which to identify, gather and understand the material issues. This is an added barrier to non-planners entering the field of contestation legitimately in development decision making.

In the short time available to prepare this Objection, I have tried to collect photos of the traffic on Cohoe St and around this intersection. I don't know how this survey has been able

Figure 7 Statutory timeframes Example

6 CONCLUSION

Throughout the examination of the case studies a recurring theme was the confusion generated by hidden and unexplained reference to the relevant legislation and the principles of 'Performance Based Planning' underpinning it. By reading a planning report alone it is not evident how the legislation affects the recommendations and this gap in a non-planners' knowledge makes higher-level consideration and comprehension a particularly difficult feat. It is this process knowledge gap that makes entering the field of contestation for development decisions very difficult for the lay person. Within the wider planning approach, however, the content appears to be accessible even if the concepts are not.

T04 | URBAN DESIGN, PUBLIC SPACES AND URBAN CULTURE

CO-CHAIRS: ALI MADANIPOUR; GABRIELLA ESPOSITO DE VITA; PEDRO GEORGE

This track brings together the themes of urban design, public space, and urban culture. Papers are invited to explore the nature and the relationship between these themes, and any of their subthemes. The processes of shaping, managing, and inhabiting the urban space have a direct relationship with the political, economic and cultural conditions of cities. Theoretical, methodological and empirical papers are invited to discuss any aspect of this interface between spatial development processes and the urban conditions in Europe and elsewhere.

What are the relationships between urban design and urban and regional planning, and in what ways are they responding to the conditions of globalisation, economic austerity, social inequality, cultural diversity, and climate change? How can they be theoretically, methodologically and empirically enhanced to address these challenges? What is the relationship between these diverse demands on cities, and are they being given the attention they need? What are the current approaches to the public space in Europe and in what ways can these approaches be assessed? How can spatial design and development, and the articulation of urban spaces, reconcile the rich cultural heritage of European cities with their rapidly changing circumstances? How can the research in urban design meet the needs of the EU Cohesion Policy 2014-2020 in terms of smart, sustainable and inclusive cities?

ID 1324 | EVALUATING THE ROLE OF PUBLIC SPACES IN PROMOTING SOCIAL INTERACTION IN DIVIDED CITIES. THE CASE STUDY OF NICOSIA, CYPRUS

ABSTRACT: Social interaction is the contact between individuals, groups and environments. There are different levels of social interaction, starting with superficial ones, i.e. observing other individuals and greeting them, to a high level of interaction that can be found in neighbourhoods where individuals form communities and share emotional investment in the same things. Public spaces such as streets, plazas and parks have the ability to facilitate and promote social interaction, because they create opportunities for people to interact in the form of activities and special events. The UN-Habitat defines social interaction as an element of public space. Divided cities originate as the result of divisions within a nation. With little to no relation between the two sides of the divided city, they continue to develop independently. In cases where the citizens of the divided cities are allowed to move across the border, one place where they still come in contact with each other and have an opportunity to interact is the public space. Thus public spaces have the potential to build connections between different groups, and cultivate good will, friendship, compassion and tolerance. This paper analyses the ability of public spaces in a divided city to facilitate social interaction. It uses a mixed method design, building an index of social interaction to quantify the ability of public spaces to promote social interaction, and conducting expert interviews to design and validate the index and its results. The results show that the public spaces in Nicosia are not used to their full potential and there is a tendency for inhabitants to focus on spaces that offer activities such as shopping, cafes and restaurants, and festivals. The public spaces which had a larger number of such activities had a higher ability to promote social interaction. The social dimension of public spaces demonstrated a high level of significance. The presence of both communities in the public spaces, as well as the occupant density had a great impact on the outcome of the index, and therefore, on the ability of public spaces to promote social interaction.

1 INTRODUCTION

Nicosia is both the capital of the Republic of Cyprus and the Turkish Republic of Northern Cyprus. A UN-administered buffer zone still divides the island and passes through the centre of Nicosia. This buffer zone, also referred to as the “dead zone”, can only be crossed through checkpoints. Currently there are three crossing points in Nicosia, around which several public spaces exist, ranging from commercial streets to parks and markets. This paper analyses opportunities for social interaction in a divided city, by focusing on the ability of public spaces in Nicosia to enable this social interaction among the divided communities.

Divided cities originate as the result of nation divisions (Kliot & Mansfeld, 1999). With little to no relationship happening, the two sides of a divided city continue to develop independently. The spatial division of a wall creates a distinct urban environment on either side of it. This division of space has a physical function as much as it affects the administrative and political structure, thereby creating an imbalanced distribution of resources and opportunities (Abdelmonem & McWhinney, 2015). It also becomes a negative feature that deters mobility, interaction and social cohesion. The built fabric becomes an object of remembrance that is paradoxical and contested, with different meanings and connotations (Bevan, 2007).

However, in cities where the citizens are allowed to move across the border, public spaces provide one option for shared spaces where people can interact (Pullan et al., 2012b), can become a common space for shared functions and social activities, and important catalysts for change which allow people to experience life on the other side and bond with their neighbors. This interaction discourages stigmatization of “the other” through shared experiences that promote mutual trust and respect. Hence public spaces, if accessible to both sides of the city, become places of exchange with a significant social role as a complex

system of open socio-spatial engagement (Marcus & Francis, 1998). Even streets can act as shared spaces and binding factors within divided cities (Bollens, 2006, UN Habitat, 2013).

Researchers have long focused on divided cities, and on public spaces within these divided cities, particularly focusing on the political or historical aspect of the division (Till et al. 2013, Öngül 2012). Others stress the importance of public spaces as binding mechanisms in divided cities, and analyse the physical aspect and the ways people use the space (Nagle, 2009). Where a physical barrier that divides the city sends a clear message of exclusion, public spaces contest this notion by presenting a shared space where everyone is welcome. Gaffikin et al. (2010) analyse the role urban design plays in divided cities, concluding that public spaces provide an opportunity for social contact, which can lead to social interaction. Others observed how people interact with the public space and within one (Abu-Ghazze 1999, Talen 1999).

In this paper we developed an index that measures the ability of public spaces to promote social interaction in a divided city, and confronted the index's conclusions with expert interviews. The results show that public spaces in Nicosia are not used to their full potential and there is a tendency for inhabitants to use public spaces where semi-public activities occur outside, in the street or in the square. The public spaces which had a larger number of such activities had a higher ability to promote social interaction. Focusing on public spaces located around the two pedestrian border crossings, we could also observe how an area marked by infrastructures of conflict (Till et al, 2013) such as the UN-administered buffer area and the wall, were slowly converting into areas where the two communities came together.

Following this introduction we discuss what are divided cities and how public spaces can enable social interaction in these cities. We then introduce Nicosia and the public spaces that were analysed, how the data was collected and analysed and how the index was built. The results will focus on the public spaces that scored highest and lowest in the index, followed by discussion and conclusions.

2 PUBLIC SPACES ENABLING SOCIAL INTERACTION IN DIVIDED CITIES

2.1 DIVIDED CITIES

Divided cities have been defined as a city comprising two or more distinct entities that have to be spatially separated, mutually exclusive and relatively homogeneous enclaves (Nagle 2009). Van Kempen (2007), and Marcuse (1993), consider highly fragmented cities to be divided cities, whereas O'leary (2007), refers to this phenomena as a political partition, where an entity becomes divided by a barricade, in form of a wall, fence or other type of physical obstacle.

The physical borders dividing cities have a practical and a symbolic function. They represent "infrastructures of conflict" (Till et al., 2013), such as walls, barricades and buffer zones, which are not only a physical divide, but also a social and symbolic one (Pullan, et.al., 2012a). The symbolic divide may be the deepest one. It causes stigmatization, feelings of insecurity and disassociation from the population on the other side (Pullan et al., 2012a). Symbols of divisions can also be "Infrastructures of peace" (Till et al., 2013), for example the "Home for Cooperation", a revitalised building in the buffer zone of Cyprus, located on a neutral territory and administered by both Greek and Turkish Cypriots. These send a message of unity and cooperation, and turn an artefact of conflict into a promise of peace (Till et al., 2013).

Even in cases where the members of the divided communities are free to move across the divide, they often opt for not to, due to personal beliefs or out of principal (Pullan et al., 2012b). In the case of Nicosia, some of the members of the Greek Cypriot population consider that by crossing the divide and showing their identification at the border, they acknowledge the legitimacy of the Turkish Republic of Northern Cyprus (Webster & Timothy, 2006).

PUBLIC SPACES

Any space accessible to the general public and part of the built environment could be considered a public space. Squares, streets, gardens, cafés and markets, among others, qualify as public spaces. Dymnicka (2010) argues that a public space is formed by the interactions of its users, while at the same time,

shaping their interactions. However, what determines a public space is a set of rules and restrictions that applies to it, and determines who can use it and how. Amin (2002) argues that most public spaces are 'places of transit' where meaningful interactions among strangers are unlikely. However there is potential for chance encounters among strangers "and in such serendipities rests the opportunity for exchange and learning that can help break barriers" (Gaffikin et al., 2010, pp. 498). In divided cities the motivation for using public spaces may arise from daily tasks, rather than to integrate with neighbors (Pullan et al., 2012b).

Public spaces have been studied based on their functions at the city level, their use and the roles of different stakeholders in shaping them (Madanipour, 2010). In its physical sense, public spaces are urban generators that stimulate communication channels with morphological, environmental and aesthetic values (Lynch, 1960; Marcinczak & Sagan, 2011; Woolley, 2003). Culturally, public spaces are points of convergence that host numerous traditional functions that allow for symbolic value embedded in identity and sense of place. The cultural and political meanings of these spaces are vital in day to day life (Low, 2000). Politically, they are spaces for demonstration, an arena for negotiations of conflict and of political actions (Van Deusen, 2002; Low, 2000; Mitchell, 1995). They can host clashes among oppositions but tensions can change over time, and the resulting effect can be witnessed in shared spaces.

The functions and activities that public spaces allow diverge extensively and so do its users. Activities in public spaces are determined by the socio-economic characteristics and political ideology of its users (Aziz, Ahmad, & Nordin, 2012; Aratani, 2010) and can change the way people behave in these spaces. Public spaces are experimental environments that groups use to legitimize themselves through decisions of where to stay, gather, and socialize (McCann, 1999). They gain genuine significance where groups can react to the condition of co-existence and overcome boundaries of division in a quest to build a consensus of shared living (Abdelmonem & McWhinney, 2015).

Thus the roles, function and even definition of public spaces can have varied connotations. In this paper, we consider a public space as an urban structure, including but not limited to streets, squares, cafés, and parks, accessible to everyone pending a set of rules applied to all users, visible and accessible from the street level, and determined by and determining the interactions of its users.

2.3 SOCIAL INTERACTION

Social interaction is the contact between individuals, groups, and environments (Talen, 1999). Individuals and groups feel the need for social interaction, and find opportunities for it within public spaces (Drucker and Gumpert 1998, Marcus and Francis 1998).

Social interaction can happen anywhere, between any two individuals or groups. Being such an elusive phenomena, it is difficult to measure. Researchers often emphasise the importance of social interaction in public spaces on a local level, i.e. neighbourhood, or residential area. Talen (1999) found that public spaces that are attractive to visitors promote a sense of community. Hickman (2013) found that much of a neighbourhood interaction takes place in spaces such as cafés, parks and shops. One of their most important characteristics is their functional role, for example acquiring goods, entertainment or recreation.

There are different levels of social interaction, starting with very superficial interaction, i.e. observing others and greeting them, to a high level of interaction, which can be found in neighbourhoods where individuals form communities and share emotional investments in the same things (Talen, 1999). When communities are physically separated by a divide and neighbourhoods are relatively homogenous, any level of social interaction becomes relevant and contributes to the social life of a divided city.

SOCIAL INTERACTION WITHIN PUBLIC SPACES IN DIVIDED CITIES

The two major communities of the divided city perform most of their daily activities on their own sides of the divide. The places where they come in contact are limited. Public spaces provide an opportunity for people to interact, by offering a shared space where people can come in contact (Hickman, 2013).

In order for public spaces to attract visitors from both sides of the divided city and become places of social interaction, they must possess certain qualities. The aspects that influence the ability of public spaces to attract visitors and interaction can be grouped in three dimensions – Physical, Social and Activities. The physical dimension includes size and accessibility, both of which define the public space – how will it be used, how many activities and visitors can it accommodate, whether big events can be hosted. The social dimension links back to visitors and their diversity. People attract more people, therefore increasing the possibility for social interaction in public spaces. Also different types of visitors, from different communities and age groups influence the atmosphere of the public space, potentially making them more inclusive. Activities determines what types of activities and events take place in the public space, which increase its appeal, and provide reasons for people to use it. The combination of these dimensions determines the way the public space will be used, and influences its ability to accommodate and promote social interaction.

3 METHODOLOGY

3.1 DATA AND METHOD

Data was collected through expert interviews and fieldwork observation. The interviews were semi-structured and aimed at obtaining information about the social interaction between the two communities and the public spaces in the city, the way they were used, what affected the social interaction in public spaces and how the public spaces influenced social interaction. A total of 13 interviews were conducted with Turkish and Greek Cypriot experts, and international experts involved in bicomunal work.

The indicators of the index were selected through a review of the relevant literature, and further aligned based on the expert interviews and fieldwork observations. The indicators were calculated in their own unit and then standardized to values from 0 to 1. The same formula was used for standardizing the indicators, considering that all of them present benefits:

$$(\text{The value of "X"} - \text{Minimum value}) / (\text{Maximum value} - \text{Minimum value}) = \text{Standardized value of "X"}$$

Where “X” stands for the value of an indicator for a public space, while the minimum and maximum values represent the lowest and highest values of the public spaces for the indicator in question. To determine the weights for each indicator, the indicators that were prioritized are those assumed as having the biggest influence on social interaction, according to the experts’ testimonies (table 1). The exceptions are the indicators “Presence of different age groups at the public space”, that was given a value 1, if members of all age groups were present during the counting sessions, and a value 0, if any age group was not present. In “Number of events taking place in the public space”, the first category (<2 events/ month) was given the value 0. The second category (3-8 events/ month) was given a value of 0.5, and the last category, (>8 events/ month), a value of 1. The “Cafes and restaurants” sub-indicator was given a sub-weight of 0.2, while the other sub-indicators were given a sub-weight of 0.1, adding up to a total of 1, because during the expert interviews this activity was mentioned as more likely to promote social interaction.

Indicator	Data collection and measurement	Rationale	Weight of indicator
Surface area (m ²)	-Extracted from the map of Nicosia. The surface area of any structure which was not a public space was deducted from the total surface area.	Surface area determines the capacity and number of different activities that can happen in the public space. More activities make the public	0.1

		space potentially more attractive and generate opportunities for social interaction (Van Deusen, 2002)	
Accessibility ¹	The road network was used to calculate the distance of each public space to the nearest crossing point. Distances were measured considering all possible combinations with every street. The closest distance was chosen as the best result.	A public space must be accessible to the population it serves (Whyte, 1988). Public spaces that are easily reachable and at a convenient location have more visitors (Shaftoe, 2008)	-
Number of different types of activities carried out	-Guided observation Activities were counted and grouped under: Shopping; Cafes and restaurants; Education; Art and culture; Religion; Private businesses; Beauty services; Non-governmental organizations and International organizations.	The variety of activities attracts more visitors to the area. Activities can be the instigator for communities to cross divide and participate in social interaction (Pullan et al., 2012b)	0.1
Number of each type of activity carried out 2	-Guided observation	A higher number of activities of the same type offers a wider choice to the visitors, increasing chances of getting the visitors interested and spend time in the public space	0.1
Number of events taking place	Information about events in the public spaces came from websites of different organizations, expert interviews, and social media. Grouped as 2 or less per month; 3 to 8 per month; more than 8 per month.	Events such as festivals or concerts have the ability to build solidarity among participants (Shaftoe, 2008). Events attract visitors and make the space more interesting (Holland et. al. 2007).	0.15
Occupant density, walking	-Guided observation Counting the number of people in the public space and dividing it by surface área. The unit of this indicator is people per square meter. Public spaces are divided into sections, of approximately the same size, via imaginary lines, called “gates”, which are observed in five-minute counting sessions. Only the people who cross the imaginary line are counted. The counting sessions are repeated at each gate at different times of day (Grajewski & Vaughan, 2001). The counting occurred at three times of day, 8am to 10am, noon to 2pm and 4pm to 6pm.	The more visitors circulate through the public space, the higher the opportunity for social interaction. The occupant density can also indicate the popularity of the public space	0.15
Occupant density, static	-Guided observation Similar to indicator “Occupant density, walking”. Number of people standing or sitting in the public space, inside each section. People who were sitting in cafés and restaurants were only considered if sitting outdoor.	The more visitors spend time in the public space the higher the opportunity for social interaction. The occupant density can also indicate the popularity of the public space	0.15
Presence of different age groups	-Guided observation The age group classes are: 0-14; 15-24; 25-44; 45-64; 65 and older (Provisional guidelines on standard international age classifications,	Presence of all age groups in the public space indicates that it meets diverse needs and that it is safe and inviting	0.05

Table 1 Indicators, data collection, rationale and weight of the index of social interaction

1. The indicator of accessibility was not relevant in the case of Nicosia, because all the public spaces identified were equally accessible, and at a close proximity to one another. Thus it would not have a significant contribution to the outcome of the index.
2. During the expert interviews, it was determined that locally owned shops and cafés have a greater impact on social interaction. Thus the locally owned activities were given a higher weight.

3.2 CASE STUDY

This paper focuses on the divided city of Nicosia, in Cyprus, which is divided by an UN-administered zone, also known as the “buffer zone”, which can only be crossed through checkpoints. Currently, there are three checkpoints in the city. The Ayios Dhometios (Metehan) crossing, located in the western suburb of Nicosia, is mostly used by cars. The Ledra Palace crossing is located just outside the Venetian walls that circle the old town, the center of the city. The Ledra Street crossing is located in the very center of the old town. Ledra Palace and Ledra Street are intended for pedestrians. Opening the border crossings has helped the economic development of both sides of Nicosia, and revived the public spaces in the area (Gaffikin et al., 2010). The analysis focused on public spaces in the vicinity of Ledra Palace and Ledra Street. The public spaces analyzed also needed to: be accessible to everyone, and no entrance fee charged; the users occupy it for an amount of time longer than needed just to pass through it; the space is used on a daily basis, not only during special events; it is used by the members of both majority communities in Nicosia. Based on field observation and expert interviews seven public spaces were considered, three of which are located on the Greek side of Nicosia (Ledra Street, Faneromeni Square and the Municipal gardens), three are on the Turkish Cypriot side (Lokmaci Street, Buyuk Han market, and Bandabulya market), and one located entirely in the UN buffer zone (Markou Drakou Street) (figure 1).

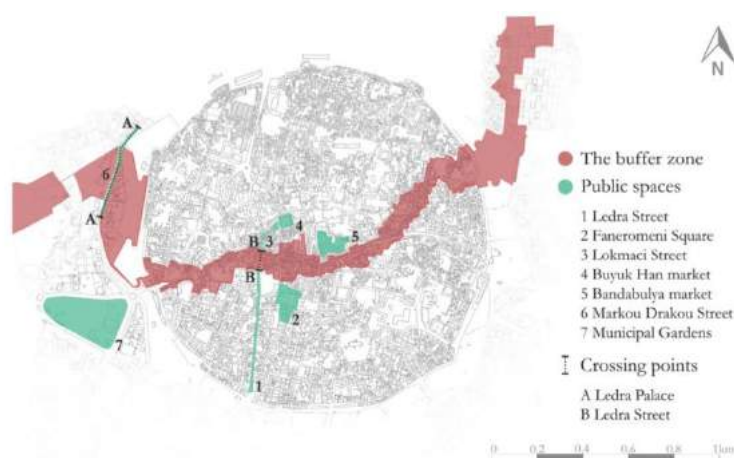

Figure 1 Location of crossings and public spaces analysed

Ledra Street is a pedestrian area with many shops, cafés and restaurants. A department of the University of Cyprus is also located there and brings students and young people to the area. According to the experts, Ledra Street and the surrounding areas were revived after the Ledra crossing opened in 2008: “Ledra Street became more alive, right now, after the borders were opened. It’s more commercialised (than the north side), [...] there are many communities, not just Greek Cypriots, and Turkish Cypriots, but many tourists walking and visiting the place.” (Interview 7).

Faneromeni Square hosts one of the oldest schools in Cyprus, a church, a mosque and a museum. The area also includes a plateau and a network of alleys with cafés and shops and is very popular with both communities. “Faneromeni is not being used because it’s a square, but because it’s part of a café. If cafés bring their chairs outside, it is still public in that sense.” (Interview 1).

The Lokmaci Street was the street of craftsmen and tradesmen, and this tradition lives on in the types of shops found nowadays. There are also local cafés. The area gained significance after the Ledra street crossing was opened. “This area emerged after the borders were opened. It was deserted before the checkpoints opened, now they have come alive. They have attracted new and interesting uses, like cafés, [...]visited by all sorts of people. The mixing of different people creates a culture of diversity.” (Interview 11)

The Buyuk Han market is used as a market and a public space, hosting cafés, restaurants and several shops, locally owned, that sell hand-made products and typical Cypriot ornaments, artist workshops and studios. Several festivals take place here, as well as food markets and live music sessions. Every Saturday, there is a standing meeting for Greek and Turkish Cypriots at one of the cafés and everyone is welcome to join -“Buyuk Han is a prime location, where Greek and Turkish Cypriots meet.” (Interview 11).

The Bandabulya market is a municipal market dating back to 1939, located in the old town. Vendors, mostly Turkish Cypriot, sell fresh fruits and vegetables, meat, ornaments and souvenirs. There are art studios, cafés and restaurants. The market attracts tourists and Greek and Turkish Cypriot population. However, the majority of the users who sit in the cafés and spend time here are the members of the local, older population. “Bandabulya is the old market. [...] here you would see the Greek Cypriots also, but I don’t know if you would see them spending a lot of time. They would go there for shopping” (Interview 6).

The Markou Drakou Street, located entirely in the buffer zone, offers a neutral ground for Greek and Turkish Cypriots, with many meetings and political discussions taking place here. International and non-governmental organizations are situated here, mainly in the “Home for Cooperation”, an educational centre, where events, dialogues, workshops and Greek and Turkish language courses take place. It also hosts a café where events are organized, such as bicomunal music nights, dance lessons, and festivals. Some experts observed that the visitors of the Markou Drakou Street are always the same people. Several private businesses also locate here, and a restaurant where many diplomatic events take place: “This space here ok, it’s controlled by the UN, but it’s usually very quiet unless somebody arranges an event or something. [...] The “Home for cooperation” is very active” (Interview 10).

The Municipal Gardens are a large park, one of the few in Nicosia. Besides benches, a children playground, and one café, there are no activities here. According to some experts, they are used mainly by other minority communities during weekends, or during events. “The Municipal Gardens are frequented by Sri-Lankans and Filipinos. The Asian minorities use it more than the Greek and Turkish Cypriots.” (Interview 13).

4 RESULTS

The main outcome of the index is a score for each of the public spaces, representing their ability to promote and facilitate social interaction between the Greek Cypriot and the Turkish Cypriot communities. The results as well as their position relative to the border and the distance from the nearest crossing are shown in Figure 2. The public spaces are presented on the map in graduated symbols, where the darker colours represents higher scores of the index and the lighter colours represent the lower scores.

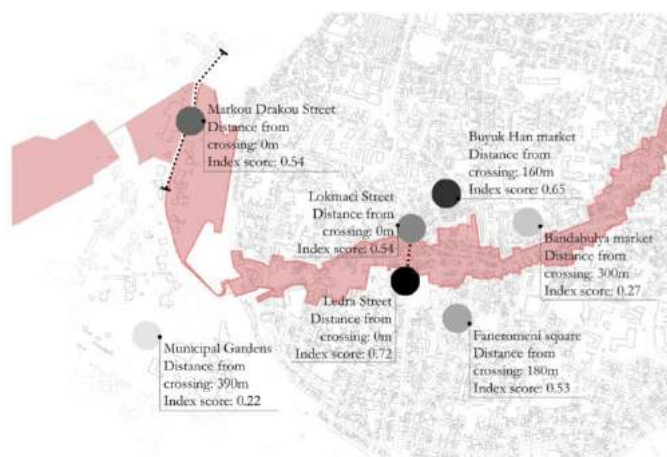

Figure 2 Graduated map of the results of the index for the public spaces.
Source of base map: University of Cyprus, 2016.

Figures 3 to 5 show the results of the standardized values, from 0 to 1. Figure 3 illustrates the physical and social dimensions of occupant density. The public space with the biggest standardized value of the surface area indicator has the lowest occupant density, both for walking and static visitors.

Figure 4 shows which of the public spaces are visited by both members of both communities and members of all age groups. Figure 5 presents activities in public space. We can see that the pattern of activities and events does not vary extremely in the public spaces analysed.

Figure 3. Standardized values of the indicators for the physical and social dimensions of occupant density of public spaces

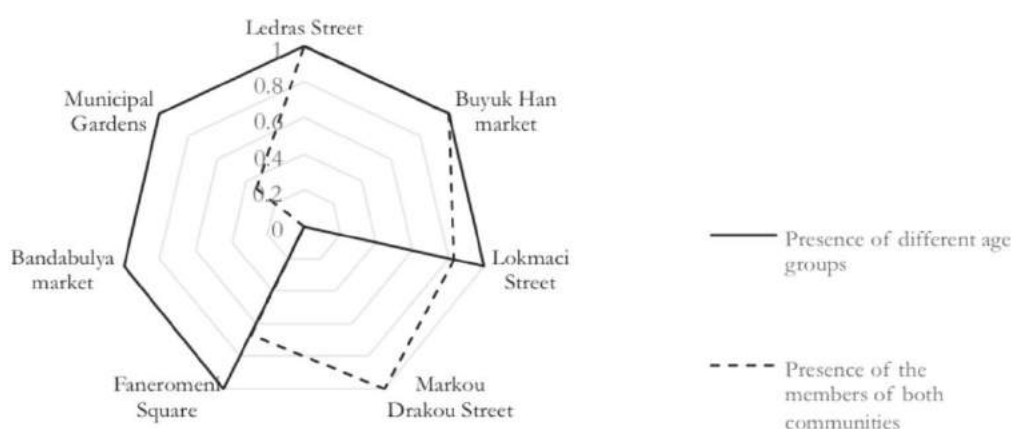

Figure 4. Standardized values of the indicators for the social dimension of diversity in public spaces

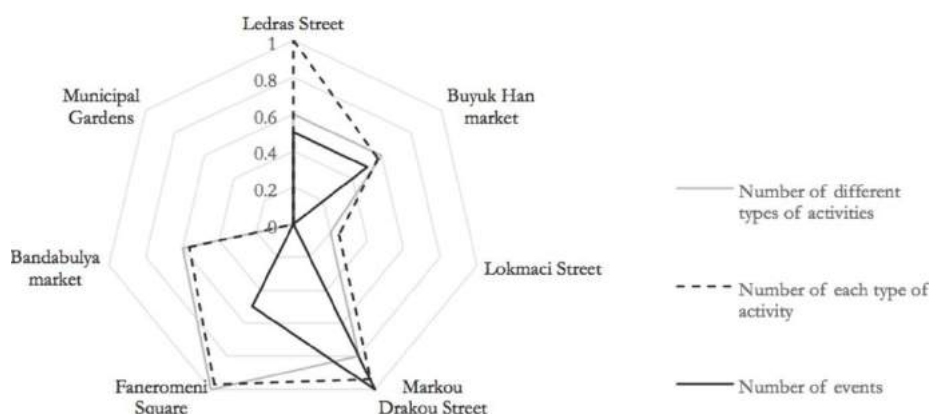

Figure 5. Standardized values of the indicators for the activity dimension of public spaces

We will present only the public spaces with the highest and lowest score in the social interaction index: Ledras street and the Municipal gardens. The results for the Ledra Street are dominated by the fact that the area has the highest number of shops and cafés and restaurants among all the analysed public spaces, both local and brand owned. There is also a high number of people occupying the public space, standing or sitting, considering its size, as seen in Figure 3. This can be related to the high concentration of cafés and restaurants, most of which have a sitting area outside, therefore making the outside area of the café a part of the public space, in the functional sense (figure 6).

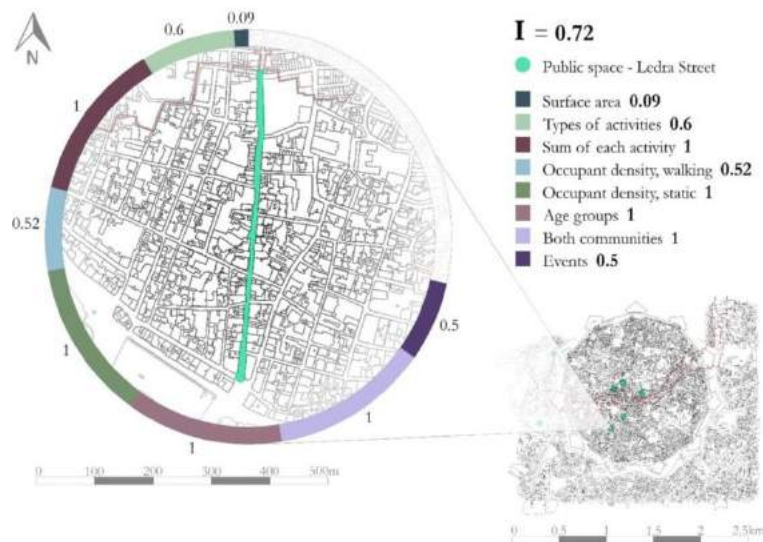

Figure 6 Result of the index of Social Interaction for Ledras Street. Source of base map: University of Cyprus, 2016

The results of the index of social interaction for the Municipal Gardens are shown in Figure 7. In most of the indicators the public gardens score 0. However, this does not mean that the occupant density for visitors that are walking or spending time in the Municipal Gardens is 0 people per square meter, it simply means that the value of these indicators was the lowest among all of the public spaces before they were standardized. Some of the experts mentioned events that happen in the Municipal Gardens, but due to the low frequency of these events, this indicator also had a low score.

5 DISCUSSION AND CONCLUSION

This paper analysed the social interaction in public spaces of divided cities. An index of social interaction was designed and used as a tool to quantify the ability of public spaces to promote social interaction, and applied to the divided city of Nicosia. Different public spaces have different characteristics and qualities that attract visitors, therefore making it harder to compare them. The results of this index were confronted with the input of experts, to better understand why the characteristics of the analysed public spaces might enable or hinder social interaction.

All public spaces analysed are publicly owned areas and properties, with free access. The majority of these spaces are located within and around the center of the city, and in the vicinity of the crossing points. Until the opening of the Ledra Street crossing, this area was heavily militarized. Even though the area was used, it became significantly more visited and lively after the crossings opened. Some of the public spaces in this area were also revived and reopened. For the newer generations of Cypriots, frequenting and sharing these spaces with the community from the other side of the divide is still a new concept. People are going back to using, or learning to use the area of the walled city and the public spaces within it for social and civic life, as opposed to having these spaces used for militarized, border defining purposes. “Infrastructures of peace”, like the “Home for Cooperation”, are being built around and replacing “infrastructures of conflict” (Till et.al. 2013) namely the militarized area. One of the main streets and public spaces in the pre-conflict era was the Ermou Street. Now, the UN buffer zone passes through the majority of the Ermou Street, restricting access to it. However, the citizens of Nicosia still remember the cooperation and sharing the spaces of the city, and commemorate it through a festival called “Ermou 1900”, organized by the “Centre of Visual Arts and Research”, an example of events happening in public spaces that evoke memories of conflict and division, but also of reunion and peace: “Greek and Turkish Cypriot craftsmen, peddlers, come here in Ermou Street, and we dress up people as they were in the 1900s, and they sell their products, as they used to in the 1900s at Ermou Street.” (Interview 12). Ermou street is an example of a public space that vanished with the division. Others emerged from it, like Markou Drakou Street that hosts the “Home for Cooperation”.

According to the experts testimonies, the role of public spaces as places of social interaction is significant because these are the rare spaces where the two communities come in contact and have the opportunity to interact. This implies that the city is acquiring new “places of contact” (Abu-Ghazze, 1999; Farida, 2013; Talen, 1999) between the two communities, the challenge now is how to turn these casual interactions into occasions to overcome the city’s divide: “I think that public spaces help people to come together, and be active, instead of being individuals. They become part of a team. It’s a place to connect. [...] I think it’s a great way to have people in an open space and react with each other” (Interview 9).

The qualities that influence the ability of the public space to promote social interaction are incorporated in three dimensions: physical, social and activity in the public space. It is the representation of these dimensions and their combination that determines the ability of public spaces to promote social interaction. The physical dimension includes the size and the accessibility of the public space. Size was considered as beneficial due to the increased surface area available for hosting various activities such as shops, cafés, events and festivals, hence more people. However, the public space with the largest surface area is the one with the lowest score of the index of social interaction. This finding concurs with the study of Abu-Ghazze (1999), who found that, in the context of residential areas, smaller open spaces felt more inviting and intimate to residents. Residents also preferred smaller public spaces because its users were then more recognizable. Even though that study was applied to public spaces in residential areas, it lends some insight into why in Nicosia, it is the smaller public spaces that have a bigger role in promoting social interaction and instigate the stronger connections between their users.

The social dimension of public spaces included the indicators of occupant density walking and static, and diversity (of age groups and communities). The public spaces with the highest score are the ones with the highest occupant density and presence of different age groups, except for Markou Drakou Street. Activities included the different types of activities, their individual number and the number of events in the public space, important aspects in Nicosia’s relationship with public spaces as seen from the expert interviews. Markou Drakou Street has the single highest score in the indicator of events in public spaces, and significantly high scores of the different types of activities and each type of activity.

The social interaction in Nicosia is place-dependent. The majority of experts agree that the form of interaction between the Greek and Turkish Cypriots depends on the place where it’s happening. However, it is present to a certain degree, especially in cafés and in areas with high concentrations of both communities.

Experts’ testimonies on the use of public spaces and their role in Nicosia acknowledge that they are not used to their full potential. There is a tendency for inhabitants to use public spaces where semi-public activities develop outside, in the street or in the square. This is the case of cafés and restaurants, via their esplanade areas, but also shops or events that “spill over” into the public street. The public spaces which had a larger number of such activities had a higher ability to promote social interaction. This might be

related to the fact that the area where most of these spaces are located is close to the buffer zone, and only recently became available. "I think the role of public spaces is not very prominent in the Cypriot culture. It's not particularly visited or populated. It's not a major element in the city. Of course it's there, and people put chairs and they sit there and they have coffee, but people go to the restaurants, they go to cafés. If you go to any part of Nicosia, you find people in cafés, rather than in a square." (Interview 11)

"I think these are the spaces which were previously the border areas that people had common memories of those spaces, and now they have been opened up. And because they are spaces gluing the city together, or linking the city together, they are available for interaction. It is also convenient because they are accessible. People who live for example in the north, they come to the area near the border, near the buffer zone, it's the same with the Greek Cypriots." (Interview 11).

ID 1332 | THE COLLECTIVE SPACES SYSTEM IN COASTAL AREAS PLANNING – THE IMPORTANCE OF BUILDING A THEORETICAL FRAMEWORK OF EVALUATION OF THE APPROACH OF DIFFERENT TOOLS

Marta Aldrabinha¹

¹Faculdade de Arquitetura da Universidade de Lisboa
marta.aldrabinha@gmail.com

ABSTRACT: The specialised literature links the collective spaces system (SEC, in its Portuguese abbreviation) to: the foundation that structures the urbanized areas; the network that coordinates the different aspects of urbanisation, relating them to each other; the set of spaces the individual travels and from which he interprets and understands the city; the grid which organizes the building and which endures beyond it; an urban value, able to trigger, on its own, other economic or cultural processes,

leading to investment and local initiatives; a driving force of local experiences; and the pillar of a Corbusian balance. Thus, inter alia, – for reasons relating to: the need of structuring the urbanized areas; the urgency of coordinating and relating the constituent aspects of urbanisation; the importance of providing interpretation to the city; the significance of organising the building; the promotion of local initiatives and local experiences; and the urban improvement itself – the role of the SEC in planning should be, nowadays, a central issue of debate. In coastal areas, where – due to agricultural productivity, fishery or energy production, or even for reasons relating to infrastructure concentration, cultural heritage and these spaces potential for touristic and leisure activities – the concentration of population is ultimately significant, this debate becomes all the more important. However, despite the fact that coastal areas planning tools have been directing a multitude of operations for the improvement of collective use spaces in these areas, these measures' contribution regarding the planning of the above areas is still unknown. Furthermore, upon consideration of thirty nine coastal areas planning tools, evidences that the improvement of collective use spaces has been promoted with environmental protection goals were, predominantly, found. If these evidences are verified, then limitations might arise with respect to the contribution of these tools for the coastal areas planning. This article aims to highlight the need of building a theoretical framework which, when applied to different cases and contexts, allows us to undertake this evaluation.

KEYWORDS: collective spaces system, coastal areas planning, coastal areas planning tools, theoretical framework of evaluation.

1 INTRODUCTION

Once acknowledged the sensitivity of coastal areas, as well as these spaces' propensity for the development of a range of activities that are, not always, in line with its carrying and use capacities, several national and international initiatives where its planning was discussed were carried out.

Worldwide, no initiatives have been identified as having the coastal areas planning as the focus of the debate, although six initiatives where this issue was ultimately discussed as a means of responding to other concerns stand out.

In the European context, six initiatives where the coastal areas planning was the focus of the concerns and eleven where this issue was discussed as an operational tool aimed at the materialisation of worries of a different nature have been identified.

Lastly, at Portuguese level, eight initiatives that focus on the coastal areas planning and eight where this issue was discussed as a means of responding to other concerns have been identified.

Despite the multitude of roles given to the SEC by specialised literature, in the context of the identified initiatives, we seem to primarily find evidences that the improvement of collective use spaces has been promoted with environmental protection goals.

If this assumption is verified, then limitations might arise with respect to the contribution of these tools for coastal areas planning. This article aims to highlight the need of building a theoretical framework which allows us to test this assumption.

2 CONCEPT OF SEC

According to Portas et al (2011), the Collective Spaces System (SEC) is:

1. the foundation that structures the urbanized areas;
2. the network that coordinates the different aspects of urbanisation, relating them to each other;
3. the set of spaces the individual travels and from which he interprets and understands the city;
4. the grid which organizes the building and which endures beyond it.

Alternatively, Portas (2012) presents collective use spaces as an urban value, able to trigger, on its own, other economic or cultural processes, leading to investment and local initiatives. By way of example, he lists the cases of pedestrianisation, boulevards, squares, parking, waterfronts, urban parks, promotion of intermodal transport networks, conversion of urban voids and integration of equipment of excellence.

Silva (2015), while focused on a specific type of collective use space – the square, highlights its role in merging the unit and its importance in boosting local experiences.

Lastly, Sequeira (2012), in a perspective resulting from his review of Le Corbusier projects, links collective use spaces to centralities and points out the balance in its construction.

For Sequeira (2012), this balance specific to the collective use spaces of Le Corbusier results from a symmetry and eurhythm – according to the original meaning of the terms – that Le Corbusier had known. In other words, this balance is based on relations established between each part and the unit, between the different dimensions of each part, and between the different dimensions of the unit, representing a construction with no hierarchy, where the perspective is not aimed at a high point.

3 EVIDENCES RESULTING FROM THE APPROACH OF THE ANALYSED TOOLS TO THE SEC

Of the thirty nine coastal areas planning tools that have been analysed, evidences have predominantly reinforced that the improvement of collective use spaces has been promoted with environmental protection goals. More precisely, with a view to combat pollution, preserve biological diversity, promote sustainable development, maintain coastal defences or adopt an integrated response to combinations of objectives.

3.1 COMBATING POLLUTION

In order to prevent marine pollution resulting from the discharge of harmful substances, the MARPOL Convention provided the basis for the rehabilitation/construction of ports that incorporate appropriate infrastructures for receiving and repairing ships that carry said harmful substances.

In the interest of protecting and preserving the marine environment from sources of pollution, the construction of waste treatment facilities derived, among other factors, from the Convention on the Prevention of Marine Pollution by Dumping of Wastes and Other Matter.

Aiming at reducing the combined greenhouse gas emissions, the Kyoto Protocol made way for a myriad of interventions, including the promotion of projects pertaining to the profitability of tidal energy.

With a view towards protecting the environment from the adverse effects of waste water discharges, the Directive on Urban Waste Water Treatment encouraged the construction of collection and treatment systems for urban waste water.

In order to reduce discharges into the sea, especially illegal discharges, of ship-generated waste and cargo residues, the Directive 2000/59/EC of the European Parliament and of the Council, of 27 November 2000, promotes interventions for the improvement and construction of port facilities that allow for the reception of such ships.

Since mitigation is one of the means to fight pollution in order to, inter alia, protect coastal waters, the Water Framework Directive resulted, among other things, in measures of remediation of water bodies; injection of water in geological formations, mines and quarries; injection of natural gas or liquefied petroleum gas (LPG) in geological formations; and construction of catchments.

3.2 CONSERVATION OF BIOLOGICAL DIVERSITY

Taking into account the conservation of biological diversity, the Biodiversity Convention lead to a wide range of initiatives, such as the establishment of the system of protected areas and the promotion of a

series of measures aimed at protecting, rehabilitating and recovering degraded ecosystems and endangered species.

In order to preserve wild flora and fauna, as well as their habitats, the Bern Convention resulted in, among other measures, several interventions aimed at protecting natural habitats and relevant areas for migratory species, as well as banning temporarily, or locally, its exploitation and introducing native species.

To protect, manage, monitor and regulate the exploitation of species of wild birds naturally occurring in the European territory, the Birds Directive introduced a variety of interventions aimed at the creation of protected areas; upkeep and management in accordance with the ecological needs of habitats; re-establishment of destroyed biotopes; and creation of biotopes.

To ensure the conservation of natural habitats in Europe, as well as of wild flora and fauna, the Habitats Directive promoted, among other measures, the development of interventions aiming at maintaining and recovering a favourable conservation status of certain species and habitats.

In an attempt to develop sustainable fisheries that will not undermine the conservation of marine resources, while guaranteeing fishermen's jobs and incomes, the European Union's Common Fisheries Policy lead to a multitude of interventions, particularly regarding aquacultures.

3.3 PROMOTING SUSTAINABLE DEVELOPMENT

In the pursuit of a model for sustainable development , a series of measures stemmed from Agenda 21 regarding conservation and restoration of habitats;, suppression of deterioration and erosion of the coastline; and improvement of coastal settlements in terms of water supply, sewage system, solid waste and industrial effluents.

With the goal of fighting against situations of imbalance caused by the demand and occupation of coastal areas, the European Coastal Charter lead to, inter alia, the construction of raised walkways designed for pedestrian movement without disturbing coastal dunes and the use of native plants at green spaces level.

In order to promote the sustainable development of the European Union's coastal areas, the European Commission's Demonstration Programme on Integrated Coastal Zone Management promoted 35 demonstration projects, including, among others, the following: Strymonikos, Rade de Brest, Vale do Lima, Mar de Wadden, Dorset and La Gironde.

3.4 COASTAL DEFENCES

Prioritizing objectives of environmental protection, the Recommendations of the European Parliament and of the Council concerning the implementation of Integrated Coastal Zone Management in Europe were at the background of protection measures for coastal settlements and its cultural heritage, as well as of the creation and improvement of certain collective use spaces.

In order to recover the natural functions of coastal systems and, therefore, the natural resilience to erosion and flooding, from the EUROSION Project stemmed interventions designed to maintain, or improve, the level of protection granted by some specific construction works relating to new defences; to relocate people and goods ; and to re-establish balance sediment and the necessary space for the occurrence of coastal processes.

3.5 COMBINATIONS OF OBJECTIVES

Among other goals in terms of nature conservation and defence, the legal texts on the drafting and implementation of POOC lead to measures of promotion and improvement of beaches classified as strategic due to environmental or touristic reasons.

Striving for the protection and promotion of certain coastal areas considered sensitive and for the improvement of estuaries, port areas and other degraded areas, as well as for urban rehabilitation and recovery of beaches, dune systems and cliffs, the FINISTERRA Programme lead to a multitude of interventions.

These interventions include measures regarding: recovery and artificial reinforcement of dunes ; beach recharge; regularisation of mouths, sediment transposition of bars and reinstatement of dredged spoils; cliff stabilisation ; maintenance and construction of groins and protective walls; demolition and removal of structures in risk areas; beach rehabilitation ; promotion of public spaces and built heritage; implementation of garbage collection systems and cleaning of beaches; creation of basic infrastructures; rehabilitation of degraded urban centres and settlements; management of habitats considered a conservation priority; artificial opening and dredging of coastal lagoons; revitalization and recovery of salterns; planning, construction and maintenance of facilities and infrastructures relating to artisanal fisheries, aquaculture and activities of recreational navigation; recovery and creation of environmental education centres; and construction of walkways, footpaths, equestrian paths and bicycle lanes.

To ensure environmental quality standards at an European level, the "Livro Branco da Política Marítimo – Portuária Rumo ao Século XXI" lead to interventions in terms of modernisation and recovery of existing terminals, construction and improvement of accessibility networks and logistical platforms, and promotion of security, quality and technological development.

In order to protect and enhance environmental resources, several interventions were promoted within the framework of "Polis Litoral", such as the framework for action of "Polis Litoral Sudoeste", which will be explained below.

Denomination	Nature of the intervention
"Proteção e recuperação de sistemas dunares e arribas" [Protection and recovery of dune systems and cliffs]	<ul style="list-style-type: none"> - Buoying and stabilisation of cliffs and risk areas - Building of accesses and parking - Shutting-down and renaturation of unnecessary paths and unpaved roads
"Reposição das condições de ambiente natural pela recuperação e proteção dos sistemas costeiros" [Reinstatement of natural environmental conditions through the recovery and protection of coastal systems]	<ul style="list-style-type: none"> - Buoying and stabilisation of cliffs and risk areas - Shutting-down and renaturation of unnecessary paths and unpaved roads - Building of accesses and parking - Demolition of constructions in compliance with a future study - Renaturation of areas generated by demolitions and of other degraded areas - Rehabilitation of Lagoa de Santo André, Cabo Sardão – Entrada da Barca, Arrifana, Amoreira – Monte Clérigo and Ponta de Sagres, recovering existing structures and creating new support structures in line with the current needs - Recovery and renaturation of dune systems through planning and signalling of pedestrian movement, construction of wood raised walkways and placement of fences, eradication of alien plant species and planting of indigenous vegetation, and preparation of cleaning actions - Planning of building centres and its infrastructures
"Renaturalização da área designada por Vila Rosalinda" [Renaturation of the area known as Vila Rosalinda]	<ul style="list-style-type: none"> - Demolition of existing buildings and routing of demolition waste to its appropriate final disposal - Environmental and landscape rehabilitation of degraded spaces, namely through renaturation with indigenous vegetation
"Valorização da Reserva Biogenética da Ponta de"	<ul style="list-style-type: none"> - Restoration of existing road network - Blocking the access for motor vehicles in some especially vulnerable places - Placement of land signs and information about existing heritage and natural values - Promotion of cleaning activities and landscape improvement of the area

<p>"Valorização e qualificação de espaços balneares"</p> <p>[Promotion and improvement of bathing areas]</p>	<ul style="list-style-type: none"> - Rectification and completion of interventions already carried out or proposed - Planning and signalling of road traffic and regulation of vehicle parking - Improvement and recovery of road and pedestrian access to the beach - Construction of fences, walkways, places of stay, palisades - Placement of land signs and information about existing heritage and natural values - Promotion of cleaning activities and landscape improvement of the surrounding area through recovery and renaturation of degraded areas
<p>"Requalificação de pequenos aglomerados costeiros"</p> <p>[Rehabilitation of small coastal settlements]</p>	<ul style="list-style-type: none"> - Creation of pedestrian paths - Construction of public spaces (pedestrian areas and squares) - Dredging and excavation of the basin - Demolition of existing supports for fisheries and construction of new ones - Licencing and construction of a restaurant in the pier - Placement of fingers, stakes and other mooring equipment for recreational and tourist boats - Creation of a bicycle lane - Rehabilitation of public spaces - Control of access, parking and motor traffic - Improvement of conditions for road traffic and pedestrian movement - Placement of quality urban furniture that will further strengthen the identity and consistency of the location - Intervention on the urban ecological structure and green spaces, creating new places of stay - Improvement of the urban image - Improvement of urban centre's public spaces - Rehabilitation of the public space on the riverside near the settlement's fishing area, according with a project drawn up by Vila do Bispo Municipal Council - Development of a green space area within the framework of cliffs, integrated in the urban rehabilitation project of Vila do Bispo Municipal Council regarding the fishing area
<p>"Ecovia e ciclovias do Litoral Sudoeste"</p> <p>[Bicycle lanes of the southwestern coast]</p>	<ul style="list-style-type: none"> - Adaptation of existing rural paths to bike lanes - Placement of land signs and information (touristic and environmental) - Creation of landscape observation and rest areas - Landscape rehabilitation of areas surrounding the bicycle lane, fostering cleaning and removal of weed species, as well as planting of indigenous vegetation - Construction of bike lanes enabling easy and alternative access to beaches - Placement of land signs and information (touristic and environmental) - Creation, where necessary, of landscape observation and rest areas - Landscape rehabilitation of areas surrounding the cycling lane, fostering cleaning and removal of weed species, as well as planting of indigenous vegetation
<p>"Estruturas de apoio ao recreio e lazer"</p> <p>[Recreational and leisure support structures]</p>	<ul style="list-style-type: none"> - Promotion and improvement of picnic sites and places of stay, emphasising these spaces as a support to guests

1. promotion of the natural and landscape heritage — incorporates the protection projects regarding dune systems and cliffs (outlined in light green in Figure 2), the reinstatement of natural environmental conditions through the improvement and protection of coastal systems (outlined in dark green in Figure 2) and the measures regarding de rehabilitation of the natural heritage (marked with circles in Figure 2);
2. territorial improvement supporting traditional economic activities — incorporates the interventions of improvement and promotion of fishing centres (marked with blue in Figure 3), of small coastal settlements (marked with orange in Figure 3) and of bathing areas (marked with yellow in Figure 3);
3. diversification of experiences in the territory, enhancing indigenous resources — incorporates the projects and actions aimed at promoting sustainable mobility (path marked in Figure 4), creation of support structures for activities of contact with nature and implementation of equipment for dissemination of natural and cultural values specific to this territory (marked with circles in Figure 4).

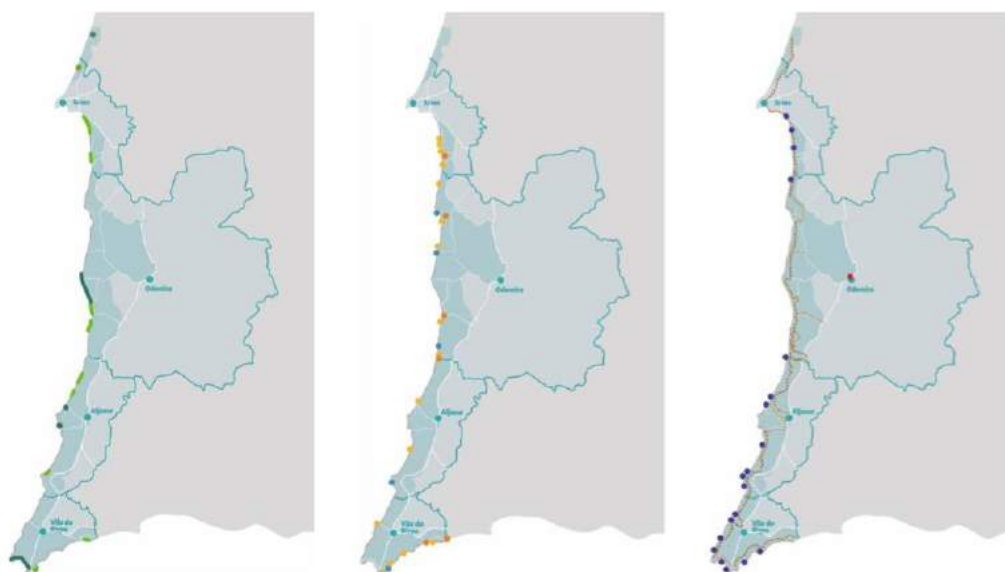

Figure 2 – Interventions fostered around the axis of promotion of the natural and landscape heritage | Figure 3 – Interventions fostered around the axis of territorial improvement for supporting traditional economic activities | Figure 4 – Interventions fostered around the axis of diversification of experiences in the territory, enhancing indigenous resources

4 CONCLUSION

The specialised literature links the collective spaces system (SEC) to: the foundation that structures the urbanized areas; the network that coordinates the different aspects of urbanisation, relating them to each other; the set of spaces the individual travels and from which he interprets and understands the city; the grid which organizes the building and which endures beyond it; an urban value, able to trigger, on its own, other economic or cultural processes, leading to investment and local initiatives; a merging component of a unit, which contributes to boosting local experiences; and a set of centralities, which are built upon a Corbusian balance.

However, of the thirty nine coastal areas planning tools that have been analysed, evidences have predominantly reinforced that the improvement of collective use spaces has been promoted with environmental protection goals. More precisely, with a view to combat pollution, preserve biological diversity, promote sustainable development, maintain coastal defences or adopt an integrated response to combinations of objectives.

From the interventions promoted to combat pollution, it is worth highlighting the rehabilitation/construction of ports that incorporate appropriate infrastructures for receiving and repairing ships that carry harmful substances, the construction of waste treatment facilities, collection systems and urban waste water treatment and the remediation of water bodies.

Regarding the interventions promoted for the conservation of biological diversity, it should be underlined the establishment of the system of protected areas, the promotion of a series of measures aimed at protecting, rehabilitating and recovering degraded ecosystems and endangered species, the creation of biotopes, and the formation of aquacultures.

Some interventions were encouraged in order to promote a model for sustainable development, such as suppression of deterioration and erosion of the coastline, improvement of coastal settlements, construction of wood raised walkways for pedestrian movement, renaturation, and some demonstration projects.

Regarding coastal defences, some interventions to build new defences were promoted, while other measures aimed at maintaining, or improving, the level of protection granted by previous construction works. Moreover, some interventions pertained to the relocation of people and goods and to the re-establishment of balance sediment and the necessary space for the occurrence of coastal processes.

For an integrated response to the combinations of objectives previously listed, several interventions were promoted, such as: promotion and improvement of beaches classified as strategic due to environmental or touristic reasons; cliff stabilisation; demolition and removal of structures in risk areas; artificial opening and dredging of coastal lagoons; revitalization and recovery of salterns; planning, construction and maintenance of facilities and infrastructures relating to artisanal fisheries, aquaculture and activities of recreational navigation; recovery and creation of environmental education centres and construction of walkways, footpaths, equestrian paths and bicycle lanes.

Since the implementation of these interventions was based on the development of specific projects that, although being promoted for the aforementioned purposes, eventually reflected other concerns, it is important to verify whether or not they convey the roles defined on specialised literature for the SEC. Thus, the need of building a theoretical framework that allows us to undertake this evaluation is seen as justified.

ID 1333 | PLANNING OF URBAN GREEN AREAS BASED ON GIS TOOLS

Fernando Cruz¹, Nuno David², Nelson Mileu³

¹LEAU/ULHT, IST, ULisboa/IGOT

fcruz@gmail.com ; nunomigueldavid@gmail.com ; nmileu@municipia.pt

ABSTRACT: Decision processes regarding the use of public resources in green infrastructure requires new approaches capable of providing on-going evaluation and trade-off analysis concerning the level of service that new urban green areas can provide in social-ecological terms. Such information is critical either to improve decision-making, planning practice (e.g. new locations) or even to improve landscape design processes. In order to solve these concerns, the present study aims to provide a model-based tool that allow to estimate service areas in Oeiras municipal ecological structure, but also capable to geographically identify socially meaningful areas for public investment regarding new urban green spaces. The study was developed in two phases. Grounded on kinematic laws and multi-criteria decision principles a conceptual model was initially shaped. Incorporating criteria and sub-criteria such as (i) the friction of slopes and (ii) the friction regarding physical conditions of the pedestrian public space (e.g. materials, dimensions, accessibility conditions, and others) into the model, the results revealed to be consistent with reality. This allowed developing a decision support system based on GRASS GIS and Bottle, in a second phase. The application was developed in Opensource environment using the Python language, which allows programming the model and having as outputs the simulation of green space service areas and the

identification of geographical locations for new ones, improving decision-making in landscape planning context and optimizing human and financial public resources.

KEYWORDS: Service area; Green spaces; GRASS; Python; GIS processing; Web-Based DSS.

1 INTRODUCTION

The importance of urban green spaces nearby residential areas, as well as solid accessibilities from such areas are increasable related with quality of life indicators (Madureira, 2012; Schipperijn et al., 2010; Figueiredo et al., 2016), and became a priority issue in terms of good governance practices. The present study aims to contribute for better decision making, concerning the optimization of public resources (e.g. financial and human) in local administrations regarding management of urban green infrastructure.

The accessibility of urban green spaces is an important issue regarding the contribution for the quality of urban environment in cities (Herzele & Wiedemann, 2003). Therefore the estimation of 'green space service areas' (GSSA), can provide a good framework for understanding the social influence of a given green space, by combining territorial coverage with a set of external attributes that can influence user's behavior (e.g. physical conditions in road network or slopes). By using Geographical Information Systems (GIS), we have created spatial illustration of distances by measuring accumulated distances through an accurate representation of urban pedestrian network in Oeiras municipality (e.g. promenades, plazas and pedestrian streets).

This accurate representation of pedestrian network and it's physical characteristics, allows obtaining a more realistic framework for decision-making, when comparing with alternative approaches based in direct Euclidean distances analysis and considering the territory as an isotropic feature. Firstly, we have combined classical mechanics principles and kinematic laws within a classification system for representing physical conditions of public pedestrian network. We used a multi-criteria analysis model in order to obtain a weighted representation of pedestrian conditions of accessibility along urban network, according to municipal experts. Combining results (accumulated distances) with demographic census information, allows visualizing the influence of existing urban green spaces, and permits a geographical identification for new potential locations in the future.

Secondly, we develop a web decision support system based on GRASS GIS and Bottle in order to operationalize the model. The advantage of this system is the fact that it is simple and straightforward, and does not require expertise in GIS applications, but only being familiar with web and the basic concepts related with green urban areas modelling.

2 METHODOLOGY

Service areas are directly related with pedestrian accessibility conditions and mobility. Beside physical conditions of users, accessibility conditions are influenced by public space attributes (e.g. quality and type of pavements, street dimensions, existence of architectural barriers) and topographic conditions (e.g. slope values along pedestrian network). The relation between pedestrian travel speed, it is also related with topographic conditions or slope degree (Figure 1).

Figure 1 -Pedestrian speed according to different slope values

We consider the maximum speed of 1.5 m/s (5.4 km/h) in a flat surface, as reference value for an adult in regular physical form. We also consider that an elderly person or someone in a wheelchair under the same topographic conditions can travel at an average speed of 1.2 m/s (4.3 km/h) (Silva, s/d). The slope (D) establishes a relation between the altimetric values of the terrain (ΔH) and distance (d), corresponding to the tangent of the angle of the terrain (φ), and can be expressed as a percentage:

$$D\% = \frac{\Delta H}{d} * 100 = \text{tg } \varphi$$

The image bellow represents an extract of a slope map generated from Delaunay triangulation (Figure 2).

Figure 2 -Pedestrian speed according to different slope values

Modal walking width (m) Typologies of public spaces	Average walking speed, (V) (m/s)	Average walking speed, (V) (Km/h)
[0,00 – 0,90]	[0,00 – 0,75]	[0,00 – 2,70]
[0,90 – 1,20]	[0,75 – 0,98]	[2,70 – 3,50]
[1,20 – 1,80]	[0,98 – 1,22]	[3,50 – 4,40]
> 1,80	[1,22 – 1,81]	[4,40 – 6,50]
Footpath	[1,81 – 2,40]	[6,50 – 8,60]
Zebra crossing	1,22	4,40
Road / parking / crossings	0,75	2,70
Car traffic separator and roundabout interior	0,00	0,00

Table 1 -Pedestrian average velocities (m/s and Km/h) according to different characteristics of public spaces.
Based on Silva, n/d; Seabra et al., 2011; Seco et al., 2008.

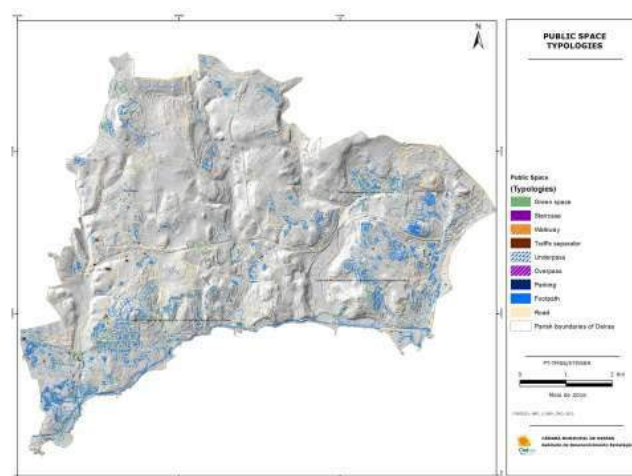

Figure 3 -Different typologies of public space in Oeiras municipality.

Through classical mechanics formalizations (Halliday, 2009), it is possible to represent space (e, in meters) and time (t, in minutes), on a friction surface (2D) using the following algebraic expressions, where R represents a spatial resolution (in meters):

$$[2] \quad t = \frac{60.e.R}{v.10^3 \left(\frac{\text{km}}{\text{h}}\right)} \text{ (min)}$$

$$[3] \quad e = \frac{v.10^3 \left(\frac{\text{km}}{\text{h}}\right).t \text{ (min)}}{60.R} \text{ (m)}$$

By generating accumulated cost surface in public space, it is possible to represent several pedestrian velocities according to different values of slope friction and distinct architectural characteristics. Weighting 60% for slope friction and 40% to characterize public space friction, a global friction surface was obtained as well as global velocities. After testing 'in situ' in a limited number of places, the results seem to be consistent with the perceived reality. As result, we propose a friction surface that represent the crossing time over each pixel in public space (Figure 4).

Figure 4 - Pedestrian velocities according to different typologies of public space.

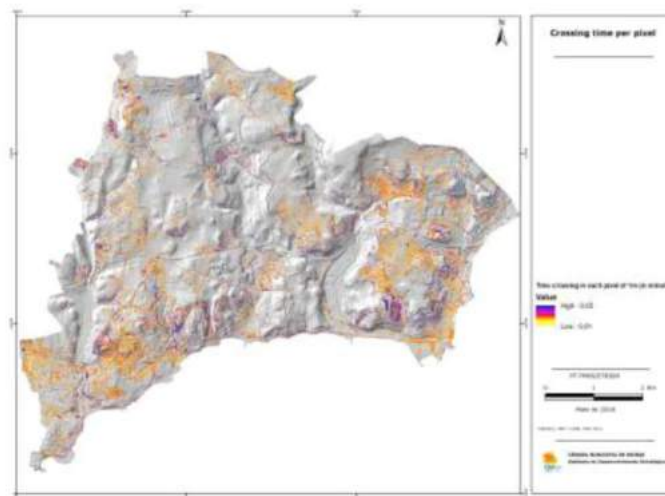

Figure 5 -Time crossing in each pixel (in minutes).

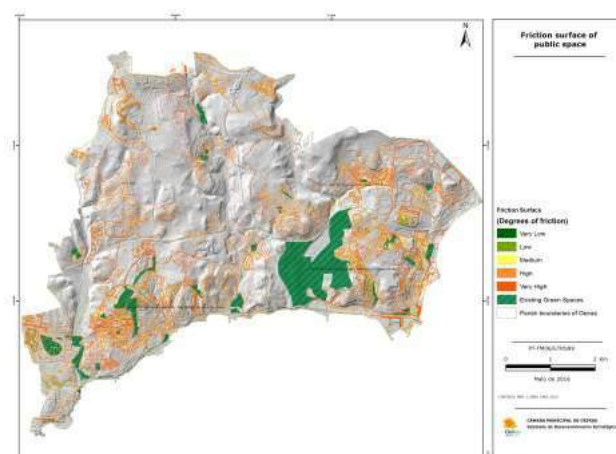

Figure 6 -Friction surface of public space.

2.1 ACCUMULATED COST SURFACE

The accumulated cost surface matrix represents the irradiation of pedestrian mobility, in 'time-distance' thought public space network, from each green space. Therefore, the influence of their distances were defined through time intervals in minutes (Figure 7), and time-distance can be represented by time-space in meters (Figure 8). The cumulative values of each pixel allows generating distances (fluxes) of influence from the radiation points or in this case, each green space. The geographical information was generated using Spatial Analyst extension from ArcGIS10.1 software.

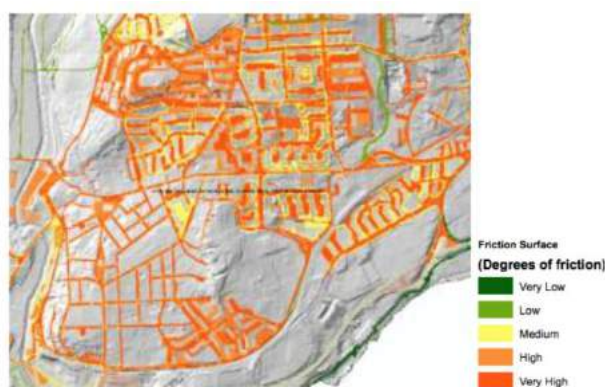

Figure 7 - Detail of the friction surface in public space.

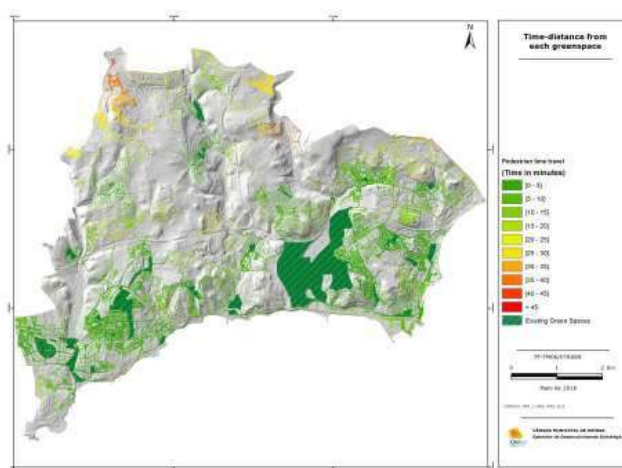

Figure 8 -Pedestrian time travel from each greenspace (accumulated cost surface).

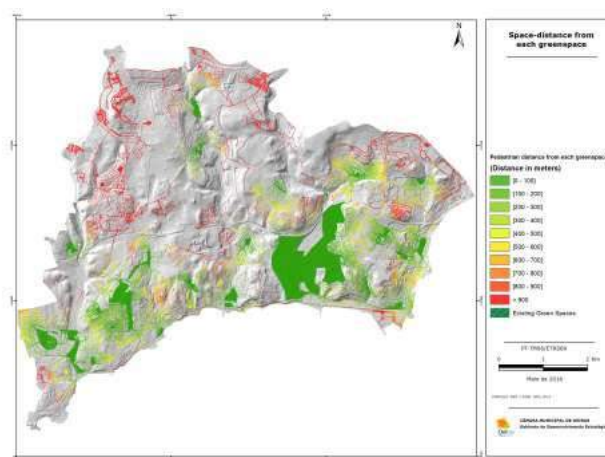

Figure 9 -Pedestrian distance from each greenspace (accumulated cost surface).

2.2 GREEN SPACE SERVICE AREA

After generating accumulated cost surface, we have conducted a reclassification in order to obtain time-breaks (in minutes) and distance-breaks (in meters). This information was intersected with census polygons (BGRI) in order to obtain a green space service area (GSSA), Figure 10.

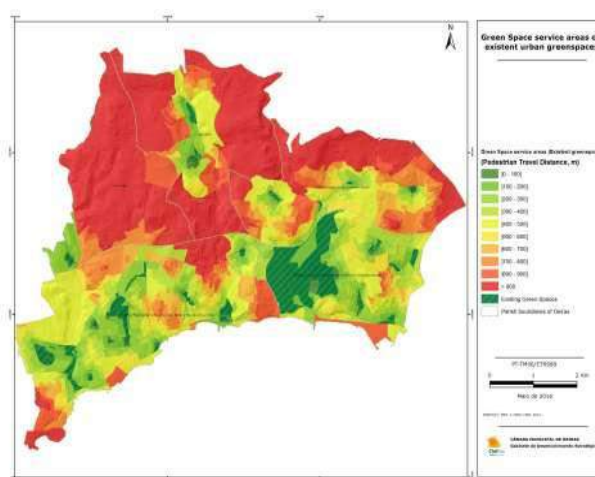

Figure 10 -Green Space service areas of existent urban greenspaces.

This analysis allowed modeling the spatial coverage of green spaces, by identifying which areas are near or distant from urban green spaces. Based on literature, we adopt 500 meters as initial reference distance in which an average individual might be willing to move in to a green space.

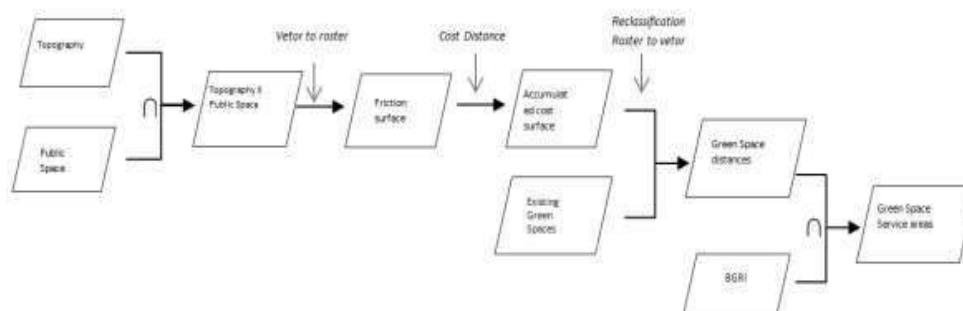

Figure 11 -Workflow for green space service areas.

Intersecting GSSA information and BGRI polygons, allows merging statistical data (e.g. individuals, families, residences, buildings) with urban plots, in order to obtain socio-demographic, socio-economic and socio-urban profiles.

2.3 COVERAGE ANALYSIS AND DETERMINATION OF PRIORITY LOCATIONS FOR NEW GREEN SPACES

In order to prioritize investments regarding new urban green spaces, we choose to use a multi-criteria decision analysis (MCDA) model, and specifically the weighted sum model. Taking 500 meters as reference distance for accessing urban green space, we have estimated low coverage areas (figure 12), as well as criteria and value scales (Table 2). Considering C1, C2 and C3, we rank $C3 > C1 > C2$, and after applying Swing Weight technique (Goodwin, 2004) the result was $WC3=0.37$, $WC1=0.34$ e $WC2=0.29$.

Criteria	Value-scales
1 Population density. This allows to identify low, medium and high density area	[0 – 25] inhabitants/hectare – low density; [25 – 50] inhabitants/hectare – medium density; > 50 inhabitants/hectare – high density
2 Cost distance	[500 – 600] m, [600 – 700] m, [700 – 800] m; [800 – 900] m and >900m
3 Transferred areas (green spaces) for public domain or potential areas local municipal domain	Binary (yes/no)

Table 2 -Criteria and value-scales for MCDA model.

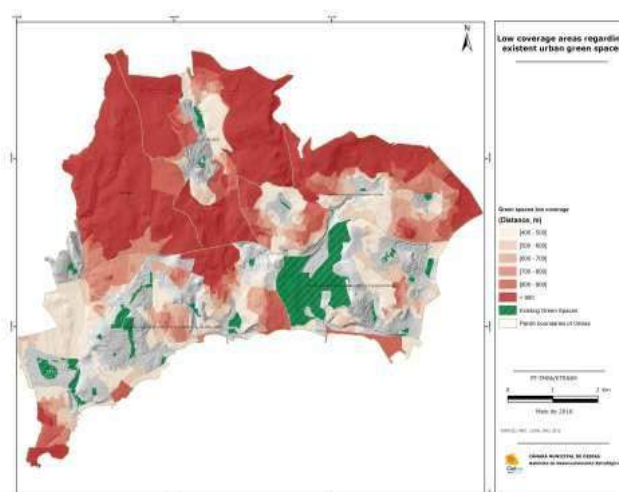

Figure 12 -Low coverage areas regarding existent urban green spaces.

In order to normalize criteria increasing (from 0 to 100 percent) and binary (yes/no) scales were used (Table 3). The priority level (P) of each green service area (alternative) is expressed in percentage and it's given by the weighed sum model [4], in which W_i express the weigh in each criteria and C_i express the value in each criteria. This model is also called 'weighted linear combination model' and has the advantage of enabling weighting criteria and allowing ranking the results (Goodwin, 2004).

C1-Population density (Hab/ha)	C1 (Value 0 .. 100)	C2-Cost-distance (m)	C2 (Value 0 .. 100)	C3-Transferred areas for public domain (Yes; no)	C3 (Value 0 .. 100)
0 (null)	0	[500 – 600]	25	no	0
[0 -25] (low)	25	[600 – 700]	50	yes	100
[25 – 50] (medium)	50	[700 – 800]	75	-	-
> 50 (high)	100	[800 – 900]	85	-	-
-	-	[800 – 900]	95	-	-
-	-	>900	100	-	-

Table 3 -Value-scale normalization.

3 RESULTS

3.1 COVERAGE ANALYSIS AND DETERMINATION OF PRIORITY LOCATIONS FOR NEW GREEN SPACES

Figure 13 expresses, in quartiles, the priority level for each green service area (alternative) inside the low coverage areas. The areas above 75% represents the ones that should be consider 'priority areas' regarding the installation of new urban green spaces. The result allows programming new green spaces that have the potential for being socially relevant, and that should be critical to better rationalize public resources, particularly in periods of great restriction regarding public investment. These reserves for urban green spaces are accessible in a maximum distance of 400 meters for the secondary ecological structure (e.g. neighborhood gardens and small parks) and 800 meters for main ecological structure (e.g. urban and metropolitan parks, urban forests).

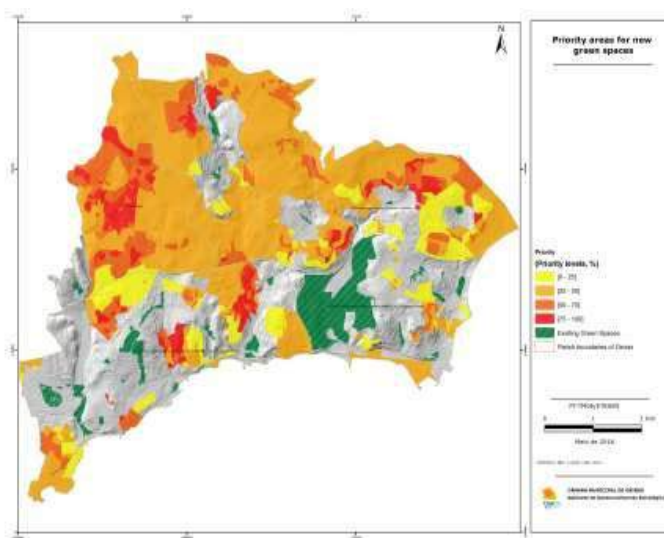

Figure 13 -Priority areas for new green spaces.

3.2 DESIGNING AND DEVELOPMENT GUADSS

The web green urban areas decision support system is based on the client\server model, following the structure shown in figure 14. The client\server approach has a three tiered consisting of: Tier1: web browser; Tier 2: web server, GIS Server, web-framework for Python and a geoprocessing server; Tier 3: data.

The system was developed using Python Tools for Visual Studio, Java Script, and GRASS Python Scripting Library for the geoprocessing functions implementation.

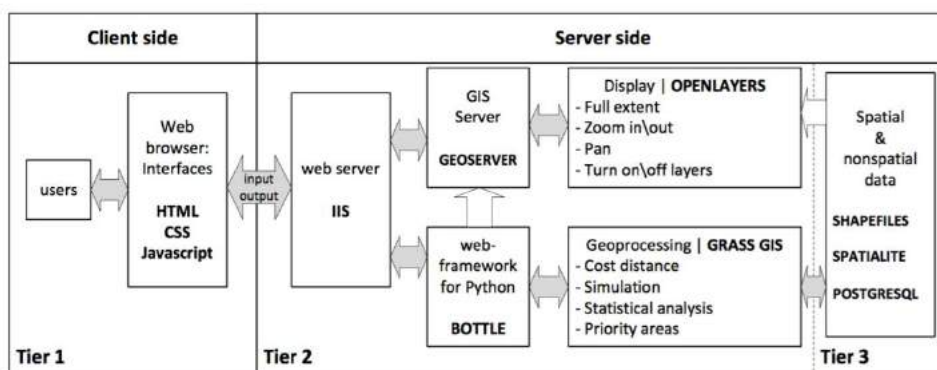

Figure 14 -GUADSS architecture.

The information flow is as follows:

1) Users initiates a request setting the input layers, the cost surface and priority layer weights and drawing (or importing the geometry) the new green urban areas on the web browser; 2) the web server passes the requests to the geoprocessing server to do the processing such as cost distance, influence of the new green urban areas, statistics and priority areas definition; 3) the geoprocessing server creates the intermediate data, the final layer and passes the results to the web server and GIS server; 4) the geographic output is displayed using Geoserver, the statistics graphics are displayed using D3 javascript library; and 5) the web browser displays the results using Ext and jQuery javascript libraries allowing all the outputs to be downloaded.

3.3 THE DECISION SUPPORT SYSTEM -GUADSS APPLICATION

The application was developed and tested using Oeiras municipality data and was deployed only for the municipality intranet users. Figure 15 shows the main interface, where it is possible to access the general GIS functions like full extent, pan, zoom in, zoom out or layer turn on/off. The three buttons near the general GIS functions are the specific tools that allow the users to upload new input layers or delete existing layers, start the processing system and access the results.

Figure 15 – GUADASS main interface.

The user needs to go through the seven sequential interfaces to start a simulation process (Figure 16). The first interface is an overview of the system. The second interface is used to select the input layers, like existing urban green areas, ceding areas, statistical sub-sections and reclassification rules. In the third interface, the user must draw the new urban green area in the map or upload a shapefile (e.g. polygon) with the urban green area project limit. The following two interfaces are used to define the cost surface and priority areas by defining weights. The weights have default values, but it is also possible to create different scenarios by setting them. In the next interface, users need to set the output workspace and output name. Since the processing takes some time, it is possible to receive an information e-mail when the process is finished. Finally, users just need to click the processing button and wait for the email, or wait until the page displays the end process message.

Figure 16 -GUADSS main interface.

Figure 17 exemplifies an analysis result, for a new green urban area in Porto Salvo parish, based on the default parameter settings. The results interface gives the possibility to download or delete the output layers, add the areas of influence of existing and planned green spaces layer as a WMS to the map window and access a statistical analysis. This statistical analysis is based on the simulation process results and over nine 2011 census variables (population, age structure, school grades, buildings), and allow a more effective support to decision making.

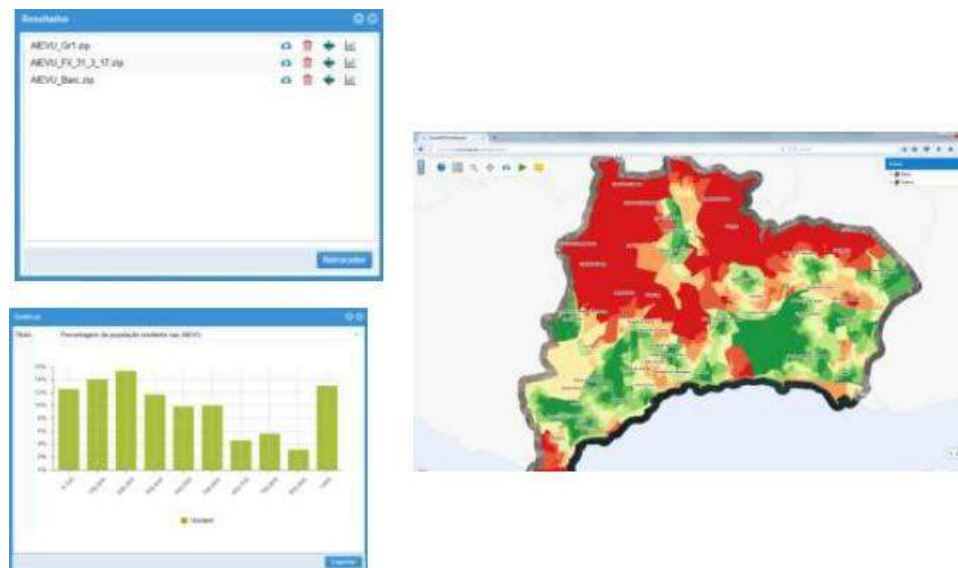

Figure 17 -GUADSS results interface.

4 CONCLUSIONS

The methodology that was used appears to be appropriate and innovative because it considers pedestrian mobility and accessibility over public space from an integrated perspective, by exploring MCDA models, which allowed considering diverse points of views in decision-making. The information regarding public space typologies in the municipality of Oeiras was characterized from considering factors like terrain roughness, architectural features and characteristics of the public space. Based on classical mechanical principles, we explore the potential given by a simple and reliable model that is able to represent pedestrian speed, travel time and space traveled. By using BGRI information, we add useful statistical information (e.g. individuals, families, residences and buildings) which allows drawing GSSA. Those were then typified by using non-euclidian intervals of 100 meters, enabling to identify low, medium and high coverage classes for the entire municipal territory. Using criteria like population density, cost-distance and the availability areas for new green spaces, we used a MCDA model that enables a geographically identification of priority areas for future green spaces. The model also provides better decision-making because it improves transparency and robustness regarding the allocation of public resources (e.g. human and financial). Regarding decision support system GUADSS, the experiments indicates that this web geoprocessing approach have several advantages when compared with the traditional desktop solution. The main advantage is time saving and the simplicity of using it. With friendly user interfaces, GUADSS allows any user to simulate different green urban areas scenarios without having specific GIS knowledge. Timely response is critical to attract the application users. However, geoprocessing with large datasets and with complex tasks takes time. This performance issue is being analyzed and all the hardware and software improvements are being considered. Another direction for futures development includes some

algorithm improvements to solve problems related with areas that don't have public space. For this problem, a possible solution could be based on the iteration over adjacent or not null results to obtain the average.

1 THE NATURE OF FAST URBANIZATION IN CHINA

According to Marx's definition, capital is a value in motion, and value is decided by social labor time necessarily put in the production of commodities. The capital's motion can be divided into four phases: production, realization, allocation and value proliferation. The four phases form a cyclic process. Through this process, capitals go through infinite reproductions. It is an upward spiral course, but this cycle won't continue perfectly forever.

David Harvey says, when consumption is weak, in order to mitigate the overcapacity crisis caused by excess capital accumulation in production field, productive consumption is needed to stimulate economic growth. Current large scale infrastructure construction and urbanization construction in China is this process. These constructions consume a large amount of means of production like steel and cement, so values of steel and cement are realized, and excess capacity is used. Also, the Cold War after the Second World War and the large-scale urbanization of suburbs in America were effective measures of using productive consumption to mitigate excess capacity in production field.

But the scale of Chinese urbanization is much larger. Within three years from 2011 to 2013, China consumed 6.5 billion tons of cement, which was even more than the total volume 4.5 billion tons consumed in the 20th century in America. The construction activities alone absorbed 25% global steel production. But Harvey believed that capitals transforming from production field to urban built environment just transferred and postponed the problem of excess accumulation of capitals but didn't eliminate the problem. He also views the initial stage of current global economic crisis as 'urbanization's financial crisis'. Urban investments normally take a very long time, and it takes even longer time to get mature. So usually it's very hard to judge when capitals are over accumulated or when over-accumulation will occur on investing in built environment.

The investments on fixed assets (broadly defined construction index) in China in 2014 accounted for 80% of the GDP. Since modern era, no country has ever reached such a high investment level. Even in Japan, in the 80s of the 20th century when construction industry was in peak, it was merely 35% of its GDP. As for America, the number has always been around 20% of its GDP. Looking in the long run, activities creating and producing spaces are obviously speculative, though these activities originally aim to eliminate over accumulation. But later on, the risk of even larger scale of over accumulation will perhaps occur in the construction and environment fields. Therefore, both urban construction and infrastructure investments have characteristics of having crisis easily. This can be seen from the periodicity presented in such kind of investments in America and Britain in the 19th century. (Figure 1, figure 2)

Figure 1 – Different Built area Investment Rhythm of UK and USA

Figure 2 –Built area per capital and land selling in USA

This large scale urban construction activity was what had been said by Lefebvre, 'Change from the production in space into the production of space itself', namely capitalized space or the urbanized capitals. So, urbanized capitals mean capitals transform from the production itself to the urban built environmental production, to mitigate over accumulation in production field, meanwhile drive the urbanization process. The essence is that space after absorbing capitals, means of production and labor's work time, turns into a commodity with certain value that can go through transactions in the market. Housing or other urban space products when they are sold out or consumed again and again, their values get realized in this way.

Lefebvre applied the logic of Marxism to social space field, he pointed out 'space production is the reproduction of social relationship'. He views space as a kind of massive social resource, which is impacted and shaped by many factors such as history, nature, society and etc. It is factually a complex product filled in with various ideology and social production relationships, a process of social relationship reorganization and social order construction. Lefebvre went on to say, 'No matter where, what's in the center is the reproduction of production relationship.'

2 THE CAUSES AND MAIN PROBLEMS OF "VILLAGE IN THE CITY" IN CHINA

In China, the urbanization process since 1990 is also a process of over accumulation of built environment. In 1994 when tax distribution system reformed in China, local government gained some financial autonomy as well as bigger competition pressure. Over 20 years since then, real estate development had been one of the most important work contents of local government. 'selling lands' was local governments the principal source of revenue. When most cities in China adopt this kind of urban development module, serious excess and over accumulation in built environment will be caused.

During 1998 – 2004, the built urban area had increased by 9027 km² in China that was the equivalent of nearly 14.5 times of Singapore's land area and 1/4 of the Taiwan Island area. Land acquisition area had expanded from 515.54km² in 1998 to 1612.56km² in 2004. And in 2002 it reached the peak at 2879.86km². This indicated Chinese cities are spreading outward at an unprecedented speed, which was called by international and domestic medias as 'Chinese way of building cities'.

However, urban villages are precisely the frontier of Chinese urbanization development, the most vigorous districts in the expansion of urban space, but meanwhile many problems exist in villages in the city.

1. Illegal buildings are many. In the fast expanding process in the city, villages are quickly surrounded by high-rise buildings. Land price, property price, rentals are also pushed up and increase greatly. Driven by rental and compensation for housing demolition, villagers make use of every bit of space to make private constructions, such as 'filling the gaps', 'new expansions',

- 'build upon old constructions' etc. Various illegal constructions are banned a number of times but never stop.
2. Environmental hygiene is poor. Basically, villages in the city don't have fences, thus unable to implement closed property management. There are many external tenants, mixed and disorderly people, poor environmental management, and various safety hazards in existence. Besides, various facilities are poor, public green space and sports utilities are in shortage, which become neglected corners of public hygiene in the cities.
 3. Land utilization is low. Villagers' buildings in urban villages are mostly single family type, which occupies large area with high density. As a result land occupation rate is high but utilization rate is low. What's more, many urban villages took up privileged locations in the city, but their comprehensive development is far lagged behind the surrounding areas, which is a huge waste of land resource. In modern urban life, people cares living environment and also the cultural environment. Villages in the city are the city's failures by the appearance with poor internal social security and low population's quality. Ordinary residents are unwilling to live in the neighborhood, so the value of lands and housing nearby urban villages is impacted and devaluated.
 4. Social security problem. The public infrastructure construction and maintenance in urban villages hasn't been perfectly incorporated into the city's system. Large parts of residents in the urban villages haven't enjoyed the same social securities as ordinary urban residents do. Public infrastructure maintenance, villagers living subsidies, old pension, medical insurance and etc. are largely paid by village's collective economy, subsequently collective assets are eaten away over time.
 5. Employment problem. Because the incomes from collective economy's dividends allocation and private house rentals are very nice, residents over the age of 35 are lack of education and labor skills and 20-year-old young people have psychological barriers with their talents smaller than ambition problem. So residents in urban villages are drifting away from the city's employment system.

Traditional villages tied with blood relationship, affinity, geography, Chinese clan, folk religion and village rules is being split rapidly as population influx increase rapidly. "Village in the city" becomes mixed habitation of villagers, immigrants and low-earned city dwellers. Thus, village in the city is the third space between city and village, which is filled with interest friction and cultural conflict, communication and cohesion. No doubt, immigrants want to integrate into city life while villagers still want to keep their rural residence.

The paper uses Jiangdong Village in Nanjing and Xi Bali Village in Xi'an as examples to analyze how the reproduction of social relationship works in the transition of village in the city.

3 CASE ANALYSIS 1. REPRODUCTION PROCESS OF THE SOCIAL RELATIONSHIP IN JIANGDONG VILLAGE

3.1 THE TRANSITION PROCESS OF SPACE IN JIANGDONG VILLAGE

According to Professor Zhang Jingxiang's research, before mid-1980s, Jiangdong village used to be a classic village based on traditional agriculture in Yuhua District in the suburb of Nanjing.

In the end of 1980s and early 1990s, mobile population was found in Jiangdong villages, they were mostly from remote areas outside Nanjing municipal scope coming to work primarily on small private businesses. At that time, most local villagers had their houses repaired or rebuilt. They prevalently changed original mud houses, tile houses and brick houses into cement steel ones.

Since 1995, along with urban economy's growth and space expansion, part of villagers' farms was taken away to run private small-sized factories and the district owned enterprises. The government granted a settlement for peasants lost their farms which was 'With farms taken away, people can work in factories'. Approximately 1-2 people in one family entered the factories and became workers, their household registration turned into urban household registration, but they still own housing in the villages. In this stage, traditional agricultural villages evolved into industrial villages.

In 2002, Nanjing municipal government made the 10th National Sports Game's main stadiums in the new district where Jiangdong village was. Along with the constructions of roads, railways and the like infrastructures, the boom of neighboring businesses and arrival of large scale shopping centers, Jiangdong village was irreconcilable with surrounding environment hence became a typical 'village in the city'. At that time, the ratio of immigrated population and local peasants in Jiangdong village was 5:1, and the immigration from outside of Jiangsu province outnumbered people within Jiangsu province. All peasants became landlords living on rentals and gained a lot of economic benefits.

In 2007, middle-class communities and CBDs bloomed in Jiangdong village's neighborhood. At that time, Jiangdong village's native inhabitants had all moved out. This urban village had already totally become a living place of mobile populations.

In 2008, the land of Jiangdong village was sold to Suning Group for the construction of international communities and commercial service facilities.

3.2 THE TRANSITION PROCESS OF SOCIAL RELATIONSHIP IN JIANGDONG VILLAGE

When Jiangdong village was converting from an agricultural village to an industrial one, the villagers were changing from peasants to workers. But in the enterprises, they were called as 'contract migrant workers' or 'unofficial workers' because they were stratificated based on knowledge and status difference. They were in the brink of classes amongst labor force. When Jiangdong village became a typical urban village, villagers all gave up work and lived on rentals. They leased houses to migrant workers who were on the even edge of the labor force structure.

4 CASE ANALYSIS 2: REPRODUCTION PROCESS OF SOCIAL RELATIONSHIP IN XI BALI VILLAGE OF XI'AN

Prior to the economic reform and opening-up, the urban-rural structure was clear. The city was a place where nonagricultural activities and nonagricultural people concentrate. Its suburbs were countryside where vegetables and meats were sourced for central city and outer suburbs were vast tracts of farmlands. At that time, Xi Bali village was close to a village in the traditional sense. There was widespread basic characteristics: Population density was low; Economic structure was single; Occupation structure was simple; Community members' values were similar and social organizations put families in the core.

Along with the 3rd industry's development, urban fringe villages utilized the geographic advantages, setting up various small industrial and service businesses, as the city kept optimizing and adjusting the industrial structure, many factories and enterprises relocated to the urban fringe. Various elements of the city like population, industry, commerce and residential properties were moving to the city's surrounding areas constantly, which had directly eaten the agricultural lands and countryside near the city. At that time, mobile population from outside of Xi Bali village began to flush in and the 3rd industry replaced the 1st industry to be the dominant power. Traditional rural communities started to decay. One story reinforced concrete buildings could be found everywhere and small shops lined up along both sides of the main roads. Countryside marks gradually declined and some farmlands, more or less, remained in places far away from main roads.

After 1997, Xi Bali village was gradually incorporated into the urban construction land. When the lands were taken away and villagers received expropriation compensation, they had a certain amount of money in the hands. Improving the living conditions became the top issue. The village in order to improve transportation conditions, built hard surface roads; In order to improve educational environment, they reconstructed primary schools. Villagers all teared down old houses for overhauls. Most reconstructed houses had 2 or 3 stories. One house had 4 stories and another house had 5 stories. In the village, except several homes people were doing transportation business outside, most of the villagers stayed idle at home, killing time by enjoying sunlight, playing billiards and mahjong. They lived a leisurely life as immortals would do, but the original plain social atmosphere in countryside settlements had obviously disappeared. People doing business in the village were all mobile population, none of them was native of the village, even the stores were all run by outsiders. Apart from rentals, the land expropriation

compensations were basically supporting their lives. The only remaining farmland was deserted, ploughed by no one. Villagers deserted the lands in advance through comparing farming profits and land's expectations. So much unused farmlands were there quietly waiting to be incorporated into urban construction lands for land expropriation compensation.

What's been increasing fast along with the city's swift development was urban lands. A lot of agricultural lands surrounding the city were all taken away by the city. Only some rural settlements remained in the cycle of urban built areas, thus forming 'villages in the city'. At this time, a lot of mobile populations flushed into Xi Bali Village, the Village became a mixed community with native inhabitants, mobile populations and urban residents. Mobile population's large demands for housing hence huge rent market had driven villagers to add and expand their houses endlessly. Houses were built in a way like sticking in a pin wherever there's room, so building density of urban villages went up rapidly, and formerly ordered space in the village started to become disordered. Large amounts of mobile population had stimulated individual businesses to grow in the urban village, which facilitated some main streets to evolve into commercial streets indispensable to the life of the village's residents. This not only created convenience to village's residences but also opportunities of gaining profits for villagers and external businessmen. Xi Bali village's villagers had transformed from previously simple peasants to current rentier class while migrant workers from outside became a new peripheral class.

5 MIGRANT WORKERS BECAME A NEW CLASS ON THE EDGE—A RESULT OF THE REPRODUCTION OF SOCIAL RELATIONSHIP

Migrant workers are main part of mobile population. From the end of the 50s and the early of the 60s in the 20th century, there has been dual economic structure in China universally. Urban and rural was opposite. Urban communities set many barriers against peasants. Household registration system was the sign of the separation of urban and rural, and became the most fundamental guarantee system when the dual urban-rural structured society runs in the status of mutual separation. Chinese citizens thus were divided into two very unequal classes in both social and economic perspectives namely the urban residents under protection and the peasants being excluded by it.

In early 80s of the 20th century, Chinese country reforms facilitated the changes to dual urban-rural structure and the loose of the mutual relationship. As for household registration management policy separating urban and rural, this was a profound crack. From then, the city opened access to peasants. What had cracked urban vs rural barrier most directly and deeply was the so called 'the tide of migrant workers' meaning people left farms to search opportunities in the cities. Rural system reforms and family joint production contract responsibility policy taking into effect, the change of values and concepts held by peasants and the fast growth of urban economy... many of these elements had created unprecedented conditions for 'the tide of migrant workers' came into being.

The number of rural surplus labor force flowing into cities are counted in tens of thousands every year in China, of which significant amount of populations always needed to rely on urban house-renting market to solve their lodging issues. Peasants entering the cities became the main body of dynamic economy. They usually chose 'urban villages' to live collectively after considering the comprehensive elements like traffic situation, rental, housing supply etc. Therefore, in a certain 'village in the city', there would be many migrant workers temporarily living together who had different backgrounds of hometowns, occupations, lacked general characters but widely interconnected. Because originally built houses couldn't meet all rent demands of large populations of migrant workers, local villagers were all lured by economic benefits to rebuild their houses thus a large batch of illegal built houses of low quality and high density appeared for the lease market. Newly built houses in the urban villages were all above 5 stories.

Unnecessary to work, native inhabitants could gain a series of profits from collective dividends and house rentals that were much higher than migrant workers do. This doubtless had been a remarkable contrast for migrant workers living under the same roof. Migrant workers became a new peripheral class, which was a result of the reproduction of social relationship in the evolution process of urban villages.

The unbalance between urban and rural development had reached to an extreme state. Average urban vs rural income gap was 1.5 times in the world, whilst it was 3.3 times in China, which was number one in the

world. Zhang Jingxiang perceived that the huge achievements of urbanization in China was gained from active creation of urban and rural difference and the plunder and exploitation of rural resources. In economy planning era, rural assets were grabbed through scissors cross of industrial products and agricultural products, rural human resources grabbed through the attraction of urbanization, and then to rural land resources grabbed through dual urban and rural land policies.

From the actual incomes of urban and rural residents, salary incomes were only a part of the family's total incomes. The gap between urban and rural residents in the asset incomes is further expanded. Continued increase of urban property price has made urban families assets significantly increase, whilst made migrant workers' late wage increase in vain. According to Professor Zhao Ming's research, the total income gap was revealed to be 5.4 times by comparing per capita income of urban families in areas receiving mobile population and that of rural families in areas losing populations, and gaps of property incomes and transfer incomes were very high with 10.5 times and 18.6 times respectively. This meant that the middle aged -centered first generation of migrant workers' families were remarkably lagged behind of the urban resident's families in terms of asset accumulation. Such a gap had weakened social mobility and would cause the solidification of classes. It was really hard for migrant workers to integrate into the cities. The gap between urban and rural was solidified.

6 CONCLUSION

The nature of fast urbanization in China is the capital urbanization. It is 'Change from the production in space into the production of space'. The production of space is actually the reproduction of social relationship and productive relationship. The result of fast urbanization in China is cities surrounding countryside, forming a large number of isolated island type of villages in the city. The process of countryside becoming urban villages was actually the reproduction of social relationship. The result of reproduction of social relationship is that migrant workers group became a new peripheral class. Due to the gap between urban and rural residents on asset incomes, the urban and rural gap was solidified, which further caused population stratification and class solidification.

1 INTRODUCTION

With the new type urbanization, the Chinese urbanization rapidly develops under the industrialization accelerating development. In 2011, the Chinese urban population exceeded the agricultural population at first time in thousands of years, and it marked a new development stage that China had began to enter the

period of urban social orientation. This also means that the characteristic of rural society which sustains thousands of years has changed. People's mode of production, occupation structure, consumer behavior, life style, concept of value has changed greatly. The life and production mode transform from agricultural production to urban-rural concurrent business behavior. These essential changes greatly broke the original stability of rural communities, and workers of rural migrants and those who go backwards and forwards between rural and urban areas exerts a great influence on the style structure of traditional communities. The traditional community can not rely on their own strength to deal with the challenge, and can not complete the system structure transform of their own. Under our country polarization development of urban and rural areas for a long time, the revival of the traditional community is ignored, therefore the traditional village style no longer exists, and what is showed in front of people is the scene that is lack of the design and planning, additionally, there is no way that residents have nostalgia. I have a deep feeling after interviewing main streets of Guoyang Community. We should calm down to trace the root of ancient village of traditional architectural culture and reflect advantages and disadvantages of the current rural construction pattern to find a way for the protection and the renewal of traditional architecture.

Figure 1- Guoang Community area bitmap

Figure 2- Guoang Community satellite bitmap

2 THE GENERAL SITUATION OF TRADITIONAL COMMUNITY DEVELOPMENT IN GUOHUA COMMUNITY

Guohua Town is located in the southwest of Guangxi Province, nearing You River, and there are 24 kilometers away from Pingguo County. The northwest border with Tiandong County, and the southwest is adjacent to Tiandong County. The railway across the zone, and there are two important highways of Fukun Line and Nanbai Line. These two mainly traffic lines are respectively lay on both sides of You River, linking the northwest to the southeast, and the lines lead southeastwards to the Pingguo County (Figure 1, 2). Local residents are mainly Zhuang, but also some han. The town has a long history. The natural environment is beautiful, and the unique cultural landscape is formed slowly in history. There are famous Guanyue Temple and Dudu Temple, and there are also unique sceneries of Youjiang Rocky Beach and Moon Bay, which are valuable to the tourism development. Guoyang Community is the location of the town government, and there retains many residential buildings that are built in 20 Century 30 to 40s. From the aged solidification, we can still recall the scene at that time.

2.1 ESTABLISHMENT

Guohua Town was established as Guohua before Song Dynasty. In 1369, it belonged to Tianzhou. In 1530, it belonged to Nanning. In 1913, Guohua Town belonged to Yongnan Province. In 1914, Yongnan Province was renamed Nanning Province, therefore Guohua belonged to Nanning Province. In 1915, after Management System Reform, Guohua Town and Guide Town merged as Guode Town that belonged to Nanning Province. In 1932, it renamed as Guohua Country that administered Centre Street and West Street of Guohua, Huaqian, Miaoguan, Liukon, Tongshe, Naji, Diliang, Shanxin and Keheng. In 1949, Guohua Country restructured as Guohua Second Area that administered Guohua Country, Boli Country and Lerao Country, and the area's government located in Guohua Street. In 1958, it was renamed as Red

Flag Commune. In 1962, it was renamed as Guohua Administrative Region. After 1970, it was renamed as Guohua Country. In 1984, it was Removed the ship of country to build the town .

2.2 NATURAL ENVIRONMENT

Guoyang Community is located beside Yang River, and the terrain is relatively flat . The river flows through the northeast and the landscape environment is beautiful (Figure 3). In addition, there are various mineral resources in Guohua Town, and is rich in aluminum, coal, iron ore. However, in recent years due to the excessive development, the resource depletion and environmental pollution are serious problems. Natural environment have been destructed, and the most outstanding performance is that the water quality of You River is deteriorated, in addition, the residents can not swim in the river .

Figure 3- Guoang Community Environment

2.3 COMMERCIAL TRADE

In the period of land transportation absence, the transportation is mainly through water. with its great geographical advantages, the commercial trade was prevailing in history. During the late Qing Dynasty to the Republic of China, the commercial trade of Centre Street in Guohua amounted to peak, and attracted a lot of foreign businessmen engaging in business. But under the Japanese invasion, inflation and land transport complement, its commercial trade showed depression. After1980 sub-fields on the basis of households, collective ownership of business circles disintegrated. Funds and goods distributed to individuals, so that business recovered. So far, a farmer market where become the center in Guoyang Community is built, and there business is relatively prosperous, but there are few foreign traders.

2.4 RESIDENTIAL BUILDING

The residential building form at Center Street and Xinxing Street in Guoyang Community is sotto portico 'Bamboo House' that empty the bottom part along the street for pedestrian passageway and the homestead is slender like bamboo. Residential buildings of other streets are similar to Center and Xinxing

Street's, but the bottom part along the street is not empty. In 1937, the residential building at Center Street was required to rebuild the front room to the form of Sotto Portico that first flood along the street was empty 3 meters for sidewalk, so that people could trade on the sidewalk, and not exposed to the sun and rain. In order to expand the business, Xinxing Street was opened up, and retained the form of Sotto Portico[1]. The following is the example of Xinxing Street(Figure 4).

(1) Plane Function Layout

1. The existing traditional Sotto Portico building (built in 1930~before the Liberation). The building width is almost same that is nearly 5 meters. The building is narrow and deep, in order to ensure that each household to frontage for commercial operation. Each household has a Central Room, and most would combine with the Secondary Room and the Subsidiary Room. Beginning from the street, there is an arrangement followed by the Central Room, the Secondary Room and the Subsidiary Room. The first floor of the Central Room was used for business in the past, and the second floor was used to residence, and the local three floor is shelving goods. But the Central Room now has been changed to live or idle. the Secondary Room includes living, kitchen and dining room, and the main features of the Subsidiary Room

include the bathroom and henhouse. The Central Room, the Secondary Room and the Subsidiary Room are combined by the courtyard that makes each room is exposed to ventilation and lighting(Figure 5).

Figure 5- The Form Of Traditional House

2. The new residential building (built after the Liberation). Recent years, it replaces the traditional house at a rapid speed. The traditional form of courtyard combination is abandoned. The plane function layout has been readjusted to adapt the recent needs of people, and the function of keeper and business in the new residential building is weakening.

(2) The style of vertical plane ornament

The building time of existing buildings at Xinxing street spans a hundred year. There retains the residential buildings of various periods that since the street has been established, and there are many significant differences in the form, style, color, material, height and so on (Figure 6). according to my survey, it is found that there is a correlation between those elements and the construction age. Therefor the existing residential building in Xinxing Street can be divided into three types: ①Building in 20 Century 30, 40s; ②Building in 20 Century 80, 90s ③ Recent Building(Table 1).

Characteristics of various types of buildings	
Types	Characteristics
Building in 20 Century 30, 40s	The building structure is brick-wood, generally two layers. The bottom zone is a store, and the form is open, due to the door plank can be fully opened. The 2nd layer use brick or wood as the window wall material, and the horizontal window that can be entirely opened occupies almost the entire wide of house for exposing the lighting and ventilation as much as possible. It can be found from the facade unit that the material is including brick, wood, tile and whitewash. Building colors are black, gray, white, dark brown. And the overall tone is uniform.
Building in 20 Century 80, 90s	The building structure of the building is brick combines with concrete. The building is generally 3 floors and has a roof terrace. The railing of the top balcony though artistic treatments that some are built beautiful patterns by brick and other are built by prefabricated hollow lattice. In addition, rich people use the colorful ceramic tile to cover the wall.
Recent Building	The building structure is brick combines with concrete, and is generally 3 to 5 floors, additionally, it has a roof terrace. Some of the external walls straightly expose the structure, which do not cover whitewash, showing the red brick and concrete gray. Some cover ceramic tiles, and it is common that the color of tiles is warm, such as orange, pink, beige and so on.

Table 2- The Type Of The House In Xinxing Street

Figure 6- The Type Of The House In Xinxing Street

2.5 THE DILEMMA OF THE PROTECTION AND DEVELOPMENT OF TRADITIONAL ARCHITECTURE

2.5.1 LIFESTYLE CHANGING AND RURAL HOLLOWING

Some structural members of the brick-wood building have exceeded its service life, and many have been damaged or corrupt structure in different degrees. Some empty houses with protective value are lack of daily care, suffering serious aging, and even become dangerous buildings (Figure 7). The internal facilities are old and shabby. Some of the kitchens have not been improved into the electrification, and are still burning firewood to cook, making it easier to cause fire and smoke (Figure 8). Because the building is narrow and deep, the ventilation, lighting and health conditions hardly meet the basic requirements of modern living. At the same time, local adults generally become migrant workers causing the Hollow Problem.

Figure 7 and 8- Abandoned Traditional House

2.5.2 BUILDING MATERIALS AND TECHNOLOGY UPDATING, AND CONSTRUCTION METHODS CHANGING

The price of traditional materials is increasing, but the price of concrete and other masonry materials is relatively low, so that local villagers gradually abandon the traditional brick-wood building.

With the growing migrant workers, the male who mainly engaged in the construction work takes back to the city's construction technology, and it becomes an accelerator that the construction technology about cantilever beam, ring beam, grade beam, structural column and so on places a great change to native buildings. With the development of construction technology, buildings can be expanded on the vertical space horizontal space, it also enrich the building plan through the bay window and the cantilevered balcony. Therefor the local building gradually separate from the original shape.

2.5.3 PROTECTION IS ABSENT, AND THE TRADITIONAL STYLE IS ENDANGERED

Firstly, due to the general economic level and the weak awareness of the historical and cultural protection, residents will not repair traditional residential buildings that are damage unless there is negative effect. Some households migrate away, and their empty houses are without reasonable use.

Secondly, the new building is lack of the architect guidance, and the villagers are indifferent to traditional culture, therefor it is a result that new buildings are lack of native characteristics, cultural connotations and artistic sense.

Thirdly, although the government and other relevant departments pay attention to the historical buildings, the funds, technology, human resources and other aspects are limited, therefor effective protection measures can not be took.

3 TRADITIONAL COMMUNITY PROTECTION AND RENEWAL METHOD BASED ON RESIDENT BEHAVIOR

3.1 ESSENCE OF PROTECTION

3.1.1 TRADITIONAL STREET SPACE

The corridor of Sotto Portico first flood along the street is the vague border to interior space and exterior space, and there are many features as the transition of internal and external space.

(1) Traffic Space

The climate of Guangxi is hot and rainy. As the main traffic space, the street is influenced by weather factors, and the corridor along the street creates a more comfortable traffic space for passengers, which makes people against the sun and rain.

(2) Commercial Space

The corridor is the extended commercial space. The space under the eaves is convenient for people to stay for completing trade activities. But now we can not see the prosperous business scene at Xinxing Street, and the business is mainly concentrated in the local farmers market.

(3) Living Space

The interest of life in rural areas is fully reflected in such the space. Usually, residents do housework at the corridor, and children play at here (Figure 9).

The Continuous Sotto Portico creates a sense of metrical vision. The continuous corridor is the linear space of material circulation, and also is the most interesting life space. This kind of space like a blood vessel, and it not only facilitate the trade, but also promote the communication of people. It shapes the live of the resident .

Figure 9- Traditional Street Space

3.1.2 ANCIENT ARCHITECTURAL STYLE AND DECORATIVE ART

The traditional building materials source from location, which mainly include the wood, the stone, the brick and the tile, and colors are white, black, grey and ochre. People with general economic conditions do not use the abundant decoration. But the rich make the style of windows and doors elegant, for example the wall under the window is embossed with birds and animals, and there are molding pillars, additionally the style of color and decoration is elegant. (Table 2)

The Doors	
The Windows	
The Pillars	

Table 2- Ancient Architectural Style And Decorative Art

3.2 THE ADVANTAGES AND DISADVANTAGES OF RESIDENTS' INDEPENDENT CONSTRUCTION

The residents' independent construction in a certain extent can meet needs of occupants, and is consistent with living habits of individuals. But it also has a lot of problems that we should pay attention to and avoid when designing the housing renewal.

1、Functional Layout Is Unreasonable

Function layout and traffic lines are unreasonable. Although the houses are large, it is not enough to use. A lot of space need ventilation and lighting, but there are not enough ventilation and lighting. Some room where people frequently pass by need quiet.

2、Infrastructure Chaos

Because the independent construction, it is lack of unified management and planning. Due to the different construction time, basic facilities of water, electricity, gas and so on are generally set by the household, therefore it not only bring some hidden dangers, but also cause the problem of basic facilities link to interior house.

3、Architectural Style Is Not Uniform

Due to the lack of an unified guiding standards, each household according to their own needs designs their house, showing the various architectural features. This also leads the disorder skyline, and the chaotic street interface (Figure 10).

Figure 10- The Sence Of Xinxing Street

3.3 TRADITIONAL AND MODERN RESIDENTIAL RENEWAL

In order to meet the residents' diversified needs, it is necessary that villagers participate in the process of designing and building. In consideration of the coordinate overall style, the villagers participation can not be too free, and should balance between the overall control and individual participation.

Firstly, the basic pattern of overall unity should be determine to control the overall style. And then the independent construction bases on the basic pattern. The unified part can be guided from the following aspects:

1、Architectural Style Guide

(1) Color And Material Guide

We distill the building color and material type from the cultural relics (including cultural relic protection units and buildings of outstanding historical value) and historical buildings (including valuable historical buildings and general historical buildings) by sampling survey and collection, and we obtain 4 colors and 4 materials (Table 3). The building should be rectified and reformed according to the color area and the part to separate primary colors, auxiliary color and harmonious color, and then according to their function, material, environment select from the recommended color and material.

Color				
Material				

Table 3- Color And Material Of The Traditional House

(2) Guidance Of Building Facade

The protection and renovation of the building facade should follow the strategy mode of protection, control and renewal, so as to repair the old as the old, and the facade decoration style is distilled from the traditional building.

2、Building Function Guidance

The function space layout of the house should be moderate guided, refer to following several principles: 1, separation of human and animals; 2, dry wet partition; 3, dynamic partition; 4, public and private zoning. In addition, to developed the local tourism, it is a problem to solve the passenger accommodation in the village. Rather than building the hotel, developing B & B is better. There is hollow phenomenon that most

of family members live in the ecdemic field except holidays, which makes the room of local house empty. Additionally, because of empty room with neglecting, it will make the living and health conditions decreased. If the room changes as the B&B, the unused room can be use when it is empty. Compared with living in a standardized hotel, the B&B can exhibit the more about the native culture, which visitors can eat and live with villagers. The mode also attracts immigrant workers coming bake to the tourism industry, and it will promote the rural revival and solve hollow.

Under the guidance of the Guoyang Community building renovation and reuse, there is following several ways:

(1)、The Adjustment Of Old Building Function

In order to promote the tourism development of the village, local Guanyue Temple except sacrifice and festivals can become the exhibition space, and it can be the multi-function space that include exhibition village history and tourist reception.

(2)、Repair And Reconstruction Of Old Buildings

Old buildings of the preserve value should be repaired, and other old buildings should be rebuild basing on the traditional style. The structure and facade of the building are preserved by restoration, and the local style of history of the structure and facade is optimized with increase the appropriate decoration to change the monotonous facade. The interior should be adjusted according to status, and the kitchen is renovated according to the standard of the transformation of electricity. Toilets would be added, and the water supply and drainage facilities would be regularized.

(3)、The New House Transforming

Although the new building is the structure of brick and concrete, the building should be built with the standard traditional village style. In the construction of the new building, the building can retain identical with the traditional style through the facade material, the proportion of doors and windows, the roof form, the architectural decoration and the combination of the house. The new building that has been built should be adjusted the above, in order to coordinate with the traditional architectural style. In addition, the transform should be integrated the concept of ecological technology, which includes the water reuse, the use of pavement that is permeable to water (figure 12, 13) and so on.

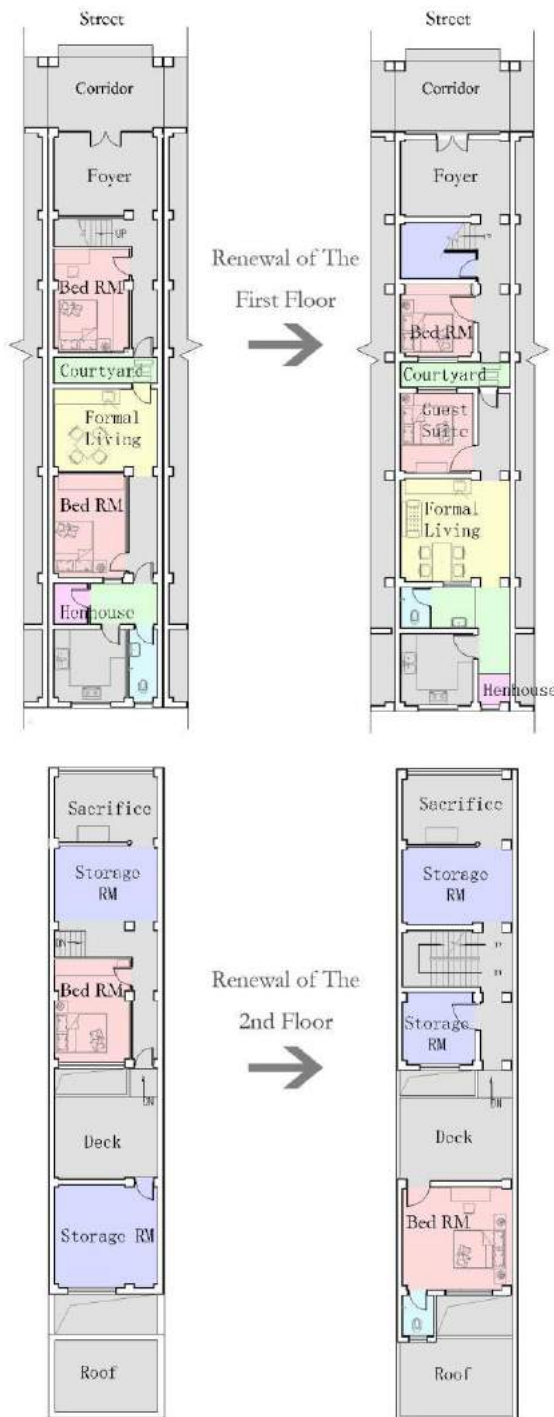

4 INSTANCE DESIGN

4.1 RECONSTRUCTION DESIGN OF XINXING STREET FACADE

As mentioned above, through the excavation of the essence of the local culture and the extraction of traditional style elements I design the facade of Xinxing Street (Figure 11).

Figure 11- Reconstruction Design Of Xinxing Street Façade

The Renewal of No.27 House:

- Replace damaged components.
- Widen the stairs.
- Increase the quantity of the storage space, and use the space that is under the stairs.
- Share the side wall with the neighborhood.
- Separate static and dynamic spaces. The bed room moves away from the kitchen.
- Separate clean and dirt spaces.

The henhouse moves away from the living room.

- Change to B&B. Increase the guest space and the bathroom
- (Figure 13).

5 CONCLUSIONS

Guoyang community landscape environment is good, and is rich in property. There are some cultural relics, and the local Guanyue temple has a great historical and cultural value. The traditional house type is worthy to study. Under such conditions, there are the potential of tourism development and the value of history, architecture, aesthetics and so on. Whether the advantage can be took needs the reasonable

measures of protecting and updating. The old building should be protected on the structure and the facade, and the internal functions layout should be adjusted and updated. New buildings should retain the style of the traditional building. The new building that has been built should be adjusted to match the style of the traditional building.

ID 1340 | TRANSNATIONAL URBAN DESIGN FIRMS AND LOCAL IMPLICATIONS FOR PLANNING

Davide Ponzini¹, Matteo Poli¹

¹Politecnico di Milano

davide.ponzini@polimi.it

ABSTRACT: International architects and urban designers are considered to be crucial for creating new urban projects and more generally for growth. Indeed, transnational firms tend, to provide complex packages of services that reassure investors and politicians, often by elaborating positive narratives such as sustainability or the smart city. By following strategies for being highly distinctive (star architects) or highly reliable (corporate-like) in the global market, design firms are now widely used by developers and investors to package and legitimize their projects. This may occur without any specific reference to local planning processes. Design firms have grown into multinationals with hundreds (sometimes thousands) of employees and they work in multiple cities sharing the same (standardized) knowledge, technologies and, most importantly, similar planning solutions that are ostensibly replicable. Public opinion and the media seem more interested in the narrative (or the technologies, or the esthetics, or the persona) than the actual urban project. In this way solutions are more and more often depicted as merely technical matters, depoliticized and privatized by developers or ad hoc local planning agencies. By investigating two critical examples of firms working on multiple continents (i.e. one star-firm Foster+Partners and one less famous, Broadway Malyan), this chapter will show that these transnational firms can operate in the absence of local planning powers (e.g. in emerging Asian countries or the Middle East), eventually be out of touch with the local physical and functional context and instrumentally use the specificities of given urban places. In the end this serves pro-growth local players. It seems important to understand these strategies and their implications for local planning, since the work of transnational design firms is becoming more and more relevant for many global and second tier cities in Asia and the Americas, as well as in Europe.

1 INTRODUCTION

In recent decades, global cities as well as capital cities of Asia have witnessed the effects of a steep increase in the transnational circulation of architects, urban designers and planners. It has become more and more common to expect world-famous "archistars" and "urbanistars" to design not only "iconic" or spectacular pieces of architecture, but also to outline the master plans for infrastructure hubs, corporate headquarters and institutional compounds or university campuses. Similarly, other sorts of large-scale development projects have resorted to branding for building political consensus and media visibility. Despite their pervasiveness, the problematic practice of transnational planning and design - both in terms of local democratic decision-making process and in terms of its urban effects - has been left to a large extent to the architectural debate.

It is recurrent to find assumptions linking the work of architects and planners to the economic performances of given cities in public debates. In particular large-scale projects and innovative solutions are intended as an opportunity for the production (via real estate appreciation) and redistribution of wealth among citizens, in terms of new infrastructures, public facilities, employment, etc. (Logan and Molotch,

1987; Clark, 2004). International planning and architecture experts are considered to be crucial for urban growth. Transnational firms tend to provide complex packages of services that reassure investors and politicians of this pro-growth rationale (sometimes supported by academia: Jencks, 2005; sometimes criticized: Easterling, 2005, Saunders, 2005; Sudjic, 2005).

According to the work of Leslie Sklair, iconic and spectacular architecture has been serving contemporary forms of globalized capitalism to proliferate and fuel the rhetoric of inter-urban economic competition (Sklair, 2010 and 2012). In other terms, one can interpret the spectacularization of contemporary architecture and of the urban environment as a means for global players to work more easily in given urban contexts. At the same time, this condition seems functional to the commoditization and commercialization of architectural design on a global scale. In fact an architectural project is at the same time a product and a media representing a city, a client or even a place, or a real estate product to market.

Several firms have grown into multinationals with hundreds (sometimes thousands) of employees and they work in multiple cities sharing the same technologies and, most importantly, the same libraries of solutions. Design service has reached unprecedented global scales. Geography and urban studies literature have focused on the characteristics, strategies and the role of international architectural studios in urban matters (see, among others, the interesting work of Donald McNeill, 2009; Leslie Sklair, 2005 and 2006). The reasons why star architects are selected for particular projects and how they compete have been studied (Ponzini and Nastasi, 2016). Despite the significant expansion of global demand for architectural design and planning services, the mechanisms of distinction are quite important with reference to the internationally most visible projects. The studios which are capable of entering the architecture star system or the circles of the rich and powerful states' elite are in fact less vulnerable to global competition for certain types of works, such as outstanding public facilities, museums, concert halls, institutional and corporate headquarters, luxury housing and so on (Kloosterman, 2010). Architectural firms may indeed be appointed for these projects through invitation-only calls or even directly by public and private clients. From this point of view, architectural studios benefit in the long term from their established reputation and networks.

One can say without hesitation that star architects rely on their distinction, technology and aesthetic style. Most innovative and renowned architectural firms are often related to the personality of particular designers or to the extraordinary ability of completing special tasks. In literature, two strategies are recognized as relevant for architectural firms to organize their work and sell their services in the framework of contemporary global competition and international mobility. Coxe (Coxe et al, 1986) synthesized organizational strategies for architectural studios: a strong idea, strong service (and strong delivery, which is not relevant to this paper). The first concentrates on supplying unique competences for innovative and creative projects, where the star or an exceptional expert can prove to be decisive. The second, strong service, targets experience and reliability in complex design, development and implementation processes. The charisma and personality of an individual designer is often at the heart of strong idea studios. Typically they are groups of workers closely collaborating with this star-like figure or using their name as a brand. They typically work in different geographical contexts, since their high level of specialization is requested on few occasions in each city.

The strong-service strategy is highly reputed because it follows efficiency criteria in the organization of the design and implementation work cycle. Time and cost reliability is appreciated by investors and leads to higher profits. These studios are not centered on the figure of a star but they tend to have a corporate image. These organizations are sometimes articulated into branches following the whole life cycle of an architectural product (including engineering, public relations, city and community planning) and they can specialize in given items: office towers, skyscrapers, stadiums and so on.

2 FEATURES AND REASONS FOR THE TRANSNATIONAL MOBILITY OF URBAN DESIGN AND ARCHITECTURAL PROJECTS

Urban geography and planning scholars have tried to cast light on the mobility of urban policies and urban development schemes. Building on the work by Manuel Castells (1996) and John Urry (2000; 2007b) and others, scholars showed that multiple urban actors tend to make policies, ideas, and approaches to urban planning, design and architecture travel from one place to another. The Journal of Urban and Regional

Research recently dedicated a symposium to these aspects (Harris and Moore, 2013), discussing the mobility of dominant models of intervention in contemporary cities (Helaey and Upton, 2010). McCann (2011) suggested adopting a wide interpretation of mobilities as a complex of agents, practices and performances that adapt ideas while they are circulating. The transnational mobility of ideas and technologies is not a linear process; one can expect different local adaptations, hybridization and assemblages with reference to local planning systems, institutional framework, actors and interests involved (Guggenheim e Söderström, 2009). Faulconbridge and Grubbauer (2015) maintain that in general the mobilities of architectural design firms and the circulation of their knowledge are strictly related to global market forces. Their ideas and knowledge are often packaged and marketed as effective globally, but indeed design ideas must be adapted locally in order to gain traction.

The organization and networking of such design firms have been investigated by geographers (Knox and Taylor, 2005; Faulconbridge, 2010) providing insight into their rationales and localization, though without reconnecting these with any involvement in designing given types of interventions in specific urban contexts, nor providing a sound link with their specific urban implications. Innovative studies showed the relevance of such investigations for understanding current urban transformations (McNeill, 2009).

Tim Bunnell (2015) explained how cities tend to generate policies by using antecedent cases in terms of prototypical examples, hierarchical imaginaries of other (highly-ranked) cities, paradigmatic and successful city models. Real estate investors tend to duplicate projects and packages of investments that have proven to be feasible and to generate adequate returns. This often includes similar building typologies, or diagrams for master plans, at times only the brand of a name architect that is expected to ease the planning process and make the real estate product more visible for global investors and local politicians (Ponzini and Nastasi, 2016).

Policy makers, planners and architects are not the only mobile actors in the game of transnational urban development. Real estate investors and developers seem to be more and more capable of working under quite different geographic conditions, depending on the institutional arrangements for allowing their business to land (Gotham, 2006). Clearly, the international movement of investors' and developers' resources, modes of planning and design are not politically neutral and they carry, as well, a bundle of socio-economic and cultural values that reverberate over globalizing urban environments.

3 THE TRANSNATIONAL CIRCULATION AND TRANSFER OF URBAN PROJECTS

In general terms, the simplest explanation refers to the tendency of multiple actors to reduce uncertainty and risk, whether by using similar designs, real estate investment schemes, policy tools (e.g. public-private partnerships) or other means. This short overview showed the multiple meanings and facets of transnational mobilities, which might or might not be related to design. More specifically, design-related concepts can only be partially derived from literature (which is still inconsistent). I use the terms "circulation" and "transfer" (Ponzini, forthcoming).

The circulation of urban and architectural projects implies that specific design-related aspects migrate among projects in multiple and geographically distant places. This has been recurring systematically for centuries with reference to common and generic architecture and urban design, but it seems more and more relevant once it is referred to spectacular buildings, complexes, infrastructures and urban environments that are supposed to be iconic and uniquely important for one city or place. The world-wide circulation of building types is quite recurrent. King (1984, 2003 and 2004) showed how circulation involved a specific history, regarding the creation and evolution of one building type, its adaptation in different contexts, and its diffusion and impact in diverse societies and cultures. Since modern times the discussion of the circulation of typologies has fostered a number of discussions targeting architectural features or their implications for local societies and ways of organizing cities.

The import and export of master plans and attention-catching architectural projects, if compared to the past, has assumed a relevant magnitude and geography, as well as an unprecedented pace in the last few decades (Nasr and Volait, 2003). A new frame of reference is available today for researching and discussing the transnational mobility of spectacular architecture, but is not fully deployed, nor systematized. Knox and Pain (2010) argued that the circulation of types and of similar buildings is part of the homogenization push of globalization, i.e. due to increasing the financiarization and de-materialization

of the real estate market, to the competing and neoliberalizing attitudes of cities, and hypermobility and indulgence of design professionals. It is important to specifically note that this circulation can be detected with reference to central facilities and urban infrastructures (e.g. stadiums, museums, etc.) or clearer transfers of actual projects. Matti Siemiatycki (2013) offers a long term view of larger “waves” of the circulation of mega-urban projects. In particular he suggested the interest of historically and geographically tracking particular kinds of urban projects (e.g. electric tramways, urban freeways, light rails) and explaining policy trends with a concrete reference to the local interests and policy arrangements, public discourse and politics, and ultimately the physical environment. In particular, Siemiatycki outlines a theory of urban project circulation based on long-term waves and (for certain types of megaprojects) in phases of trendsetting, promotion and local adaptation, spread and decline. These waves can radically vary in their length and outreach depending on cultural but also local conditions, since projects are adapted and pushed forward by local interests and coalitions.

The second design-related way of importing and exporting spectacular projects can be described as a specific transfer when substantial features of one given building or landmark, of one master plan or of the structure of one exiting area is directly translated from an original place to one or more geographically distant destinations. Of course, the transfer concept can imply direct imports and exports having different degrees of accuracy in practice (with reference to building features: height, overall surface, functions, main materials, building structure, relationship to the master plan for the area or to infrastructure and public spaces).

From the point of view of the firm it is clearly more efficient to design one solution and apply it multiple times, eventually adapting the technology, aesthetics and narration to the local environment. Various types of design software in use among strong-service firms (and strong-idea as well) allow firms to buy or develop libraries of solutions that are shared by branches across the world: building information modeling is one example. Narratives like the “Bilbao effect,” the smart city and the like are reinforced when repeated and enacted locally. Real estate developers (and the investors backing their project) are reassured by projects that proved to be successful elsewhere, expecting marginal adjustments to be needed to obtain the same returns. Local politicians use the architect’s name and fame to cast positive light on the projects and themselves in the media. Other auxiliary actors (service providers, academia, intellectuals, etc.) can be in favor of growth in more or less general terms according to the project.

In this picture the connections between the key players in urban development are clear, though the urban implications for planning and effects at the local level have been investigated less. The profile and projects of two different transnational firms can help explore these aspects.

3.1 BROADWAY MALYAN AND THE TRANSNATIONAL CIRCULATION OF WATERFRONT COMPLEXES

The UK-based firm Broadway Malyan was founded in 1958. It covers all the typical expertise of architectural practice, from master planning to interior design. They have a quite mixed portfolio and wide array of clients in over 60 countries. According to the firm (Broadway Malyan 2013) they have a high rate of repeated business. For this paper I could find solid data only with reference to projects from the late 1990s to the present (deriving most information from the official website: www.broadwaymalyan.com). The localization of their satellite offices (sixteen overall with more than 500 employees) was both due to the expansion of the firm and to a set of partnerships with other offices (e.g. Latin America). Outside the UK they are mostly concentrated in Asia, with offices in Singapore, Shanghai, Mumbai and the Middle East. The 65 analyzed projects show that the firm increased its presence in Asia in the late 2000s, due to the economic slowdown in Europe. In particular, the spread from the UK and Europe to the East is quite evident (Fig. 1). This also implied a change in the political environment in which they operate, from fully democratic and free countries to partially free and not free countries (see Fig. 2).

Figure 1 – Localization of completed projects by Broadway Malyan in the 1998-2016 period

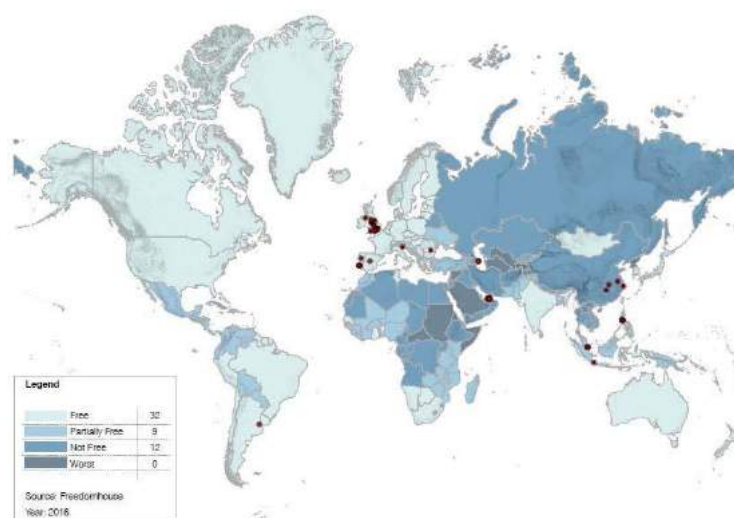

Figure 2 – Localization of completed projects by Broadway Malyan in the 1998-2016 period with reference to the level of freedom in each country, using the classification and data by Freedomhouse.com (Free, Partially Free, Not Free, Worst)

The presence of offices and the orientation toward repeated business clearly brought the firm to strengthen their relationships with local decision makers. In the Persian Gulf region, for example, they established two offices (one in Abu Dhabi and the other in Dubai). In 2009 Broadway Malyan was appointed to deliver and develop prototypes of architectural design for schools and educational centers in Qatar with the Ashgal programme and in Abu Dhabi for the ADEC School Programme (Ashgal is the national agency for public works of Qatar, while Abu Dhabi Education Council manages the educational system of that country). This means that they were in charge of developing one flagship school project and eventually dozens of others (more precisely forty in Qatar and twelve in Abu Dhabi). It is clear how this strategy implies the circulation and transfer of similar design solutions across one country and region, potentially developing common functional and aesthetic features.

An evident circulation of design features can be seen in the case of waterfront complexes in the UK, UAE and Azerbaijan. In the UK the firm experimented a receding floor system to enhance the presence of terraces overlooking the waterfront. This solution is known, but found success in the NV Buildings in Manchester and some obstacles in St. George Wharf in London. The residential complex using the same building type and overall scheme of Battersea Reach in London started in 2003 but took a long time to implement, being completed in 2014. In the same years the firm developed two similar projects, respectively in Abu Dhabi (Al Bandar) and in Baku (Port Baku Residences) (for a systematic comparison of the three projects see: Matevska, 2016).

Figure 3 – From the top, the complexes of Al Bandar in Abu Dhabi (photograph by Michele Nastasi), Battersea Reach in London (photograph by Michele Nastasi), and Port Baku Residences in Baku (image retrieved from: <https://it.pinterest.com/pin/237987161536546943>)

The development in Abu Dhabi involved the redesign of the shoreline and radical transformation of the environment lead by the real estate developer Aldar. The latter is the leader in development in this Emirate and one of the largest operators in the Middle East. It has developed several quadrants of Abu Dhabi and its most iconic buildings, such as the hotel and Formula 1 track on Yas Island. Its Headquarters building stands as a landmark for Abu Dhabi as well. Its portfolio includes entire islands near the main island of Abu Dhabi and a number of commercial and residential projects.

The Al Bandar project was started in 2007 and completed in 2011. If compared with the antecedent of Battersea Reach it has similar height and a slightly larger scale (90,000 sqm as opposed to 70,000 in London). Quite similar design solutions and materials had quite different effects, due to the different contexts: a former industrial site in a predominantly residential area in London; new man-made landfill and coastline removed from the city and marketed for its exclusivity and direct access to the sea.

These and other Broadway Malyan projects inspired the development of Port Baku in the capital of Azerbaijan, Baku. It was initiated in 2011 and was completed in 2014. The same system of receding floors was adopted for a much larger scale (about 400,000 m²) and less direct exposure to the waterfront (which is a few hundred meters away from the complex). The surrounding area is much more mixed in uses and more valuable if compared to the other two.

The developer and investment bank Pasha is extremely influential in the Azerbaijani national system, being closely related to the Aliyev family (in power in this oil-rich country since 1993, after the Soviet Union's collapse). The Port Baku project is part of a new residential and commercial development of the area and connected to a large mall. The complex does not have direct access to the water but faces a buffer zone of public spaces towards the waterfront. While the London project had to face a slowdown in the real estate market, in the cases of Abu Dhabi and Baku the project was completed at a dramatically high pace. In part this is due to the different planning systems and regulations, but one must notice that the market plays a less relevant role where "government-led urban elites ... define the political economy of the city and future development" (Valiyev, 2014, 45).

Besides the Port Baku Residences, Broadway Malyan designed another flagship project in Baku, completed in 2015. The National Gymnastic Arena originally was a key project for Baku's candidacy for the 2024 Olympic Games bid. The power structure is quite centralized and personalized (see: Guliyev, 2012) and the connection with it is of central importance in this country. Multiple commissions in this country may imply coming to terms with this monocratic and clan-like elite, and with its view of the city and urban growth.

3.2 FOSTER+PARTNERS AND THE TRANSFER OF A COMPLEX FROM ABU DHABI TO ASTANA

Today Foster+Partners is a multinational firm with several branches. Their initial work during the 1960s-1980s was mainly completed in the UK, but rapidly reached international recognition. The major breakthrough was the completion of the Hong Kong Shanghai Bank Headquarters in Hong Kong in the mid-1980s. Procurements came from Europe (e.g. Germany and France) and subsequently from other continents. Since the mid-2000s the firm started to work more systematically with emerging countries. The firm has been in the spotlight for several decades now and for multiple reasons, spanning from technological innovation, ecological care, architectural aesthetics, to the ability of designing and implementing iconic new buildings, of retrofitting existing heritage buildings and of managing complex development processes. It has attracted substantial attention among architecture, urban geography and planning scholars (among others: Mc Neill, 2005 and 2009; Poli, 2010).

Figure 4 – Localization of completed projects by Foster+Partners

One of the explanations for the transnational strategies of the firm can be derived from a documentary movie dedicated to it: “Foster has become placeless to quite an extraordinary extent. Bashes with bankruptcy have overshadowed many architects’ careers. So once Foster had the chance to work outside Britain, he saw that building a global practice was the key to survival. Downturns on one continent can be compensated for by booms on another. The experience of working on a world-wide scale has transformed Foster and his work. You can see now that there is a certain level of impatience with the way old Europe does things. He wants to bring home what he has learned.” (Carcas and López Amado 2010)

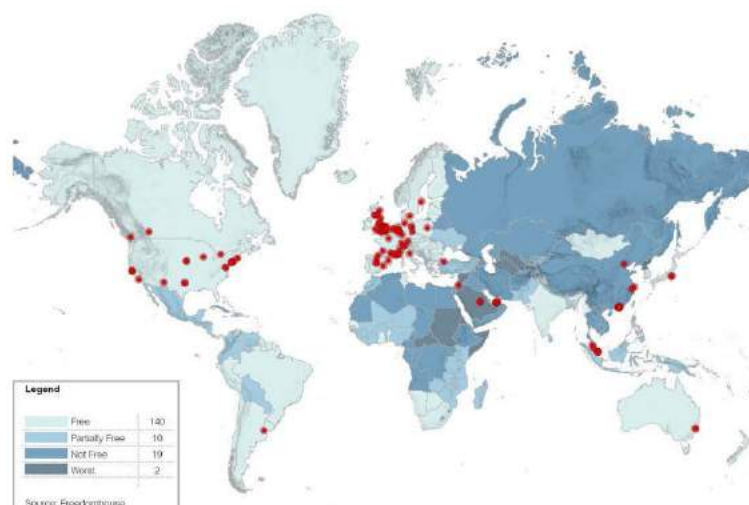

Figure 5 – Localization of completed projects by Foster+Partners with reference to the level of freedom in each country, using the classification and data by Freedomhouse.com (Free, Partially Free, Not Free, Worst)

The firm has worked in a number of countries and different institutional arrangements, including autocratic countries. Among the emerging countries where Foster works, the UAE and Kazakhstan seem very important in explaining the relationship with the elite and its transnational features. The firm was involved in a number of key projects in both countries, which were very important for their practical and symbolic relevance. In particular Foster designed the UAE pavilions for the 2010 Expo in Shanghai as well as the 2015 one in Milan, the Index in Dubai and the Masdar Institute master plan. The latter was intended to be the first zero-carbon eco-city, but was only partially completed (Gunel, 2016; Cugurullo, 2013).

One evident example of transfer of a Foster+Partners design can be considered. The site of Abu Dhabi's central market was once the place of a lively souq of mixed-income shop owners and users. The new project designed by Foster+Partners - also known as the World Trade Center Abu Dhabi - is a mixed-use facility including exclusive offices, luxury residences, a mall and shopping area and a hotel. Its design

involved specific architecture and aesthetics and technological devices for thermic comfort which, according to the designers, are a contemporary reinterpretation of traditional bazaars in the region. In the firm's words: "Central Market will be a reinterpretation of the traditional market place and a new civic heart for Abu Dhabi." (cited in Elsheshtawy 2008b, and retrieved from <http://www.fosterandpartners.com/news/archive/2006/11/abu-dhabi-central-market-to-be-transformed>).

The height of the main tower (Mohammed bin Rashid Tower) is also considerable not just because it is the tallest building in Abu Dhabi, but also compared with ones in the neighborhood, which have medium-rise average. Besides the expulsion of the lower strata of shop owners and users, the place lost its souq atmosphere in favor of a spectacular impact on Abu Dhabi's skyline. The project has a direct link to a distant place. The president of Kazakhstan, Nursultan Nazarbayev has been in office since independence from the USSR in 1990. He has planned a new capital city – Astana - leveraging the country's booming gas economy to generate tremendous expansion (from a small village to over 800,000 people now) and international visibility (Anacker, 2004; Koch, 201; 2013a and 2013b). Two of the most iconic buildings of the new capital were commissioned to Foster: the Palace of Peace and Reconciliation and the Khan Shatyr Entertainment Centre.

One of Astana's most notable complexes of luxury hotels, retail, office and housing space - the Abu Dhabi Plaza – followed quite literally Abu Dhabi's Central Market development format. Norman Foster+Partners designed the master plan for this development, which was in fact promoted by Aldar and backed by President Nazarbayev. The official press release of the design firm reports that "the scheme is inspired by its sister project in Abu Dhabi - the Central Market Redevelopment" for "creating a new landmark on Astana's skyline" (<http://www.fosterandpartners.com/news/archive/2007/11/designs-unveiled-for-a-new-mixed-use-development-in-astana-kazakhstan/>). Despite their opposite climates, Abu Dhabi and Astana (with peaks respectively of +40C and of -40C), shared a similar rationale in design terms since some parts of the mall were expected to draw on the traditional Kazakhstani bazaars (in the firm's words "reinvention of a traditional marketplace" <http://www.fosterandpartners.com/news/archive/2007/11/designs-unveiled-for-a-new-mixed-use-development-in-astana-kazakhstan/>) and to implement the newest technologies for maximizing the gain from solar light during winter. The project is located nearby the monumental axis that includes most representative and institutional buildings of the city and the nation. The Abu Dhabi Plaza project in Astana derived from a special agreement between Kazakhstan and Abu Dhabi, involving the creation of a Special Economic Zone, waiving taxes for both construction and management of the compound and expecting further direct foreign investments. It is clear how the local and national government supported Aldar, despite the fact that local critics and Members of Parliament contested the fact that the municipal budget will not benefit from this operation, which is located in a prime site in the city. In particular, the political relationships between the Abu Dhabi and Astana transfer are quite personalized and generated ad hoc conditions for specific projects (Anceschi, 2014). The sub-culture of the elite counts and can have paradoxical effects for planning and more general state policy (Jones 2015). These were conditions that did not grant any particular planning restrictions for the project.

After a grand public and international announcement, the final design was handed to HKR Architects, which describes itself as "an architectural consultancy for the new global economy [...] Our network of offices in the UK, Turkey, Russia, Kazakhstan and the UAE enables us to offer a full scope of services to our clients, delivering international experience and local knowledge to each project, regardless of location" (Retrieved from <http://www.hkrarchitects.com/about-us/> in April 2015, italics added by the author). Construction started in 2009; the main tower (over 350m) will be the tallest building in Central Asia. In the process several adaptations were made, losing the innovative signature design and aesthetics of Foster. The fact that this building (the tallest in the city and the country) will be adjacent to the monumental axis of the capital ironically show that the only actor fulfilling its goals is the real estate developer Aldar. The client has a more costly and less iconic complex, the state cannot levy taxes on the new development, the design firm lost the job along the way and eventually citizens will have a less interesting urban realm than expected with the approval of the project.

4 CONCLUSIONS: TRANSNATIONAL DESIGN FIRMS AND LOCAL URBAN PLANNING

Star architects' clients seem interested in the functional outcome of architectural design as well as in the returns in terms of reputation that the figure of a renowned architect can induce. As the two cases showed, famous architects are not hired for the expected positive urban impact only, but also for other symbolic and political reasons both at the macro (promotion of the national or urban image) and micro level (same operators). Representing architectural aesthetics, technological innovation or general narratives as determinant factors does not respond to the actual procurement processes. Nonetheless, the firm's distinctiveness has been the means for disseminating certain types of behavior among decision makers and has provided architects, pro-growth politicians, real estate developers and other actors with favorable conditions for their business (Sklair, 2006 and 2010). Despite the fact that architectural and urban design become a means to reassure local actors about the feasibility and innovation of projects to be more or less literally transplanted (which is efficient for the design firm), the final outcome depends on a series of

adjustments. The latter may mean the simplification (and eventual banalization and cost-cutting) of the original project that was delivered under different conditions.

A broader picture may derive from this analysis. The economic crisis, or the Arab spring did not change much in the development of large-scale projects in the Middle East (Barthel and Vignal 2014). The recent slowdown of the Chinese economy did not stop the rapid urbanization process. In such countries, design firms can experiment new solutions (among others: the abovementioned eco-city of Masdar in the UAE) and eventually implement them at the highest speed. The availability of money, concentration of power, the absence of democracy, urban tabula rasa and other conditions may sometimes be extreme. But designers understand what this means for their business. Owen (2009, 10) gives a clear example: "Foster's Terminal 3 in Beijing was designed and completed in four years, the length of the public enquiry into Richard Rogers' Terminal 5 at Heathrow – a project that reportedly took a total of 20 years to complete." The firms' mobility does have an impact in the way they operate (e.g. a more economically efficient design process implies standardized solutions to be replicated, with incremental customization according to the occasion) and the knowledge they carry around as they travel. At the moment the long-term implications related to the trajectories of important transnational actors who operate in different geographic contexts in search of favorable conditions has not yet been observed. What they eventually "bring back home" after their mobilities in countries with radically different political and institutional settings and rather simplified planning systems and processes may imply some problems.

The global financial crisis of the late 2000s was in part originated by the functioning of the real estate market and its financial arrangements and it had significant repercussion on urban policy and planning (Ponzini 2016). When both public and private resources become scarce, urban policymakers and planners may tend to lower the standards and quality of the planned interventions, in order to keep the available investments flowing and maintain political consensus among relevant stakeholders. This is quite visible in several cities of the Western world, especially in Southern Europe. A quote from Norman Foster may summarize the designers' point of view: "We now have a tremendous amount to learn from the best of those emerging economies and the way in which they are thinking big, thinking strategically, taking bold initiatives. Hum... examples in a way almost so obvious. Thus I wonder why it takes so long for the penny to drop" (Carcas and López Amado, 2010). It is difficult to tell if this is a blunt call for technocracy or a more nuanced inclination toward the import of eventual models for large-scale and fast-track projects that derived from Foster's experiences in the UAE, Kazakhstan, China and elsewhere. For sure, one can see how the same technologies, aesthetics and narratives circulate internationally making the life of the rent-seeking and local elite easier (Sklair 2017), but not necessarily delivering better plans and projects.

In the case of Foster's transfer from Abu Dhabi to Astana, the developer Aldar is presumably the only winning actor at the end of the game. The design firm lost the job on the way. President Nazarbayev wanted an icon on the monumental axis and had in return a quite generic complex, designed by a lesser-known and eventually place-indifferent firm. I am not sure if these are the kinds of planning processes and outcomes that cities in the West may be able or want to experience in the near future.

ID 1343 | CHINESE RETURN TO THE PUBLIC BENEFIT AFTER THE WAVE OF MASSIVE URBANIZATION - A CASE STUDY OF THE SHENZHEN BAY RECREATIVE SEAFRONT BELT

Jincheng Weng¹, Yiwan Li¹

¹Shenzhen Urban Planning & Land Resource Research Center
weng_jin_cheng@163.com

ABSTRACT: Shenzhen is located on the South of China; east of the Pearl River Delta; while bordering Hong Kong on its south. It is one of the fastest growing cities in China with a strong economic vitality. Started from a small fishing village in the 1970s, Shenzhen has become a mega city with a population of twenty million in 35 years. As a developing coastal city, Shenzhen had most definitely neglected its residents need of leisure. Especially recreational use of waterfront space. Shenzhen's municipal government activated the relevant works of Shenzhen Bay leisure seafront in 2003. The project started west of the Nanshan Hotel, all the way east to the Mangrove Nature Reserve Area. It spans throughout the east coastline of Shenzhen Bay, with a total length of 15 km. The project objectives are specific in the followings: comprehend the importance of coastal natural resources of Shenzhen Bay, make full use of the shoreline. Construct a complete form of ecological system while improving the current ecological function basing on the Mangrove Nature Reserve Area; opens the closed seafront; returns the natural waterfront space to the public; uses international consultation as the standards to reshape the coastal characteristics; encourage public participation in the process of planning and design. Holding these objectives, 9 kilometers of coastline on the east side were completed in 2011. Upon its opening, the Shenzhen Bay leisure seafront belt had won the public praised and regional recognition the Shenzhen and Pearl Harbor Delta area almost immediately. It had then become the symbol of Shenzhen, as a modern coastal city. Summary: This leisure project demonstrated that urban space is not only a carrier economic development and construction. For a better life tomorrow, adhering to the people-oriented, nature-oriented, and positive concepts are needed. They are there to guide urban planning and construction activities in the city tomorrow.

KEYWORDS: Public space, Public interest, Coastal Characteristics, Shenzhen, China

1 PREFACE

The Shenzhen Bay is an estuarine bay shares between the city of Shenzhen and the city of Hong Kong. The west end of Shenzhen bay, bounds to the Pearl River Estuary, while the east bounds to the Shenzhen River; the bay holds roughly 80 square kilometers of area. The water depth gradually shallows from the east to west. The shallowest depth of the water holds at 1 meter. The Shenzhen Bay referred in this article is within the administrative boundaries of Shenzhen.

The new Shenzhen coastal waterfront emerged when the reclamation of the new Shenzhen Bay Checkpoint and Shenzhen Bay Bridge were completed at the end of 2003. Under this circumstances, the municipal government of Shenzhen began to reflect the urban development of past 20 years, including the significances of the Shenzhen Bay regarding to natures, urbans and the publics.

The Shenzhen Bay Coastal waterfront space has superior geographical location and unique landscape resources. It would be an unreasonable wasted, if Shenzhen Bay was not able to convert into public use due to the lack of reasonable use objective. Meanwhile, the shoreline has become increasingly prominent as the inner marine of Shenzhen and the gateway to the city image. Unfortunately, it has no coastal features.

For all the illustrated reasons, Shenzhen municipal government started the relevant works of Shenzhen Bay recreative seafront. Which spans 15 kilometers west from the Nanshan Hotel, along the Shenzhen Bay shoreline till east to the Mangrove Nature Reserve Area.

Figure 1 – Location of Shenzhen Bay

2 REFLECTING TOWARDS THE DEVELOPMENT OF SHENZHEN BAY

2.1 FUTIAN CITY CENTER'S COASTLINES SERVED MANLY FOR INDUSTRIAL PRODUCTS, NATURAL AND RECREATIONAL SHORELINES ARE RELATIVITY SCARCE

The earliest economic development of Shenzhen was the opportunity of undertaking Hong Kong's manufacturing industry. Due to the fast-paced industrial urbanization, the city ignored people's needs and basic living. Many production facilities were set up along the administrative boundaries. The city developed rapidly from its east side towards its western base on its geographical and market factors. Uses of shoreline were mainly industrial; however, the public hydrophilic coastline was almost non-existence.

While most of the coastline were industrial, Shenzhen do have one unique feature of nature at its city center. The Futian National Mangrove Nature Reserve is a the only natural coastline of Shenzhen Bay, as well as is the only urban center nature reserve in the entire world. The Futian National Mangrove Nature Reserve and Hong Kong Mai Po wetland composed an important transit point for the international migratory birds in the eastern hemisphere. More than ten thousand of migrant bird rest and stop in the Shenzhen Bay every year. Since the nature reserve is a closed manage facility, and only 120 visits can be taken under reservation daily, most of the public has difficulties to reach and connect to this magical land.

Figure 2 - International Migratory Birds in Eastern Hemisphere(Left)
Figure 3 -Nature Reserves in Shenzhen Bay(Right)

2.2 SHENZHEN'S COASTAL SPACES WERE CLOSE FOR VISIT WITH MANY NEGATIVE IMAGES. THEREFORE, THE SHENZHEN BAY AREA SERVED NO RELATIONSHIP WITH EVERYDAY URBAN LIFE

Early planning and design of the water did not fully consider public's leisure and spiritual needs. Coastal regions were often occupied by non-penetrable buildings, ports, checkpoints and expressways. Sea sight could not be reach by urban population. The Shenzhen Bay area served no relationship with its urban

population. Rapid urbanization ignored the social public space consciously, and the real embodiment of the city charm of the city spirit was given way to the market economy.

2.3 SHENZHEN AS A COASTAL CITY HAD NO COSTAL REVELATION

As a rapid growing city, the demands for land were high. The water area of Shenzhen Bay was reclaimed as land, and it was reduced from 108 square kilometers in 1977 to estimate 83 square kilometers today. Massive extrapolation on reclamation was to meet the needs of city's early economic development; nevertheless, the original waterfront space and environment were not considered under the early planning stage. The construction of large-scale port and transportation facilities resulted shorelines to be enclosed and revitalized. These constructions had also changed the ecological resources in the city environment. Expressways such as Shahe and Binhai are acting as border walls that separates the urban population and the seafront spaces. Locating on the coastline, but cannot sense the sea. It's an embarrassing impression of Shenzhen as a coastal city. Coastal features of Shenzhen were facing endanger threat from the it rapid development.

2.4 AS THE CITIZEN'S LIVING STANDARD RAISES, HIS/HER SPIRITUAL NEEDS ALSO INCREASE. THE PUBLIC STRONGLY DEMANDS THE REOPENING OF WATERFRONT SPACE

Water is the source of life; human nature is hydrophilic. Ancient Chinese had a saying where "live beside the water, habitat by the water ". Nowadays, waterfront space does not only bear the city public activities, cultural heritage, ecological conservation, but it also reflects its city spirit. The value of waterfront space depends and changed on the public demands during different stages of city development. It was used for agriculture production at an early age, and progressed to industrial and manufacturing services during industrialization. With the transformation of urban industry and improvement of resident's buying ability, the function of waterfront space needed to be reevaluate and reassessed. The waterfront spaces will return to urban life as a citywide trend.

3 THE PROCEDURES OF SHENZHEN BAY RECREATIVE SEAFRONT CONSTRUCTION

3.1 COMPREHEND THE IMPORTANCE OF COASTAL NATURAL RESOURCES OF SHENZHEN BAY, MAKE FULL USE OF THE SHORELINE. CONSTRUCT A COMPLETE FORM OF ECOLOGICAL SYSTEM WHILE IMPROVING THE CURRENT ECOLOGICAL FUNCTION

An ancient Chinese sage Lao Tzu explained the relationship between man and nature two thousand years ago. "Everything exist together in a delicate balance, human being has to respect and learn from the earth, the sky and the entire nature."

Therefore, to take better care of the sensitive and fragile ecological environment, we must give priority to the primary needs of the natural biosphere. Including the birds, mangroves and so on. Pay full respect to the mangrove reserve's international influence and its sensitivity. Large-scale constructions are forbidden near the reserve land. Ensuring no disturb wildlife habitat, we need disperse the pattern of human activities and controls the types of activities that are taking place near the reserved land. To reduce the impact of human activities on the wetland ecosystem, human activities are taken far away from the mangrove, where the birds live.

The Shenzhen Bird Watching Society also participated regarding on the overall layout and functional organization for the mangrove. Goals to preserve large natural mudflats for benthic ecology and migrant

birds. In this new aspect of urban development, humans and birds, city and nature all coexist harmoniously.

With the establishment of large-scale physical hydraulic model, we can then simulate the artificial shoreline filling form and scale for the Bay area water flow. It can encourage a substantial contraction of reclamation area. Bay reclamation can be done per the needs of coastal activities, and moderate adjustment of the Shenzhen coastline can be taken to an accurate account.

Figure 4 - Establishment of Physical Hydraulic Model

3.2 REOPENS THE CLOSED SEAFRONT, RETURN THE NATURAL WATERFRONT SPACE BACK TO PUBLIC

Alleviates the physical isolation of the expressways, improves the connecting facilities such as overpasses, underpasses and traffic accessibility to the coastal area. Many measures can be all taken place to reshape the richness of coastlines and create a subtropical city coastal leisure space, while increase the chance of various functions, such as leisure tourism, occasional sports, fitness and so on. The connections and bounds of public activities will entitle the impression of this coastal city, promote the idea of the Shenzhen Bay from the urban edge to an undeniable urban function. It achieved the goal of psychological and social connections through physical transformation.

3.3 USES INTERNATIONAL CONSULTATION AS THE STANDARDS TO RESHAPE THE COASTAL CHARACTERISTICS

3.3.1 ACQUIRE HIGH DESIGN THAT QUALIFIES FOR AN INTERNATIONAL WATERFRONT

In 2003, the city planning bureau established the design, bidding with a clear task. It had received 58 design application worldwide. A team of experts selected 7 qualified design firms for the competition, and a committee of both domestic and foreign experts, elected the four most prominent proposals from these 7 firms. The design that scored the project is a collaboration work of China Academy of Urban Planning and SWA Group. In the following two years after its successful bid, the team had an abundance of time to improve their design. After the design and engineering had fallen into places, the project started its construction in 2006.

Figure 5 – Winning Design

Figure 6 –Improved Design

3.3.2 AVOID ADMINISTRATIVE INTERFERENCE, STAY LOYAL TO THE ORIGINAL DESIGN, AND ESTABLISH HIGH STANDARDS OF ENGINEERING

Phase one construction of Shenzhen Bay Recreative Seafront started in 2006 and continues till 2011. The design team acts as the general coordinator and it continues to advise government departments, stakeholders, drafting units as well as the construction company. Ensuring the spirit of design being unaltered.

3.4 IMPLEMENT PUBLIC PARTICIPATION THROUGHOUT THE ENTIRE PLANNING AND DESIGN PROCESS

Ever since the consultant information had issued internationally, the project of Shenzhen Bay had grabbed the attention from national, provincial and local media. Example as the People's Daily Paper, China Southern Metropolis Daily Paper, Shenzhen TV Broadcast Company..., etc. They had carried out detailed follow-ups regarding of the process of this project.

The planning bureau had displayed the top four designs on the government website and related planning exhibitions. Goals to communicate and gather publics' ideas. The responses that were received displayed a great public interest in the planning process. Not only did the public browsed planning exhibition site, went online and filled out questionnaires; they had also suggested through phone, email and on-site.

The design with the most public votes happens to be the same one chosen by experts. The public had displayed these following reasons for their choice: it conforms to the natural environment; it highlights the themes of ecology and leisure; it is suitable for modern lifestyle that requires sustainable development; it has a clear and rational layout; it creates a unique environment for the city; it enriches cultural elements that this city desperately needed; and it is full with local characteristics.

While the display design was available to the public, the municipal government organized a public meeting that invited hundreds of general publics, real estate entrepreneurs and design institutions. The meeting had reached a consistent decision after a fierce discussion: the outpost of Shenzhen Bay should advertise the development of the entire bay area in the future, and the real estate companies should bear more social responsibilities regarding on this mission.

At the end of the public involvement, the planning bureau received 736 responses with comments. They included ecological preservation, regional functionality, and implementation strategies..., etc. The planning bureau and the design team had analyzed these responses and corresponded to all the public suggestions. Fortunately, the design team had considered and perfected their design base reasonable suggestion from the publics.

Figure 7 – Public Participation

4 RESPONSES FROM THE SHENZHEN BAY RECREATIVE SEAFRONT PROJECT

The 9-kilometer coastline on the east side finished its construction in 2011. It had gained Shenzhen and the Pearl River Delta region's public recognitions and was praised almost immediately; It had become the symbol of Shenzhen as a modern coastal city; it had received numerous awards, including the 2014 China habitat environment award, and the ninth International Federation of landscape Architects Award.

Figure 8 and 9 –Citizens' Favorite Public Spaces

5 PERORATION

The core idea of urban planning is to ensure the city's livability and provides citizens a peaceful, convenient, and enjoyable environment for work and life. This project of Shenzhen Bay Recreative Seafront is a reflection and a breakthrough of modern city concrete forest stereotype. Shenzhen often received this stereotype of as a public space and nature ignorant; nonetheless, this project demonstrates a rational decision of rus in urbe after twenty years of insane urban constructions. Urban space will no longer serve as the urban economic development sorely; urban spaces in the future will be people-oriented, nature-oriented. Only incorporating public leisure spaces, ecology preservation, and sustainable living into urban planning will guarantee a better city tomorrow.

1 INTRODUCTION

Neighborhoods parks are core living environments that create an important part of the public life which help to fulfill residents' social needs and satisfaction through social relations of neighborliness and familiarity. Neighborhood parks can ideally provide various opportunities for the well-being of especially those whose daily lives are bounded to their place-of-residence, such as women, children and elderly people. In fact, they can be used as parochial realms by these "groups-in-need." In daily life, however, not all of these groups do and can use neighborhood parks in the ways as desired, because the access to park use is not equitable among all. In order to improve urban planning and urban design strategies that

support equitable access to neighborhood parks, we need to investigate the factors causing inequitable access to the use of neighborhood parks and especially how neighborhood parks evolve on daily basis as the parochial realms by the groups-in-need.

Literature mostly tends to analyze neighborhood parks as public realms. However, as Bose (2005) also state studies that are limited to “binary conceptualization (public-private)” loose the interconnections between public and private realms and obscure the experiences of women in between these realms as (Bose, 2005). So this study considers that especially “groups-in-need” use neighborhood parks as their parochial realm. Ultimately, the physical and social factors that cause these perceptions should be investigated.

Parochial realms are shaped as a result of a sense of shared benefits among acquaintances or neighbours who are a part of close interpersonal networks that are located within communities of neighbourhood or workplace (Lofland, 1989). Parochial realms are areas where people accept the physical, cultural and social differences among themselves and share the commonalities. Hunter (1985) and Lofland (1989) define public realm as the world in streets, parks, public transport or commercial spaces that create chances for strangers to come accross, while personal affair of each individual in the homeplace can characterize the private realm (Hunter, 1985; Lofland 1989). Parochial realms are located at the intersection of public and private realms and the boundaries in between these realms are fluid and flexible. Such flexibility helps these areas to function like ties in between and makes it easier both physically and psychologically for people to travel in between public and private realms (Gehl, 2011). According to Wessendorf (2013) the differentiation among private, parochial and public realms depends on the degree of social relations and familiarity among people (Wessendorf, 2013). Familiarity can be defined with “a sense of commonality among acquaintances or neighbors who are involved in interpersonal networks that are located within “communities.”” (McKenzie et. al. 2006, p. 118).

More than defining a physical territory, parochial realm of neighbourhoods define close relationships of daily lives and can house to various narratives and ways of lives especially for people who are bounded to residential environments due to variety of reasons. As number of close ties in a public space and the level of intimacy among the inhabitants and their knowledge of the space increases, the spaces start to function as private realms for its inhabitants. Negotiation on the activities starts at this point. Negotiation means that inhabitants start to treat those areas as they are treating to their homes and they start to use those areas for their own private purposes with more informal and casual behaviours which are different than the original intentions for those spaces and people start to behave as if they also own the proprietary rights of those settings (McKenzie et. al., 2006).

In order to improve the use of neighborhood parks, we need to investigate factors affecting the perceptions regarding neighborhood parks especially for groups-in-need. Along with the importance of familiarity and social relations, this study highlights the importance of several other factors that may affect the perceptions of neighborhood parks as important examples of parochial realms where uses can be easily transformed and negotiated by users according to their needs. These factors are design of neighborhood parks and their surrounding environments, their accessibility, social relations among users and their feeling of safety; and secondly the socio-economic characteristics of users such as their age and gender.

To understand the role of these factors, questions of “how physical and social characteristics of neighborhood parks and their immediate surroundings, and potential park users’ socio-economic characteristics affect perception of parks as parochial realms?” and “how does the perception of neighborhood parks as parochial realms affect park use by people whose daily lives are bounded to residential space?” is answered in this paper.

2 FACTORS AFFECTING THE PERCEPTION OF NEIGHBORHOOD PARKS AS PAROCHIAL REALMS

Together with users’ socio-economic characteristics, parks’ physical and social characteristics affect park uses and perceptions differently and thus, might cause inequitable access to parks (Van Herzele and Wiedemann, 2002; Carr et. al., 1992; Low et. al., 2005). Socio-economic characteristics and resulting traditional daily responsibilities can play an important role especially for groups-in-need with physical,

social, economic and cultural limitations to use city space and have limited access to other public spaces. These factors may bind them to the neighbourhood space. Yet Neighbourhood parks may provide opportunities for women with children and housewives to socialize (Mackenzie, 1989; Kaplan, 1997; Greed, 2007); prevent social exclusion of elderly people with limited mobility (Chaudhury et. al, 2016); serve facilities for children to gain the habit of exercising as they are close to home place and easily accessible and arguably safer (Coşaner et. al., 2014). These opportunities cause groups-in-need to perceive neighbourhood parks as parochial realms – as the extension of their private spaces – and they may use neighbourhood parks for interaction with their immediate environment.

In order for groups-in-need to perceive and use neighbourhood parks as parochial realms, parks' physical characteristics such as design of neighborhood parks and their surrounding environments, their accessibility in relation to home or workplace of users, and parks' social characteristics which is based on the social relations among users, opportunities that parks provide such as cultural and social activities in parks and the relationship between different familiar groups of people who are using the park and the surrounding environment together.

Physical characteristics and quality of green spaces have serious effects on the determination of behavior patterns, chosen activities, the ways and frequencies of park visits, ideas and feelings regarding their immediate environment and the chances of escaping from the stress of the daily life (Van Herzele and Wiedemann, 2002 cited in Kemperman and Timmermans, 2008). While park design can promote opportunities for socialization, and, encountering with nature, when parks are not well designed to fulfill the needs of potential users, than those same parks can be used for incivilities including homelessness, voyeurism, exhibitionism, sexual gratification, drug use, thievery and so on (Byrne and Wolch, 2009)

Studies indicate that higher levels of park use is also related with the accessibility of parks which means the availability of attractive, pedestrian friendly walking routes (Booth et al., 2000; Michael et al., 2006). Accessibility of parks increases the likelihood that especially groups-in-need can visit a park and potentially engage in physical activities. Specific characteristics of parks' surrounding environments such as slope of the terrain, park density, connectivity, land-use mix, attractiveness and physical appeal can be associated with the active park use and the life satisfaction of residents (Moudon et. al., 2006 and WHO, 2007 cited in Donder et. al. 2013; Parra et. al. 2010). Negative issues and problems in the access to the parks such as crossing roads and walking on rough pavements, or a poor general overall appearance can be strongly felt negatives (Fokkema et al., 1996; Scharf et al., 2002) and they can work as barriers to use a park.

Social characteristics of both users of neighborhood parks have a crucial role in neighborhood's social life since they provide chances for building and maintaining a certain level of social relationships (Hunter, 1985; Bedimo-Rung et al., 2005). Additionally, relations of neighboring provide support, feeling of safety along with personal identity and place attachment (Kusenbach, 2006).

3 CASE STUDY: NEIGHBORHOOD PARKS OF BALÇOVA, İZMİR

The research focuses on the findings of the case study site in Balçova, a district of İzmir, a metropolitan city on the Aegean coast of Turkey . Balçova is located in the south of İzmir Bay with a total of 6km long shore (Figure 1). Balçova has the oldest population when compared to other counties of İzmir and Balçova is the mostly preferred county by retired people in İzmir (Balçova Municipality, 2016). Balçova's location between shores of İzmir Bay and hills of Teleferik Mountain, provide many waterfront and mountain recreation area opportunities. In addition to waterfront open green spaces; there are 32 neighbourhood parks (Balçova Municipality, 2016) in variety of sizes and characteristics depending on the residential settlements, level differences on the north-south direction and dense traffic routes.

3.1 STUDY METHODOLOGY

For this study, we had observations in each parks of Balçova, a user survey in 4 elected parks, and interviews with parks users at 2 parks. Observations were about land-use at park surroundings, park design and amenities, use of parks, and physical thresholds around parks. As a result, we selected four parks according to their number of users, surrounding land use diversity, park's physical characteristic and

amenities and surrounding thresholds. At these four parks, we had a user survey with 159 participants about people's personal park use habits such as use frequency and durations, their perceptions regarding parks' physical and social settings, and surrounding environments, their experiences in relation with their socio-economic characteristics. Ultimately, we determined the number of regular and non-regular park users and their park satisfactions in four parks. Out of these four, we focused on two parks, Duru Park (See Figure 1, 2 & 3) and Süleyman Ersever Parkı (See Figure 4, 5 & 6) according to number of non-regular park users, satisfaction level of regular park users, characteristics of parks' surrounding environments, total park area and provided amenities in parks. Ultimately we developed in-depth interviews with 30 park users, 5 focus group interviews with women at nearby community houses and also interviews with 8 men working in these parks to find the details of people's park perceptions and park use experiences.

3.1.1 CHARACTERISTICS OF PARKS WHERE THE STUDY REALIZED DURU PARK

Figure 1 Map of Duru Park

Figure 2 and 3 - View from Duru Park

Figure 4 Map of Süleyman Ersever Parkı

Figure 5 and 6 - View from Süleyman Ersever Parkı

3.2 RESULTS AND DISCUSSION

Two parks that we focus on in this study have different physical and social characteristics, which cause major differences in perceptions and uses of neighborhood parks. Paper outlines findings of the study in three main parts. The first part concentrates on the importance of feeling of familiarity as a factor that supports the sense of safety and comfort in neighbourhood parks and perceives them as parochial realms. The second part focuses on the physical characteristics of parks such as park design and provided amenities and parks' surrounding environments such as land uses and their users as factors that make users perceive and use neighbourhood parks as parochial realms especially by mothers and elderly users. The last part raises the importance of accessibility. Being in close vicinity of mothers' and elderly's daily routine routes can increase the use of these parks' as they have higher accessibility and can easily be reached by walking. So they are used as a space for socialization opportunity with others but usually with the ones who have same daily responsibilities.

3.2.1 FEELING OF FAMILIARITY TO SUPPORT THE SENSE OF SAFETY AND COMFORT IN THE PAROCHIAL REALM

This study finds out that being together with familiar people affects park use preferences of women significantly. According to interview results in Süleyman Ersever Parkı, different than Duru Park, most of the users are frequent users and they have a familiarity towards each other and the environment. This familiarity in Süleyman Ersever Parkı is partially based on the relative residential stability of the surrounding neighborhood, existence of school nearby and the existence of the café which is being run by the same family for the last 15 years. These support the feeling of familiarity. Most of the respondents mention that they feel like a family and they never experienced any negative looks or actions towards them in Süleyman Ersever Parkı. Especially women whose children are at the school mention that they can sit together with other mothers while waiting for their children and socialize in the park. Observation results indicate that women get together in the park in large groups, bring food from their houses and buy beverages from the café and spend long hours in the park. Sometimes the same group of women also comes to park during the weekends for birthday parties of their children and use the park as a spot for getting together with neighbors.

"There is family environment. I know who is coming here why. If a stranger comes, I can recognize. If I feel discomfort, I can go and tell this to Murat Ağabey (owner of the café) and he takes care of it" (Woman, 40, married with one child).

Whereas in Duru Park, the level of familiarity for women users is much lower due to surrounding commercial facilities and their users who are coming from all parts of Izmir. In between shopping these outcomers use the park for resting. Existence of tea houses around the park, their male users, the way that they extend their tables to the interior of the park and use of the park by people who are not from the same neighborhood affect the feeling of familiarity especially for women.

One of the dominant user groups of Duru Park is elderly men of the neighborhood. As most of them are retired and want to spend their time in open air with their friends they prefer to come to Duru Park and

spend all day there. However, dominance of male users is perceived as discomforting for women users of all ages. So while elderly men use the park for longer hours for sitting and chatting with their friends, mothers prefer to use the parks for their children and elderly women for resting for very short periods.

"I go Duru Park but I do not like there. Men are looking at women with dirty eyes. Especially elderly men! I heard an incident. A man sat next to a woman i and asked her whether she is a widow. He told that he wants to marry. I heard this I swear. He told that he has a car and a house. So I am worried about these things. They should leave the park to women" (Woman, 53, married with one child)

On the contrary to women users, results of the interviews with men who are working in the park indicate that elderly men use Duru Park very comfortably together with their friends for very long hours. These men come to park early in the morning; most of them sit on the same benches everyday. They chat together about daily matters and order tea from the teahouses and spend all their leisure time in Duru Park.

"I've been living almost for twenty years. We all know each other here. When I come to this park I always meet with my friends. I know all the users of this park, all of them are from this neighborhood and I come here everyday to see them" (Man, 62, widow with one child, sitting at the same bench all day and everyday)

Neighborhood parks not only create socialization opportunities for children but also for their mothers. While children can easily find playmates in the playground who are living in close proximity and going to the same school, mothers also meet with other mothers while realizing their traditional daily routine of childcare.

"The playground in Duru Park is very important for my daughter to get rid of her energy and more importantly to socialize with other children. As we come here very often, she had many new friends and I also met with their mothers. So her socialization helped me to socialize as well" (Woman, 26, married with one child)

3.2.2 PHYSICAL CHARACTERISTICS OF PARKS AND SURROUNDING ENVIRONMENTS

INCREASING FEELING OF FAMILIARITY

Surrounding uses and users affect feeling of safety and comfort based on their socio-demographic characteristics. Overall user survey results indicate that 44% of the respondents feel positive (comfortable and safe) when parks are surrounded by residential facilities. A larger group, almost %50 of respondents, state that they feel negative (overwhelmed and insecure) when parks are surrounded by commercial facilities. While most of the respondents in Süleyman Ersever Parkı which is surrounded mostly by residential facilities feel positive (34%) about having residential facilities and negative (30%) about having commercial facilities around the parks; in Duru Park which is surrounded mostly by commercial facilities mostly feel negative (36%) about having residential facilities and positive (50%) about having residential facilities (Figure 7 & 8).

Figure 7 Perceptions of having residential facilities around parks

Figure 8 Perceptions of having commercial facilities around parks

Yet depending on gender of the respondents, satisfaction about the kinds of land use at park surrounding show differences. When there is the dominance of a single user group whether men, elderly, or children, the other users may start to feel uncomfortable and they do not feel welcomed in those areas. While men do not have any complaints regarding the surrounding stores or tea houses, women mostly comment negatively having tea houses or other activities that have dominant male population around the park.

“Existence of too many men in Duru Park is very disturbing. I cannot spend time there comfortably. Tea houses are too much integrated with the park. For instance in Süleyman Ersever Parkı, men and women can sit together, it is not disturbing. Because all men are from this neighborhood and they are parents of kids from the school. So no one disturbs each other” (Woman, 40, married with two children).

In addition to the characteristics of the park surrounding, parks’ design such as the availability of amenities like seating units, tables, pergolas, lighting elements, different play and sports equipments, cafes, and programming such as periodical activities like courses, concerts and celebrations at the park play a crucial role on the feeling of safety and comfort of the users.

LACK OF SITABLE SPACE AFFECTING THE USE OF NEIGHBORHOOD PARKS

Duru Park can be divided into two main areas, pool side and playground side. On each longitudinal sides of the pool there are 6 fixed benches with a shading element on top. However, on the playground side there are only 2 benches with no climate protection. In Süleyman Ersever Parkı, there are three main areas, cafeteria, playground and pool side. Cafeteria has its own movable chairs and tables, and only a portion of it protected from rain and sun. The playground side has no seating elements. In the pool side there are few fixed stone benches with no climate protection other than a couple of shade trees next to benches. Results indicate that lack of sufficient number of seating units in the close vicinities of playgrounds where mothers can have eye contact with their children is a major problem in both parks and either force people to use the utilities cafes and spend money or wait for their children standing. In addition to insufficient number, lack of protection from weather conditions is another problem.

“I wish there was more shade in here. Especially, we, mothers, need to sit by the playground but it is impossible in summer. There should be something to block the sun” (Süleyman Ersever Parkı, woman, 38, married with two children).

According to user survey results, mostly complained problem in neighborhood parks in Balçova is the lack of climate control (28%) in relation with seating areas (Figure 9). 43% of the whole respondents state that they want solutions for climate control problems (54% of this group is women).

Figure 9 Climate control as the mostly complained issue in parks

According to detailed observations in Duru Park at the same times of the days during spring and summer, user number significantly decreases during summer time observation and respondents complain from lack of shade elements, planting and water elements that can cool down the air. During summer there are almost no children and women around the playground and almost all users are elderly (Figure 10 & 11).

Figure 10 Duru Park on a mild temperature spring day

Figure 11 Duru Park on a hot summer day

Flexibility of the seating units and existence of tables is also important especially for young park users so that they can change the layout according to activities and use together with friends to chat, study, do handcrafts, rehearse music rehearsal, picnic or celebrations instead of just sitting and watching the passer bys.

“They put benches in military order. They are close to each other and fixed. Two rows of benches are looking face to face. Everytime I walk in between these benches, this layout gives me the feeling that all eyes are on me. They do not give the chance of moving according to what I like. So if I come here in a group of 3 or 4 we cannot chat properly” (Duru Park, woman, 26, single).

Existence of Food Related Amenities and their Effects on Perception of Familiarity

Considering the importance of eating activities in Turkish culture like in most Mediterranean societies, the provision of suitable physical conditions in parks for such activities is crucial. According to interview results, along with the importance of the type of the food, the location of it, quality and price the most important factor that affects the feeling of safety and comfort is the familiarity of the staff that run the place and the users of those food activities.

While existing döner or kokoreç kiosks are being complained constantly due to their concerns about hygiene, smell, prices and dominant male users in Duru Park mostly by women, the café in Süleyman Ersever Parkı is being appreciated and used often especially by the mothers who are waiting for their children getting out of the school. Those women express that they feel comfortable and safe as they know the owners who is a family from the same neighborhood and thrust them for years whereas in Duru Park the staff of the döner kiosk is all temporary and changing often.

"I come here everyday to be together with my friends, drink tea and chat. This café is a resting place for me. I like it so much. We know the owner Murat Ağabey. If we need something he helps. We can live our bags and he keeps an eye on it." (Süleyman Ersever Parkı, woman, 53, married with one child).

Park Use after Sunset and Feeling of Safety

As Madge (1996) also state feeling of fear is directly transferred to the public space use behaviors and creates a hesitancy for using certain spaces at certain times of the day (Madge, 1996). In neighborhood parks of Balçova, the level of night use is very low when compared to other time frames during the day. Almost all respondents highlighted the importance of lighting in the night on the feeling of safety.

"I can use parks anytime I want in Balçova. Of course if the lighting wouldn't have been enough or it was isolated I could not be able to use the park, then I would be afraid. Lighting is very important for safety." (Woman, 35, married with one child)

According to user survey results, majority of the respondents prefer to use the park before sunset (91%). Mostly mentioned reasons for such use are the lack of suitable lighting and lack of activities. Especially existence of an activity which creates human crowd and well lit environment affects safety perception.

Although Duru Park also has a special lighting design (different than all other parks in Balçova), since it is surrounded mostly by commercial facilities, after a certain time those stores close off and the surrounding of the park becomes very dark and isolated so the night use is very low. However, when we look at Süleyman Ersever Parkı, even if it is not much, there are few users in the evening as well. Especially during Ramadan, municipality organizes activities and such activities attract people in the evening to the park.

3.2.3 ACCESSIBILITY OF NEIGHBORHOOD PARKS INCREASING THE CHANCES OF BEING A PART OF PAROCHIAL REALM

Study results indicate that especially women with children and elderly people see parks that are on the route of daily routines and accessible by walking as extensions of the private space that they are assumed to belong, an area where they can create opportunities to get together with their friends and carry certain household habits to which starts to convert these public spaces into areas of parochial spaces.

"I have two daughters and we like to have our breakfast here. We leave across the street. So for breakfast, I prepare everything and come here to the park. We sit on the picnic tables and have our breakfast. It creates a change. When we are here, I also see my friends and they join us. We sit for very long hours. It is so nice to have these opportunities near home" (Women, 45 married with two children)

Accessibility of the park is a very important issue especially for elderly people. Since a large group of park users are elderly people with limited mobility in Duru Park, busy traffic around the park, taxi stop with several taxis parked in front, food vendors and their customers at the edges of the park create accessibility problems in Duru Park. For instance during the observations, there was a case when a women with her old mom wanted to get into the park and sit on the benches, the elderly mother had difficulties in crossing the

street and between the parked taxis at the edge of the park. So couple of taxi drivers had to help them and carried women to the benches. When we talked to these women, we found out that the mother likes this park a lot and wants to benefit from the sun but day by day it gets harder for her to come because of the increased traffic and the “wall” (she defines the cars, food vendors and trash bins) around the park.

Accessibility of neighborhood parks can also be defined as connecting routes of daily routines to users’ homes or to workplaces, childcare facilities to shopping activities or providing amenities that can also help women to turn their traditional daily responsibilities into an opportunity to be a part of parochial realm. Although literature defend that due to traditional daily responsibilities such as taking child to the school or going to grocery shopping roles, women end up giving up with using public spaces for leisure or socialization purposes (Kaplan, 1997), accessible parks can enhance women’s chance of participating to social life. Existence of different landuses and resources around attributes different uses to parks (Dines et. al, 2006) and improve parks’ accessibility.

Neighborhood parks not only create opportunities for children’s recreation needs but also create an opportunity as a meeting place for women from the surrounding neighbourhood to get together to talk with friends and relatives (Hutchinson, 2009). In neighbourhood parks women justify their park use through their children. Since children wants to be in the park they state that (to their husbands, family members or curious neighbour sitting on the window) they have to come to park. These strategies give them the courage to negotiate on uses of public realm of neighborhood parks and turn them into a form of parochial realm.

“Usually women work and after they go home and continue working. I got off from work. I should have stayed at home and cook but I needed to do shopping. As we got outside my daughter started crying to go to park. After the park I will continue shopping and go home” (Duru Park, woman, 26, married with one child).

Süleyman Ersever Parkı’s location next to the school is one of the great opportunities for women to turn their duty of taking child to school and picking up from school into a socialization opportunity to sit together, drink tea and chat with friends while waiting for their children. It is a good example how women use their daily responsibilities as an opportunity to socialize and be a part of parochial realm. The most dominant user group in Süleyman Ersever Parkı is mothers of the children who are in school.

“Most important thing is comfort of my child. I wait in the park in case she may need something. We are lucky to have a park next to school to sit and wait our children. I also have the chance to see my friends. In case I run late, I ask my friend to take care of my daughter” (Woman, 40, married with two children).

When school is closed park use level significantly drops. Neither the mothers with children nor the people working in the school come to this park during summer. This indicates that parks are not sufficient to attract users without a well considered surrounding environment. (Figure 12 & 13).

Figure 12 Limited use of Süleyman Ersever Parkı when the school is closed

Figure 13 Increased use of Süleyman Ersever Parkı when the school is open

4 CONCLUSION: PERCEPTIONS OF NEIGHBORHOOD PARKS AS PAROCHIAL REALM CHANGING THE PARK USE EXPERIENCES OF USERS WITH DIFFERENT SOCIO-ECONOMIC CHARACTERISTICS

Neighborhood parks are used and perceived as parochial realms especially by mothers with children and by old women and men, especially retired ones. While Lofland (1998) defines parochial realm as the world of the neighborhood, workplace, or acquaintance network, in this study, neighborhood parks appear with the extensions of activities that are assigned to private realm and opportunities for frequent users' (especially mothers' and seniors') socializing around these activities. Next to users' gendered roles and responsibilities shaped by their aging, these socializing opportunities are also highly influenced by design and planning of neighborhood parks and their surrounding areas.

Land uses in parks' immediate environment (e.g., schools, tea houses, commercial or residential uses), design of parks' layout and provided amenities in parks (e.g., cafes, vendors or taxi stops) carry a great importance for perceiving neighborhood parks as "safe" and welcoming parochial realms. For instance, while a nearby school attracts more mothers with children to parks and creates a meeting point for middle-aged women, tea houses around another park attracts mostly elderly men and serves as a socialization opportunity.

Types of the provided amenities in relation the needs of potential users (e.g., playgrounds, seating units or shading elements), the ways these amenities designed (e.g., flexibility and size of seating units and tables or lighting design of the whole park), and the location selection of amenities are also other factors that affect the perceptions regarding neighborhood parks and enable people to negotiate on the existing uses according to their needs. While design and location of existing shading elements and seating units in relation with the design of playgrounds are quite important for mothers who wants to sit, chat and eat together with their friends or do hand-crafts while keeping an eye on their children; location of seating elements and their relationship with each other and distance to other park amenities like playgrounds is critical for comfortable park use of elderly women and men who wants to have some level of privacy and quite time.

On the contrary to common suggestions for crime prevention by lighting design (Atkins et. al, 1991; Lab, 1997), this study suggests that lighting design cannot fully create safety perception and highlights the importance of familiarity on the safety perceptions. For comfortable park use not only lighting but also working hours of the surrounding landuses and familiarity of the other users is crucial.

Familiarity of the users of the park and the surrounding facilities, and also the familiar staff of the café or vendors in the park affect perceptions of safety of women and men differently. For instance while owner of the café whom women can depend on for the maintenance of the park or familiar people in the park whom mothers can thrust for the safety of their children or men sitting at the café who creates a safety feeling in the case of any negative event are important factors for women, such factors do not have any effect on the safety perceptions of men.

ID 1366 | URBAN NIGHTSCAPES: SPATIOTEMPORAL NARRATIVES AND LIVED PERCEPTIONS, THE CASE OF NIGHTTIME LISBON

Vasiliki, Fragkaki¹

¹University of Thessaly Argonafton & Filellinon
vassia_fr@hotmail.com

1 INTRODUCTION

The basis in writing this article is the dialectical relationship between urban space and human, focusing on the interaction that these two factors demonstrate during the night. In this context, the research interest is directed on the way the urban nightscape experienced from users on the possibilities of (public) space at night and how they affect human behavior and management of leisure, and conversely, on how the nightscape is affected and reshaped by the behavior and social practices of the users, especially young people.

2 AIM AND GOALS

It has to be noted that selecting the investigation of the urban nightscape as culture forming space, it was assumed that research will be primarily based on the behavioral approach of night life in the city. Moreover, the urban experience is examined in the aspect of the night as a leisure or recreation time, therefore, it does not concern those who consider night time as working hours. Additionally, in this case, the time limits of night are specified approximately, in order to meet research needs. If we consider that at midnight according to the etymology of the word has been signified as "the middle of the night", night lasts from the time the sun goes down (between 19: 00-20: 00) to 21: 00- 22:00, followed by initiation of the night, lasting until dawn (5:00 to 6:00). Therefore, to overcome this ambiguity, it has been chosen to be noted as the beginning of the night, the time period of 22:00, which coincides the time out for many people and especially for youths.

3 THEORETICAL TOOLS AND BACKGROUND

The dialectic relation of absolute, relative and relational space in correspondence with the spatial triad (Figure 1) according to the dialectics of space theory (Lefebvre, 1974), drives Harvey in an expanded frame interpretation of socio-spatial relations, the "grid of spatial practices".

Figure 1.: The spatial triad by Lefebvre Source: Urban anarchy, 2014

In addition, it is taken into consideration the concept of psychogeography, which is a methodological tool in some modern approaches of the city, as originally expressed by Guy Debord and the Situationists (1950) who were influenced by Lefebvre. Psychogeography concerns the dialectic of the geographical environment and the human psyche. It is also applied the method of wandering (*flânerie*) and the technique of city discovery through the spontaneous, continuous rotation of the urban environment (*dérive*) which highlighted to identify “hidden desires” and reshaping everyday based on these desires.

Moreover, the concept of “ambiance” refers to a feeling or mood associated with a place, to its character, tone, or to the effect or appeal it might have. It is also used to refer to the place itself, especially to the small, neighborhood-sized hubs of the city called unities of ambiance, parts of the city with an especially powerful urban atmosphere. The “entry” into a concept (here: state), or - using the Harvey definition - in a relational space (time), perceives a spontaneous homogenization of the subject's mood.

The environments that combined together create the atmosphere of the place, are according to Debord (1958), the “soft” environment which concerns the presence or absence of human activity and the type of light, sound, time and ideas, and the “hard” environment on the structured, stable environment. The most “powerful” atmosphere basically involves the flow rate, the feeling and the ‘pulse’ quality mainly sizes which somehow are the measure.

The multiple atmospheres sections of the urban landscape, and the alternatively space qualities, since they are interrelated parts of a single structure, meet each other creating that which the Situationists called “atmospheres nodes” to identify those areas that function as connecting links and attract the wandering, so switched to them (Moras, 2005). The structural features (infrastructure, morphology) of public space at night show a diversity that is usually decisive in its use. The layout and orientation of the public space, the interaction distances allowed, the urban equipment, the obstacles, the altitude difference (levels) and the natural green, affect the human activity. For example, the centrality of a street or a square often determines the observed mobility and use of space when the darkness falls. In particular, in the night, the presence of adequate lighting contributes to the feeling of safety when somebody is wandering in a public space, or its absence, makes this public space potentially dangerous. These elements are sufficient “to concentrate human activities or to disperse, integrate or isolate them, attract or repel them, facilitate or impede them” (Kostourou, 2012).

When somebody moves within the city, almost every sense of you is being activated, so that the mental images, the representations of the urban landscape are the composition of all these senses (Lynch, 1960). The composition of the city's image at night varies considerably from day to day as the concentration of activities shifts and their content varies, groups of people change, and the sensation and aesthetics of the landscape changes. The mental map comprised by the city users essentially concerns the personal representation of each of them for the urban space. Moreover, it is inevitably influenced by the culture, social background, emotional state, etc. The personal experiences of each user of the urban space highlight value codes and perceptual filters.

4 METHODOLOGY

The followed methodology includes the qualitative analysis method, as long as most of the data are qualitative.

At the same time, bibliographic research has been a guideline and assessment of the validity of few early conclusions, while it has been complementary finding historical and other elements. Finally, the results of the research, when it was possible, have been graphically represented through map production using GIS software (Qgis). The produced maps (Table 1) were based on Harvey's spatial practice grid (1990), from which two of the four categories were selected.

Spatial practices	Accessibility and Distanciation	Appropriation and use of space
Material spatial practices (experience)	<ul style="list-style-type: none"> Youth flows by day/ by night Built environment by night 	<ul style="list-style-type: none"> (material) Elements of appropriation Public space used during night Population density by day/ by night
Representations of space (perception)	<ul style="list-style-type: none"> Mental cognitive maps 	<ul style="list-style-type: none"> Symbolic nightscapes Spatial dominance of certain youth cultures
Spaces of representation (imagination)	<ul style="list-style-type: none"> Urban nocturnal ambiances Emotional maps 	<ul style="list-style-type: none"> City fests Street art- performance and graffiti

4.1 FIELD WORK

- Case Study, conducted in the historic center of Lisbon within 5 months of duration (March-July 2015), of which a more systematic process took place during the months of April-May-June. The choice of the historic center is attributed to a markedly increased concentration of night activities, its historicity and symbolic significance, the multidimensional identity of its users, the abundance of public spaces, and the increased number of young people presence at night.
- Observation and documentation of land use during the night, the structure of public space, elements of architecture and urban planning at night, night activities, different nightlife rhythms, behavior and habits of users.
- Carry out measurements of human flows and population density in the public space at night, as well as soundscapes at night. The duration of systematic measurements is not unvarying but ranges between 2-5 hours per point of interest, with a frequency of 5-7 visits per public space.
- Interviews: 15 interviews were conducted among 19-25 year old people, ages that basically have a stronger involvement in the nightlife of the city, to cover as many areas as possible of the historic center. This restriction reduces the sample, increasing this way the chances of converging behaviors and batch results. Also, the method of selecting the interviewed persons approximates the cluster or cluster sampling, since the respondents were chosen randomly based on specific geographical clusters. In particular, the historical center of the city was divided into zones - some corresponding to neighborhoods - in which random number of people were selected (Figure 2).
- Questionnaires: In order to reinforce the information obtained, some questionnaires were created with similar content of these interviews. Additionally, images from the urban night scene of the study area were added, which respondents were asked to evaluate for their emotional reaction. This choice served the purpose of the survey by exposing all respondents to the same visual "controlled" stimuli, while making the completion process more attractive. The questionnaires

were personally sent to 35 people, while they were posted to fill in some local cultural site websites and official university web pages in Lisbon. Overall, the received answers came to 50.

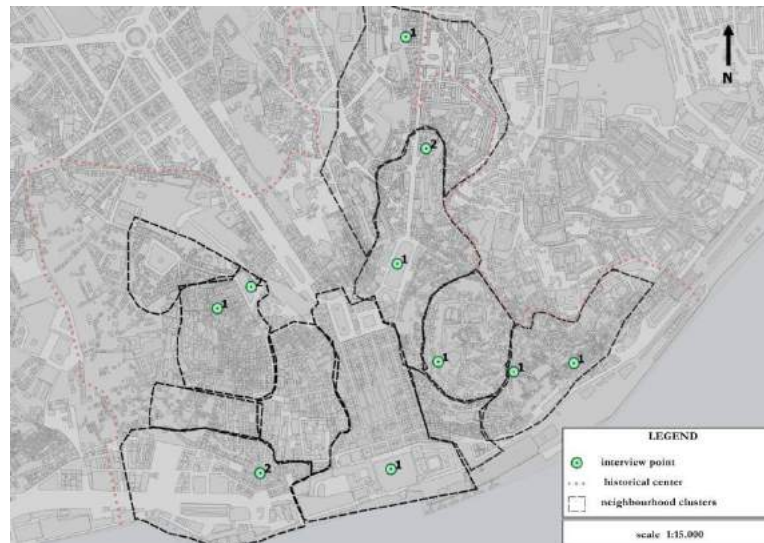

Figure 2.: Points and number of interviews Source: personal editing

The type of interviews approaches the semi-structured, as the goal was to map out a distribution of behavior. Beyond that, as it turned out to be, in practice, the structure of the interview left room for freedom in the debate, which often provided valuable information. The duration of the interviews ranged from half to one hour, and the content of the questions related to regular night activities (frequency and duration), night out areas, public space at night and the respondent's relationship, culture preferences, and the people's character and, respectively, of the space-social practices, the emotional experience in the urban night landscape and the view of the city wandering at night.

5 RESULTS VISUALIZATION

5.1 ARRANGEMENT AND MORPHOLOGY OF URBAN SPACE

There is a difference in the size of the building blocks between the areas of the historic center. The older quarters, which survived the earthquake consist of smaller building blocks and, while respectively the most recently rebuilt quarters, larger and often single building blocks. Accordingly, the distance of the intersections shows a variation between these districts. Frequent crossings and small property in the districts of Alfama, Mouraria, Castelo São Jorge and less in Bairro Alto and Bica, facilitate communication between residents and enhance the feeling of neighborhood and spatial cohesion.

Figure 3.: Street layout - patterns

Figure 4.: Typology of public space - squares and pedestrian streets
Source: gis database by Camara Municipal de Lisboa, personal editing

Figure 5.: Typology of public space - miradouros
Source: gis database by Camara Municipal de Lisboa, personal editing

The scale of public space varies, with paved, large-scale squares in central locations, while in the most densely populated districts (Alfama, Mouraria, and Castelo) public space appears to be limited in size and with a more spontaneous and discontinuous pattern. In addition, its form is different, offering a variety of landscapes and sensations, favoring different types of night activities and meetings. For example, the most popular spots with privileged location and excellent view (miradouros) are scattered across the seven hills of the city. Their acreage varies, with São Pedro de Alcântara being the largest in Bairro Alto.

Figure 6.: Meeting points in public space Source: Flickr, personal archive

Furthermore, the street, in Lisbon's case, is particularly important in nightlife, as an organic part of the public space. The fact that the largest area of the historic center has limited traffic creates the right conditions for the pedestrians to take up narrow streets. Particularly in the Bairro Alto, Alfama and Mouraria districts, where the streets are narrow and the distance among the square blocks small, casual

users of bars or random people of each region take the streets, creating a human-scale situation that gives vivacity and attractiveness.

5.2 URBAN LIGHTING

In fact, urban lighting defines the city's image and experience at night, since it acts as an indirect guide and scenographer at the same time, capable of "turning the simple crossing of a landscape into alternating zones in which everyone can behave in different ways" (Mbembe and Nuttall, 2004, as reported in Rink, 2013).

Public street lighting, facades of buildings, and lit shops make up disparate urban environments that mark the center of Lisbon. Further, they shape the urban visual and emotional experience, while on the other they act as the "face" of the city, giving it a specific identity. Both the traditional lamps on pavements and facades of Lisbon buildings, as well as the most modern street lighting equipment, give a warm yellow light, which refers to earlier times. In addition, the intensity of light varies from region to region, creating alternations of the atmosphere and the emotional experience, causing admiration, romance, nostalgia and fear sometimes. "Lisbon as a maze - city with dark and low-lighted streets causes a mixture of prolonged agony and awakening but at the same time of intimate comfort" (A. Robello, 2015- interview).

Figure 7 - Characteristic Lighted Buildings in historical center. Source: personal editing

5.3 SOUNDSCAPES

Overnight, the greater part of the historic center enjoys its quietness, since the rare traffic of vehicles minimizes noise pollution. At the same time, the concentration of nightclubs in certain neighborhoods allows the rest of the city to "sink" into the night's silence. In addition, a sufficient portion of the public space is located well away from the road, whether squares and openings surrounded by buildings, or miradouros, of which only one side has a face on a road and usually not a highway. At night the generally low noise levels caused by scattered speeches, laughs and other urban sounds make up the soundscapes of the city. At the same time, the range of musical sounds that are heard in public places is interesting. These data, as recorded, are represented in terms of intensity and duration (Figure 8).

The sounds in the urban night landscape from a psychogeographical point of view are a stimulus decisive for the wanderer route choice. Depending on his psychology, each person evaluates the sounds differently and he/she is attracted or repulsed by selecting or excluding parts of the urban fabric.

Figure 8: Soundscapes by night
Source: Results from personal measurements (2015), personal editing

5.4 COGNITIVE SHAPES OF URBAN NIGHTSCAPE

The familiar Lynch categorization (1960) was used, according to which, people tend to form mental images of the city in relation to five formations of urban space. Adding the night-time dimension as a limitation it attempted to attribute the urban iconography of the center of Lisbon to the texture and character of these formations. In essence, based on the experiences of the different surveyed people through their descriptions, the mental map (Figure 10) of the city at night was emerged.

Figure 9: Lisbon night images according to Lynch theory of spatial cognition
Source: Flickr, personal archive

Figure 10.: Mental-cognitive map of the historic center at night
Source: personal editing

In Lisbon, the majority of young people at the historic center at night distinguish nine districts, based on different criteria. The three are the Bairro Alto, Bica and Cais do Sodré areas, and the other four, Mouraria, Castelo, Alfama and Anjos, represent a combination of night-time wanderings, alternative fun and underground culture. The latter two, Chiado and Baixa, function more as transitional areas at night, since they serve the passage of passers-by to and from other areas. These areas, at night, are presenting “liquidity” in terms of their identification by visitors/users. Everyone's mental map encompasses or blocks spatial data, depending on the degree of frequency and personal experience. Comparing the mental map with population density measurements during night and day (Figure 11) it is observed that the pattern of the mental map approximates that of the population density map at night. Consequently, the mental map actually gives a picture of the city at night based on the orientation and frequency of use in urban sites.

6.1 YOUTH CULTURES AT NIGHT

In the attempt to map and categorize the youth groups and (sub) cultures that make their presence noticeable at night and exhibit distinct spatial practices, the following table emerged (Table 2). Apart from the academic groups of praxe and the social-political collectives, the other three categories are of varying degrees of heterogeneity, so they do not represent universally and strictly all young people who meet individual criteria. Nevertheless, a general picture of young people and how it moves to the historic center at night are being explored.

((Sub) cultures of young	Biophysical space (historical center)	Characteristics	Communication Codes	Community Sense
Student group Frase	Public space, squares, parks, miradouro	Mutual clothing / appearance	Strict adherence to orders and internal rules	Strong cohesive bonds
	Neighborhoods: Upgraded and 'Secure': Chiado, Bairro Alto, Bica, Cais do Sodré	Strong hierarchical organization Sense of prestige	Authoritative behavior of higher to inferior in the hierarchy	Moving by groups High Sense of community
Alternative and artistic young groups (hipsters, new boem, new hippies, etc.)	Public space, as an organic part of the urban landscape, squares, urban gaps, miradouro	Distinct clothing and style Special music preferences and more prone in drug use	Special vocabulary and phrasing Extraversion and mood for interaction Relaxation and emphasis on fun and art	Loose cohesive relationships depending on the group / company Solidarity and companionship Medium sense of community and usually with spatial report
	Neighborhoods: mainly those with monumental and symbolic capital features: Bairro Alto, Bica, Alfama, Castelo, Intendente, Mouraria, Cais do Sodré	Modernized simulation and revival of finite political trends Moderate degree of commercialization of the culture and often involvement with substances		
Socio-political youth collectives	Public space, as an organic part of the urban landscape, squares, urban gaps, miradouro, street	Horizontal organization and uninterrupted structures	Specific vocabulary and phrasing Challenging attitude to modern capitalist morality Dialogue through anti-	Strong bonds of solidarity and companionship Collective decisions on actions on political and social projects
	Ownership (former occupation) of buildings and creation of self-	Logical self-realization (DIY) and autonomy		
Ghetto Youth cultures	organized sites (heterotopias)	Legitimate lawsuits and actions	hierarchical assemblies	High Community sense
	Neighborhoods: Intendente, Mouraria, Graça, ógia Alfama	Radical politics of social development Transcendental culture (transgressive) with elements of delinquency and possible use of drugs	Respect for the different, equality, anti-sexism, antipatriarchy, Restrained extroversion and mood for interaction	
	Limited territorial separation (concentration of slums out of center)	Special clothing and style of the '80s -'90s	Local dialect and peculiar phrasebook	Different bond level depending on group and race
	Public space (often more isolated) Cheap bars and dance scenes Neighborhoods: Intendente, Mouraria, Alfama, more rarely Bairro Alto	Particular musical hip-hop preferences with African elements (tribal) and African dances Transgressive culture with elements of delinquency and possible use of drugs	Distant behavior, sometimes offensive and aggressive towards the "others" Physical contact, directness in communication	Abstract but high community sense
Broader mainstream cultures	Mainly private space: shopping malls, bars, restaurants and clubs	Social (and class) heterogeneity	Often competition tendency	It is not detected
	Public space when hosting a specific official cultural activity	Trend for unprecedented modernization and consumer behavior	Reproduction of social stereotypes and acceptance of social hierarchy	
	Neighborhoods: Bairro Alto, Bica, Cais do Sodré, Príncipe Real, Chiado, Bica	Communicative aesthetics Indifference to the public Rare drugs involvement

6.2 THE EXPERIENCE OF URBAN NIGHTSCAPE

Lisbon's historic center is a major nightlife attraction for most young people despite the fact that there are two younger entertainment clusters in the east and west of the city. The economy produced at night arises from the entertainment sector and is therefore interwoven with the frequency and timing of the use of space by residents. However, the time of use does not mean exclusively the mediation of a financial transaction, since the public space in the historical center varies in size and morphology, accommodating different social groups but at the same time favoring social mixing and coexistence. So, it seems that young users usually seek a combination of bar and public space, with a high percentage of them looking in priority, gathering and entertainment in the public space of the city.

Figure 15 : Youth gathering places at night, by category (%)

Figure 16: Preference of young people in nightlife in neighborhoods
 Source: data from questionnaires and interviews (2015), personal editing

Figure 17.: Preference of young people in nightlife in neighborhoods
 Source: data from questionnaires and interviews (2015), personal editing

The night atmosphere that exudes historic center based on the experience of young people (Figure 16) is evaluated by most as multicultural, reflecting the degree of social mixing and orientation of the night economy. The experience of the urban night landscape offers a varied selection of music, taste, image and culture, as in Lisbon anyone could find people from diverse racial, ethnic and cultural backgrounds. Second in importance appears to be emerging alternative view of night city, both because of the abundance of artistic and cultural event and the trend of adopting alternative models (night) life and entertainment, such as tolerance to drugs, alternative shops, the abundance of graffiti etc. As for the modern look, this inevitably resemble the western-European model, which is inextricably interwoven with night economy and tends towards globalization and homogenization of urban nightlife, something that currently is in a process in Lisbon.

Figure 18: Evaluation of urban nightlife in the historic center
 Source: data from questionnaires (2015), personal editing

Especially at night, the subjective perception of space is clearly influenced by the textures and qualities of situations involving any urban place, which shape the aesthetic and atmosphere of the landscape. Consequently, there is a fragmented picture of the city, composed with different "ambiances", in succession with each other, like the scenes of a theater.

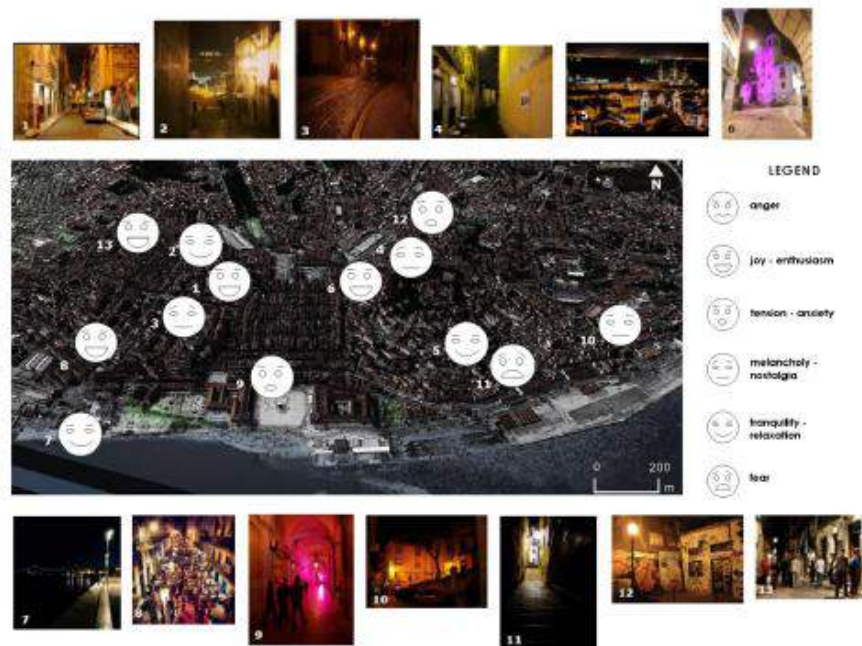

Figure 19: Unities of ambiance at night by emotional state of users

6 CONCLUSIONS

The various elements of intimacy that occur in the public space of the city incite its increased use at night. Both the human scale of design, which allows a sense of comfort during the arrival and stay in an open space, as well as the variety of surfaces for attitude and relaxation, resulting from the terrain and the architecture of the city, create the conditions for wandering, gathering and collective action.

Nevertheless, as has been noticed, even among young people there is no single identity, but different cultures, social perceptions and spatial practices are distinguished. There are various groups of young people who act within the bounds of the established social organization to differentiate each other (hipsters, mainstream people, 'sk8er guys', etc.) without, however, displaying or pursuing clear claims.

The different trajectories of young people at the urban nightscape tend to either converge across regions (Bairro Alto, Bica, Cais do Sodré) and under certain circumstances (city festivals, spontaneous parties) either to diverge and collide by delimiting and temporarily encoding meanings in the urban space (marches and actions of a rightful and emancipatory character, cultural festivals and events, artistic interventions).

In the end, the city at night is seen as the field where every change, remodeling and experience is possible. Diversity in both the urban landscape and the social groups allows us to choose each time a different role and to experience an out-of-bound experience, to lose to the different cultural elements and symbolic images of space and finally creating the imaginary space-time where our identity is unique and instant.

ID1370 | ASSESSING THE QUALITY OF NEIGHBORHOOD PUBLIC SPACES, A CASE STUDY OF MISURATA CITY, LIBYA

Ibrahim Abaid¹, Yue Tang¹, Richard Jarman¹

¹University of Nottingham

ibrahim.abaid@nottingham.ac.uk ; yue.tang@nottingham.ac.uk ; dik.jarman@nottingham.ac.uk

ABSTRACT: The public space of the city neighbourhoods is one of the major indicators of the urban quality and the residents’ satisfaction (Carmona, 2010, Carr, 1992, and Gehl, 2013). In Libya, the government has adopted a redevelopment scheme of providing new homes to the local residents, to build thousands of new housing units around the country since 2005. This plan was aiming to offset the shortage in housing numbers due to the high growth of population and rapid urbanisation (Worldometers.info), 79% of the country population live in urban areas (Salhin, 2011). This high demand of providing houses to the citizens all over the country has made a significant change of the urban planning composition of the country, especially the residential areas. This paper focuses on two samples of a typical neighbourhoods in Misurata city as case studies. It investigates the role of public spaces of the traditional neighbourhoods (TN) and governmental neighbourhoods (GN). It compares the conditions of public spaces in both types of neighbourhoods in terms of physical and intangible qualities and examines the relationship between the residents in terms of social integration and community cohesion in both types of neighbourhoods. In addition, it attempts to find out whether this new strategy has affected the social relationship of the local community or not and finding out the extent of possible impact on the daily activities. Furthermore, the paper discusses the extent of interaction among the residents regardless of their age, gender and cultural background. This research is based on mixed methods approach including qualitative and quantitative methods through case studies of two neighbourhoods in Misurata City, Libya. 158 Questionnaires were distributed to an adequate sample of the neighbourhoods’ population. The in-depth interviews conducted that included three categories, a) residents b) decision makers c) professionals. Moreover, according to the possibility of limitations in the data collection stage, site observation was used to focus on the residents’ activities as a supporting tool. The results show that residents in TNs feel more attached to their community, socially satisfied and comfortable while this perception was lower in the GNs. Research also found out that the relationship between the residents of the neighbourhood plays an essential role to improve and promote the social satisfaction of the residents which therefore will contribute to high-quality communities. Hence, it assists the development of the urban quality in significant parts of the city.

1 INTRODUCTION

This research was based on the impact of the latest policy of Libyan government when it planned to construct a large number of housing units, not only in Misurata city but all around the country. This policy was set mainly to make a solution of the shortage in the housing units as well as to regulate the rapid urbanisation within a developed plan for a period of 20 years from 2005 to 2025. The construction of new housing units by the government aims to provide comprehensive projects of neighbourhoods in line with the increase of the population growth. The government claims that this new strategy aims to fill the shortage of houses within the shortest time which planned for a maximum of five years as a first stage of the whole mentioned plan from 2005 to 2025. Therefore, a phenomenon of establishing communities with mixed users has started to emerge newly in the country, which is different than traditional residential settings. The Traditional Neighbourhoods (TN) often includes families who live together as neighbours for a long period of time, all residents know each other very well and this form usually has strong community cohesion. However, the Governmental Neighbourhoods (GN) has indicated a less social cohesion due to the differences in the cultural background of their residents (Lee et al., 1994). Hence, this research attempts to assess the quality of both types of neighbourhoods GN and TN from a social perspective through deep qualitative discussion, in order to establish a specific framework of the future neighbourhood projects which may contribute to the urban development of the city, indeed, to the other cities of the country.

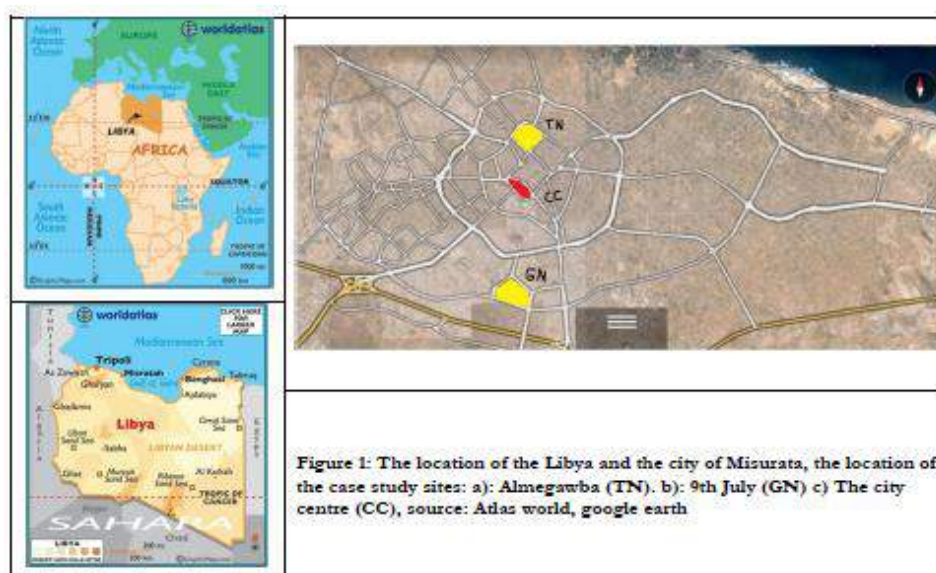

In this research, 'public space' is defined as a space being used and shared by all the people who live in the neighbourhoods of the city regardless of their age, gender, status and cultural backgrounds (Iveson, 2011). Examples of public spaces form in the neighbourhoods such as parks, squares, gardens, children playgrounds and green spaces (Madanipour, 2013). This type of public space plays a significant role in the urban development and quality of life (Das, 2008). This research investigates the social satisfaction of people using the public space of their community. Therefore, there should be an examination of the quality and effectiveness of the public space within the neighbourhoods by measuring the availability and provision of many elements such as playgrounds, facilities, and green areas in order to assess the residents' satisfaction (Kim and Kaplan, 2004). In addition to that, the research examines the social aspects and the level of the interaction between the residents (Cattell et al., 2008). Due to the moderate temperature and humidity conditions in this region during almost of the year, people usually use open public spaces in all seasons but not enclosed spaces as it is not popular in this country because of the climate conditions. Thus, this research focuses on the open public spaces of neighbourhoods in particular regarding the case study in Misurata city, Libya, with taking account of the advantages of the weather conditions in this region.

2 RESEARCH CONTEXT

According to the former mentioned policy of the Libyan government that planned to build a large number of houses within a short time, this action may create some negative affection such as social isolation, less interaction and community disorder (Behrad and Bahrami, 2015). Potentially the new residents of these new GNs do not know each other before moving in, because they likely come from different parts of the city and probably from another cities of the country, so they are not ready to have a strong interaction and social communication. And also, the new neighbourhoods contain hundreds of housing units, occupied by users from different backgrounds, which means that they have different habits, status, education levels and different mentality. This large number of residents meeting each other in a first time make the social interaction and involvement in social activities such as sharing the public spaces in their new neighbourhood a challenging task. Hence, it is important to know how the residents feel about themselves and about others, how they use the open spaces around their houses and what activities that link their interests, in order to provide opportunity for these residents to interact and participate effectively in the public spaces around them. Creating a sensible attractive spaces for the users encourages them to engage and interact with others which is the first achievement to enrich the community. Watson and Kessler (2013) states that there is an evidence shows that the design concept and green areas have fundamental impact on the users in these neighbourhoods in many aspects such as their health, comfort and feeling of safety and security (Jalaladdini and Oktay, 2012). Thus, the investigation should not excludes the physical characteristics such as, sidewalk/paths design, seats, green areas and playgrounds, in order to gain the insights of the community composition and to evaluate the impact of these elements on the local community.

3 METHODOLOGY AND CASE STUDIES

Initially, there are three advanced approaches to collect data of research: quantitative, qualitative and the mixed methods (Creswell, 2013). Nevertheless, these three methods may seem separated, but practically they are used in various approaches for different purposes depending on each discipline and the nature of the study, the elements of the research methods in which the result become more contributable (Beins, 2012). The mixed methods research is placed in the central position between the two other methods, because it integrates components from both quantitative and qualitative approaches.

The case study approach which usually is identified as a qualitative study design, 'e.g., quantitative experiments or qualitative case study (Creswell, 2013). It has been suggested from many scholars and professionals that the appropriate research approach in such a research which has a social and technical aspects is the mixed approaches method. This approach is a combined of quantitative and qualitative case study work (Merriam and Tisdell, 2015, Yin, 2013). The case study includes two sites, a) Site 1 named 'Almegawba' which is a traditional neighbourhood (TN) and b) Site 2 named '9th July' which is a governmental neighbourhood (GN) in the city of Misurata, Libya, as per figures (1, 2 & 3). All the quantitative data gathered from the questionnaires has been input to the statistics programme 'SPSS' to be able for analysis and Nvivo version 10 software has been used for the qualitative data gathered from the in-depth interviews. A mixed strategy used in terms of data collection including random and snowball policies to ensure the accuracy of the information and avoiding bias answers (Woods et al., 2015).

3.1 QUESTIONNAIRE

200 questionnaires were sent out to the residents of the two above sites, a total of 158 questionnaires were returned as following: Almegawba neighbourhood 81 participants and 9th July neighbourhood 77 participants. The questionnaires include a number of open-ended, closed and multi-choice questions.

Oppenheim (2000, p43) stated that "A sample's accuracy is more important than its size", a 2000 sample can give us more reliable results of a population of millions. In order to define the appropriate size of the survey sample, tables were used with a precision (e) of +/-10%, and from the population of (2000-3000), 80 was determined as an adequate sample size, with a confidence level of 95% (Israel, 1992) and (Kotrlik and Higgins, 2001).

3.2 SAMPLING STRATEGY

A sample selection was obtained using a snowball technique, "This involves asking people who have participated in a survey to nominate other people they believe would be willing to take part sampling continues until the required number of responses is obtained" (Kitchenham and Pfleeger, 2002 , p19). Participants joined to take part of the research through an invitation from other residents and so on. Data collection was stopped when the appropriate number of questionnaires (81 for the TN and 77 for the GN) has been reached and repeatable answers from the last few participants were noticed (Kotrlik and Higgins, 2001).

3.3 INTERVIEWS

In-depth interviews were conducted to provide a further understanding of the existing situation as well as to gain clearer features about the quality of the public spaces of the case studies. Moreover, firstly, to collect appropriate evidence that clarifies the research issue and contributes to solving the research matter. Secondly, to create a coherent framework to be used in the future policies. There were total of 16 interviews conducted during the field work as following: 4 Decision makers (governors), 4 Professionals (independent), 4 Residents of GN and 4 Residents of TN.

4 THE RESIDENTS' RELATIONSHIPS

This paper focuses on the social side of residents' relationships in the public spaces of neighbourhoods. The residents' relationships within the residential areas and cities' neighbourhoods are one of the most fundamental issues that urban quality is facing in the country of the case studies (Salhin, 2011). In the following section, research attempts to illustrate the significant of these relationships and its impact on the urban development of the residential areas including the both types of common neighbourhoods of the local region the GN and TN.

5 THE SOCIAL INTERACTION BETWEEN THE RESIDENTS

Establishing an effective relationship between the neighbours depends on many factors. Creating the opportunity to meet and interact is one of the important steps. Public space is one of the places that provide this opportunity for the residents to get involved in several activities. Behrad and Bahrami (2015 , p89) clearly states that "People have an innate need to establish social relationships and therefore, they can provide opportunities so they can experience the social relationships". Social relationships in the local community of Libya are one of the most important elements that residents appreciate and hope to improve because it impacts on the social satisfaction and psychological comfort within the neighbourhood. This can be noticed from the Libyan history, there are more than forty famous traditional terms explains the importance of the neighbour-ship, for example "people should buy the neighbour before the house". And "be neighbour of the happy people you will be happy" (Mohamad, 2005 , p1) which highlights the crucial role of these community characteristics.

According to the research data, it has emerged that the relationship between the residents of the neighbourhood is one of the strongest characteristics in the local community within the two sites. Firstly, it can be seen in Figures 4, 5 and 6 that around 75% of the participants are either agree or strongly agree that residents should have a good relationship, support each other and exchange favours. This belief from the majority of the respondents reflects the perception of the residents toward the value of the social relationships. The results are similar in the two types of the neighbourhoods which indicate the strength of

this element and it is the same in the two types of neighbourhoods, however this result show the desire of the residents. The evaluation of the current situation show a lack of achieving this desire in the GNs due to the lack of social interaction and level of involvement in the public sphere. Therefore, this point can be considered as a permanent characteristic of the local community which is desired by all types of residents regardless to the change of the neighbourhood variables.

All the participants of the residents' interviews also provide similar information, interviews data shows an insistent desire from the majority of the respondents to have an active and positive relationship with their neighbours. Moreover, most of them pointed out that the public spaces of the neighbourhoods is the most appropriate place to practice their social activities. For instance, activities such as watching children in the playground, sitting as groups or families and walking in the public space increase the interaction and the communication between the residents. In the same way, Behrad and Bahrami (2015 , p92-93) clearly concluded the following statement from a similar research in Pavan Residential Complex of Sanandaj, Iran. "The results of this study indicate that public spaces having attributes such as socialization are an important supplement to the socialization of individuals. Furthermore, the socialization of public spaces promotes a spirit of solidarity, personal growth, development and improvement of appropriate behaviour patterns". This natural relationship of the residents creates a kind of familiarity among the residents, thus, it leads to a stronger relationship.

On the other hand, some of the participants from 9th July GN expressed their disappointment of the minimal opportunity of communication with other residents of the neighbourhood due to lack of quality public spaces in this regard. Residents have less chance to build up their relationship with other neighbours through interacting activities in public spaces. As a result, many of them have a strong relationship and social communication with the close neighbours which about four to six next families rather than the whole neighbourhood as the TNs. This has limited the range of communication to very important and large events only rather than integrating the whole neighbours together. According to the qualitative data from the in-depth interviews, the reason of this low level of relationship between the residents of the same neighbourhood is because of lacking of high quality public spaces that could encourage people to meet and talk to neighbours. Respondents clearly stated by many of the interviewees such as (participants, IB and FB) that "this weaknesses of the social relationship between some of the residents of the same neighbourhood is due to the lack of the public spaces". Public space enables the residents to meet outside of their houses in a more casual and flexible manner because this space belongs to everybody and their children can enjoy playing comfortably at the same time (Carpiano and Hystad, 2011).

6 CHILDREN'S ACTIVITIES IN THE PUBLIC SPACE

In the local population of Libya, children represents a big percentage of the whole population of the country which is around 32.8% for the age from 0 -15 years as per Figures 7 and 8. This high percentage means that there should be significant consideration towards the needs of this category of the residents. In addition, the children and young residents aged between 5 up to 15 years particularly are stated in numerous research as the main beneficiaries of the open spaces either the public or the semi-public of the neighbourhoods (Woolley, 2006). These activities have a major impact on the people during their childhood which is one of the most important periods of our life (Islam et al., 2014). Being a period of time that almost everyone could remember, it has significant impact on the person's personality and their social skills, such as the way of communicating with others in the later age periods of life (Woolley, 2008). Therefore, understanding the social and health benefits of involving this category into the open spaces is crucial to the research. And also, finding out what kind of impact that may improve the quality of their life through the design of public spaces is important for the future success of new neighbourhood developments.

According to the research literature, there are many essential points have risen regarding the healthy environment of the children and the health benefits of applying the physical activities on open spaces. Gehl (2011, p21) highlights that "people in general inspired to others action, children see other children at play and get the urge to join in, or they get ideas for new games by watching other children or adults". One of the measurement tool in this research is discovering the ease of using the open spaces around/near the houses clusters. Almost 70% of the participants disagree to the statement "Children have easy access to the public space such as the play area, playground and open green space" which illustrate the weaknesses of the connection quality between the houses and the public spaces. Figures 9 and 10 show exactly the percentage of the respondents about this issue in both neighbourhoods.

Regarding the answers from the respondents, there is a lack of physical equipment on the site such as the play area, football pitches, facilities and green spaces. Residents complain that the ability to use the public spaces of this neighbourhood is limited because the government does not build playground and such facilities for children due to poor management system in Libya as stated by the decision-makers group in the interviews. The priority of the government is to provide houses for the people as an essential need, there is a lack of understanding the importance of the landscaping and providing facilities for the open public spaces in the neighbourhood. Therefore, the children have no better place to practice their activities and making new friends. They have to use the other surrounded space rather than designed public spaces for their outdoor activities, which may not be appropriate for the activities and also have serious concern regarding on health and safety issues, see Figure 11. It can be seen that children play along the main road which might cause a car accident.

With regard to the social aspect of the children activities, there is clear evidence from the research data that children's areas play a fundamental role not only in terms of children entertainment but also in strengthening the integration between the families of the community as (participants FI, MG and SM) who are residents of these neighbourhood stated that they have strong and positive social relationship with the neighbours whose children play together with their children. Hence, one of the key interactions among the residents is the place of the children in the public area of the community. That is when people usually get involved in the basic communication such as greeting, chatting, sitting and sharing some food or drink. This spontaneous and natural way for the neighbours to meet each other at the first time is high value, thus, these actions are likely to be developed by the time to a stronger relationship.

**Figure 12: Shows the types of activities that children apply in daily bases activities,
Photos by author 20/10/2016 9th July GN neighbourhood**

Regarding the age groups in this research, results show that children often use public spaces as a place to discharge their energy and making friendship with other children during the play activities in their free time. Therefore, the successful open space is not only there to provide space but also to make it attractive to the

residents especially the children. Findings show that in terms of social impact, the children have a strong impact to support the social relationship for the adults through the opportunity that can gather all the categories of the neighbourhood in one place. This chance of enabling the neighbours to meet together is more likely to be developed in a deeper interaction and very close communication, as per Figure 12.

The other factor which relates directly to the activities of the children, especially in the open spaces, is safety. Participants pointed out in the interview data that the largest concern is letting their children play outside their houses due to issues of safety. As there is limited area of the appropriate place for the children activities which need to be secured and safe. For instance, the available places are not surrounded with fences which might be dangerous for children, especially in early ages. In addition, some of these areas are located near the roads which pointed out by some of the respondents, they are trying to provide indoor toys to fulfil the children desire to keep them engaged rather than outdoors. Although, residents are aware that playing outside and having physical activities is much more beneficial to their children in many aspects including the health advantages. This can show the importance of safety of the outdoor play facilities. To sum up, neighbourhoods of the city are facing a real challenge in terms of supporting children activities. In this sense, there should be significant care regarding this issue for the development of the open public space of these neighbourhood to be more convenient and appropriate to fulfil the children needs in terms of quality, safety and social aspects.

7 COMMUNITY INTERACTION AND SOCIAL VALUE

In terms of social interaction, the majority of the participants of both sites stated that neighbours often used to meet in the semi-public space near their houses to drink coffee, chat, and discuss the life's challenges and exchange ideas and advice. They believe that these social activities are very important for their quality of life therefore to their feeling of happiness. A similar study conducted by Zhang and Lu (2016 , p32, 34) in Beijing, China to compare the satisfaction of the residents in traditional neighbourhoods and redeveloped ones. One of the crucial findings of this study is that, "The residents in traditional neighbourhoods are generally more satisfied with their physical environment than the residents in redeveloped neighbourhoods". This outcome due to the importance of social and traditional activities as the study states, "In traditional neighbourhoods in Beijing, courtyards and hutongs provided semi-public spaces for neighbourhood interactions. Thus many daily activities, such as washing clothes, washing vegetables, and playing with children, took place in the courtyards and hutongs". This high level of social interaction has made the residents feel more integrated as one of the participants stated "Courtyards, to some extent, can be seen as our public living rooms". In this research also, one of the interviewees, (participant, L SH) who is a psychologist highlighted that based on a recent study and long experience about communities' interactions, that public space in the neighbourhoods plays a fundamental role to improve the quality of the residents' life by providing a direct communication through the daily activities which are happening between the houses such as gathering over a coffee, playing a traditional 'card games' and watching children play. In traditional neighbourhoods, respondents stated that the level of interaction between the residents is positive because they have known each other for a long period of time. This sense of familiarity enable them to get involved in the social and daily activities more easily which is relatively limited in the GNs, especially in the first few years.

One of the keys of having a good opportunity of human interaction is having the appropriate space to encourage them to be present which can help initiate the social interaction (Peters and de Haan, 2011). Rasidi et al. (2012, p465) clearly suggests that "A sense of interaction among urban residents provides an opportunity to get to know their neighbourhoods and as well as their friends in the area". In similar line, Abada et al. (2007 , p2013) emphasise the important of the place making and highlights the social negative impact when there is lack of interaction "... lack of integration may contribute to feelings of hopelessness, thus increasing the risk of depressive symptoms". A previous research illustrates that people have a better chance to interact in the favourable spaces for activating social interaction, although, newer communities recently may have less social interactions with strangers, because in some cases investors focus more on the physical elements and providing modern architecture rather than considering the cultural and social dimensions of these spaces (Mahdavi and Habib, 2016). Most of the people might feel more comfortable communicating within the groups that are belong to rather than to be open for the social interaction with others (Pinkster, 2016). Thus, it can be concluded that interactions with strangers are likely to be less common than those with known people either individuals or as groups (Rasidi et al., 2012). In this context, there is a sensible need to apply these characteristics in the new developed

neighbourhood to provide keep the social value and the level of social interaction in a good quality, therefore, to achieve a better successful neighbourhoods which have a social quality in addition to the physical and design qualities.

In fact, the social value of the community is directly linked to the open and public spaces as they are the main spaces regarding interaction (Gehl, 2011). These activities create a better chance for the residents to interact, therefore, this will strengthen the level of relationship between the residents by involving them in activities that can build a good level of communication (Gehl, 2013). Moreover, the social function of the public space can help to get residents more involved and promote the level of participation between the neighbours. Indeed, the poor quality of public spaces is also having significant impact on peoples' interactive behaviours (Weaver, 2016). Instead, they use the private spaces in their houses such as gardens and open area most of the time. Therefore, both lack of appropriate public spaces and low quality spaces have resulted in less interaction that have weakened the social value of the community.

From a social perspective many participants indicated in the interviews that when the revolution in Libya was started on Feb 2011 many social problems had happened in the GNs such as serious arguments and force some of the residents to leave the neighbourhoods. On the other hand, less problems were occurred in TNs because most of the neighbours know each other from long time and they care about each other, thus they had to take the same decision to the majority of their neighbours. This sense of unity and trust between the residents of one neighbourhood in a very difficult situation indicate the strength of their relationship which clearly is far less in the GNs where the residents are less interacted and don't know each other well. This case confirms that the relationship between the residents of the same neighbourhood was not enough to support the residents who come originally from other cities. Many residents had to move from a certain neighbourhood to another, as they acted differently to what their neighbours were expecting. Therefore, the residents who are not originally from this community prefer to return to their original area or city because the social links was very weak. While in TNs this situation did not happen because all the residents knew each other and they face all the problems and the reaction of the government during the revolution together and they help, share, cooperate and support each other.

To conclude, the most common forms of the social interactions between the residents in the public spaces of the neighbourhoods are meeting other residents, exchanging ideas and chatting (Iveson, 2011). These activities creates a high level of social integration which confirms the preference of the integrated communities.

Therefore, based on the research findings, public spaces of the neighbourhoods is the most effective area that impacts the level of interaction between the residents and therefore to the cohesion of the community.

8 THE FEELING OF EQUITY AMONG THE RESIDENTS

The equity in this research means that every one of the neighbourhood has the same opportunity to practice their own activity regardless to their gender, age and other elements, because...?. Residents need the same chance of participation in the public space of the neighbourhood where they are supposed to enjoy their daily activities such as social, entertainment, play and sports activities. For instance, Musterd et al. (2016, p234) argues that "We expect that households prefer to move to areas in which residents are not very different from themselves". This expectation is based on a case study which shows clearly that inhabitants prefer to live in the community which they feel the sense of equity in their status in this case. In other cases, people might have different perception as they probably consider the equity of religion or the culture background is a priority to them. Therefore, understanding the features of the residents who are going to use this place is the key of providing the right solution in the appropriate form that meets their needs. The urban design of the neighbourhood should be based on a deep investigation of residents perception in order to fulfil their desires, thus to provide them equal opportunities that enable all the categories of the residents to get involved together and interact socially within the same neighbourhood.

It has been argued by many scholars that to create a preferable and successful public neighbourhood, there should be a balance provision of economic, environment and social dimensions including equity and justice (Saha and Paterson, 2008, Walker, 2015, Jacobson and Forsyth, 2008). Hence, the social aspects such as equity is one of the intangible elements that impact on the quality of the neighbourhood, this lead

to the key of its importance to be analysed in this research to find out a comprehensive understanding of its impact on the local community.

The Figures 13 and 14 highlight the attitude of the respondents of both sites towards the equity among the residents. The figures show the percentage of the respondents who agreed or disagreed to the following "This public space is appropriate to all the residents' age group, gender... etc." and it can be seen very clearly from the figures that more than 75% of the respondents in the GN 9th July disagree to this statement. In TN Almegawba also about 55% of the respondents disagree. It appears that in both neighbourhoods, especially that most of the participants in the GN, are not satisfied in terms of equality within their neighbourhoods. The results also show that many of the neighbourhood's residents are facing a lack of equivalency such as female, elderly and disabled people.

According to the survey findings, the total percentage of the respondents who were disagreed to the previous statement in both sites together is around 65%. Furthermore, in-depth interviews highlight that there are three main categories of the residents who are feeling lack of equity in using the public spaces of their neighbourhoods. a) The youth: this category who aged from 12 up to 20 years are facing a lack of amenities such as football pitches, tennis courts and other sports equipment, also a lack of prepared landscaped open space which can be used in many adequate activities for this specific age. b) The disabled and the elderly: disabled residents feeling isolated from other residents who are in their age due to the lack of the creation and infrastructure that can help their movements from place to the other. Elderly who also cannot find a place where to spend some time with the people of their age. c) Female residents: this category has expressed their feeling of injustices in many parts of the research methods. These three categories should be taken on account in any future development as they are representing almost 60% of the residents. This overall result points out that more efforts need to be applied to create more opportunity for the rest of the residents who could not find their appropriate place such as female spaces, quiet sitting area for elderly and special pathways, routes and slopes 'ramps' and for the disabled people.

9 CONCLUSION

To conclude, the research has pointed out that both physical and intangible elements have a major impact on the quality of the public spaces of the neighbourhoods. These elements in fact related to many factors, including the relationship between the residents, social interaction and cultural aspects. It has been noticed in this research that the relationship between the residents depends very much on the time of neighbourhood. The longer time for the neighbourhood is the stronger the relationship will be. As Nasar and Julian (1995 , p180) state that "Sense of community is a key psychological construct that the residents of urban neighbourhoods build over a period of time". Therefore, the length of residence thus becomes important in fostering a sense of community, in addition to neighbourhood association and mutual cooperation" (Chitrakar, 2016 . p215). This indicator illustrates why in the TNs the relationship of the residents often is much higher and stronger than it is in the GNs. The main feed for this relationships is the social communication such as greeting, sitting, chatting and sharing activities. In both sites, the result has discovered a reasonable range of social interaction between the residents but, yet need more improvement in order to make integrated community which is one of the aims of this research.

The children of the neighbourhood are one of the most active and vital of the residents categories, they have more energy and wide range of activities to be shared as Gehl (2013 , p158) importantly indicates that "Children's play has always been an integral part of city life". The research has emphasised that children play a fundamental role in improving the social interaction and enhancing the residents to get involved in more social activities. For instance, the playgrounds and sports activities usually bring the parents and adults together and encourage them to communicate in these places. Moreover, it can be seen from the results that the TNs are more integrated and have a higher community cohesion, this indicator has been explored due to the strong communication and social involvement between the residents of the TNs. On the other hand, similar elements have been observed only in a small groups in the GNs which is built up by the time through daily interaction than to a more social communication.

Finally, this research has revealed that there are a few categories of residents who have less opportunity to enjoy the outdoor spaces, these categories being the female, the disabled and the elderly. They are not provided equally with the local needs and the appropriate spaces to apply their social activities in the public or semi-public spaces of the neighbourhood. It has been widely emphasised that public spaces such neighbourhoods parks should serve all types of inhabitants as Rouhi et al. (2016 , p458) indicates that "The best parks are those that pay attention to the social, cultural, psychological needs of different age and sex groups and provide charming and appropriate atmosphere for them". The research has concluded that these categories need more attention in the future urban development and in the new projects in order to maximise the community and personal value of the public spaces for these particular users. The research may have several limitations such as covering only two sites to compare and measure the intangible and tangible elements, it could have be more comprehensive if covers more sites. Also, there might be another methods can be apply to investigate deeper and to gather more specific information regarding the local community characteristics. It can be suggested that more investigation is required in this topic especially in the social relationship and traditional elements which are relevant not only to the urban redevelopment, but also to the quality of the residents' life and their social satisfaction.

ID 1375 | GOMM PARK. INEFFICIENT MANAGEMENT (DUE TO) AND CAPITAL PRESSURE, SOFTENED BY THE COMMUNITY AND COLLECTIVE CREATIVITY

Roberto Ghidini¹
¹Sociedad Peatonal
rocktusb@gmail.com

1 INTRODUCTION, OBJECTIVE AND CONTEXT

The article demonstrates the challenges faced by a Collective when it claimed back a communal space - with a strong social and cultural salience, high environmental interest, which had previously been protected -but was 'escaping' via financial and capital pressure. This had been occurred in Curitiba, a city which call itself 'socially and ecologically just". The space in question is the Gomm Park, comprised by Casa Gomm (1913) -a unique house, built in Massachusetts style -and its bosk, both listed as Parana's Cultural Heritage.

This paper will provide remarkable records, from press articles and interviews , to fragments of social media posts from 'Salvemos o Bosque da Casa Gomm' (Help The Gomm's House Bosk) -the group who decided to fight for the communal heritage and the immaterial resource the "space" now represents.

The relationship between people and power, when this is a part from those, it's the so called democracy. The Greeks, in Agora, met and decided, with one vote each, all the subjects in the current agenda. Time took its toll and weakened this dynamic, but its essence lasts in all current democracies, either direct or indirect, which are sometimes consensus others subjected to maneuver of power, depending whether people's influence in decision making is high or low.

On evolved democratic societies we are faced with people's participation and transparency templates, which aim to provide better life quality with consensus use of public resources, and as consequence, increase social and justice equality.

Many theories and templates such as 'Gobernanza2.0' or 'open government' provide examples of thought and design of successful methodological process, but the kickstart to positive results can only be reached through will and detachment of the constituent power, otherwise conflicts of interest will always be extinguished without resignation, and in most cases, in favour of few against the collective interest.

According to Manuela Carmena , "urban litigation, in case of subject to the Justice, produce a complicated outcome, because the Commercial Justice, which adjudicate on process related to City disagreements, is now misplaced when it comes to adjudicate any urban process, therefore a new approach should be taken when judging urban conflicts, such as territorial, social, environmental, etc".

The objective is to expose the reality and make a statement for the next public administration regarding the importance of people's voice and wishes, instead of ceding in favor of power and speculative capital.

2 "THE HISTORY"

Curitiba, a city of explored by Portuguese colonization -similar to many other Brazilian cities in the upcoming year 1808 -when the raw materials of the South region of Brazil, like wood and yerba mate, produced wealth to their masters, and foster the emergence of an local aristocracy, the country houses and mansions of the Batel, neighbourhood along with Alto da Glória, where are the main "surnames" of the city.

A black and white aerial photograph of a city, likely St. Louis, showing a dense urban area with numerous buildings and a prominent river or waterway running through the center. The image is oriented horizontally, with the river or waterway running from left to right. The city is characterized by a grid-like street pattern and a high density of buildings, particularly in the central and right-hand portions of the image. The river or waterway is a wide, light-colored feature that cuts through the urban landscape. The overall scene depicts a sprawling, developed city area.

729

The decline of the extractive economy with the emergence of industrial processes, put an end to many economic interests, you haven't heard see or boost your business. The Gomm, were a few of them.

"The property was sold by the family in the early 1980, when the City of Curitiba then tried to establish there the Batel Park (1987), which today would be a Central Park in a verticalized urbe. However, the new owner defeated the city, knocking over the Public Utility Decree for the building on highest instance of Brazilian Justice. In 1989, the brick and mortar Gomm's House, and its bosk were, listed by the Historical and Cultural Heritage of the State of Paraná, which in principle 'protected' it from destruction. But it still wasn't enough.

The bosk would be gradually cut in subsequent years, losing its splendor. The House, little by little, was almost destroyed by 'greedy and exotic termites'. All too soon it almost became a hotel or a convention center or a club etc. Many projects were drawn and later discarded, due of limitations arising from the listing Decree.

But the solution is not going to fall from the sky.

Years later, the same State of Paraná which had listed the House agreed to misrepresent the Listing Decree: the House would be dismantled (to be 'treated') and reassembled in the back of the old family property Gomm, where before there were stables for horses, near the bottom Valley of Ivo River. The bosk, drastically diminished, and became 'squeezed' into a specific real estate registration, as a result of the break-up of the area in five batches. The House would then be donated to the State of Paraná and the bosk and gardens donated to the Municipality.

In the midst of all this, the result is a huge piece of land, 'free' from the burdens of the listed building and its bosk, for which it would be possible to be built in its entirety in titanic proportions.

It was a sophisticated 'bypass' to the listing regulations, signed off by State Governor Jaime Lerner.

In 2013, with the great 'Mastodon' shopping center about to inaugurate, the leftovers of the Heritage would be once again massacred by the opening of an asphalt street for cars, in a project approved by IPPUC and the coordination of the Cultural Heritage of the State of Paraná (same body that protected House and Bosk in 1989).

Help The Gomm's House Bosk (SBDCG), stood-up and said No to this street. One of the main arguments put forward at the time, was that a street would eventually finish segregate the House from its enveloping area (bosk and gardens), creating a mere simulacrum, permanently surrounded by cars in motion -and not a garden to give it some sense, as stated in the Listing Decree of Parana's Cultural Heritage"

Earlier, in mid-2011, the IAB-PR (Institute of Architects of Brazil-Paraná), took a proactive attitude in formally addressing the owner of the real state, the Shopping Patio Batel, to proposal a partnership and make public use of the House and the remaining forest (not that one listed in the Decree).

Maybe if the proposal had been accepted, it could have democratized the space, unfortunately the shopping had already been inaugurated. We transcribe below what had been the proposal (item 3 of the document), which included also the Design Center Batel.

"Draw up a STUDY to identify the conditions and provide technical solutions to facilitate the unification of the remnants of 'Batel's Bosk', installation of new urban equipment, allowing the local population and also customers of two shopping centers to make use of the space as leisure equipment, adding value to enterprises.

Prepare the STUDY with a view to transforming the Gomm's House in cultural equipment to the memory of architecture and Batel District, as part of the activities of both commercial enterprises".

"The urban design as a tool for planning, if facing the powerful forces of the speculative capital appropriates of the city. The urban property becomes the object of transfer and concentration of capital and globalizes the great metropolis. The town became object of purchase of major investors."

3 "EL ESTADO DEL ARTE"

The forms of governance today, seek to encourage community participation, as a best practice for the governance of cities, which told us Carlos Giménez "have always been adverse and diverse", thus the inequality is not something that occurs by chance but something political and therefore must be planning something equally political.

"The city is a human and collective creation, so politics and should be regulated by legal landmarks, that there are not always satisfactorily."

Among the first milestones for participatory urban planning, is the Alboorg Letter that came to be the screen for formatting of Agendas21 and soon Local Agendas 21 or AL21. This important initial step to adopt a participatory policy in the early 1990 was and is crucial.

The municipalities that today lead 15 to 20 years or more, with use of local agendas, already have a vision beyond the processes of AL21, where raise issues such as information and transparency and the renovations to Open Government, participative democracy and transparent rendering of accounts.

The sense of participatory democracy is seen to form intra-administrative (personal, economic and legal), with actions and results, with updated systems of indicators and constant visibility of the impacts of AL21 governance.

In this sense, the new technologies (in particular the Apps) for dissemination and communication are very useful, as well as GIS for timely diagnosis and planning are among others.

The current demands of society, require more and more issues such as transparency of public administration and popular participation, especially when it comes to large projects or strategic projects to a municipality or a region, otherwise not work agreed upon nor did appropriate to the results obtain.

Alberto Ortiz de Zarate Tercero suggests different scenarios of citizenship, on considering the form of activity of the Government and the scope or surroundings where they are inserted, generating active or passive and civic citizenship.

However, if there is a simple structure, enabling mechanisms for governance and popular participation, which guarantees to associations and citizens, cooperation and democratic practices, independent and autonomous administrations and technicians (working groups and academia), they can apply their knowledge, standards, mechanisms of action with transparency, could reach a successful conclusion.

This set of agents, we should add a coordinating or Council to plan and a follow-up Committee that would give independent progress for each project.

This form may be reproduced to a greater or lesser extent, but your essence must contain the expectation resulting from such diversity and adversity that is a city and that is satisfactory to the interests of the collectivity, never in favour of speculation, even of those who profit from inside information or influence (personal, economic and legal).

4 GOMM PARK

"The community and civic experience of the Gomm's Park's -even if not a park there was -a victory for the whole city. From 2013, curitibanos from of every neighbourhood, of all ages and from various political groupings come together, occupy, sow, reap, sing, paint, composted, swap, join pieces, interact, take care and live in PEACE in a modest symbol of the resumption of urban planning of Curitiba. This is-and will remain-to Help The Gomm's House Bosk (SBDCG), not just in a tiny Park at Batel, but in the whole city."

The collective, SBDCG (who 're-proposed' the creation of the Park), managed to develop with the IPPUC, a project in which everyone agreed, though, after all this a new deception, there were news that contradict this agreement.

"Yes, the Park project deployment now devastated what we had sown (literally) and does not reflect the needs and desires of the community. Park's draw was signed in 2014 by public authorities and citizens was refurbished by the municipal government, which decided in 2015-2016 for composing politically and with the coordination of the Cultural Heritage of the State of Paraná the existence illegal parking site enclosing all areas and 'confiscate' to the city 2/3 Gomm's Park. In other words, the city kicked, back a step and succumbed to the autocratic wishes of 'State House', doing 'overlook' for trespassing by the municipal State Parking ...

... And the emergency way? Ah, the emergency way!

In place of simple cobblestones seated in sand at the same level of the grass, ran a base and highway infrastructure, with meters of excavations and gravel. A plan mapped out not to think of a fanciful road evacuation of the Mall, but a 'Trojan Horse' in future paving and 'binarization' in the area-large enterprises that disfigure the four corners of the city, promote a excluding a city urbanism unsustainable ...

... The House is even more segregated and sealed without the landscape values. The visual effect of a 'turkey at sourcer', tells Mrs. Irene Gomm, the last resident of the House still in life, was sharp. If the House was already tight 'in' a real estate registration too small, the emergency way just squeezed more."

It is observed in these reports, as well as in the history of the century-old property, which always aroused interest because your privileged location, and your high ecological, cultural and economic content, and increased disputes between various urban actors, that governance was very shy throughout the period in which the House was no longer a House of the aristocracy and became the object of these interests since, by one way, created all protection mechanisms, with a public decree, by other, gave way to the subdivision and to trading with speculative capital.

"Found in the records of the action filed against Municipality, Soifer, Group Paraná State and Municipal Secretary of Environment in the 5th Public Farm Curitiba audience. Was presented by the State of Paraná in your rebuttal to that action and is part of the administrative process of tipping the House Gomm and your Woods (started in 1987 and that would occur in 1988).

In it can see a plant may 1987 (figure 3), prepared by Roberto Requião (Mayor of Curitiba) management IPPUC, named 'PARQUE DO BATEL'.

According to the master plan of this park, the area that would later be knocked over (whose owner was Soifer, Berman & Cia Ltda.-19,430 m2) and TWO MORE areas of other owners (Egon Alwis Mueller and Marese Lanconi, respectively with 2,818 m2 and 1,002 m2) – all in a grand total of 23,250, m2 -would be aimed at creating a beautiful complex environmental, cultural and leisure in the midst of the city's central area.

The House Gomm and your garage both in their historical positions would be fully restored original and intended for a Museum, library, library and video room. In other existing buildings would be deployed a restaurant with terrace for outdoor tables, a tea house, an outer deck, etc.

In addition to the existing Forest, would be planted new trees and shrubs and lawns to deployed flowered walks and contemplation. And note well: connecting the two sections of Hermes Fontes Street would be made with a hiking trail for PEDESTRIANS and cyclists, of little width and integrated into nature.

A beautiful outdoor stage and amid the trees would be destined to small musical events. Banks for passers-by would be equipped with hearing sound of music in headphones (!)."

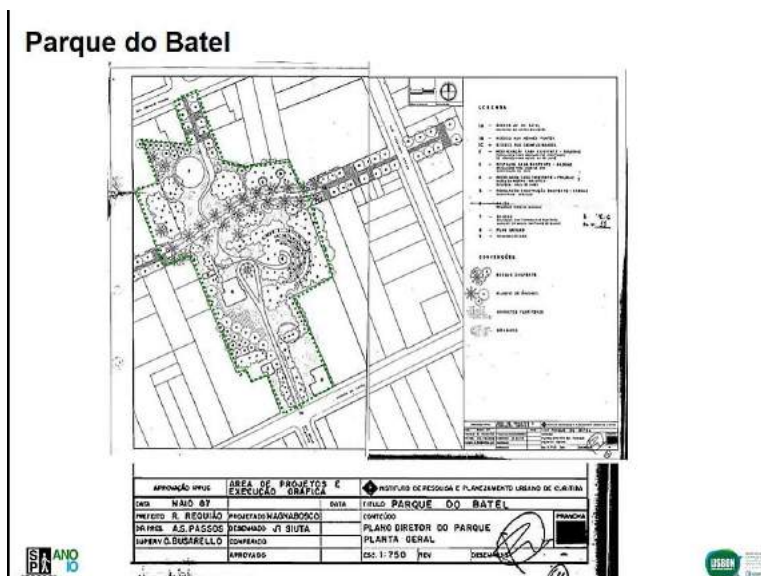

Figure 3 : Schematic of the Parque do Batel-IPPUC (1987) source: SBDCG, own Edition

In 1989, the public decree The House, the Bosk, the Valley of the River, began to throb as limiters of the interests of the new owner of these 19,430 m2 situated on Avenida Batel, 1829, acquired four years earlier.

Figure 4: source: 1989 ENGEFOTO File, own Edition | Figure 5: source: IPPUC 1999 – database, own Edition

Figure 6: source: IPPUC 2003-database, own Edition

Figure 7: source: HERE Maps-Nokia 2016, own Edition

This graphical sequence, well presented, since the decree signed in 1989 (Figure 4); When put into gear the 'bypass' in 1999 (Figure 5); the change of place of home (which nearly ended up in agronomics, at school of the Wood Engineering), in 2003 (Figure 6); and finally, the denouement of the Mall and the formalization of the Park in 2016 (Figure 7), synthesis in chronological order, the administrative inefficiency and the power of capital.

It remains therefore applaud the collective SBDCG, your determination and power of conquest, although having to accept the charges and have to swallow the interference of those who have the pen in hand to sign decrees, because without this good roll and mobilization the Park hardly exist.

Figure 8: Gomm's Park design and signed by all – SBDCG

"For now, Gomm's Park is still a sketch, in the municipal decree signed by Gustavo Fruet (mayor) – this, a documentary and legal victory of the movement.

In the real world, the Park (Figure 8) would have us swallow is not the Park we used four years ago, in an obvious symptom of disconnection of public (regional and local) with the community they claim to represent."

5 THE CASE OF CURITIBA (IS NOT BY A CHANCE...)

Curitiba, enjoys international renown due to the deployment and subsequent implementation of the master plan of urbanism of 1965, prepared under the direction of architect Jorge Wilhelm who contributed a new way of doing things, opposed to the guidelines of the 'Plan Agache -it was envisioned under the concept of urban's functional zoning -to the idea of growth along the structural axes.

The result of this strategic plan, the IPPUC (Institute of Urban Planning and Research of Curitiba) as a body designed to draw the future strategies and urban interventions for the city, in addition to proposing certain immediate actions that were performed by the city.

Between this, actions, already in the early 1970 the closing car circulation of a number of streets in the Centre, around the 'XV de Novembro' Street and the creation of structural axes, were later circling the 'express'

These urban trends were the vanguard, which later came to be the object of playing in cities of the five continents and which made the projection in the city of Curitiba, as a role model.

The city, proceeded to make a fuss of its achievements and modernity. In the years 1980 if the self-titled debut 'ecological capital' and in the late 1990, with the new paradigms of participatory governance the 'social capital', but a series of articles and thesis, demonstrate the opposite, that there was no environmental improvement and social capital of Paraná, even a big city-marketing around that occurred at that time, for almost three decades.

In counterpoint, a belated initiative of the State Government, through the Department of Water Resources and Environment, tried fruitlessly to spread the idea of creation and implementation Local Agenda 21, including an international seminar, celebrating in Ponta Grossa, along with the UEPG, which later gave rise to a document called 'PARANÁ – 2010 SUSTAINABLE PACT', where some general guidelines were agreed in the thematic tables points of debate during the seminar in screen.

In Curitiba, the lack of mechanisms of citizen participation promoters if notes in most performances of the municipality. Although there is the call for participation in the LOA (Annual Budget), occurs in reckless and shy, with diffusion of press releases on the web, often with little time, sometimes in difficult times, the same occurring with the 'public hearings', both mandatory practices according to the status of cities law.

Performances as the bidding of public transportation in 2010 and the proposal for a subway to Curitiba (2009), which had a boot with the project of the 'modern tramway' (1992), demonstrated a predisposition of municipal administration, to limit exclusively to law enforcement, with regard to participatory mechanisms. In the case of the bidding of public transportation, this came to occur only after judicial sentence, and 10 years of the start of past demand filed by prosecutors.

The results provided insignificant improvements to the collective.

In the case of public transport, this new regiment has given to those who were already the system operators, a status that until then had not, the dealers of public transportation (they were just with permission to explore, the concession was the URBS) and were almost as much 25 years perpetuated.

For the subway, with poor project to the city, which just replaces the modal BRT by subway, implying in costly disorders, during the works and low benefit, beyond just the increasing transport capacity and some reduction of air pollution; When through a project of this size, with a new track, it could perform an urban transformation in underserved areas or degraded in the city.

In both cases, public hearings, not translated or contributed anything to the project, which was already consummated. There was no even an initial exposure than it was intended to accomplish, to be discussed, there was no debate, no discussion, and of course there was low turnout.

Prior to that, previously to the landmarks of citizen participation (Letter of Alborg, 1994) could be saw a case – the 'Connector 5' or the 'New Curitiba' or 'Ecoville' (1972) – which also raises comments on the appropriation of the speculative capital over the city, a mega refurbishment operation of land use.

Make use of fragments of my DEA Thesis to report the case.

"From the 'Campina do Siqueira', passing by 'Mossunguê' and reaching the 'Campo Comprido', became what until then were areas of little farms and inhabited, in 1974, sanctioned law No. 4,773 defining a new zoning for the city and creating the connector routes (which already existed physically in a total of four and the proposition of a new connector, with a special zoning) for the purpose of spatial integration with the Industrial City (CIC).

The initial proposal for the deployment of this new axis, format and constructive potential of structural axes, would be to build houses for the new CIC workers who come from other regions of the State or the Country.

For the implementation, in the late 1970, would be taken two distinct programs and funding agents, one of them the BID (Inter-American Development Bank) for implementation of the road system and another through the BNH (National Housing Bank) for the construction of housing estates over these.

The first line of credit was contracted, but the second, inexplicably, was left aside, for reasons apparently unknown, but you can think of a clear goal: large enterprises and real estate speculation, which resulted in the present day"

"Governance has to be legality and not private interests. The privilege of information is at the service of private interest" Further, recently, the revision of the master plan: The revision of the Curitiba master plan, began at IPPUC, in 28 March, and provided for public consultation, in the period from April 12 to 15 August 2014 for submitting questions, criticism and suggestions. Also the Forum of the Curitiba master plan that had your first public hearing in 15 April 2014.

The series of ten public hearings and six groups of studies, events that made up the Forum, intended to support and collaborate with the discussions surrounding the Curitiba master plan review, planned for the year 2014. The Forum was open to all entities and municipalities organised civil society and has been a Commission proposal of town planning and public works of the city of Curitiba.

"So, as a corollary, that as much as administrations, professional associations, trade unions, academies, citizens associations have to do with any participatory process to occur, these attempts are either shy, or devoid of vanity, enough to make advances that are not only self-serving, undermining dialogue and the general interest"

ID 1386 | AN INDOOR SOUNDSCAPE SURVEY ON THE USER'S COPING METHODS FOR NOISE ANNOYANCE, DISTURBANCE AND LOSS OF CONCENTRATION IN PUBLIC STUDY AREAS

Volkan Acun¹; Semiha Yilmazer¹

¹Bilkent University

volkan.acun@bilkent.edu.tr

1 INTRODUCTION

During last decades, group study areas has started to be a common feature, especially in libraries. Unlike a traditional library, where the students are delivered library services, these spaces are encourage students to take command of their own (Bennett, 2007). These spaces are also popular especially among undergraduate students as they incorporate academic work and social activities by providing informal grounds (Applegate, 2009; Bryant, et. al., 2009). The flexibility of usage allowed open learning spaces to be used for both collaborative and individual study. In contrast with the strict silent zones of traditional library study areas, these informal study areas are prone to possible issues regarding the sound environment.

In silent study areas, sound levels can become a source of frustration (Çankaya & Yilmazer, 2016; Harrop & Turpin, 2013), but in the informal public study areas, the students can get to adapt the sound levels even though it possible gets much higher than silent zones (Bryant et al., 2009). It was also expressed by the students that sound levels expressed a positive contribution to the social identity of space in open learning areas (Harrop & Turpin, 2013). This positive contribution to the place identity is not solely caused by the sound levels but by the expectation which is highly related with the context of sound environment. With this regard, the acoustic environment of the public study areas should not be evaluated solely based on the sound levels, but also with the individuals' perception of the soundscape.

According to the ISO, soundscape is defined as the “the acoustic environment perceived or experienced and/or understood by a person or people, in context” (ISO, 2014). Soundscape approach has become popular during the last decade. Numerous case studies showed that it is not always the sound levels that matter, but also individuals’ interpretation and the content of sound (Acun & Yilmazer, 2015; Acun, et. al., 2016; Bora & Yilmazer, 2015; Brown, Kang, & Gjestland, 2011; Davies et al., 2013; Mackrill, Cain, & Jennings, 2013).

Public study areas are mostly found within the libraries but it does not mean that they are limited to the library building. Especially in last couple of years, public study areas are created in various locations in Bilkent University Campus. One of the aims of this research is to explore the acoustical environment of four distinct public study areas, compare students’ satisfaction with the sound environment, perceived loudness and overall satisfaction for each area. The second objective is to identify the sound sources and their contribution to the sound environment and satisfaction. Finally, to identify the coping methods employed by the students when the sound environment causes disturbance or dissatisfactory.

2 METHODOLOGY

The research was conducted at four public study areas located within the Bilkent University Campus. These study areas were located within the 77th dormitory, the library, the Faculty of Science (SA building), and the Faculty of Fine Arts Design and Architecture (FC building) (Figure 1). Each of these locations has slight differences. The FC building housed a Starbucks right next to the study area. The study area of SA building was located in the atrium of the building and had a small fountain. Setting chosen within the library was the common study area, which was crowded most of the time. In contrast to this, the dormitory study area was more of a desolate space.

In-situ measurement of sound levels (LAeq) were held in each study area to provide a brief information about sound levels of these spaces. Bruel & Kjaer Sound Level Meter type 2230 was used to measure the LAeq. Sound level meter is placed at central locations of all areas, at the height of 125 cm, and measured over 15 minute time intervals. Number of measurement locations differed for each space, based on the shape and floor area. All measurements are conducted simultaneously with the questionnaire survey.

Questionnaire survey was conducted with 30 student from each study area, with a total of 120 students. The age of the sample group ranged from 18 and 26, 45% being male and 55% female. All the participants are chosen among those who were studying and those that were performing unrelated activities were avoided. It took participants average of 5 minutes to complete the questionnaire.

In order to conduct a perceptual of the public study areas’ soundscape, a questionnaire was prepared. The questionnaire used a 5 point Likert scale and started with demographic information, the frequency and length of visit. For the second part, participants were responded to statements such as “ I am satisfied with this study area”, “ This sound environment is not loud” and “Sound environment of this study area does not disturb my concentration” (1-Strongly Disagree, 5-Strongly Agree). These are followed up by questions regarding the indoor environmental quality of the area (natural lighting, ventilation, etc.) with emphasis on the satisfaction with the acoustic environment (1-Very dissatisfied, 5-Strongly satisfied). This part also included questions concerned with the methods employed by the students to cope with an unsatisfactory sound environment. For the last part, participants were asked to rank the given sound sources based on how frequently they hear them (1= Very rarely, 5= Constantly) and based on disturbance (1= Very disturbing, 5 = Not disturbing at all).

Figure 1: Locations of the case study setting shown on the Bilkent University Central Campus.

3 RESULTS

3.1 THE SOUND ENVIRONMENT

Statistical analyses were conducted using IBM SPSS Statistics 21. The Cronbach's α obtained for the questionnaire is 0,706. According to the descriptive statistics 57,5% of the participants are satisfied or very satisfied with their study environment while 24,2% is neutral and only 18,3% are unsatisfied or very unsatisfied. However, total of 28,3% of the participants expressed that they are dissatisfied and 10% expressed that they are very dissatisfied with the sound environment (Figure 1). Also, 47,5% of the participants disagreed with the statement of "This study area is not noisy"(Figure 2).

Figure 2: On the left, participants' satisfaction with the sound environment. On the right, participants response to the statement of "This sound environment is not loud".

In-situ measurements showed that mean Equivalent Continuous A Weighted Sound Levels (LAeq) for all the study areas are; 55.7 dB(A) for SA building, 57.2 dB(A) for FC building, 62.2 dB(A) for library, and 47.2 dB(A) for 77th dormitory. ANOVA F-Test is used to compare whether there is any difference between the study areas in terms of perceived loudness and satisfaction with the sound environment. In terms of perceived loudness, no statistically significance is found between the study areas ($F(3,116) = 2.681$, $p > 0.05$). Similarly, no statistical difference has been found among the study areas in terms of the satisfaction with the soundscape ($F(3,116) = 2.412$, $p > 0.05$). It was interesting to see no difference between these study areas, in terms of satisfaction and perceived loudness, even though there was almost 14 dB(A) difference between the quietest (77th dormitory) and the loudest (library) study area.

Overall satisfaction with the study areas were also compared by ANOVA F-Test. However, Levene's test for equality of variances was found to be violated for this variable ($F(3,116) = 2.818$, $P = 0.042$). Therefore, analysis continued by using Kruskal-Wallis H-Test, as it is the nonparametric equivalent of one way ANOVA F-Test. Kruskal-Wallis test indicates that there is a statistically significant difference between the study areas in terms of overall satisfaction ($\chi^2(3) = 8.133$, $p = 0.043$). Tamhane's T2 post hoc test suggest significant differences in overall satisfaction were obtained between library and 77th dormitory ($p = 0.023$).

3.2 ASSESSMENT OF THE SOUND SOURCES

Sound sources found within each study area were identified through open ended questions during the pilot study. Based on this, nine types of sound sources are identified. These sound sources were, intelligible speech, unintelligible speech, laughing, footsteps, ventilation, water sound, music, computer sound (keyboard, mouse, fan), and environmental sounds (door, chair, etc.).

As part of the interview, participants were asked to rank frequency of perception for each sound source, from "1 – Very rarely" to "5 – Constantly". The most frequently heard sound source in the study areas are all human generated sounds (Figure 2). Unintelligible speech is the most frequently heard sound, with 32% of the participants stating that they heard it constantly. It is followed very closely by intelligible speech (30%) and laughing sound (29.2%). Water sound (74.2%) and ventilation (63.3%) sound are the least heard sounds, with vast majority of the participants saying that they heard them very rarely. However, the water sound coming from the fountain is exclusive to the SA building. Therefore, ventilation is the least heard sound in reality.

Figure 3: Frequency of perception of the sound sources for all four study areas

When the participants were asked to evaluate the sound sources based on disturbance, intelligible speech is most disturbing sound (Figure 3). One fifth of the participant found intelligible speech very disturbing and 43.3% said that it is disturbing. Laughing sound is also very close to intelligible speech, with 15.8% of the participants stating that it is very disturbing and 45.8% disturbing. Consistent with the literature, unintelligible speech is found to be less disturbing than the intelligible speech (Pierrette, Parizet, Chevret, & Chatillon, 2014).

The disturbance caused by the sound sources and students' perceived loudness are compared with their satisfaction with the sound environment. Calculated Spearman's rank correlation coefficients can be seen at Table 1. Based on these results, a statistically significant relation is observed for 7 of the items. When we consider the correlation between the satisfaction with the sound environment and the statement of "this sound environment is not loud", there is a moderate positive association. In order to properly interpret this result we need to consider that the Likert scales for satisfaction is "1 = very dissatisfied and 5 = very satisfied", and Likert scales for loudness is "1= strongly disagree, 5= strongly agree". This indicates that satisfaction increase as they perceive the sound environment less loud ($r(120)=0.540$, $p<0.01$).

Figure 4: Disturbance caused the sound sources.

Strongest amount of relation has been observed for laughing sounds, among all sound sources. There is a moderate strong positive association between the disturbance caused by the sound of laughing and satisfaction with the sound environment ($r(120)=0.511$, $p<0.01$). This can be interpreted as, the students get more satisfied with the sound environment (1-Very dissatisfied, 5-Very satisfied) as they get less disturbed by laughing sounds (1 – Very disturbing, 5- Not disturbing at all). Laughing is very closely followed by the unintelligible speech ($r(120)=0.502$, $p<0.01$) and intelligible speech ($r(120)=0.471$, $p<0.01$), with both having moderate positive association. No significant relation has been observed for background music, ventilation and water sounds (Table 1).

	Satisfaction with the sound environment	Self-rated concentration
Loudness	-0.540**	0.472**
Ventilation	-0.027	0.051
Laughing	0.511**	0.531**
Footsteps	0.250**	0.357**
Intelligible Speech	0.471**	0.529**
Unintelligible Speech	0.502**	0.538**
Background Music	0.076	0.177
Water Sound	0.067	0.093
Computer sound	0.192*	0.306**
Environmental Sounds	0.237**	0.279**

Table 1: Spearman's rho correlation coefficients for disturbance caused by sound sources (* $p<0.05$, ** $p<0.01$).

Loss of concentration caused by the sound environment is self-rated by the participants. They were asked to respond to the statement of "Sound environment of this study area does not disturb my concentration" from "1= Strongly disagree" to "5=Strongly agree". Their response to this statement is correlated with disturbance caused by each sound source (Table 1). Moderate positive association is found between the perceived loudness and self-rated concentration ($r(120)=0.472$, $p<0.01$). Possible reasons why this relation is not stronger will be discussed in the discussion chapter. Similarly with the satisfaction, highest correlations are observed for unintelligible speech, laughing sound, and intelligible speech. However, this time unintelligible speech has the highest correlation coefficient ($r(120)=0.538$, $p<0.01$), and having

moderate positive association. This indicates that self-rated concentration increases as participants get less disturbed by the unintelligible speech.

3.3 COPING METHODS

During the pilot study, students were asked what they do when they are unsatisfied with the sound environment. Based on their responses, five coping methods were identified. These methods are, putting on earphones (to listen to music, etc.), moving to a quieter place, leaving the study area, intervening to the sound source, and not doing anything at all. Afterwards, as part of the questionnaire survey participants were again asked to choose from “1= strongly disagree” and “5= strongly agree” for each condition.

Figure 5 - Coping methods employed by the participants

As seen in Figure 4, majority of the students stated that they would put on earphones (39.2% agree, 29.2% strongly agree). Another common method of coping is relocating to a quieter place within the area (40% agree, 12.5% strongly agree). Leaving the study area is another common method, with 25.8% agreeing and 13.3% strongly agreeing. In contrast, intervening to the sound source is absolutely not favoured among the participants with 31.7% strongly disagreeing and 30% disagreeing.

4 DISCUSSION

This study investigated the sound environment of four public study areas found within the Bilkent University Campus. The study areas are compared in terms of overall satisfaction, perceived loudness and satisfaction with the sound environment. In-situ measurements of the LAeq are also conducted. The statistical comparison of perceived loudness and satisfaction with the sound environment showed no difference between study areas, even though there are differences between the spaces in terms of sound levels. Only difference is observed for the overall satisfaction in two of the study areas.

The most frequently heard and disturbing sounds are all caused by human activities such as, laughing, walking, intelligible and unintelligible speech. When these are compared with satisfaction with the sound environment, results indicated moderate associations. Same activities also caused moderate effect on self-rated concentration. When exposed to negative or dissatisfying sound environment, the most common coping method is found to be putting on earphones.

One of the issues that came up during the research is regarding the fountain in the SA building. As the other three study areas do not have a water element, the descriptive statistics regarding the water sound is very limited. Although, according to the ANOVA F-test results there is no difference between the SA building and the other study areas in terms of overall satisfaction, perceived loudness and satisfaction with the sound environment.

An interesting finding is related with the loudest (Library) and the quietest (77th dormitory) study areas. Even though the inferential statistics found a difference between these areas, this difference is not regarding the satisfaction with the sound environment or with the perceived loudness but with the overall satisfaction. The in-situ measurements also found average of 14 dB(A) LAeq difference between these two study areas. These findings support those found within the literature. It is clearly seen that sound energy alone is not enough to make a judgement about the perception of soundscape (Brown, et. al., 2011)

Even though the option of “leaving the study area” is stated as a coping method during the pilot study, it should not be considered as an actual method of coping with the soundscape. As the setting is an indoor space when you leave the area you also leave that sound environment. Thus, it is more like not coping with the unsatisfying sound environment.

The option of intervening the sound source is spread into two types of intervention. First one is to verbally intervene a human generated sound (such as laughing). Other option is to physically intervening a non-human sound source, such as the sound of the ventilation system or the coffee machine. One of the reasons why this option is strongly opposed by the participants is that it is not always possible to actually intervene the source. This could either be due to practical or social concerns.

Putting on ear phones, the most commonly accepted coping method, raises some issues. Earphones cause an isolation from the sound environment. It was even mentioned by a number of participants (even written on the questionnaire) that they do not have too much to say about the sound environment as they use earphones almost the whole duration of their study period. This situation can possibly be the reason of relatively low strength of association between the self-rated concentration and perceived loudness ($r(120)=0.472$, $p<0.01$). If the sound environment is loud, students put on earphones during concentration demanding tasks. Thus, loudness does not effect their concentration as much as it should. During the survey, it was observed that earphones are most commonly used during individual study. Those engaging in a collaborative study do not use earphones and as it was also indicated by the literature do not easily get distracted by loud sound environments with exception of peak sounds (Bryant et al., 2009).

1 INTRODUCTION

In 2011, the National Arts Council (NAC) Singapore started an initiative of establishing the 'Community Arts and Culture Nodes' in Singapore's heartlands that extend beyond the traditional art venues, such as museums, art galleries or theatres to incorporate various public spaces and facilities. The objectives of this initiative are to provide greater access to arts through regular quality arts programmes in the local housing neighbourhoods, to activate neighbourhood public spaces through arts and culture and to increase the opportunities for social interaction and community bonding. 25 of such nodes are envisioned to be established island-wide by 2025.

With reference to 'Community Arts and Culture Nodes' strategy, this paper discusses the capacities of five Singaporean neighbourhoods to create culturally rich and vibrant environments through unique art experiences and participation opportunities for the local residents. The key focus is the neighbourhood spatial opportunity analysis that involves mapping and assessing available neighbourhood spaces, their characteristics, strengths and weaknesses, as well as the symbiotic relationship between the quality and capacity of space design and programming in relation to arts and culture events and activities. The process and findings of neighbourhood analysis provide a guide for choosing the most suitable spaces for the arts as well as the strategies to activate community spaces through arts and culture activities.

1.1 WHAT CAN ARTS DO FOR SPACE AND COMMUNITY? - ARTS AND PLACEMAKING

The concept of placemaking has emerged as a response to the systematic destruction of human-friendly and community-centric spaces of the early 20th century. In a reaction to top-down planning, scholars and urban sociologists, since 1960s, began questioning how public space was appropriated (and by whom) and for what it was used (Gehl, 2010; Stern and Pray, 2014; Whyte, 1980). According to Silberg and colleagues (2013), the practice of placemaking concerns the deliberate shaping of an environment to facilitate social interaction, improve community's quality of life, increase public engagement, boost civic pride and empower urban dwellers. In this view, public arts, which is defined as all work of art that is displayed or performed in the public realm, including community arts (Artscape, 2016a; Cartiere and Willis, 2008), is considered a particularly fruitful means of placemaking.

Art can be a powerful medium that informs our imagery of an area and this power to literally produce places is used differently in different geographical, economic and cultural contexts. Arts and culture strategies help to reveal and enhance the underlying identity, value and character of the physical and social form of a community (Soule et al., 2016).

1.2 WHAT CAN SPACE DO FOR THE ARTS? - CULTURAL ECOLOGY

According to Gehl (1987), the overall physical quality of urban space influences the type, nature, mode and frequency of activities occurring in that space. While for the 'necessary' activities (such as going to school or a bus stop, for instance), the design quality of space would not influence the use significantly, for 'optional' and 'social' activities (such as reading, resting or family gathering, for instance), well-designed conducive environment is often critical. The premise is that, since arts and cultural activities belong to optional or social activities, the design quality of urban space would be of great importance.

For the arts to make a significant difference in an urban neighbourhood, one needs to consider its entire cultural ecology rather than focusing on individual assets (Stern and Pray, 2014). An arts ecosystem refers to all 'hard' and 'soft' resources. 'Hard' infrastructure includes not only arts-related facilities, such as studios, exhibition halls or galleries, but also function rooms, workspaces, cafés, commercial spaces, streets and public spaces that provide critical social and economic spaces for interaction, production and promotion of arts activities (Artscape, 2016b; GovHK, 2015). These can be classified as: (a) arts-related spaces - spaces for performance and exhibition (art consumption); spaces for education and training (rehearsal); and spaces for arts production; and (b) supporting infrastructure - various public amenities; and good public space and spaces for interaction. These spaces, each infused with a mix of uses, meanings and experiences, play multiple roles as places of inspiration, connectivity and expression that make up the creative urban fabric.

'Soft' infrastructure refers to a blend of community, educational, recreational, cultural, entrepreneurial and entertainment institutions and non-profit organisations, their associated stakeholders (interest groups, cultural producers, artists, entrepreneurs and residents) and the formal and informal networks formed between them (Stern and Pray, 2014). Committed supporters, including fellow artists, local businesses, audiences, community groups, volunteers, residents' associations and politicians, are also essential for a successful and sustainable cultural scene. The concept of cultural ecology is, thus, particularly useful for understanding how to leverage the potential of clustering of creative resources and activities within an area. The presence of creative and cultural sector workers and businesses in a neighbourhood results in face-to-face networking and social exchange, which further facilitates collaboration, finding of markets and suppliers and cross-fertilisation between various stakeholders (Artscape, 2016b). The amount of informal arts activity in the neighbourhood significantly correlates to its stability and improvement and provides evidence of 'magnetisation' of the area (Taylor, 2008). The idea that neighbourhoods can be "magnetised" by participatory arts practices is powerful, and it appeals to civic leaders.

Therefore, to fully benefit from the presence of arts and culture in local communities, it is necessary to foster an environment that allows for exposure to the arts in many ways. In that sense, different publicly accessible spaces in a neighbourhood can serve the multiple spatial needs of cultural ecology.

1.3 ARTS AND CULTURE INITIATIVES IN SINGAPORE

According to the most recent 'National population survey on the arts' (2015), the number of Singaporeans expressing an overall interest in the arts has significantly increased since 2005. Moreover, both arts attendance and participation experienced their peaks in 2015. The survey also reveals that Singaporeans tend to attend art events and activities mainly because they find them enjoyable and as venues for spending time with others. Such positive findings might be related to recent trends in Singapore's arts and culture initiatives that reveal stronger intention to activate the neighbourhood spaces for better accessibility to arts within the community and encourage social interaction through arts. Such trends also align with the recent shift in Singapore's cultural context from focusing on the 'hardware' of art and culture to the 'heartware' through more community focused policies and programmes. Since 2010, the government has implemented the 'Framework for Arts Spaces' to support the changing needs of a growing and increasingly diverse arts sector, provide platforms where artists and arts groups can collaborate with each other and to

bring arts to the surrounding communities (NAC, 2016). The framework offers artists and arts groups a variety of accessible space options to practice, display and interact, as well as numerous financial incentive schemes.

In 2012, the 'Arts and Culture Strategic Review' (ACSR) was launched to chart a course for Singapore's cultural development till 2025. Since then, various community arts and cultural initiatives and programmes have been conducted intensively. The People's Association (PA) launched the 'PA PassionArts Movement' in 2012, with an aim to energise neighbourhoods across Singapore by carving out spaces for collaborations between professional artists, community talents and grassroots organisations. It also enables the residents to volunteer and actively contribute towards developing the arts in their community.

Also under ACSR, the NAC initiated the 'Community Arts and Culture Nodes' strategy to create a network of arts touch-points for the residents at their neighbourhoods, with regular activities and events occurring throughout the year. In order to sustain this initiative, NAC has partnered with various neighbourhood institutions, as well as non-profit organisations, and created a network of nodes at 3 levels, namely: regional nodes, neighbourhood nodes (in partnership with Community Clubs, Libraries and SAFRA Clubs) and street level pocket nodes, which incorporate more informal venues for the arts, such as various public spaces in the neighbourhood. Not only does this approach bring more vibrancy to the arts and culture sector in the neighbourhoods, but also creates more diverse experiences and opportunities for the local communities to enjoy arts on a regular basis.

2 APPROACH AND METHODOLOGY – NEIGHBOURHOOD SPATIAL OPPORTUNITY ANALYSIS

Five nodes and their surrounding neighbourhoods (areas of 400m radius around the node) were selected for case study analyses of spatial opportunities for arts and culture venues. Community arts and culture node partners are all different in nature, with their specific visions, target audiences and spatial capacities, ranging from indoor spaces within nodes' premises to public spaces within the neighbourhood.

Case study 1: Kallang CC (Community Club) is one of the oldest neighbourhood nodes whose main target audiences are families with children and senior citizens. It organises regular events on a monthly, quarterly and yearly basis. Besides its own premises offering an indoor multi-purpose hall, open courtyard and smaller indoor facilities, this node also extensively utilises various public spaces in the neighbourhood, such as Boon Keng Plaza next to the subway station or a nearby mall street (Figure 1). The CC is a home to several local artists and arts interest groups who programme in the neighbourhood as well as across the island.

Figure 1 - Arts Venues at Kallang: CC Courtyard (left) and Boon Keng Plaza (right) (Source: by authors)

Case study 2: Woodlands Regional Library (WRL) has been a node partner since 2013 catering mainly to families with children and young adults. With a strong focus on the performing arts and workshops, WRL has established a 'Monthly Music Series' called 'RE:SOUND' and 'Art Fresco Theatre Club' for children. Various spaces inside the library are used as venues for arts events, such as an auditorium, programme zone, functions rooms and exhibition spaces (Figure 2).

Figure 2 - Arts Venues at WRL: Auditorium (left) and Programme Zone (right) (Source: by authors)

Case study 3: Singapore Armed Forces Reservists' Association (SAFRA) is a club for national servicemen and their families. Traditionally known for sports activities, SAFRA Jurong has recently embraced the arts programme termed 'ARTS@SAFRA' and started organising various art events on quarterly basis at the entrance atrium as well as other rooms within the club (Figure 3, left).

Case study 4: Tanglin Halt (Block 88), Queenstown is a one of the first street-level 'pocket' spaces initiated to develop Queenstown as a neighbourhood node, partnered with My Community, which is a non-profit organisation, whose aim is to showcase the diversity of intangible cultural heritage of the neighbourhood and to provide a sustainable platform for budding local artists. Music, theatre plays, traditional local arts, visual and literary arts, are some of the art events organised within the neighbourhood, the majority of which are held at a sheltered public space at Tanglin Halt (Block 88) next to the subway station, supermarket and a foodcourt, an area with high pedestrian traffic (Figure 3, middle).

Case study 5: Bedok Town Square is another 'pocket' node space in which NAC organises art events, yet without a regular partner. Located at the town centre, which contains a shopping mall, integrated public transport hub and a hawker centre, this recently built large sheltered plaza with high pedestrian traffic, serves as a space for community events and gatherings (Figure 3, right).

Figure 3 - Arts Venues at SAFRA Jurong: entrance atrium (left); My Community, Queenstown: Tanglin Halt open space (middle); Bedok Town Square: sheltered plaza (right) (Source: by authors)

The neighbourhood spatial opportunity analysis consisted of three main steps.

Step 1: Literature Review – Research Framework Development. A set of criteria was derived from literature review concerning attributes of good public space as well as features that contribute towards favourable venues for the arts. Good public space, a pre-requisite for an optional activity such as arts participation, is understood to possess a combination of physical attributes and socio-perceptual qualities (Cho et al., 2016). In addition, walk-through interviews with key community members, who have experience with organising events in the neighbourhood and have detailed knowledge of the community and spaces, were conducted. The intention was to gather qualitative data from the ground and to validate and refine the criteria distilled from the literature. The result is a framework for the evaluation of neighbourhood spaces in reference to their suitability for arts and culture events and activities.

Step 2: Primary Data Collection – On-site Investigation. All publicly accessible spaces in the neighbourhood were identified. A series of observational methods including visual ethnography and on-site observation of activities were carried out to evaluate these spaces against the criteria derived in Step 1.

Step 3: Data Analysis and Synthesis – Map Overlay Technique. The primary method of gathering and analysing collected data is visual mapping. The maps, indicating the presence or fulfilment of the criteria set by the framework, are then overlapped to reveal neighbourhood spaces with conditions that are the most conducive for holding arts and culture events or conducting arts-related activities. Map overlaying proved to be a fruitful means for filtering or distilling the most suitable spaces in the neighbourhood for arts and culture. Such filters, however, should not be taken as prescriptive, but rather indicative.

2.1 FRAMEWORK FOR NEIGHBOURHOOD SPACE EVALUATION IN REFERENCE TO ARTS AND CULTURE

The overall aspects mapped and evaluated form the framework for identifying neighbourhood spatial opportunities, which includes: Filter 1 - general spatial conditions; Filter 2 - locational aspects (intensity of pedestrian movement and stationary activities); and Filter 3 - criteria for good public space and suitability for arts and culture events (Figure 4).

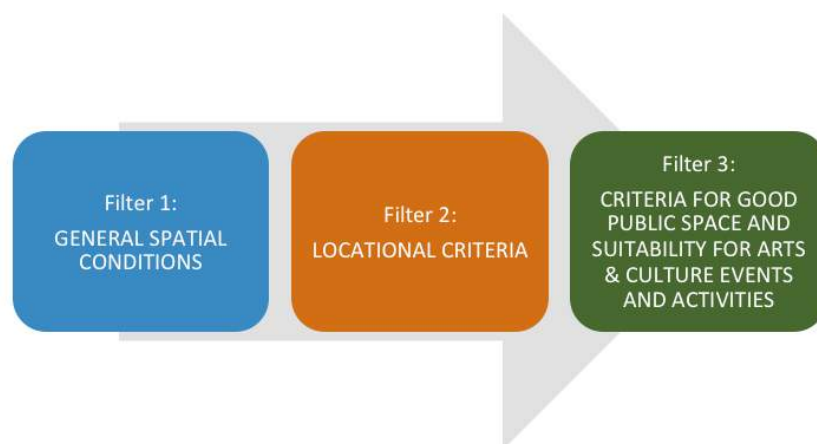

Figure 4 - Framework for Identifying Neighbourhood Spatial Opportunities (Source: by authors)

2.1.1 FILTER 1: GENERAL SPATIAL CONDITIONS

General spatial properties, including scale, shape, enclosure level and type of floor surface, describe the basic pre-conditions of neighbourhood spaces to become arts and culture events venues (Table 1).

Scale. The scale of the space (categorised into S, M, L, XL and XXL) is determined by the number of audience it can accommodate. In general, the larger the space, the more people it can accommodate and, therefore, the more desirable it is as a venue for big art events. However, large venues pose some challenges. There is a maximum distance at which the performers are visible to the audience, beyond which the connection between the two is lost. While crowds attract crowds, the opposite is also true; large spaces might make the audience seem scarce, discouraging new audience from joining the event. The largest spaces, more often than not, tend to be unsheltered or unpaved, which makes the logistics required to host events there more extensive than in smaller venues. Finally, some art activities demand smaller and more intimate venues.

FILTER 1: GENERAL SPATIAL CONDITIONS	
SCALE	S - Small: up to 200 m ² M - Medium: 200-500 m ² L - Large: 500-1000 m ² XL: 1000-5000 m ² XXL: larger than 5000 m ²
SHAPE	Linear Compact Fluid/Hybrid
LEVEL OF ENCLOSURE	Open Covered Enclosed
GROUND SURFACE	Paved Unpaved

Table 1 - Filter 1: General Spatial Conditions

Shape. Spaces can be classified as linear, compact and fluid/hybrid according to their shape. While linear spaces may be favourable for certain kinds of art interventions, the majority of arts events benefit from being held in a compact space with good sightlines towards the performance.

Level of enclosure. In terms of exposure to weather conditions (sun and rain), spaces are categorised into open, covered and enclosed. Arguably, the enclosed spaces, like classrooms or auditoriums, offer the best environment since they allow control over background noise and weather conditions. However, such spaces are often less accessible to incidental audience than open public spaces.

Ground surface. Paved surfaces (hardscape) are considered more preferable than unpaved ones (softscape) as they offer a more rigid surface to place seating and equipment, better acoustic conditions, and easier maintenance (among other benefits). In Singapore, the possibility of it raining is high throughout the year after which, unpaved ground can get slushy and inaccessible without additional flooring provisions.

The process of overlaying layers mapped in Filter 1 in the Kallang neighbourhood is shown in Figure 5. Darker areas indicate spaces of greater suitability for the arts and culture venues.

2.1.2 FILTER 2: LOCATIONAL CRITERIA - INTENSITY OF PEDESTRIAN MOVEMENT AND STATIONARY ACTIVITIES

While physical characteristics, without a doubt, contribute to quality and identity of a space, good public space is also a function of its users and the activities it accommodates. From the point of view of community arts engagement, sites adjacent to major movement paths have the most exposure to potential incidental audience. Moreover, according to Whyte (1980), a high proportion of people in groups for social or optional activities (those who are using the space out of choice rather than necessity) can be seen as an indicator of 'selectivity' and vibrancy. This step, therefore, involves evaluation of neighbourhood spaces in terms of both their proximity to the frequently used circulation paths within the neighbourhood and the number of people engaging in stationary activities within them (Table 2).

Figure 5 - Filter 1: Mapping of neighbourhood spaces around Kallang CC node according to Levels of Enclosure (top left); Types of Ground Surfaces (top right); Scale (bottom left); and Overlaying of all layers in Filter 1 (bottom right) (Source: by authors)

FILTER 2: LOCATIONAL CRITERIA	
Intensity of pedestrian movement – proximity to most frequented pedestrian movement paths	
Intensity of pedestrian stationary activities – proximity to well-used spaces	

Table 2 - Filter 2: Locational Criteria

Tracing moving patterns and people counting. Groups of pedestrians were discreetly followed from points of origin such as the train stations and the housing blocks to identify the most highly used routes through the neighbourhood. The hierarchy of movement paths, identified by tracing, was then verified by counting the number of people passing by carefully selected points of observation across the neighbourhood. Counting was done for two minutes at each observation point at three different times of the day as well as during one weekday and one weekend day. The pedestrian routes were then traced on the maps using different thicknesses of lines to indicate relative volume of transient usage.

Presence and type of stationary activities. In this step, stationary activities occurring in and around each observation point were noted down to understand whether the space was used for necessary, social or optional activities. The number of people within each observed space is indicated on the map. The size of circles is proportionate to the total number of space users involved in both stationary and transient activities.

The process of overlaying layers mapped in Filter 2 in the Kallang neighbourhood is illustrated in Figures 6.

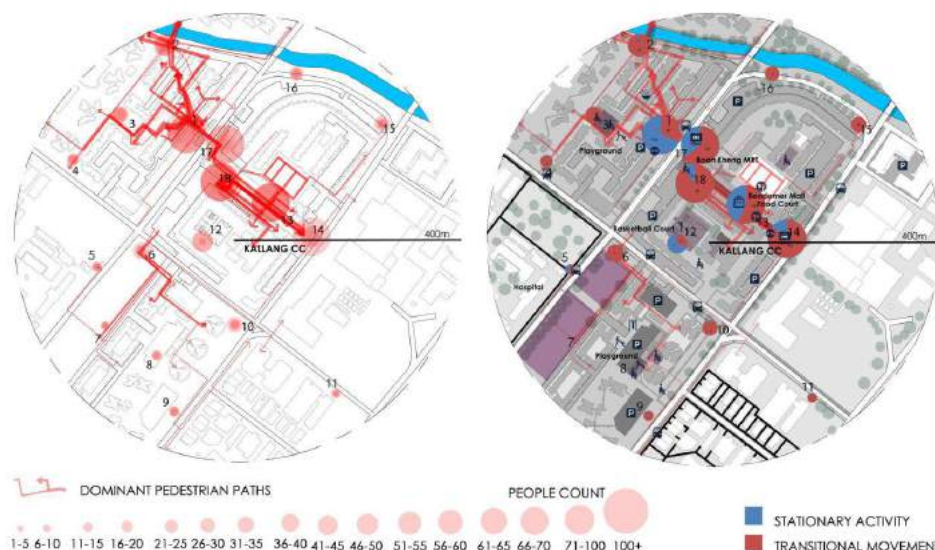

Figure 6 – Filter 2: Mapping of Pedestrian Movement Patterns and Stationary Activities (left) and Overlaying with shortlisted spaces in Filter 1 (right) in the Kallang CC neighbourhood (Source: by authors)

By super-imposing maps in Filter 1 and Filter 2, four main categories of neighbourhood spaces emerged, namely: (A) spaces next to major pedestrian movement paths and stationary activity; (B) spaces away from movement paths but contain stationary activity; (C) spaces next to major pedestrian movement paths but without stationary activity; and (D) spaces away from both movement paths and stationary activity (Figure 7). These categories provide an indication of how an arts and culture event might synergise with the space and available amenities. This will further be elaborated on in the conclusion.

Figure 7 - Examples of categories of neighbourhood spaces: (from left to right) Category A - Bedok Town Square, sheltered plaza next to the subway station and a shopping mall; Category B - Space adjacent to food court, badminton court and a green open space in Woodlands; Category C - Paved open space between the housing blocks in Woodlands, next to a frequently used covered walkway; and Category D – An empty underused amphitheatre in Bedok

2.1.3 FILTER 3: CRITERIA FOR GOOD PUBLIC SPACE AND SUITABILITY FOR ARTS AND CULTURE EVENTS AND ACTIVITIES

In this final stage, all shortlisted spaces (resulting from Filter 1 and Filter 2) are evaluated against an extensive list of criteria for good public space and suitability for arts and culture events (Table 3). Different types of art events have different requirements and this detailed evaluation of spaces is meant to act as a guide to indicate which types of events the venue is most suited for. These criteria are classified under 'hardware' (design values) and 'software' (programming and socio-perceptual values). Under 'hardware', we evaluate the physical qualities of the space, such as accessibility, flexibility and configuration, which contribute to making it good and suitable as an art and culture venue. In general, 'software' relates to programming and social value of urban space and focuses on the relationship between people and the space with issues related to diversity of uses, choice of activities, seating amenities, interactivity and privacy, as well as ambience/image, to name some.

The outcome of Filter 3 is a detailed evaluation that can help organisers to understand the specific strengths and weaknesses of each space and synergise it with the requirements of a particular art

program. For example, the Tanglin Halt Node satisfies many of the Filter 3 criteria. It also has a variety of adjacent activities that are synergetic with the art venue. Namely, it is located between a food court and a supermarket, both of which are essential amenities that are well used by the local residents on regular basis (Figure 8). The food court has an indoor seating area where the audience can have dinner before the performance and also an outdoor area which serves as an extension of the event area from where people can watch the performance while they eat. The challenge of the space is that its favourable location creates competition for use.

In the case of the events organised by the Kallang CC, the challenge of the open air venue is that if it is raining at the time of the event and a temporary shelter is not put up, the stage has to be moved from the plaza to the shelter of the subway station (Figure 9). This also demonstrates the strengths of the node - both in the ability of the node partner to make timely decisions and manage the logistics required for such a change, and in the flexibility that the venue allows to accommodate such a change.

FILTER 3: CRITERIA FOR GOOD PUBLIC SPACE & SUITABILITY FOR ARTS AND CULTURE EVENTS AND ACTIVITIES	
HARDWARE – spatial design criteria	
ACCESSIBILITY	Is the space visible from a distance? (Marcus and Francis, 1997; Project for Public Spaces, 2009; Talen, 2011)
	Is its interior visible from the outside? (Carmona et al., 2010; Carr et al., 1992; Project for Public Spaces, 2009)
	Can people use a variety of transportation options to reach the place? (Project for Public Spaces, 2009; Urry, 2007)
	Does the space function for people with special needs? (Carmona et al., 2010; Levine, 2003; Project for Public Spaces, 2009; Shaftoe, 2008)
CONFIGURATION	Is the space free from columns and other obstructions? (Kallang CC Chairman, 2016)
LOCATION	Is the space adjacent to noise sensitive areas? (Kallang CC Chairman, 2016)
SUPPORTING INFRASTRUCTURE	Does the space have electrical points? (Cho et al., 2016)
	Does the space have adequate lighting? (Levine, 2003; Marcus and Francis, 1997; My Community, 2016)
	Does the space have public toilets? (My Community, 2016; Shaftoe, 2008)
SOFTWARE – use and socio perceptual criteria	
MULTI-FUNCTIONALITY	Is the space multi-functional i.e. do multiple uses and activities happen in the space? (Evans, 2001)
SOCIABILITY	Are there opportunities to talk and listen? (Project for Public Spaces, 2009)
	Is the space used by people of different ages? (Project for Public Spaces, 2009)
	Are people in groups? (Project for Public Spaces, 2009; Whyte, 1980)
	Are there places to sit and stay? (Project for Public Spaces, 2009)
	Are there choices of things to do? (Carmona et al., 2010; Gehl, 2010; Project for Public Spaces, 2009)
IMAGE	Does the space make a good first impression? (Project for Public Spaces, 2009)
	Is the space clean and free from litter? (Cho et al., 2016)

3 DISCUSSION

In reference to four main categories of neighbourhood spaces identified through spatial opportunity analysis, certain strategies to activate urban spaces can be discussed. The discussion of the preliminary findings is framed by the three key question posed in this study: (1) What can space do for arts?; (2) What can arts do for space?; and (3) What can arts and space do for the community?

3.1 WHAT CAN SPACE DO FOR THE ARTS?

Spaces close to movement paths and containing stationary activity (Category A) provide greater access to the arts at the neighbourhood level. These spaces generally have the highest number of users in the neighbourhood and are situated near subway stations, town centres or other major amenities, like food courts and shopping centers. They are the most favourable venues in the neighbourhood in terms of greater exposure of the arts and culture activities and, therefore, suitable for diversifying and broadening the audience for the arts (McCarthy and Jinnet, 2001). However, the challenge of these spaces is that they are often designated for commercial activities that also benefit from the high pedestrian traffic, resulting in an intense competition between different users. Moreover, these are also spaces used to perform necessary activities and may not be designed to encourage people to linger. As a result, they can also be over-crowded and noisy, which may not necessarily provide the most conducive atmosphere to enjoy certain types of arts and culture events and activities.

Spaces that are not adjacent to major movement paths but contain stationary activity (Category B) in Singapore's housing precincts are numerous. They are community gathering spaces, such as schools, Community Clubs (CCs), basketball courts, hawker centres, playgrounds or simply green lawns. These spaces often function as gathering places for residents with limited mobility, such as mothers and maids with young children and the elderly and can act as ideal venues for art and culture activities and performances. Art activity can be introduced into these spaces to further foster social bonding between residents and deepen arts engagement.

3.2 WHAT CAN THE ARTS DO FOR SPACE?

There are also spaces near movement paths but without stationary activity (Category C), such as void decks, pavilions and covered linkways. These spaces are frequently passed-by by the residents, but since they are not next to amenities, almost nothing encourages people to stay there for a little while. Performing arts can capitalise on the potential audience in these spaces while simultaneously magnetising and enlivening them with a sense of fun (Taylor, 2008).

Performing arts can also be used to test out possibilities in underutilised spaces that are away from both movement patterns and amenities (Category D), so-called "white elephants", such as amphitheatres and roofs of car parks, for instance. In fact, many of these spaces often provide very conducive environment for art events. Through temporary alterations of aesthetics or programming to set the stage for an event,

arts can help to test out or discover various ideas which could lead to permanent improvements being made to the space. Finally, there are also spaces, such as ground car parks or school amenities that may be only temporarily available or less accessible, but can also be considered for re-use and holding occasional arts and culture events.

4 CONCLUSIONS - WHAT CAN ARTS AND SPACE DO FOR COMMUNITY, AND VICE VERSA?

Social interactions between people in the neighbourhood public spaces are likely to be of greater depth than those in city centres as places in residential streets are accessed by a limited number of people (Whyte, 1988). This indicates the greater potential of neighbourhood spaces to sustain or form social interactions between audience at art and culture events than public spaces in city centres. Arts and culture events magnetise by creating shared experience and therefore encourage people to spend more time in a space, increasing the exposure of neighbours to one another and providing more opportunities for them to progress along the stages of 'neighbouring', namely: familiarization with strangers (passive face-to-face contact), mutual recognition, shared experience, further interaction and friendship (Grannis, 2009).

Moreover, arts can encourage community participation and volunteerism, which are critical for building sustainable, creative and resilient communities. The resources needed to organise frequent arts events at the neighbourhood level present a challenge that can be met with a stronger neighbourhood arts ecology. The involvement of professional artists can play a role in the transference of skills and mentorship to amateur neighbourhood performers in the form of workshops or participatory arts projects. The community arts and community interest groups, for instance, play an important role in the organisation and (return) audience building for the quality arts programs. In Kallang, for example, the organisers, professional artists, interest groups, volunteers and some audience members together support the quality/professional art programmes. The ecology of a continuous community art practice in the Kallang neighbourhood is crucial to sustaining the organisation of the quality arts performances (Figure 10).

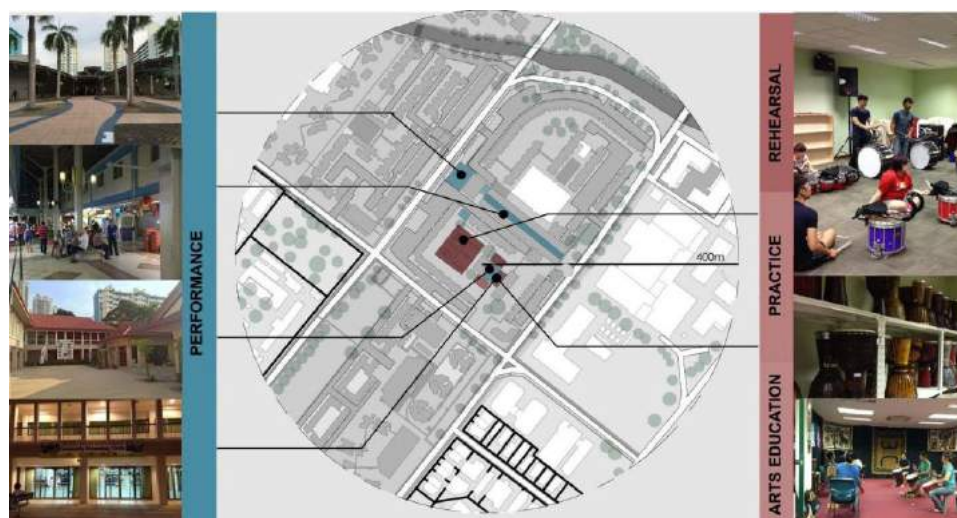

Figure 10 - Neighbourhood Arts Ecology for Community Arts in Kallang (Source: by authors)

Community art, public space and cultural facilities together help in building community cohesion. In order to achieve this, among other factors, it is important to: understand the neighbourhood and the community and all its material and human resources and skills (community assets); provide adequate infrastructure and programming to boost vibrant neighbourhoods (formal and informal arts and culture venues - arts ecology); empower the community to take an active creative initiative (community engagement, ground-up initiatives and volunteerism); and develop collective community vision and partner network.

Cultural planning is a process that inevitably begins with identifying the key goals and strategies, including both overall (common) and specific goals set by each arts and culture node (together with NAC and local community). The choice of spaces for holding arts and culture events and activities in the neighbourhood

would depend on the establishment of such goals and strategies. Accordingly, the filtering process explained in this paper serves primarily to assist in decision making, rather than being a prescriptive tool. With the guide for choosing and activating spaces (and communities) in the neighbourhood, this study hopes to contribute to the establishment of a vibrant neighbourhood cultural ecology with an aim to bring the arts into individual's everyday lives, boost a stronger sense of neighbourhood identity and attachment through arts, diversify, broaden and deepen arts and culture provision and engagement, and encourage stronger community bonding.

ACKNOWLEDGEMENTS

The content discussed in this paper is part of the research project 'Arts and Culture Nodes in the Heartlands of Singapore: Exploring Strategies, Spatial Opportunities and Impacts (Phase 2)' conducted at the Centre for Sustainable Asian Cities (CSAC), School of Design and Environment (SDE), National University of Singapore (NUS), in collaboration with and funded by the National Arts Council (NAC), Singapore.

1 INTRODUCTION

Recognized as a global phenomenon, the gated community has provoked heated discussions from various perspectives, including social, political, economic, anthropological, and geographical ones. Particularly due to the obvious spatial demarcation and social segregation embodied by the fortress-like forms, the social-spatial aftermath of gated community, has become the major focus of those multidisciplinary debates. Moreover in the practical world, despite the fact that the gated communities, have embraced unprecedented levels of prevalence, pervasion and variety, notably in China where such patterns have become the standard form of contemporary residential development and widely welcomed by all social classes and groups, it has been gradually noticed that the predominant gated communities in China have raised other public issues than social and spatial segregation, such as the greatly reduced land-use efficiency, the restricted transportation network and the negative impact on the well-being of public spaces (Huang and Feng, 2008; Wang, 2010; Wang, 2014). Under such circumstances, Chinese government has officially announced the reforms of the current urban residential wards in China by gradually removing the gates of the contemporary gated communities and “danwei” (work-unit compounds), which has inevitably provoked a variety of controversies (Liu, 2016).

As any materialization of place and locale as urban form is not a result of arbitrary architectural or planning interventions in the urban realm, but is fundamentally shaped by and embodies the deeper, more enduring social, political and cultural forces that emanate from the whole process of the urban development (Lefebvre and Smith, 1991). Therefore the paper will attempt to identify the significance and specificity of the social and historical context in Chinese cities that substantially resulted in the adapted gated communities in specific loci and to understand how ethics have influenced the pattern of residential settlement. Finally the paper will aim to suggest some pivotal elements that should be preserved in the face of housing reforms in China.

2 THE GATED RESIDENTIAL PATTERNS IN CHINA: ORIGIN AND EVOLUTION

The gated enclosure has been an ingrained feature of the urban residential pattern in China. Following a chronological sequence, the closed pattern has experienced two typical periods: the traditional walled residential wards and inward courtyards in the feudal monarchy; the “danwei” (work-unit compounds) in the socialist era and the contemporary gated community that have emerged since 1978. The section will review the traditional form of settlements in Chinese history in order to find out the historical origins of the contemporary gated community and the morphological characteristics inherited from the traditional enclosed forms.

2.1 THE FEUDAL MONARCH

With a rigidly hierarchical and controlled social structure, Chinese cities before the Song Dynasty (960-1279 AD) were physically characterized by walls and fortresses. The most typical model, Tang Chang'an (618-906 AD) is a walled city that has been divided into 108 “fang” (rectangular residential wards) and two designated markets by eleven north-south and fourteen east-west major streets (Heng, 1999). The residential quarters (fang) were fortified with earthen walls and within the quarter, there were organized courtyard dwellings and an internal road system (Dong, 2004).

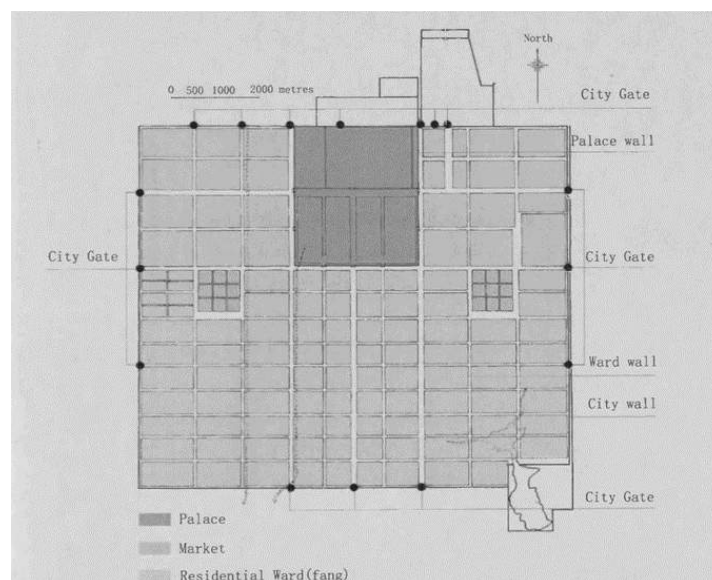

Figure 1 – “Li Fang” in Tang (Wei and Yao, 2012, p.2891)

Later in the Song Dynasty (960-1279 AD), the economic growth, facilitated by long-term social stability and the revolutionary improvement in agricultural technologies, became the decisive stimuli to overthrow the previous demarcated and restricted urban residential form (Heng, 1999). Despite the main street-block structure remained, the ward walls and the street encroachment have been demolished (Heng, 1999), which resulted in the emergence of ‘hutong’, a street connecting the dwelling units in ‘fang’ (Dong, 2004). Although it functioned a linear communal space providing a strong sense of community, the “hutong” was generally restricted to local inhabitants with a door and a nameplate at the gateway (Ibid).

Figure 2 – “Fang Xiang” in Song (Wei and Yao, 2012, p.2891)

In all, notwithstanding the fact that streets (hutong) have become more accessible to passersby with the ward walls being dismantled, it were still the high blank walls rather than the dwellings that continuously and directly confronted the street (hutong). Hence, the residential pattern has still remained enclosed in the following feudal monarchies, with the walls as an elementary component in the reformed urban form to separate the private family space from the public urban environment.

Schulz (1985) has posed two fundamental aspects of the meaning of places which are identification and orientation respectively. Through identification of the surrounding environment, humans possess their social identities while orientation indicates the spatial organization which allows life to take place. Thereby residential forms have manifested the ideal living environment desired by a social or cultural group and revealed the social and cultural meaning behind these places (Rapoport, 1969). That is to say, traditional residential patterns have inevitably become a medium, through which to exhibit and Confucian ideologies and social structure in Chinese society. One of the core concept in the Confucianism is “Li” (propriety), which referred to an all-embracing system of defined ritual social behaviors (Lin, 1938). As was stated by Confucianism (Analects, 8.2),

“Respectfulness without the rules of propriety becomes laborious bustle; carefulness without the rules of propriety becomes timidity; boldness without the rules of propriety becomes insubordination; straightforwardness without the rules of propriety becomes rudeness..... It is by the rule of propriety that the character is established”.

Hence “Li” was codified as the main social grammar for Chinese people to direct them to the appropriate hierarchy of behaviors and interpersonal relationships to achieve a harmonious asocial order. As a result the hierarchical philosophies and ideologies of the Confucianism has impelled Chinese to highlight the spatial order in the residential pattern, which could be defined and maintained by the walled-enclosure. Moreover the elementary ideology of social interaction in Confucianism is “Xiao” (Filial Piety). From the Confucian perspective, there was a direct linkage between family and the nation, as was claimed that “when the family life is regulated, then the national life is orderly; and when the national life is orderly, then there is peace in this world” (Lin, 1938, p. 197). As a result, Chinese people were generally “family-minded” instead of “social-minded” (Lin, 1989, p. 172). In Confucian society, the primary concern was not the people’s obligations to the society but their loyalty to their families. Hence the enclosed multi-courtyard housing has somehow symbolized and strengthened the coherence of a family. Furthermore as was described in the proverb “Si Dai Tong Tang” (Four generations under one roof), the big Chinese family comprised of a long patrilineal line was traditionally accommodated in the multiple-courtyards housing compound (Huang, 2006). The rooted Confucian propriety (Li) believed that the best spatial organization of a house should not merely felicitously embody the hierarchical kinships between, but also maintain the individual privacy among family members. For instance, the segregation of gender was a considerable concern in Chinese family (Lin, 1989), as was regulated in the Book of Rite that “The men should not speak of what belongs to the inside (of the house), nor the women of what belongs to the outside.....

Things spoken inside should not go out, words spoken outside should not come in". Hence the High walls has restricted the access to the inside spaces for unmarried females to minimize the interaction between the inside and the outside. In this regard, according to Knapp (2000)'s description, a housing with a series of wall-enclosed courtyards was the best layout to apply the Confucian approach to resolve the tension separateness and togetherness, through a spatial sequence created by the transitions between individual spaces, the communal spaces shared by the family members and the outer society.

The traditional residential wards have universally exhibited three major morphological characteristics, namely the collective living pattern, the closed courtyard, and the gated enclosure. Moreover such long-existing gated tradition and collective and inward living patterns have been found to continuously play a significant role in urban settlements in China during the Socialist Era.

2.2 THE SOCIALIST AND POST-SOCIALIST ERA

Since the People's Republic of China was founded in 1949, China has stepped into the Socialist Era, during which the Chinese institutional economy and urban planning were significantly influenced by the former Soviet Union (Dong, 2004). However the urban residential patterns under Mao were far more than the replica of Soviet models with the distinctive Chinese invention of "danwei" (work-unit compound).

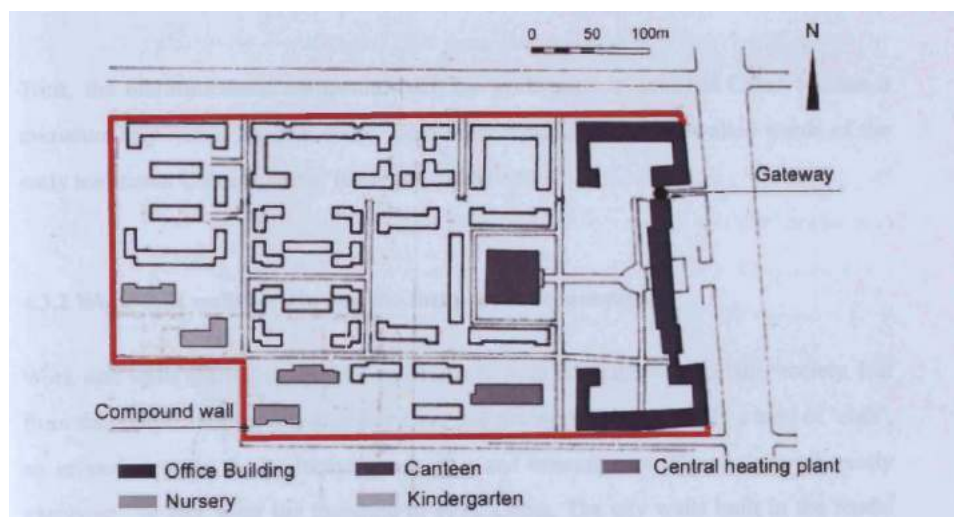

Figure 3 – Work-unit Compound (Hua, 2006, p. 45)

Unlike the spatial separation of residential districts and workplace in the Soviet models (Bater, 1980), the work-unit compound (danwei) in China resembled a miniature society which has endeavored to integrate working and living space in close territorial proximity with the provision of social services (Lu, 2005). Enclosed by overwhelmingly ubiquitous presence of walls and guarded gates, the work-unit compounds were merely open to the workers and their family members (Ibid).

At the end of the 1970s, cities in China have witnessed an overwhelmingly housing shortage and poor living condition (Wu, 2005). Hence a series of housing reforms programmes have been successively launched, in accordance with the reforms social market economy, to tackle the housing deficiency in 1980 (Fong, 1989; Wang and Murie, 1996), which hence resulted in a nationwide boom in commodity housing markets in the following decades (Chen and Gao, 1993; Wu, 1996 and 2005). Consequently, as the maintenance and management of commodity housing were taken over by specialized estate management companies, the enclosed residential developments became gradually pervasive in China by means of the reproduction of the exclusive feature of the "danwei", which exhibited a strong echo of the global phenomenon of the "gated community" (Wu, 2005).

After decades of reform, "gated community" has become the predominant residential pattern in China whereas previous work-unit compounds have still played an indispensable role in the urban housing sector (Ibid). However as was widely noticed by researchers in their survey on a variety of gated communities around the country, the contemporary gated community has witnessed distinction changes compared with

the work-unit compounds and the enclosed residential wards in the feudal age (Li and He, 2007; Wei and Yao, 2012; Wang, 2014)

Figure 4 – Gated Community Model: Central Garden (Li and He, 2007, p. 94)

Fundamentally, the size of enclosure has changed dramatically from the residential ward in Tang dynasty to the contemporary diversified gated communities. Starting from the residential area accommodating hundreds of households in the Tang dynasty which was strictly controlled by aristocratic power with depressed commercial activities, it has then shrunk to the courtyard housing for one household per unit during Song dynasty with the rise of the mercantile society. Thereafter in Socialist era, the enclosure size increased in the work-unit compound which is like a large spatial entity encompassing workplace and residence for thousands of workers and their families with the provision of most supporting facilities and services. Finally like the palimpsests of successive layers of the growth of size over time, the contemporary gated communities have manifested a hierarchy of enclosure, with courtyard style buildings, enclosed in the “hutong” like residential groups and ultimately gated in a loose grid residential community which has significantly inherited the Soviet model of “super-block and wide-avenue”.

Figure 4 –Wall in “Hutong” (Author, 2015) | Figure 6 –Wall of “Cheng Nan Yi Jia” in Chengdu (Author, 2017)

Moreover, the boundaries had changed greatly that have been shaped by the monotony in aristocratic controlled feudal empires and diversified thereafter from the socialist time.

Despite the fact that the contemporary urban settlements are continuously featured by the traditional form of gated enclosure, these greatly varied elements have been identified to significantly exacerbate the social, spatial segregation and even resulted in other urban issues (Huang and Feng, 2008; Wang, 2010; Wang, 2014).

3 THE CULTURE CONNOTATIONS OF GATED COMMUNITIES

The section will critically evaluate the cultural ideologies and values which have arguably resulted in this gated tradition and the identified spatial characteristics. Based on the study the section will attempt to explore how ethics have influenced and shaped the pattern of residential settlements in China's history.

3.1 THE CULTURE OF COURTYARD

One morphological characteristic is too vital to be ignored of contemporary gated communities is the gated open space which resulted from the obsession of introverted courtyards among Chinese. Such ingrained attachment to the introverted courtyard has arguably conformed to the willingness to pursue the ultimate nature-human harmony in Daoist philosophy and the interpersonal harmony from the Confucian perspectives.

3.1.1 DAOIST NATURE-HUMAN VIEWS

In the philosophy of Daoism, “yin” (negative) and “yang” (positive) are two basic components of the universe that should be integrated in perfect balance to create the ultimate harmony of the world (DAODEJING). Therefore, as buildings and structure were solid which have generally represented the force of “yang” (positive), an open space defined by walls and gates were seen as void and natural that form an enclosed courtyard space to complement the negative component in the gated community (Knapp, 2005). Hence the movement between buildings and the courtyard was deemed as the interaction between “yin” and “yang” (Du, 2004).

Furthermore, From the Daoist perspective, the courtyard was deemed as the pivot between the heaven and the world, the nature and human, the void and the entity. (Zhou and Yang, 1998). Hence, Chinese people tended to situate their dwellings inside the enclosed courtyard, with a manmade garden in order to communicate with nature (Knapp, 2005). In this way, humans could indeed sense the order of nature and realize the harmony with nature in their courtyard, and finally achieve the ultimate dream of “Tian Ren He Yi” (unity of the heaven and human beings). As was described by Hu (2008), “When a resident stood in his courtyard, as if he stood in the universe, he could be in touch with the sun, fresh air, winds, rainwater, his family, and even his gods” (p. 359).

3.1.2 CONFUCIAN “YUE”

Another essential concept in the Confucianism is “Yue” (music). As was stated by Confucianism, ““Yue” is (an echo of) the harmony between heaven and earth; “Li” reflect the orderly distinctions (in the operations of) heaven and earth” (Confucius.). Hence, in terms of the social relationships among Chinese. “Li” restrained people’s behavior to maintain the social order while “Yue” focused on the emotional communications and interactions between people to facilitate the harmony of the society. Therefore, as the medium between the private and the public realm, the courtyard on the one hand has enhanced the interactions between local residents and emphasized the engagement in the collective life (Gehl, 2011). On the other hand, the semi-public features allow the quiet and peaceful inward courtyard to be relatively segregated and enclosed from the chaotic external society, which strengthened a sense of self-protection (Newman, 1996).

In all, the enclosed courtyard form has perfectly fulfilled the demand of the physical and psychological space among Chinese.

3.2 THE CULTURE OF WALL

As the old saying goes: “Guo you feng bi cheng, jia you feng bi yuan” (The nation is safeguarded by the Great Wall while the family has been protected by the ward walls), China has the largest amounts of walls and walled structures (Nuttgens, 1997). Walls, as the physical boundaries and thresholds that explicitly defined the interior and exterior spaces, were deemed as the symbol of places in China (Xu, 2008). In the

long history, the wall has developed into a cultural phenomenon which reflects the Chinese patterns of thinking and behaving (Hu, 2008). Therefore the strong reliance on such physical boundaries have arguably represented the territorial consciousness, the introverted personality and the awareness of identity among Chinese.

3.2.1 THE TERRITORIAL CONSCIOUSNESS

Originated from villages and tribes, the Chinese cities have been dominated by agricultural civilization for thousands of years, during which, land has provided the material foundation for the survival and reproduction of Chinese generations. As a result, Chinese people have attached great importance to the land. As was claimed by Xunzi that “De di zhe sheng, Shi di zhe si” (A man with land could survive while a man without land would die) (Zhou and Yang, 1998, p. 131), the land was regarded as a dispensable component in a Chinese’s life. Moreover as was advocated by Confucians, human beings were an element of the earth (Du, 2004, p. 7). Such strong attachment and obsession to the earth manifested in the philosophy of Confucianism has implied that Chinese has been traditionally possessive towards space and land. As consequence, the strong territorial consciousness would push Chinese to explicitly define their personal realm by physical and visible boundaries, such as walls to enhance their sense of territory (Altman, 1975).

3.2.2 THE INTROVERTED PERSONALITY

“Xu” and “Jing” were firstly proposed by Guanzi as two essential approaches to cultivate a decent and noble personality (Dai, 1996, p. 11). “Jing” referred to the peace and quiet inward state while “Xu” indicated the distance between the inward state and the outside society. In terms of the ideologies of Confucianism, the introverted personality was widely affirmed to acquire the honor and grace via remaining peaceful inner state. Hence, Chinese people have always showed a consistent tendency to isolate themselves from the external turbulent world so as to depend their sense of well-being entirely upon their inward state.

Furthermore, Chinese believed in the positive correlation between “Xu” and their moral characters, meaning that the more distant they were to the external environment, the more quiet the inner state is, and hence the more virtue could be cultivated (Dai, 1996). Therefore, walls and gates have been built in order to increase the physical and psychological distances to push away the outside away from the inside.

3.2.3 THE AWARENESS OF IDENTITY

As an old Chinese proverb says, “Birds of a feather flock together.” The worldview and the value of an individual would be reflected by his social network. Hence one of the core principles for social intercourse in the philosophy of Confucianism was “Those whose courses are different cannot lay plans for one another” (Confucius), meaning that a noble-minded person would merely interact with and build a friendship with those who shared the same aspiration and interests, followed the same moral codes and obtained the same level of education. From the Confucians views, what kind of friends did a person have has revealed who he was. Moreover, considering the introverted personality has resulted in the close social intercourse among neighborhoods within a community instead the wider society, therefore, Chinese people preferred to use physical boundaries to delimit their neighborhood, as well as their social circle to fulfil the awareness of identity.

4 REFLECTIONS AND CONCLUSIONS

The essay has explored the historical development of enclosed settlement patterns in China by looking at four typical models, dating back to the walled residential wards in Tang Dynasty, through to the enclosed work-unit compounds of the socialist era and pervasive and diversified gated communities to date. It has been identified that the contemporary gated communities, though being introduced from Western countries (Wang, 2010), is ubiquitously the continuity of the traditional enclosed settlement pattern which has been

shaped by the deeply rooted Chinese civilization and dominated by the philosophy of Daoism and Confucianism. Moreover three morphological features are remarkable for this morphological continuity identified in the study, which are the persistent tradition of collective living patterns, the introverted courtyard-style housing complex and physical boundaries clearly defined by walls and buildings. This, on the one hand, presents a comprehensive historical and cultural background for understanding the performance and prevalence of gated communities in Chinese cities today; on the other hand, it has manifested the ingrained worldviews and values behind the cultural ideology of walls and courtyards among Chinese. Therefore, these features should be carefully considered, sustained and adapted to show respect to the long history and rich culture in China.

However the discussion of the conservation of certain enclosed characteristics as historical legacy and the alternative ways forward for today's community design should be centered on the interaction between the gated community and the well-being of neighboring public realm in order to promote a more integrated urban form. What are the possible impacts gated communities could bring to the qualities of local public realm, and how could they be mediated by means of physical adjustment to conventional gated community design practices? To answer the intricate questions, two design features have been identified by the author in the reviewing of the entire development process of gated community in China.

Firstly, the gated communities in contemporary Chinese cities have been noticed to manifest a loose grid urban structure which fundamentally resulted from the wide-road-and-large-block pattern in the lengthy feudal empires and the Soviet model of 'super-block and wide-avenue' in socialist era. However the enclosure size should be stipulated and properly regulated in the regulatory plan to reduce the negative impacts of the gated community on the wider surrounding public space. On the one hand, the appropriate scale of enclosure will help to ensure a permeable, accessible and walkable urban districts. On the other hand, neighborhoods with medium or small gated areas could embrace more diverse communities with a variety of prices, housing types, or tenures. With the guidance of appropriate planning and design policies, the whole neighbourhood could be developed into a socially and physically heterogeneous districts, in which, each smaller size gated community remains the homogeneity and expresses the shared interest by the residents within it. Therefore, the careful subdivision of land and relevant policies to control the enclosure size could effectively guide subsequent developments towards a mixed use and heterogeneous urban neighbourhood centered on local public spaces, notwithstanding the presence of gated communities.

Secondly, the boundary is where the gated community encounters the public realm, which demarcates the gated community and the surrounding public realm not only spatially but also functionally in terms of its supporting role in facilitating activities in the adjacent areas (Bobic, 2004). The linear feature has been characterized by a series of the elements including the length, the materials, the frontages, the permeability, and the surveillance conditions, which play a crucial role in promoting and enhancing the interaction between the gated community and its adjacent areas. For instance, the exclusive and hostile wall could be made softer and friendlier by means of lower height, transparent materials or different sorts of plants providing a rich variety of forms and colors (Bobic, 2004). Moreover new development could be framed and defined by building frontages facing outwards which can potentially introduce various activities, which nevertheless, should be accompanied by detailed design with regards to the scale and material of frontage, the accommodated uses and access from the street. In particular, the ground floor façade and uses are crucial in the interaction between the gated community and passers-by (Gehl et al., 2006) Finally, the last potential intervention for the boundaries is to introduce ambiguous space for public uses, such as lakes, public parks, squares, etc., which could not only function as buffer areas between gated communities and the bustling public environment, but also be mutually shared, physically or visually.

All boils down to one point, despite the globally criticized social, spatial and physical challenges and problems in the gated communities with respect to the quality of the neighboring public realm and the local urban area as a whole, these specific patterns in China enjoy particular historical and cultural legacy. Therefore urban designer should carefully sustain the physical structures and characters to respond to the Chinese residing tradition but appropriately "open" the gate via introducing more human-scale enclosed community and much friendlier boundaries to accord with the contemporary urban life style.

1 INTRODUCTION

Following the current trend of global urbanisation and the growing attraction of cities for families with children, urban environments are becoming principal contexts wherein new generation of children will thrive and grow. Though cities were traditionally designed for adults and cars and not children, Zukin (2010) observes an ongoing shift in her book 'The Naked City'. She notes that through gentrification Western cities are experiencing a revaluation of streetscapes through commercial and cultural activities. Boterman and Karsten (2015) have titled this ongoing urban transition as 'the march of city families worldwide'. Examples can be found world-over, in European cities like Paris, Berlin, the Scandinavian capitals and London (Authier & Lehman-Frisch, 2012; Butler, 2003; Karsten, 2013; Lilius, 2014). Not restricted to the west, examples can also be found in countries that are on the rise like India where 41.2 million children under the age of six live in urban spaces. An increase of children in cities comes with rising analytical and policy interest for families with children in urban environments through child friendly cities, and in children's geographies.

Ongoing work on child friendly cities explores and highlights the role of housing, transportation, community networks, play and green, and governance as important prerequisites for living in the city with children. With the expanding reach of children's studies within the social sciences, urban analysis is essential to improve contextual understanding of children's contemporary problems and needs in the city. Particularly the designs of neighbourhoods influences the geographies of everyday life for children, though the neighbourhood is a mere backdrop for many full-time employed and commuting adults (Carroll, Witten, Kearns, & Donovan, 2015). However in neighbourhoods where families settle for example, patterns of varied consumption, activities, and needs are more evident (Karsten, 2013), reflecting an intensive consumption of the city and also new practices of public parenting. Karsten (2014) argues that this transformation goes with the production of a new city. Families as consumers claim their own urban environment through the development of a range of family facilities that can be summarized in three types: child directed facilities, family directed facilities, and child and family friendly public space. Sidewalks are being transformed into places to play and to socialise.

Occupying the outdoors used to be typical working-class behaviour, today has become part of the behaviours of middle-class families. The rise of this family friendly consumption spaces is in part initiated by the families involved, but also by governments, NGO's, and developers. There is also an ongoing push from academia towards policy to encourage family directed consumption spaces within inner cities.

This paper positions the possible learnings for urban planning and design within the creation of child friendly environments. Structured as follows, the first section provides a literature review on planning for

families with children. Following this, context of planning for children in cities in the Netherlands is expanded on. The second section outlines the objectives and methodology used to develop on existing typologies of indicators on three important daily living domains – street, green spaces and play spaces within four neighbourhoods of Eindhoven in the Netherlands. The third section, provides analyses of three important daily living domains – street, green spaces and play spaces - through observations, surveys, workshops and interviews. Discussing the increasing need for family and child directed consumption spaces in city areas. Data from the four neighbourhoods reflects that though there are processes in place that progressively contribute towards the inclusion of changing urban lifestyles, importance of outside play, the concerns on safety, and separation remain high. These concerns can be addressed through planning and design by employing small DIY solutions or larger interventions at the neighbourhoods or/and city level.

2 CHILDREN, PLANNING AND CITIES

Rapid urbanization around the world is now a well-documented trend. This ongoing development has a number of effects including a shifting trend where not only young urban professionals are choosing to move into city- areas, but also families (Boterman, 2012; Bowles, Kotkin, & Giles, 2009; Karsten, 2013). Families moving into or deciding to stay in inner city-areas belong largely to a well-educated middle classes with enough resources to buy themselves an urban family home, and afford daily care of children (Karsten, 2013). It is estimated by the UN that 60 per cent of the world's children will live in cities by the year 2025. What this is indicative of is that for millions of children the contours of their everyday life and experience will be shaped by city environments. This has renewed an interest on children's lives in cities within the fields of social sciences, geography, planning and design (Karsten & Vliet, 2006b; Matthews, 2003; Wridt, 2010). The impacts of these ongoing demographic shifts have initiated a discussion on urban planning discourses for their inclusiveness of family life in cities. These discussions are focused on social and psychological aspects, health, education, and a growing awareness of the role of urban planning and design.

The advantages of city living are many, services, social networks, cultural resources, shorter commutes between work and home, and it is this daily combination of tasks, preferences, and budgets that motivates families to opt for an urban residential location (Hjorthol & Bjornskau, 2005). What this implies for urban planning is (re)defining the nature of planning for families in urban areas. Karsten and Vliet (2006a) for example have identified the lack understanding and recognition by planners of the importance of the local scale in the everyday lives of children and their parents, and plea for more family inclusive policies. With obesity levels increasing and social capital decreasing within children (Niekerk, 2012), themes such as importance of outside play, independent mobility, urban health, are pushing the role that planning can play in the creation of child friendly cities. These foci can be well served by developing an urban understanding of the interdependencies between different dimensions shaping child-friendly spaces and their impacts.

Creating child friendly communities is central to building strong and vital neighbourhoods, cities and regions. Though planning for children is not new, from mid 1940's UNICEF has been advocating for rights of children, creating initiative's such as 'Mayor Defender of Children (1992), 'Child Friendly Cities' (1996), and developing frameworks for defining and developing a Child Friendly City. To facilitate this there is a growing body of research into the development of child friendly communities. While much of this research focuses on addressing challenges within neighbourhoods for children, the research on the role of design and planning tools for improving practices related to child friendly communities is still on the rise. Various initiatives around the world are pushing the conversation on family friendly strategies for inner cities. Examples include, 'Playful City', a non-profit organisation KaBOOM! is dedicated to bringing balanced and active play into the daily lives of all kids, particularly those growing up in poverty in America (Kaboom, 2017), the 'Child and Youth Friendly City Strategy' of Surrey (Canada), is an example of increased policy interest for inclusive design with families. Through community engagement, creation of community spaces, housing choice, youth programming, and community partnerships, planning can be used to bring together various stakeholders.

3 RESEARCH APPROACH

In order to develop insights into the role of planning and design for family friendly cities, the paper analyses three important daily living domains – street, green spaces and play spaces - through observations, surveys, workshops and interviews in the city of Eindhoven (NL). By using environment-focused planning indicators connected to aspects to the built environment, quantitative and qualitative data was collected. Divided into two phases, the first phase consisted of semi-structured interviews and surveys with 204 families living in three inner-city and one suburban neighbourhood, we identified use, challenges, and requirements for families with children under the age of 12. Three of the four neighbourhoods are centrally located within walking/cycling distance of the city centre, and the fourth neighbourhood is served by good public transport connections to the centre. The neighbourhoods were all working households with varying levels of education from middle to high levels, socio-economic status, and gentrification.

The interviews covered, among other topics, housing preferences, play areas, green spaces, daily activities, commute, advantages and disadvantages of having children and living in an urban environment, and mapping activities to point out preferred walking route and locations. The interviews were fully transcribed and the results of the survey collated. The families and parents interviewed used the city and various facilities on a daily basis in various ways, with positive and negative experiences. The interviewees spoke about their daily involvement and experiences, and the transcripts about the city from the perspective of family friendly planning. Results from the four neighbourhoods were compared with each other to identify the best possible neighbourhood to carry out the next phase of the research. Phase two of the work was carried out in a gentrifying inner-city neighbourhood that is facing demographic changes, has active participation from parents of the neighbourhood and schools in the area. We held two intensive workshops for children and parents, at the school and a community centre, to verify challenges and identify methods of possible co-creation to address planning for families. Apart from this, neighbourhood coordinators and policy-makers were interviewed to document current attempts at addressing changing needs and existing initiatives. Finally, we conducted both desk-based studies of literature and policy documents on the initiatives in the city and global responses.

By using the findings, elements for the construction of alternative urban discourses rooted in the daily experiences and challenges can be identified. This paper is a small step in broadening the scope of urban planning discourses in the direction of family friendly cities.

4 THE NETHERLANDS: CENTRAL ROLE OF PLANNING FOR CHILDREN

Cities have always been full of children, and city children have somehow always found outdoor spaces to play in. The rise and decline of play spaces in urban areas can be seen as a metaphor for the changing dynamics of families living in cities. Karsten (2014) describes the historical dynamics of families in cities. At the start of the nineteenth century, streets were the most important space of play for children at the time, but also not the most suitable. Children had to share the streets first with traffic from horses and later by cars and various economic activities taking place on the street. However, this changed dramatically with the success of the private car around 1960 when mass suburbanisation started. The city was seen as overcrowded, unsafe and unhygienic. Families that could afford it left the city to surrounding districts. The suburbs became the child-rearing district of society (Ward, 1977). The Dutch VINEX-policy cemented the wave of families moving to the suburbs.

Following this, extensive urban renewal of Dutch cities resulted in central urban areas becoming increasingly attractive as living spaces. Manufacturing industries, the harbour and other industrial employment in cities are replaced by new forms of clean employment: a service economy, culture and tourism. Cities regained popularity as centres of new employment and possibilities for consumerism and culture (Zukin, 1995), and are becoming hubs for young families as well. With a population of more than 17 million people and still growing, the Netherlands is a densely-populated country, positioned as the twenty-second within density rankings (World Bank, 2017). The Dutch Environmental Assessment Agency (PBL) also highlight that in the following decades three quarters of the population growth will happen predominantly in urban areas (PBL, 2016b). Currently about 75 per cent of the population lives in cities. As a consequence of constant growth and transformation, the built environment of the Netherlands has substantially grown in the last decades and is today characterized by a polycentric urban structure, and as a melting pot of urban cores at relatively short distances from each other.

For a long period, families with children were considered to be a non-typical city household. The years of suburbanization of mostly middle-class families led to the almost 'natural' idea that families do not belong in the city. Households who stayed within the city were often considered to have weak socio-economic positions (Musterd & Ostendorf, 2012). Today we are experiencing a modest countermovement, it is mostly the highly-educated professionals who are increasingly choosing to remain in the city after the birth of their children. The city acts as a magnet for young people, especially when they pursue higher education, progressively finding their first job, housing, and eventually starting a family in the same place. The creation of more single-family housing and child-friendly neighbourhoods in places like Leidsche Rijn (Utrecht), IJburg (Amsterdam), and Ypenburg (The Hague) has enabled families to stay in urban areas (PBL, 2015). Parents are 'reinventing' the city as a place to live (Karsten, 2014).

As a response to and recognising that cities within the Netherlands are 'engines of the economy', in 2015 the Dutch Government launched 'Agenda Stad' (Rijksoverheid, 2015). A national urban agenda to promote economic growth, improve liveability and stimulate innovation in urban areas. As an addition to this agenda the PBL (2016a) published a report titled 'De stad: magneet, roltrap en spons. Bevolkingsontwikkelingen in stad en stadsgewest' (The City as a Magnet, an Escalator and Sponge) where a long-term vision on the population and spatial development is envisioned. This report highlights that there is a renewed interest for living in the city, also among young families. The metaphor of 'the magnet, escalator and sponge' is used to describe the shifting population dynamics in cities and their increasing popularity as places to live and inhabit. Cities also grow as a result of (im)migration, and this cohort belongs to the age group who are just before or in a stage of life where they are looking to have children (CBS, 2017a). This can be seen through the growing number of families with children in the four main cities (Amsterdam, Rotterdam, The Hague, Utrecht) of the Netherlands, while this number is decreasing at the national level. Driven by the large number of people in their twenties and thirties in these cities, more babies are born in these four big cities than the rest of the Netherlands.

Living in the city also has obvious downsides, the lack of affordable family housing being one main deterrent, and the image of space, quietness and green of suburbia influences many parents' decision to leave the city for suburbia (Boterman, 2012). Not for all families however. Various studies have shown that families deliberately choose to live in the city and the trend of young people moving from cities to suburbs once they have a family is slowly changing. Research by Karsten (2007) for example analyses why these households disconnect the seemingly traditional relationship between families and the suburbs. Underlying their settlement choice are identified as, (1) Time and geographical reasons: Residential location is a key factor to combine childcare with paid work, which often takes place in the same city. Not only the location of the workplace is a strong determinant of their residential location, also the broad range of urban cultural activities that the city has to offer; (2) Social embeddedness: The diverse composition of the city provides many opportunities to connect with other people. This can have a mutual benefit for both the parents and the children. Children connect families who live in close proximity, these connections can then develop into supportive communities with the mutual benefits for exchange of assistance and advice; (3) Identification as true urbanites: Families living in cities construct an identity of themselves as resolute families that can deal with negative sides of living in the city. They recognize there are serious considerations for living in the city but define themselves as city people who could not live anywhere else. As Karsten (2007) notes, "the choice of residential location is subject to continual reflection and renegotiation".

Questions however still remain on if the increase of families in cities is a structural or a temporary phenomenon. Boterman and Karsten (2015) expect that this trend of urban families in cities will persist for a while. In particular families with strong cultural capital ties who will want to stay in the city. More so as cities are increasingly becoming tailored towards their lifestyles and preferences. Traditional lines of separation between domains that exclusively belong to adults and exclusively to children are fading. Some neighbourhoods specialize in this kind of environment. In Amsterdam for example this is visible in increasing family consumer patterns. Cafes serve 'babychino' (a child friendly variant of cappuccino), cultural programs in the city made for children (museum activities) stores aimed especially at children are a few examples (Leclaire, 2015). These city neighbourhoods are transforming to welcome the settling of families. It will not be the increasing number of migrants, their birth-rates are shrinking, it is the middle class that bring new children to the city (Boterman, 2012). Other examples include municipal initiatives from the city of Rotterdam, 'Building Blocks for a Child Friendly Rotterdam' or 'Kindvriendelijke bouwblokken', or the development of the Kindlint as a safe route for children that encourages independent mobility through the neighbourhood, connecting the most important facilities like the school, play areas, the park, etc. through visible markers.

5 EMPIRICAL CASES: FOUR NEIGHBOURHOODS IN EINDHOVEN

Eindhoven over the last decade has been increasingly transforming into a city for young adults and families. In 2015, the PBL reported that in the year 2000, the city had an overrepresentation of people in the age groups between 20 to 40. The surrounding region in contrast showed an underrepresentation of this age group. In last years, this disparity between the city and the region is becoming starker, while the city is attracting younger people the surrounding region is aging (Jong, Vriens, & Beets, 2016). The reasoning behind this shift according to PBL is the presence of various higher educational facilities and its growing innovative high-tech cluster. However, there appears to be a growing trend where many students are choosing to move to other regions of the Netherlands once they finish their education. Between 2005 to 2016 we can observe a slight decline within the representation of population group between 20 to 40 years from respectively 32,5% to 31,8% as a percentage of the total population (CBS, 2017b). The same pattern is also visible for children of 0 to 14 years from 15.9% to 14.9% on a city average for the same duration. Eindhoven in this sense is different from the other four large cities in the Netherlands Amsterdam, The Hague, Rotterdam and Utrecht where children between 0 to 14 make up respectively 15.3%, 17.6%, 16.4% and 17.4% of the population (CBS, 2017b). To analyse how the city is responding to the changes in population and need for better child-friendly planning, the research looked at four different neighbourhoods within the city: De Bergen, Blixembosch-Oost, Woensel-West and Lakerlopp. With relatively young populations, three of the four neighbourhoods were inner-city, and one was in the suburbs. The cases were selected based on three factors: Firstly, the social economic status and cultural background of the neighbourhood. This was done on the basis of financial indicators such as the average home value (WOZ-waarde) and the average income per household. Ethnic composition of the population was also considered. Second indicator was the location of the neighbourhood within the city. The four neighbourhoods should reflect the diverse geographical pattern of Eindhoven. One neighbourhood in the city centre was chosen, one neighbourhood within the inner-city ring, one outside of the city ring and one at the edge of the municipal boundaries. Third indicator was the appearance of the neighbourhood and measured with the housing composition and urban morphological type.

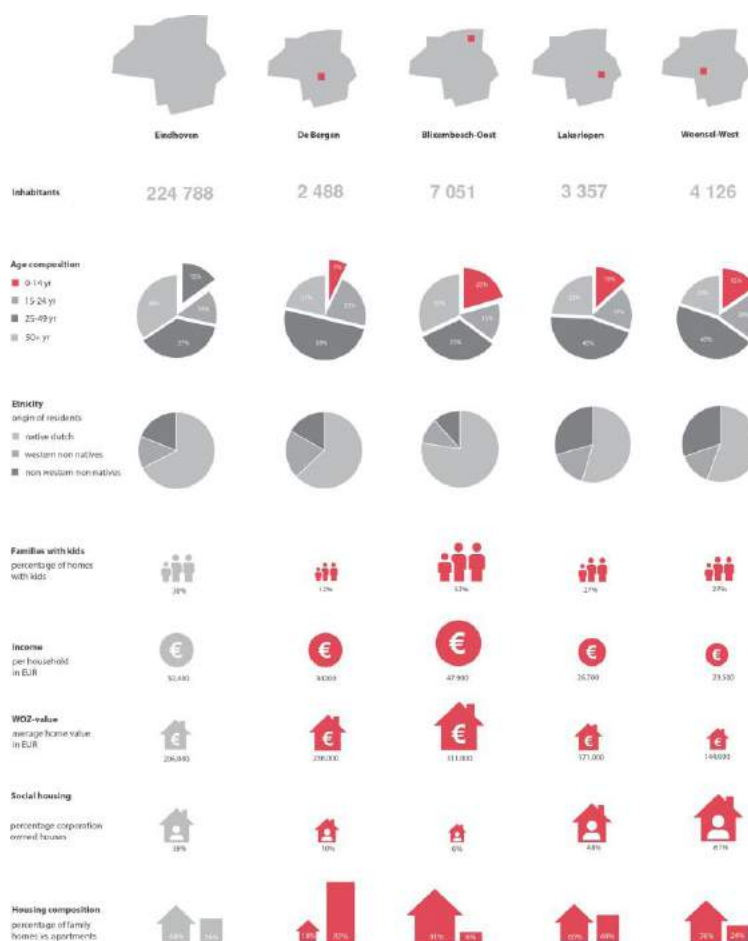

Figure 1: Location and demographic information of the four neighbourhoods. Source: Authors.

6 POSITIONING LEARNINGS IN CONTEXT

Based on the findings from the quantitative and qualitative data from the four neighbourhoods, we can position specific learnings and challenges of the neighbourhood along certain thematic lines. With the help of indicators based on the urban environment and systematic methods of data collection, cities can assess their levels of addressing child friendly planning and understand the changes over time.

6.1 STREETS AND PERCEIVED SAFETY LEVELS

Despite the various measures taken for street safety within all the four neighbourhoods, perceived safety in the street is low in all of them. In three out of the four neighbourhoods (De Bergen, Woensel-West, Lakerloper) more than half of the parents admit that they do not find the streets safe for their children to play in. A recurring observation was the number of cars on the street and the attitude of the drivers, apart from these, reasons such as speeding cyclists in De Bergen to bad visibility in the streets of Blixembosch-Oost deter parents from encouraging their children to play outside. While some parents are able to cope with this and appeal to common sense, like this parent in Lakerloper, "...don't do stupid things, then it's safe", for most parents this is not the case. Interestingly, in De Bergen children were even less satisfied with their safety than their parents. Of the children who participated in the intensive workshop within the neighbourhood only one third of the children found the street safe to play in, but half of the children said they do regularly play in the street (responses were a mix of personal and parents' choice).

Of all the four neighbourhoods, Blixembosch-Oost was the neighbourhood where parents considered the streets most safe. Blixembosch-Oost, a suburban VINEX neighbourhood, consists mainly of access roads that also have a low intensity of use. Although traffic safety remains a challenge, two third of the parents were satisfied in this neighbourhood with regards to safety. One parent answered, "as a mother I am not satisfied, but in comparison to other neighbourhoods, then yes I am. If I had to give it a grade, it would be a seven (out of 10 ed.)". Though levels of perceived safety were quite high, play activities in this neighbourhood do not take place on the street but more within assigned play areas (e.g. playgrounds). The abundance of play facilities around the neighbourhood appears to deter from playing on the streets.

Parents from De Bergen on the other hand were concerned about the speed of traffic, and when asked on how improve this situation, all pointed towards traffic calming and more safety: "Make the neighbourhood car-free, make the bike lanes safer and provide less parking for tourists." One of the parents mentioned speeding cars that crashed into people's home. Others stressed on creating better signages and control. Though it was not only traffic related reasons that contributed to lower perceived safety levels. Social and environmental factors were also associated with a lower perceived neighbourhood safety. In line with earlier research 'stranger danger' appears to be causes of parental anxiety in relation to their children's safety in the neighbourhood (Carver et al, 2008). Findings from this research follow the same pattern. Examples include the presence of homeless people in De Bergen and (activities related to) prostitution and drug abuse in Woensel- West. Not only adults contribute to an unsafe feeling where also older peers of the children (teenagers) appear to be a reason to avoid certain places as the workshop in De Bergen showed.

The perceived safety levels can also be related to the popularity of walking around the neighbourhood. The findings show that Woensel-West is considerably the least popular neighbourhood to walk in. Respondents say that the situation has improved from previous years though some parents generally do not let their children walk or play around the neighbourhood unsupervised. Parents generally check up on them after some time or make agreements on how far the kids can go, one example being "the kids walk on the streets by themselves. I let them walk to the playscapes sometimes, but after a few minutes I will check if he is alright". De Bergen and Blixembosch-Oost are considerably more popular neighbourhoods to walk in, with Blixembosch-Oost being praised generally for its safety and social control.

6.2 DESIGNATED PLAY VERSUS UNDESIGNATED PLAY

The importance of outside play has been stressed in the literature ranging from health to children's geography (Aarts, Wendel-Vos, Oers, Goor, & Schuit, 2010; Christian et al., 2015; Hinkley, Crawford, Salmon, Okely, & Hesketh, 2008; Vries & Veenendaal, 2012). Within our research, we found that the

majority of children play outside every day, and that they play mostly in designated play areas i.e. places of organized play (such as the playground, sports field, schoolyard, park) rather than undesignated playing areas (such as streets or side walks).

The ample availability of designated play areas in all the four neighbourhoods can be identified as the primary reasons for this behaviour. We should note here that though designated areas are easy to identify visually and spatially, undesignated playing areas are more difficult to determine. More so as these spaces cannot be identified through analysis and observation alone, and need input from children and/ or parents to point out where else play happens. Between the four neighbourhoods, designated outside play was most evident in Blixembosch-Oost and undesignated play areas were most evident in De Bergen.

The number of designated playgrounds in Blixembosch-Oost (almost double when compared to the others) appears to encourage playing outside. Though a number of parents complained about the quality of playgrounds and that there weren't enough spaces tailored for older children. "We need more for teenagers, all playgrounds are for little children. And I see teenagers hanging around the playgrounds", says one parent of two children under the age of ten. Parents appeared largely satisfied with the quality and number of available facilities. Other observations included the need for variety of playgrounds, natural, sport, and creating more attractive play and activity spaces (urban farms for example). In comparison to Blixembosch-Oost, quarter of outside play in Woensel-West happens on the streets. It is also the neighbourhood (along with Lakerloper) that has been identified as a transition neighbourhood, and is also the most diverse in population. Woensel-West is also the only neighbourhood in the city where the Kindlint was introduced to provide a safe route for children through the neighbourhood connecting school, playgrounds, and the park (Wassenberg & Milder, 2008). Based on a workshop with elementary school children in the neighbourhood about the Kindlint showed that the children are yet to grasp the meaning or knowledge of the various safety elements along the route (e.g. posts for a safe crossing). Interestingly, the children indicated various elements along the route - designated or not - as places for play. Though levels of perceived safety were low, children were still allowed to play on the streets, more so as the number of designated play spaces were also the lowest.

Between all the four neighbourhoods, parents emphasised the need for more centralized and diverse play spaces, and improvements of the playing environment. Like a participant in Woensel-West said: "I want the play areas to be bigger and more together. Not one piece of play-equipment on every street, but a bigger dedicated place where not only children but also parents can gather". A common observation was the absence of activities for parents or waiting spaces while the children played in designated spaces. It was also striking that all the answers about improvements were about designated play areas and nothing was mentioned about adapting undesignated play areas. One of the advantages of undesignated play spaces is the accessibility for all children (Wilson, 2012). The workshop with children in De Bergen revealed children indeed appreciated undesignated play areas because it's close to their home, especially when designated play areas can be more difficult to reach. Moreover, children temporary own and imagine these spaces, encouraging a large variety of play themes: what game can I play here? (Frost, 1992). Car-parks that are accessed by placing a brick under the garage doors, some appropriation of sidewalks and private courtyards (e.g. Bourbonhof in De Bergen) are very popular to name a few. As streets are considered unsafe by children in De Bergen, a private courtyard of a gated community appears to be a popular alternative to cope with the capricious city environment.

Of the interviewed children in De Bergen, there was also a big difference in preference of play spaces between genders. Girls are much more negative about the place and name bad maintenance as a deterrent to play, variety of play equipment and the threat of older teenagers are other nuisances pointed out. Boys would like to see improvements on the maintenance of the soccer field, and additions of more sport facilities. Interestingly they both point out that more attention needs to be paid to diversity of ages within the neighbourhood.

6.3 URBAN GREEN SPACES

Urban green spaces (UGS) over the past years have become central to a number of research themes, sustainability, physical health, mental health and safety (Barrera, Reyes-Paecke, & Banzhaf, 2016). Studies show that accessibility to and the presence of green attracts play, which is important for physical, social and cognitive development of young children (Amoly et al., 2014; Louv, 2005). Children's access to

local child-friendly environments, including green spaces, contributes to sustainable development in several ways, like diminished car transportation and support for children's healthy development, physically active free play and concern for the environment (Jansson, Sundevall, & Wales, 2016).

The issue of accessibility to UGS is one of the crucial aspects of sustainable urban planning and it is linked to the growing concern on the wellbeing of urban population, particularly in children (Gupta, Roy, Luthra, Maithani, & Mahavir, 2016). Studies from the perspective of the child on the design of urban green spaces show that children felt that the management of their local environments was not adapted to their preferences (Roe, 2006). This appears to be the case for Eindhoven as well in terms of use and accessibility of urban green spaces. While the data was collected independently for play and green, in practice however they are closely related to each other. The embedding of playgrounds in green areas, green spaces often provides opportunities for play (natural playground) or just an informal patch of green in front or back of the house.

Within the inner-city neighbourhood of De Bergen, the park is the most visited greenscape for play according to findings from the children's workshop. This was confirmed by the data from the survey with the parents. Remarkably, this park has no specific play facilities for children. The children invent their own games or make creative use of what is already there, like using an art object as a playset to climb on. The design of the Anne Frankplantsoen (De Bergen's city park) and its enclosed character also provides possibilities for informal group play, like hide and go seek for example. During the workshop, an eight-year-old girl described how through their own imagination she created a park that was the exclusive domain of the children. This description fits in line with the research that shows that play in a natural environment is more varied than play in non-natural play spaces. Play in natural environments is also more sensational, explorative and constructive (Berg, Koenis, & Berg, 2007). Natural playgrounds, like the ones that can be found in Blixembosch-Oost, are especially suitable for this.

Blixembosch-Oost is the neighbourhood with the most greenery from the cases researched. Because of its suburban character, it has the highest volume of private gardens, which also contributes to the green character of the neighbourhood. At the same time Blixembosch-Oost has the least amount of solely aesthetically purposed green. Most greenery in Blixembosch-Oost has a double function as it is a playground as well as a grass field for aesthetic purposes. This doubling of function translates to a high quantity of different play opportunities in this neighbourhood. This quantity and quality of green also appears to contribute to the high rate of outdoor play in designated spaces in Blixembosch-Oost.

With the other neighbourhoods researched, quality and access to green was much lower. A number of parents raised this issue including a parent in Lakerloper: "A larger park would be nice, there are a large number small green patches in the neighbourhood, but still a single large one would be nicer". Parents also gave examples of what they would like in terms of greening streets and addition of play spaces. Findings of the workshop also highlighted importance of greening schoolyards. These findings fit in the line with a push towards increasing green Dutch schoolyards (NOS, 2017).

6.4 IMPACTS AND ROLE OF THE SOCIO-CULTURAL ENVIRONMENT

Within a community, the physical (built and natural) environment cannot be detached from social, economic, and political realities of the neighbourhood. While the role of the physical environment is central to the wellbeing of children, from the need for walking and cycling facilities to the preservation of green space, social and cultural features also shape behaviours and permeate into activities. Though contestations exist within research on parental values between high, middle and lower class families on raising children, the difference between access to activities and amenities was evident through this work. Between the four neighbourhoods studied, it is relatively easy to demarcate lower class and upper-middle class families. Families belonging to the lower-middle classes are neither rich nor poor, though have limited to medium resources (cultural and economic capital). The relatively rich neighbourhood of Blixembosch-Oost appears to have very different forms of activities and capital in comparison to Woensel-West or Lakerloper. With diverse immigrant status ranging from Turkish, Moroccan, other African and Asian backgrounds, Woensel-West and Lakerloper typify a very visible generational upward mobility of migrant families. The gentrifying De Bergen is a neighbourhood composed of a well-educated upper-middle class families where almost all have a native or highly skilled immigrant background.

Given the diversity in the spatial layouts and demographic composition of these neighbourhoods, it is noteworthy, that the parents were generally satisfied with the wide range of social services in the neighbourhood and the quality of the social environment. Not restricted to social capital of residents, parents with children feel most welcome to local business in Blixembosch-Oost, and value the friendly environment of semi-private and commercial spaces within the neighbourhood. An interesting observation is found in De Bergen, where semi-private and commercial spaces are considered least inviting children. Although there are some very positively rated commercial spaces (e.g. those especially aimed towards children), residents identify the conflict of interest between the commercial (restaurants, bars etc.) and the living areas as an issue of future improvement. While commercial activities formerly exclusively belonged to adults, parents note that lines between adult and child oriented spaces are fading.

As one of the more affluent neighbourhoods in the city, within the four-researched neighbourhood Blixembosch-Oost also has the most number of private and commercial activities available for children organised through neighbourhood organisation. Blixemkids, one such example, is a group of volunteers organising activities for children, an interviewee expands: "We celebrate for example Sinterklaas, and on National play day Blixemkids brings waterslides, inflatable bouncers and more". Although positive, multiple interviewees identified the importance of (and absence of) mixture of people with different backgrounds: "We think the culture of the people in this neighbourhood is 'too white'. Nowadays we live in a multicultural society and I want my children to grow up knowing this multicultural society".

In contrast to Lakerloper, where activities for children are not as common ("there are a few activities, but they're organised just once a year", says one parent) and support groups for parents are less known or even wanted. A parent who is aware of such activities highlights "There is a support group for parents at the elementary school, but we don't go or need that". Based on the small sample size here it is hard to position the reason behind this. Similarly, low levels of participation can be observed within activities organised by the neighbourhood association, where turnouts are low. One of the interviewee observed that the organization itself, and therefore the activities, might be a bit outdated since there are only seniors on board. In line with Bell et al (2008), who underpins the importance of a varied group of citizens participating in for example community groups, and the need for feeling of ownership to the success of any participation process. By far the most diverse neighbourhood within the study, Woensel-West has been successful in banding together to realise the Kindlint, and organise various community activities. The diversity of this neighbourhood, also lead parents to comment on the need for more inter-communal activities. "...add more common activities for different groups, promote more mixing of people or children with different backgrounds", says one parent. Some parents raised concerns on the presence of the red-light district close by, and other noted that the differences in socio-economic status implied variance in access to amenities. "While they have the means to access services and special care, not all families have that ability (lower income, lesser social networks). Also, improvement of (mis)communication between people in the neighbourhood through lack of Dutch language comprehension", is a noteworthy example of the differences between the four neighbourhoods.

Interestingly, De Bergen, also a neighbourhood in transition attracting skilled and affluent native and international workers, has been successful in encouraging various co-creative initiatives for child-friendly environments. Reflecting on the active involvement of its residents and civil society organisations, Stadstuin de Bergen located in the heart of de Bergen is one such example. The aim of the resident led initiative is to transform a decayed parking space and playground through greening activities into an environment that facilitates interaction between residents, children, and civil organizations such as a home for veterans and social day care facilities for disabled people. The initiative is supported though municipal funding, but also in kind by the various neighborhood organizations and local entrepreneurs.

7 CONCLUSIONS AND RECOMMENDATIONS

The results of this research from four neighborhoods in Eindhoven on child friendly spaces both confirm patterns of consumption and use as reported in literature, but also add new insights for urban design. It is useful here to distinguish between the following, role of urban planning and design can play in highlighting the importance of children's geographies, the levels of possible interventions, bottom up and top-down, and accommodating for changing demographics in cities. The role that urban planning and design can play in highlighting the validity and agency of children's geography in planning processes is vital within the changing profile of cities. This can be seen through the issues raised on repeated concerns regarding

safety, awareness, maintenance, and more family friendly spaces, which can be addressed at various scales and levels of interventions as seen below through selected examples.

Level of recommendation	Concern addressed through possible interventions
Micro: The smallest level of intervention possible	
Playful street furniture	Streets are potential places for children to learn and play. Research identifies adding urban furniture around the neighborhood could facilitate observing children at play. Adding a bench between the street and home can have two functions, a buffer between private and public spaces, and increase opportunities to connect with neighbors and other children.
Sidewalk games	Outside play is not restricted to designated play spaces only, but should extend to public space at large. Playing games on the sidewalk encourages more types of social play, introduces a larger variety of play themes, and increases social interaction. Sidewalks also provides access to all children to use it as a play space.
Street green	Literature shows that the design and management of urban green does not always reflect the needs and preferences of children. Underlining this, neighborhoods resident's plea for small scale greening. The importance of turning hard gray urban spaces to softer, natural aesthetics is vital and can also help with rainwater drainage.
Climbable objects	Any object can become an element to scramble up on: a piece of art in the park, some steel objects on the sidewalk, a tree. For children, climbing on objects is more than just fun. Scaling an object teaches them vital lessons, such as dexterity, risk assessment, focus and planning. They have to decide how high they're comfortable to climb and find the best way to get there.
Alternating pavements	Traffic safety and awareness levels can be addressed in many ways, one of the easier DIY solutions is creating awareness through design interventions. Informal demarcations are a subtle but clear way to mark different zones of ownership or use of space through alternating tile patterns, using colors within pavements etc.
Temporary street closure	Streets safety is a repeated concern for families in urban areas. A temporary solution is the closure of a street for a day (once a month for example) to create a play-street. Due to its temporary nature residents can be stimulated to create a festive day to set an example for alternate possibilities.
Natural play areas	Children's access to local green spaces supports healthy development, physically active free play and awareness for the environment. Natural play areas are more suitable for different age groups and offer another type of play-space and meeting space. Creating softer alternatives to urban landscapes.
Shared space	A recurring observation in the research is the number of cars on the street and the attitude of the drivers. When streets are not considered safe to play in, less play happens on streets. One way to increase safety levels and at the same time improve the walkability streets is through the introduction of shared space.
Narrowing: visual and physical	The attitude of drivers is an important determinant when trying to improve traffic safety. Physically and visually narrowing the street can help to reduce the speed of drivers.
Lighting	Adding better street and floor lighting is a solution that can have immediate effect. Through the use of adaptive and LED lighting, neighbourhoods can create special atmospheres, and increase safety. One could also think of creating an illuminated path (with various colours) along the child route, resulting in a pleasant route by day and night.
Maintenance and awareness	Concerns related to dirty and depreciated play equipment, pet feces in play spaces, old sidewalks and general neglect of play equipment and play spaces can be deterrents to play. Clean streets, attractive open and green spaces, well maintained signs, buildings, and roads all contribute to high spatial qualities of a neighborhood.
Flexible schoolyard	Schoolyards are locations that are only used at certain times of the day and mostly only during weekdays. School yards have a potential to become much more than just a playground during school hours. For example, they can be opened up for bringing and dropping children at school, play spaces in the weekend, etc.
Meso: An intermediate level of interventions at the district or neighborhood level	
Multiple use of spaces	Schoolyards are locations that are only used at certain times of the day and mostly only during weekdays. School yards have a potential to become much more than just playgrounds during school hours. For example, they can be opened up for bringing and dropping of kids at school, play spaces in the weekend, etc.
Neighbourhood child route	Cities are growing in attraction for families with children, renewing interests in child geographies. Cities are now responding to this growing trend by actively looking at family friendly developments. Though there is a long way to go to create family friendly cities, incremental shifts can create more awareness.
Macro: The highest and the most complex level of intervention at the city level	
Encouraging child participation	Children are often overlooked when it comes to decision making. Adults decide for children what needs to be done or how it should look like. The rich local knowledge of children and families often remains an untapped source of information.
Family friendly city strategy	A family friendly strategy starts with various public and private stakeholders; governments, developers, NGO's, residents. Rotterdam (NL) is a successful example in developing and evaluating Child Friendly Cities, by adopting 'child friendliness' as a valuable urban planning tool to design a livable, sustainable city.

In the context of the Netherlands where increasing institutionalization is visible in a number of cities, Amsterdam, Rotterdam etc., the importance of children's geography in planning and design is growing. However, these forms of institutionalization need to be balanced between top-down and bottom-up approaches. With growing diversity in urban areas, cities and planning needs to develop mechanisms through which the interests of young children and families are better represented and articulated within planning and design.

1 INTRODUCTION - A RELEVANT RESEARCH QUESTION?

In spite of its 'youth', Public Space theory is now facing recognition of its role in space production of contemporary urbanity. However, public spaces' conventions (naming, codes, laws, rules, standards...) generally are not referred to by the needs they cover, neither by the services they provide, but as 'qualities and attributes' those spaces must possess. This practice leads to a notion of public space based on 'exceptionality' and on quality perception prevalence, rather than relational and organizational factors related to its production, use and meaning. So while awareness of Public Space has positive effects on available resources, mainstream concepts are narrowing representation of public space values.

This is the knowledge deficit that PSSS research aims to tackle: to give conceptual primacy to needs public space must satisfy, requiring a critical analysis of space production processes (both of its hardware and its software) and leading us to a model focused on service, on the public value it involves and on the systemic way it is organized. For this purpose PSSS – Public Space's Service System (an interdisciplinary research project led by IST - Lisbon University, with Oporto and Barcelona Universities' urban research centres) aims to develop new concepts and tools to foster awareness of public space service value. We shall offer an integrated assessment methodology – through literature review, study of public space production and its interdisciplinary framework, case-study presentation and stakeholders' interaction.

So we need to agree upon theory, naming relevant questions or problems, so as to allow a discussion on physical and cultural contexts with relevant urban diversity trends: What are the current motivations for public space production? What approach is needed to 'translate' those motivations into notions of public space service, and its values, as a part of urban systems?

2 A SHORT REVIEW ON PUBLIC SPACE AND ITS THEORY

If Urban Design 'geographies' show relevant and globally spreading conceptual diversity, its 'history' is still a short story of last decades of public space observations and assessments, with ongoing discussion. Final outcome need theoretical 'refurbishing' to understand space production: its economic, social, morphological and ideological components, with different interpretation of public space return values.

During CIAM crisis of the 50s to 60s, Jose Luis Sert's activity at Harvard University showed opportunities for new reflections on recently coined Urban Design matters. Studies from pre-World War II attempts out of architecture field (Chicago progressive sociologists), until post-war approaches of Sert and Giedion launching centrality's theme (Sert, 1952), and in the sixties the new critical generation of 'Team 10', showed that Urban Design opportunities would come through Modern Movement criticism and not just from trading between architects, landscapers and planners' disciplinary gatekeeping.

Lynch (1960), Jane Jacobs (1961) and first followers, such as Alexander (1965), Gehl (1971), Leslie Martin (1972), Whyte (1980), Appleyard (1981) and others observation on urban life and peoples' perceptions of outdoor activities, led to the revalorization of streets and street life as a major urban structuring element. In that turning point, different theoretical inspirations led many towards a nostalgic reaction to functionalism: on the one hand by returning to European architectural historicism references (Krier, 1984; Rossi, 1966), on the other hand moving towards new ecological and environmental psychology concerns on spatial character and contexts (Cullen, 1961; McHarg, 1969; Norberg-Schulz, 1980). In Urban Design practice a line of thought came to light with diversity – in some cases, with nostalgic conservative agendas, such as "New Urbanism", influenced public awareness about Public Space.

With socio-geographic theoretical base for urban globalization critics, coming from Harvey (1990), Sennet (1992), Zukin (1995) and others mostly in USA, were promoted new reflections on public space economic and social contradictions. In Europe, structural lines of thought from Lefebvre's "Production de l'Espace" (1974), and Castells' "Information society" (1989), to Ascher's "Metapolis" (1995), gave a structuring sense to new theories on Public Space and on urban value global theory. Connections between theory, practice and politics converged in new policy actions under European left governments, at the end of the 20th century, such as in Barcelona's transformation for '92 Olympics (Bohigas, 1985; Borja, 2003) or, in the UK with Urban Renaissance (Urban Task Force, 1999 under Rogers coordination) and CAFE (2001, 2006).

For the purpose of PSSS and the understanding of different interpretations of "what is Public in space", we may recall two state of the art reflexive inputs, leading our work and our research questions:

"In this «American» model of public space, the ideal city no longer influences the real city. Instead, the stores, entertainment complexes and art museums that are important interventions in public spaces are shaping an ideal city based on consumption (...) the projects of «public space» people talk about – without irony- include growing numbers of coffee bars, «Disneyfied» streets, and large interior shopping complexes that provide attempt to provide an overarching spatial metaphor for social identity." (Zukin, 1998)

"El espacio público nos interesa principalmente por dos razones. En primer lugar porque es donde se manifiestan muchas veces con más fuerza la crisis de la «ciudad» y de la «urbanidad»" (y del urbanismo?) "Y en segundo lugar porque las nuevas realidades urbanas, especialmente las que se dan en los márgenes de la ciudad existente, plantean unos retos novedosos al espacio público: (...) las nuevas centralidades y la fuerza de las distancias que parecen imponerse a los intentos de dar continuidad formal e simbólica a los espacios públicos" (Borja & Muxí, 2003)

Figure 1 - Barcelona's transformation, by public space production. In the 1980's and 90's Barcelona is a reference for urban regeneration projects (Source: Archivo Fotográfico de Barcelona)

3 PUBLIC SPACE PRODUCTION - DEFINITION AND MOTIVES

If Public Space itself is rendered as a subject of quality perception, we may ask: are spaces quality perception the same everywhere? Do we really know how to define it? Is it self-defined, as a motivation?

The fact is that twenty years after publishing "The Image of the City" (1960) Kevin Lynch made something rare in urban theory by putting under suspicion the concept of "spatial quality perception" he himself had launched twenty years before: "Enquiry sample size being too small(...)" he asked:

1. "What was not foreseen, however, was that this study, whose principal aim was to urge on designers the necessity of consulting those who live in a place, had at first a diametrical opposite result... professionals were imposing their own views and values on those they served."
2. Method had no sense of development dynamics in it... On how perceptions might change in future based on experience, or on cities modification. This fed the designers' illusion: "that a

building or a city is something that is created in one act, then to endure forever” (...) mistaken as a matter of value.

3. “Interesting as this work is, it labors under the difficulty that places are not languages: their primary function is not the communication of meaning”. If they can be considered not only as a silent discourse on the past... in their own nature... meaning could bring to richer results.
4. “Last, perhaps I would criticize our original studies because they have proved so difficult to apply to actual public policy (...) to change the way in which cities were shaped (...) True city design -, dealing directly (...) in collaboration with the people who sense it – hardly exists today”. (Lynch, 1984).

More than 30 years after (until now), this honest intellectual reflection is still passing by more or less ‘incognito’, while all the rising interest on Urban Design and public space projects production all over the world, has been growing without a credible Public Space assessment being done.

Nowadays it seems that ‘spatial quality’ and ‘vibrant urban environments’ are representation for the same globally desired urban lifestyle (UN-Habitat, 2015). In fact, a high percentage of urban design motivations call for the same attributes for leisure, tourism and cultural use, soft mobility or pleasant landscaping contexts, with a tone in management, more and more based on consumption models. These actions have been somehow ‘translated’ from global affluent real-estate market, images of ‘quality of life’ are reproduced everywhere with narrowing ‘colonized’ representations of space values’ criteria. In this direction, public resources are invested in public spaces, focused on image and fostering economic value of urban leisure spatial types (touristic historic styled places, waterfronts, iconic cultural or commercial developments).

Figure 2 - Ronda Litoral and Port Olímpic, Barcelona (Source: Archivo Fotográfico de Barcelona)

In Barcelona's '92 Olympics, besides the event promotion itself, the main goal was to develop in a short period of time, a new centrality's space system – where public space as an urban recipe is the basic feature continuity of leisure activities, street life, public Art, consumption centres, waterfronts, new urban parks, etc., meeting a larger rank of objectives including new infra-structuring system's and maybe landscape adjustments' updating strategies (Figure 2).

Not far in time and space, in Portugal, a specific turning point can be traced down to Lisbon's EXPO1998 World Exhibition project, where issues as environment, quality of life, public space and leisure were being targeted by policies and design actions, from central and local governments. Connected to a cycle of economic growth and large public investments, symbolic relevance as paradigm of “new Portuguese society” the event marketing theme was Portuguese discoveries (Figure 3).

Figure 3 - Parque das Nações, former EXPO '98 area. Lisbon. (Source: Ana Brandão 2009)

Visibility and success of these events had important spill-overs not only by setting new standards for urban transformations and public space, but also by generating urban values (Brandão, 2006) several public investments (and also private operations) disseminated the new paradigm over both countries. In Portuguese cities, cases like POLIS and PROCOM programs, supported dozens of urban projects, in historic central areas, waterfronts, urban parks and leisure facilities, with important political components of central and local government, and stakeholders demands for images of public space 'quality' (MAOTDR, 2007).

Whatever the scale, aesthetics and model's dynamics may be, we may even consider it familiar looking at Dubai's instantly coming from nothing (Figure 4) to a global leisure-consumer centre, and in many other places worldwide, with similar approaches in space production - where 'space quality factors' (liveability, vitality, vibrant, attractive, delightful, distinctiveness, ...) are presented as the means to explain anything anywhere as space 'imagery', and still running to fame... when global urban images are selling ok.

Figure 4 - Waterfront sidewalk in Dubai (Source: travel4all.org)

Truth is, however, that not all urban contexts and spaces respond easily (or adequately) to standards or desires of so called 'qualities'. For instance, in disperse or more peripheral areas – suburbs, peri-urban spaces, the diffuse city – there is a larger diversity and superposition of dynamics that do not typically correspond to clear paradigmatic urban models or recipes: "fragmented and discontinuous urban form is the result of a layered urban landscape with a big variety of urban patterns"(Valle & Travasso, 2014).

What is the need for (and what kind of problems are posed by) public spaces as founding elements of urbanity in these areas? (Figure 5)

Figure 5 - Urban dispersal in the northwest Portugal (Source: Filipe Jorge)

This is a relevant question that current planning instruments, research production and design knowledge are not solving. Several European recent policy's initiatives on urban regeneration are leaning on institutional programs and planning logics, using Public Space as the main ground to conduct transformations and deliver valued benefits. Despite these strategy, it is not uncommon that these actions focus on isolated units or segmental goals (air and noise control, energy saving, environmental risks, etc.) supported on legal legitimations, more than true effects on valued public benefits that may be related to funding sources, management structures, stakeholders' action, or a policy trends favouring appealing urban areas.

Frequently, Public Spaces lack integration with other urban systems to provide sustainability and social, cultural or economic returns and we acknowledge weakness in social cohesion, economic activity, basic landscape promotion, due to poor evidence of networks structure. Meanwhile there is growing interest on systemic approaches to urban problems – especially in relation to ecological and infrastructural aspects of urban spaces connection. Considering that such policy issues still remain apart from each other, it is obvious that new Public Space production needs an integration concept - as a public space services system.

If we broaden our perspective about public spaces of contemporary urbanity, we may find that it should no longer be restricted to a feature of urban life based on traditional city spatial references. Some programs are now understood within urban changes: increasing mobility, social and economic connectivity, new 'time typologies' (24h spaces, shared spaces...) of heterogeneous and conflicting characteristics.

Public space production is now embedded in all urban dynamics and requires interdisciplinary and integrated approaches: "What is clear is that contemporary trends in public space design and management are resulting (over time) in an increasingly complex range of public space types" (Carmona, 2010). Once Urban Design has recognition as an interdisciplinary area of urban knowledge and action, the time has come for deeper collaborative reflections on Public Space and new questions to ourselves:

- What is public and what is public in space? Isn't it public to serve public deeds?
- What is its service or benefits to the public? Is it connected to common needs?
- Is Public Space organized by design styling units? Or as a system of public service?
- Can we define service needs by design goals? In different and changing urban contexts?
- What defines a public space service system? And how to define its value or values' service?
- How do kinds of space services express kinds of value? Is there a taxonomy of urban values?

4 VALUE OR VALUES: WHAT IS VALUED IN PUBLIC SPACE?

Much of public investment, supported by a notion of Public Space benefits, is based on affluent leisure enjoyment in connection to representations of “happy lifestyle”, fostering natural or cultural “styles of life”, identity and even wishful thinking. More often in peripheral urban settlements, desires for urban self-representations are expressed in roundabouts, entrances and other visible locations with ‘works of art’, referring to concepts of value, added to commercial activities and real estate surroundings, “plaza” types of public spaces. But what are today’s mainstream Public Space values’ assessment focusing on? Do they regard ‘public values’, or just qualities of space’ marketability, as commodities with ‘exchange value’?

Many studies on interaction of people with spaces have as a starting question “What attracts people?”. As the questions’ motive is to understand users’ options, to identify reasons why some spaces are used and others aren’t, meaning ‘what works and what doesn’t’ (Carr, Francis, G.Rivlin, & M. Stone, 1992; Gehl, 2010; Whyte, 1980). These approaches may use simple tools and methods to answer basic questions about space frequency, like “How many?”, “Where?”, and “For how long?”. They rely on the sense of observers’ judgment, to address setting’s complexity and simultaneous activities, using techniques such as direct observation, mapping users’ activities and behaviours, complemented with interviews and a direct involvement in space’s activities (Gehl & Svarre, 2013).

Other assessment methodologies, developed for community’s users, intend to raise awareness of public space issues and demonstrate how to address them. They are mainly based on on-site diagnostic tools that gather perceptions to initiate a constructive debate between diverse actors. Confrontation between different perspectives allows to identify problems and seek improvements to be introduced into spaces (CABE, 2007; Cowan, 2001; Project for Public Spaces, 2000). More specific research analyses urban design quality effects in space performance and value generation translated into benefits (CABE, 2001; McIndoe et al., 2005). This idea, that space generates values, is developed by distinguishing positive effects that may arise as a sum-up of diverse (contradictory?) values, like use value, image value, social value, environmental value, cultural value and so on (CABE, 2006).

Finally, approaches focused on design process and space management aim to incorporate aesthetic objectives with economic requirements and users’ preferences. These methods combine guidelines and project recommendations with qualitative assessments regarding space’s success, highlighting the engagement of different stakeholders, especially users (Brandão, Águas, & Carrelo, 2002; Marcus & Francis, 1998).

In general, evaluation of public space is based on features and assets normative (usually quite extensive) that a successful public space must have or provide, identifying a set of “universal” positive qualities for public spaces (Carmona, Magalhães, & Hammond, 2008): clean and tidy; accessible; attractive; comfortable; inclusive; vital and viable; functional; distinctive; safe and secure; robust; green and unpolluted; fulfilling with the premise that a higher quality space has them all. Although these attributes may express ‘qualities’ that a space must satisfy, it is not easy to identify them as evaluation issues, nor to dissociate them from urban, social, environmental, economic, or other contexts they integrate (Khan, Moulaert, Schreurs, & Miciukiewicz, 2014).

Mainstream ‘state of the art’ assessment of Public Spaces seems now inadequate, with the use of flue expressions ‘place making’ and ‘place pride’ as kinds of tools, while a service fields criteria is missing in assessments models. PSSS tools for upraising Public Space Service shall be considered in three service types:

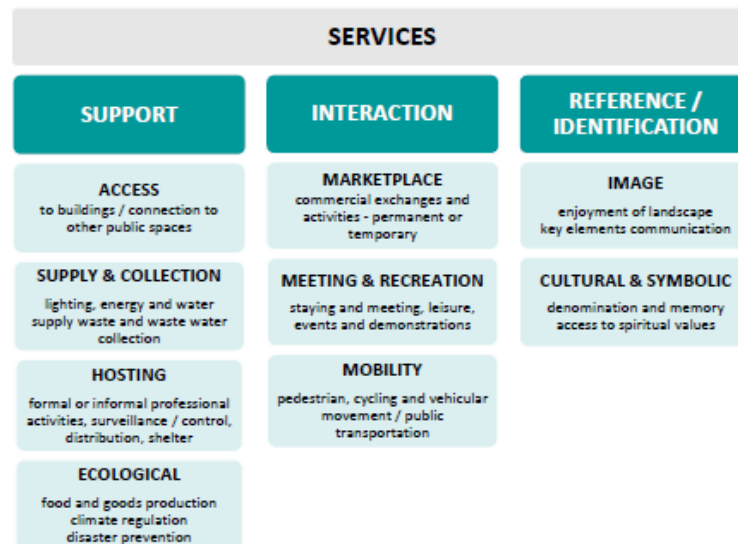

Figure 6 - Public Space Services. Organization in progress (Source: PSSS, 2017)

5 A SERVICE FOCUSED SYSTEM - TO CLEAR EPISTEMIC TROUBLES?

Several epistemic clarifications are needed, as cultural differences in urban matters of theory and practice are often due to differences in language (disturbs happen between languages and how they generate confusion about common words ambiguous meanings, such as “city”, “urbanism”, “plan”, “project”, “development”, “speculation”, “common”, “liberal”, and so on...). So as to clear epistemic base regarding ‘Public Space Service System’ (this project) we must clarify what is Public Space and what is a Service System.

Although ‘service assets’ concept referred to Public Space(s), basically have identical expressions and meaning regardless of regional or local diversity, in some environments they may not correspond specifically to the same thing – just to give an example, in many Latin American cities, sidewalks are privately owned and some streets may have entrance gates – is it a contradiction? On the other side, if we see a difference between ‘public sphere’, referring to interaction areas of social life (Habermas, 1989), and ‘Public Space’, referring to physical spaces, may we correctly word both the same way? So wording precision is needed both in Latin and English expressions, regarding fields of media and ideological concepts (like the meaning of “publicness – the quality of being public” that may translate as “publicity” - “advertising”).

The same is true for older concepts: such as the “Commons” notion (more specific in English expression), meaning an open property, accessible, usable and cared for by a community, while “Public Space” means “publicly used, cared, managed...” and in specific cases “owned by public authority”. It may then be more effective a definition as “commons”, when there is less than an “ownership” meaning, but more than a “functional” meaning. Anyhow, when we say something is “Public” that is understood as something that is not personal, but somehow shared, referring to a community group, or else to everyone.

Sharon Zukin (1998) while naming gentrification and privatization as the “USA model”, expressed it with the example of New York “success” of Collective Space (like Times Square, Nike Town, Bryant Park), as specific demonstrations of a perversion sense of what is “Public” in Public Space (Figure 7).

Figure 7 – New York perversion of what is “Public”: Times Square, Nike Town, Bryant Park.
(Source: nycgo.com, nyhabitat.com, formatmag.com)

In what regards notions of “service” and “public value”, they generally refer to what is “public”, or to a “public character”, that everyone may commonly expect from Public Space, although some “nuance” may exist between political interest, ideological interpretation and lay people discourse, in urban matters.

Regarding language in technical literature, it refers to Public Space as the type of open and freely used spaces in urban context (sometimes related buildings fronts, named as “urban landscape”, option that could be rejected by professionals) and a Public specification is different from Collective (privately owned spaces, opened to more or less free use or passage by people generally referred to as clients, rather than users or citizens). Differences between “service” notions may exist between the understanding of Public Space values in connection with Economy subjects (service as trade), and with Social subjects (such as in public services). Finally, in Urbanism, Engineering or Ecology disciplinary areas, “service” meaning is generally equivalent – either in concepts regarding infra-structural service, eco-system’s service, or urban morphology service, with the acceptance of Public Space as a service concept – an ethical base for administration’s accountability, defining urban citizenship as its final objective, within an urban deliberative process.

Despite its importance and its central role in the city, Public Space turns out to be the result of many different actors, agents, processes and contexts that are not always competing, but collaborating. The ability to assess this diversity of interactions, conflicts or synergies, should be part of everyone’s goals - not always to solve these issues, but to make them more understandable and intelligible, as contradictory parts of urban life. So we may define a Public Space System as a spatial mode of organization that serves citizen’s concerns and needs. Integration of space dimensions appeals to urban citizenship as the common place of “all of us”. This means (such as in Remesar, 2000), regarding Urban Design, that it doesn’t have to be made for people but with, or by them, if citizens actively participate in decisions. So public authorities and professionals must regard benefits coming from Public Space’s service and become better facilitators of the “publicness” that they serve, through Public Space Service Systems.

“If the public authorities think and act like private firms, it means their basis for decision making would also be similar to that of the private sector firms, which is primarily to seek exchange value. This would enable them to meet the demands of the economy, but would reduce their ability to meet some needs of the society, especially that which cannot be met through market mechanisms, which need public support. The remit of the public authority, therefore, is to provide use value, and to strike a balance with exchange value, rather than be primarily driven by it.” (Madanipour, 2006)

6 CONCLUSION: PUBLIC SPACE EVALUATION IS AN INTERDISCIPLINARY TASK?

As said, Public Space production still lacks an assessment practice focused on the services provided to common spatial needs: what is the kind of organization designed to provide them, with what costs and benefits being at stake. Specific goals should be defined to promote some kind of 'liability' of urban design shared values regarding public expectations (all actors and all users, comprised in a "citizenship" concept of stakeholder) and also public administration who funds, programs and delivers most of space products.

How are values and services assured and how do they relate to stakeholders' will? PSSS at the least shall upraise and clarify assessment questions, based on needs and resources provision, scale organization, integration, continuity... between other systemic concepts, while regarding public space values.

Figure 8 – Afurada, Vila Nova de Gaia. Urban systems shared space: Infrastructure+Landscape+Public Space.
(Source. Adam Jones, Wikimedia commons)

What shall be our aim, regarding Public Space systems' interdisciplinary evaluation process?

As an interdisciplinary practice subject, Public Space and its multidimensional approach may express its potential (and limits) as a spatial services' provider – that is its central character and attribute to be assessed. Other relations express service values in time, such as continuity, adaptability, scale... A system that connects, relates and often coincides in space, with other systems – landscape, infrastructure, communication and other, organized around a set of institutional relations between different kinds of needs' understanding, disciplinary knowledge convictions, legal constraints, economic resources, design practice.

Decision making process involved in Public Space production must be interdisciplinary and democratic. Its assessment is a spatial integration production practice, by recognition of space's public values within an interdisciplinary rational, concepts and tools. To understand social, economic, environmental and cultural values of urban systems, a multidimensional assessment of overall value of Public Space is necessary. But such assessment must also be based on common claims of rights – sharing participation and legitimacy of public value, have to be defined, characterized and organized, as part of space production practices.

"There are pressing needs that public space can help to satisfy, significant human rights that can be shaped to define and protect and special cultural meanings that it can best convey. These themes (...) reveal the value of public space" (Carr et.al., 1992)

Democratic participation in Public Space governance is something of a different nature than a "performance", separated in various disciplinary fields and several service indicators – from street life to transportation mobility, from ecology to social cohesion, from public art to economics, from cultural activities to infrastructure, from communication to landscape and more... Most likely, we can't evaluate all actors and partners' satisfaction, trying to define public value as a measurable or a design quality proof, where all social groups could recognize themselves as the central stakeholder, in decisions, resources and

so on. A Public Space system is mainly a structuring network (as in “The grid is the generator” Martin L., 1972), an organization of services provided as a whole, to all users, and it must be assessed in that quality.

In practical terms, creating public value relies upon taking an approach to the delivery of public services, through the principles of equity, accessibility and participation. Specific PSSS intends to develop references of public space service assessment, shall be useful for:

- diagnose of public space systemic services real and/or potential benefits in different contexts;
- support for strategic public space decisions in planning management and investment program;
- improve governance integrating stakeholders shared visions regarding what are the public values;
- public space rational reference of production, ex-post assessment on goals, expectations and results;
- support a “road map” for urban policies focusing on public space service value, advocacy and voice.

We have defined Public Space service value, not as a mechanism but as an operative instrumental concept. To conclude we need the understanding that Public Space best characters should arise from its systemic and multidimensional approach with a users’ centred rational, arising from service provided and not from a set of undefinable qualities, nor from a ‘value’ transaction of ‘public space commodities’.

As such, a new meaning arises: that Public Space has a diversity of contradictory stakeholders (all those who have a part in it) with conflicting interests. So, when we use the singular form – “value” – we could be referring or be understood as meaning just one of the values (eventually the one arising from “economic transaction value”) but it could also represent another level of Value, meaning citizenship. For that, the commons need procedural and deliberative methods with governance platforms agreed upon.

“To think about the city is to hold and maintain its conflictual aspects: constraints and possibilities, peacefulness and violence, meetings and solitude, gatherings and separations, the trivial and the poetic, brutal functionalism and surprising improvisation. The dialectic of the urban cannot be limited to the opposition centre-periphery, although it implies and contains it. (...) In thinking about these perspectives, let us leave a place for events, initiatives, decisions. (...) All the hands have not been played” (Lefebvre, 1985).

ID 1426 | THE ROLE OF PUBLIC SPACE SYSTEMS ON URBAN TRANSFORMATION: A REVIEW ON LISBON SOUTH BANK REGENERATION PROCESS

Ana Brandão¹, Pedro Brandão¹, Ana Ferreira¹

¹CERIS, Instituto Superior Técnico, Universidade de Lisboa
ana.luisa.brandao@tecnico.ulisboa.pt

1 INTRODUCTION

Many urban regeneration processes, today, use public space as the main ground to implement urban transformation policies – economic, social, cultural, etc. – and deliver valued benefits. Recent discussions about public space relevance in contemporary urban dynamics – privatization, gentrification, etc. – are also a reflection of its role, not just as political or institutional terms, but acknowledging itself as an “urban value” (P. Brandão, 2005; Portas, 1999). These initiatives include from central and historic cores to former industrial areas, from large waterfronts to small scale projects for local communities, which encompass several urban dimensions, dynamics and stakeholders.

As urban areas grow, other typologies of public space arise – as transport interchange, shopping centres, waterfronts, theme parks, etc. (P. Brandão & Remesar, 2004) where categories of public-private-collective are mixed together, in a wide range of activities and urban settings. Public space’s traditional purpose (meeting and making social connections) is often colonized by trends of leisure, consumption, movement or marketing. As urban areas spread, public space may lose its central role of structuring and anchoring urban activities. Does this mean a possible crises or disbelief on public space role in the urban process? Or a need for a new approach?

Regardless of this strategic importance, it is not uncommon that public space projects still focus on isolated units or sectoral actions related to mobility, environment, energy, social cohesion, risk management... This may be related to a funding source, management structure, stakeholders’ action, or a trend favouring appealing urban areas. Frequently they lack integration with other urban systems to provide sustainable social, cultural and economic returns. So despite the growing diversity of places and urban contexts, dominant views of planning, designing and researching public space still focus on traditional typologies - the square, the park, the market – and still target local scale - the neighbourhood or

close proximity – even though urban structures are extending greatly. Finally, the assessment of public space role in urban change is commonly based on the consideration of a sum of units, not considering wider and interaction capacities.

New approaches are needed to address public space, as it is faced with these issues of discontinuity, lack of interaction and outgrowth of its traditional scale. The aim of this paper is to present a systemic perspective on public spaces and their role in urban change. This growing interest on the systemic approach to urban features is now developed concerning public space and its interaction capacities in urban systems .

This discussion is supported by presenting the study case of Lisbon South Bank regeneration process. This part of Lisbon Metropolitan Area grew and developed mainly due to its strong industrial background but today it has a larger diversity of urban contexts and mixed patterns of growth and decay. In the last decades major efforts for urban regeneration were made, and many actions included public space transformations. We register the emergence of an approach on public space not only focused on neighbourhood insertion and local focus, but as a part of larger networks of relations and services.

The paper will first address the relevance of a systemic perspective on public space, through a literature review and example discussion, developing a contextual and conceptual framework. Further we will analyse Tagus South Bank by a survey and empirical work , creating a time-line of public spaces and urban regeneration process (projects, policies, planning documents, etc.). Finally we examine the growth of a systemic approach on public space understanding, production and use, discussing its suitability for urban research and urban design practice (Pinto & Brandão, 2015).

2 SYSTEMIC PUBLIC SPACE REFERENCES

The diversity of urban fabrics and related problems is translated to the production of public spaces: “What is clear is that contemporary trends in public space design and management are resulting (over time) in an increasingly complex range of public space types” (Carmona, 2010, p. 172). These new multidimensional facts present several dilemmas: growth of scale and distance (dispersion), growth of complexity and diversity (indeterminacy), and growth of non-systemic actions (disruption) that call for new ways to address public space role within urban transformation. Can a systemic view of public space address this gap?

Most definitions of system emphasize a 'complex whole', a 'set of connected things or parts', an 'organised body of material or immaterial things' and as a 'group of objects related or interacting so as to form a unity' (McLoughlin, 1969). In this set of interconnected parts, each part can be seen individually, and also can be considered within another wider system. Interaction between different parts and the systems complexity guarantees its functioning as “The whole is other than the sum of the parts”.

There is a growing interest on the systemic approach to urban features – especially in relation to ecological and infrastructural aspects. But the parallel between systems and cities and urban development can be easily found throughout urbanism: city as a developing organism or ‘evolving’ in relation to its environment (Geddes, 1915); network-oriented thinking in urban planning (Dupuy, 1998 referring Cerdà, Arturo Soria y Mata and others); a view of the city as a system that evolves (McLoughlin, 1969); urban complexity appreciation (Alexander, 1965; Jacobs, 1961; Lynch, 1960); the rise of the network society (Castells, 1989) or the study of functional and spatial structures of cities and the relation between them (Hillier & Hanson, 1984).

In this systemic view, the different sets of components have to establish connections in order to form a system. They share structural elements – links, networks of relationships - understood in a dynamic way, since they respond to ever-changing conditions (Dupuy, 1998). So if the city can be perceived essentially as a system, thus the essential structure that guarantees relations and dynamics has to be public space.

Therefore public space should be considered, not as a sum of isolated space types, but as a network of places (Pinto, 2015), with shared set of properties, interdependences and interaction. A complex system “a system of systems, where layers of functional networks – infrastructural, cultural, economic, and environmental – intersect and complement each other in a mutually reinforcing and beneficial way.” (UN-Habitat, 2015, p. 42). From this starting point further development can be made.

By extending the notion of public space to a systemic idea we are enhancing its interaction potential: the infrastructural system, the landscape system and the public space system, build a city, integrating hardware and software. Such features are also the more lasting elements of urban fabric, supporting transformation over time (and enabling the systems survival). Some clear examples illustrate easily this: a street is still a public space even if it extends for miles (as in Manhattan, Paris or Barcelona), if it integrates intermodal transports, includes sewage networks or if it is a tree-lined street housing different bird species. Nor do we discard a public space perspective on many transport systems, or on parks systems.

So ecological views of public space refer to natural features and natural life supporting systems in the city - as wildlife, water courses, green structures, etc. – continuous structures that can be fostered and integrated in urban environment, so they can provide us with more and better goods and services. Infrastructural views of public space include, by definition, many sectoral system and utilities that frame and support urban life (such as road, transport, sewage, drainage, energy, etc.)

Each of these different perspectives (A. L. Brandão & Brandão, 2017) – public space as interaction, sharing and identity capacities, infrastructure as a mobility facilitator, urban activity support and landscape as production potential, ecological sustain) – offer several functions and services that can be valued and assessed, either by tangible on intangible aspects.

In fact the public character (of public space) comes to a large extent from the integration (or combination) of services and values not only with regard to its morphology (physical structure) but also fostering functional (activities and users) and symbolic (meaning) sense. This character does not derive from size or scale (proximity) but from interaction (common space). Thus, in addition to the more obvious physical systems that can be identified in the city – as ecological systems or the various infrastructures - we should also frame systems of meaning and of communication, related to the software dimension of public space.

Can this perspective be fostered and implemented in policies, development planning and public-space driven strategies?

3 LISBON SOUTH BANK TRANSFORMATION PROCESS

Lisbon South Bank area urban growth was sustained by industrial development and later by suburban dynamics. Some of these processes have been anticipated or succeeded by planning instruments and structuring projects, while others have “bypassed” legal planned actions. As result of rapid and uncontrolled urban expansion, many spaces are characterised by disconnected parts or poorly designed public spaces, similarly to several south European urban change processes. Recent urban strategies have tackled some of these deficits, developing regeneration actions. What was the role of public space on this transformation process?

3.1 THE RISE AND DECAY OF THE INDUSTRIAL CITY

Within the South Bank area, urban nucleuses were traditionally located close to the estuary, with river accessibility to Lisbon, rooted in fishing, trading or productive activities. From the early twentieth century, investment on industry and port activities lead growth around these centres, “fed” by migration from rural areas to these “new urban areas”. These industrial areas also promoted over time, both the settling of other industries and social and cultural services to workers, strengthening the bond and identity relationship of the entire population.

During the “Estado Novo” dictatorship, several urban plans started to be developed for this area (in the 40’s and 50’s), to plan industrial development and provide housing and facilities to a growing population. Most plans were not implemented (due to financial and operational difficulties) yet urban centres continued to expand, many of them based on uncontrolled allotments process or linear sprawl with poor urban qualities.

Some exceptions in planning actions were undertaken: (1) some parts of Costa da Caparica and of Almada’s Civic Center urban plans and (2) some initiatives of working-class (or low income) housing neighbourhoods. The firsts were developed in a garden city urban scheme, as suburbs of Lisbon,

combining housing areas, with leisure and green space: Costa da Caparica as a touristic area, Almada as a peripheral nucleus. Almada's urban plan was further developed including a set of central public spaces – Renovação Square (today

Movimento das Forças Armadas Square), Civic Center Garden, D. Nuno Álvares Pereira and D. Afonso Henriques avenues has urban structuring elements. The seconds aimed to tackle the insufficient housing offer: in Barreiro workers quarters were built by industrial companies (CUF and Rail Company); in Barreiro and Almada public housing initiatives were developed. Social segregation was common, but some development included facilities and services, but in either cases new developments were an “island” within existing urban structures.

In these decades we can also find references to some gardens and central parks, designed by relevant landscape architects. In 1939 opened Oliveira Salazar Park (presently Catarina Eufémia Park) as part of new urbanization area of Barreiro, Coreto's Garden in Alcochete was designed in 1953 and Montijo's Municipal Park was designed 1956 as part of the new Court building surrounding. These spaces are probably the result of a sum of wills and particular cases, rather than a policy or strategic action.

3.1.1 SUBURBAN GROWTH

In 50's to 70's public works policies focused on infrastructure and economic activities conducted the 2nd phase of industrialization³. In the 60's industrial development reached its peak with socio-economic and cultural implications. Although depending from large public investment (Planos de Fomento), this production model promoted other forms of private investments (mainly housing) furthering suburbanization – particularly boosted by a bridge connection to Lisbon in 1966. New accessibility, demographic growth and land availability spurred urbanization, mainly through illegal (or largely uncontrolled) allotment processes with a variety of housing typologies, but clearly with no adequate infrastructures, facilities, public spaces or urban amenities. Lack of autonomy and incapacity of local authorities to manage urban growth resulted in a complacency with these process. In some areas these deficits still endure despite major efforts in qualification.

In this scenario of urban planning inefficiency, public space projects are not common. Nevertheless in the 60's and 70's the ones that got built have more relevance within urban structure - Bento Gonçalves Avenue's Park in Barreiro (1961) – and definition of an urban green structure - Moita's Municipal Park (1971).

3.2 DEINDUSTRIALISATION AND DIVERSIFICATION

In the 70's, several changes (economic crises, political instability, etc.) drove deindustrialisation: many industries progressively and over two decades were decommissioned or abandoned, in a disordered process. In the first years of the democratic period, lack of tools and adequate funds made urban planning action rather difficult, consequence of strong social pressures for policies to focus on adequate housing, infrastructure, public amenities and transportation. Several municipalities begin their territorial planning process, whereas the priority action was on urgent specific problems and populations support: basic sanitation infrastructure, water supply, school facilities, housing support, converting illegal housing, accessibility, waste collection, etc.

Later developments (80's, 90's) consolidated the centre-periphery model, reliant in Lisbon, with accessibility infrastructures, land availability, but in addition the already present real-estate “suburb” dynamic, other processes begun anchored in service economy or increase in commerce and logistic investments. Recently created urban planning system (Plano Director Municipal) was the main product (and main goal) of municipal urban planning: plans were drawn up for the entire South Bank: Seixal in 1993, Barreiro in 1994, Almada, Montijo and Alcochete in 1997. Despite the effort, PDM somehow lacked management and predictive capacity as most territories were already urbanized in a deregulated manner and without adequate infrastructures. Public space, urban design or local actions were not a priority.

3.3 URBAN REGENERATION ACTIONS AND PUBLIC SPACE

Efforts had to be made to reverse the significant deficits inherited from several decades of deregulated growth. During the following decades, important investments (mainly through EU's funding) start to change the disqualifying and damaged image of the South Bank area. The driver of change was the success of Lisbon's World Exhibition in 1998, in which urban design and public space projects were held responsible for quality of built environment and set new standards for quality of life.

Important road and rail infrastructures improve internal connectivity as well as links to Lisbon; better accessibility rapidly attracts commercial sector; investment in cultural, leisure and sports facilities and finally urban regeneration actions, including public space projects. Municipal strategies set an emphasis on urban image requalification, public spaces production, identity and cultural aspects in physical interventions, environmental recovery and natural spaces, etc. In the next pages, we detail these different actions.

3.3.1 HISTORICAL CENTERS AND URBAN REHABILITATION

Expansion cycles disregarded South Bank's historic cores, so rehabilitation of these areas was largely needed. Most actions include not only built environment interventions but also (some more than others) economic and job creation incentives and social, tourist, nature related initiatives.

The Nova Almada Velha Urban Rehabilitation Program (1996-2000) in Almada brought together economic and social promotion actions with physical requalification interventions (Figure 1). New public spaces were created or recovered – outdoor spaces of Old Almada, Jardim do Rio and Casa da Cerca's Botanical Garden - new connections were ensured – waterfront connection from Cacilhas and Boca do Vento public elevator. Later on Almada Velha-Ginjal Urban Regeneration Partnerships (2008-2012) initiative, carried on central spaces requalification in Cacilhas' area, including cultural animation activities and boosting the area's economic promotion (tourism, leisure).

Other actions in urban cores are linked to traditional trade revitalization. Examples include interventions featured in Montijo's Downtown Project - redesign of Praça da República (2001), pedestrianisation of some commercial streets or placement of new street furniture. Or partnerships with private actors, as the requalification of the of Barreiro's central market and surrounding area, developed together with a nearby shopping centre.

Figure 1 – Nova Almada Velha, Almada | Figure 2 - José Afonso Park, Baixa da Banheira
(Source: Ana Brandão 2015)

3.3.2 WATERFRONTS

Since the 1980's municipal action started to prioritize actions in waterfronts areas, strongly embodied in local identities linked to river activities, to foster recreation and leisure functions.

This intention is first put into action by Moita municipality through projects and planning instruments (e.g. land acquisition for green spaces, tidal mills recovery, riverfront urban studies, etc.). The result of this effort was José Afonso Park (1993), in Baixa da Banheira, a green public space that redesigns the entire urban connection with the riverfront, together with semi-natural spaces and important facilities make a unique

design in its surroundings (Figure 2). This attention for quality of riverfronts had continuity on other urban areas (Salinas Park in Alhos Vedros, Canoas Park in Gaio, Picnic Park of Rosário's river beach, etc.).

In 2001, this strategy led to the elaboration of Pró-Tejo - Riverfront Improvement Program, which set guidelines and projects for integrated municipal action. Public space projects were developed (2006) in central Moita: recovery of the Caldeira (Figure 3), redesign of Marginal Avenue, new waterfront promenade and sewage and drainage networks renovation. Recently, another waterfront link was assured, connecting central Moita to Rosário's Beach with environmental recovery actions and foot and cycling paths creation.

During the 2000s other municipalities also developed actions or strategies related with waterfronts. In Seixal the strategy was to develop a connect waterfront promenade around its Bay - Seixal, Arrentela and Amora – but implemented in several parts over time. This public space had great impact on this area image, identity promotion and acts as meeting point for several neighbourhoods. The following Valorization Plan of Seixal Bay completed and consolidated this strategy with a set of integrated projects regarding environment, tourism, economic activities, urban regeneration, cultural and social promotion (Figure 4).

In Barreiro investments were made in the riverside areas of Verderena's and Santo André's parishes – known as Recreational City Park (2008). The project included the restoration of Caldeira do Alemão, riverfront connections, street redesign and connection to the City Park. Following these actions was developed a Waterfront Municipal Program (IMPAR), which has drawn a global and integrated vision Barreiro's riverfronts.

The north part was qualified through Repara - Alburrica's Regeneration Program, with actions of physical requalification, economic, social and cultural promotion and Alburrica's area qualification (pedestrian paths, beach recovery), requalification of avenues and public spaces associated with facilities.

In Montijo was developed in 2001, the Riverside Structuring Plan (PEZOR), a connected set of environmental and urban regeneration projects encompassing 267 ha. Only some of them were carried out including: the relocation of the ferry boat terminal, restoration of Carlos Loureiro Municipal Park, the Tide Mill recovery of and redesign of central Montijo's waterfront. Despite the relatively small dimension of the redesign waterfront (compared to other municipalities) it transformed the city's image and its tourism and leisure uses.

In Alcochete was developed an Urban Regeneration Operation encompassing the entire municipality riverfront. Some of the projects were implemented by the Regeneration Action Program: riverfront redesign, central public spaces and traditional areas redesign, connection to cultural and social facilities, environmental promotion centre.

Almada's waterfronts public spaces have a rather distinct character given the municipality's characteristics. While the seafront was subject to an extensive urban project (see 3.3.5), the riverfronts have been redesigned within historical cores regeneration actions.

3.3.3 PARKS AND GREEN STRUCTURES

Despite the construction of some parks and gardens during the industrialization years, urban growth far exceeded the catchment areas of these spaces. Thus, with a new focus on environmental, landscape and socialization concerns, parks and green structures have grown in number and dimension, in relevant locations and with important impacts on urban and ecological structures.

In Almada the design of Paz Park (1995) was made possible by a land acquisition process framed by a detail planning action (PP7/PP9 Partial Plan). The park plays an important role in social and leisure activities as a gathering element of various urban fabrics. The diversity of spaces and ecosystems also allows support of important wild fauna and flora habitats. Previously, the Comandante Júlio Ferraz Park (1987) made possible a green central space long planned for that part of the city. This policy of green spaces dissemination throughout the municipality also extends to other urban centres: Costa Caparica Park (2008, see 3.3.5), Sobreda's Multiuse Park (2009), Adventure Park of Charneca de Caparica (2009), Fróis' Park (2013).

In Seixal, Paivas Park (1990) was one of the first green spaces to be set in a very dense and uncharacterized urban fabric, bringing new uses and nature features; while Quinta dos Franceses Park (2001) was developed with activities and functions related to the riverfront and with new cultural facilities. Barreiro's City Park (2000) takes advantage of the grounds of an old cork industry complex, linking several urban areas with natural spaces and various sports, cultural and leisure areas.

At another level, the definition of the metropolitan ecological structure advocated by Regional Planning (2002) foresees its implementation at the municipal level, with the definition of green and natural infrastructures. These municipal ecological structures, can diversify green spaces and connect them in network system. An example is the Salgueiro's green infrastructure in Montijo that it is developed along a water course and is framed in different ways in the urban network.

3.3.4 MOBILITY SPACES

Regarding mobility there is diversification of actions, not only focused on road infrastructure and car movement, but seeking greater compatibility with other transport modes, including soft mobility and with public space.

The construction of light rail network – Metro Sul do Tejo (MST) is an example of this change, aiming to connect the municipalities of Almada, Seixal, Barreiro and Moita (at different phases) and strengthen cohesion (Figure 5). The first part was inaugurated in 2008, articulating centrality areas and transport interfaces within Almada's municipality (reaching to Seixal's municipality) throughout very different urban fabrics. Several restrictions (budget and operational) limited the completion of the network. The design of a dedicated lane and the insertion in consolidated urban fabrics led a specific public space projects design, but with mixed results: in some cases new joints and easier connections are promoted, in other incompatibilities still persist. Despite these weaknesses it has potential for connecting several urban units and promoting urban mix.

Several ferry terminals were relocated or expanded with a park & ride logic - Barreiro (1995), Seixal (1997), Montijo (2002) - benefiting from the construction of large parking lots. Despite ease of access and connection to cars, it disregarded other transport modes and proximity to other urban amenities.

Mobility is also integrated within other regeneration actions: car traffic mitigation is a subject especially in historical cores – e.g. creation or extension of pedestrian areas - cycle paths and footpaths are design in new public spaces – nature features, waterfronts, avenues. The majority of these features are often isolated and fragmented, nevertheless present potential for further linkage. An exception can be found in Trafaria-Costa da Caparica cycle path. In a tourist area it connects the ferry boat to Lisbon with a sequence of urban beaches and leisure areas. The path follows the existent urban structure, connecting a diversity of urban fabrics, public spaces and uses. As a result, the cycle path comprises different sections and designs, ensuring connectivity and space for recreational activities and social interaction.

3.3.5 URBAN PROJECTS

In addition to local government regeneration actions, larger projects were developed by central administration – as the POLIS program (for more information see MAOTDR, 2007) – based on urban and environmental requalification. In the South Bank it targeted Costa da Caparica – an urban and touristic hub of Lisbon Metropolitan Area, encompassing a large extension of the seafront and some related inner areas (a total area of 650 hectares). The urban project pursued various actions: urban design (beachfronts requalification, green structure and new public spaces), improvement of residents' quality of life (new social facilities, re-housing), touristic valorisation (dune recovery, new accesses and hotel units) and improvement of mobility and accessibility (traffic restriction, soft mobility and intermodality).

A strategic plan defined various action areas and structuring projects, corresponding to each one a Detail Plan. The first phase of the urban project was completed in 2008-2009, with the construction of the Costa da Caparica's Park, redesign of public spaces in the seafront and of urban beaches facilities (Figure 6). Further completion of planned actions extended over time and encountered several difficulties.

4 LISBON SOUTH BANK TRANSFORMATION PROCESS AND PUBLIC SPACE SYSTEM INTERACTIONS

Despite the South Bank's industrial growth built environment disqualification, some public spaces (mainly small parks) were built in central zones, with a strong socialization role, urban image and even urban growth structuring. The suburban expansion occurred in the 1960's, mainly after the bridge connection to Lisbon, along with new accesses. It started mainly in Almada's and Seixal's municipality, but in the 1970's, 1980's and 1990's, the suburbanization process extended throughout the South Bank, with legal and illegal processes, extensive in some areas and intensive in others, but invariably unstructured and feebly equipped.

Since the beginning of the democratic period, the redesign of existing public spaces and construction of new spaces ones became a priority, leveraged by different mechanisms (municipal initiatives, EU funding, central government programs). Public space action has been a part (often instrumental) of other public policies regarding economical dynamics, city marketing, social cohesion, tourism, environmental and sustainability issues. New procedural characteristics can be identified:

- increasing diversity of public space typologies and uses;
- larger territorial scale, beyond local dynamics;
- identity features related to new views on industrial background or new reference images;
- new infrastructures as qualifying elements;
- environmental and economic issues as part of urban design problems;
- new design and planning tools – urban projects, strategic actions, engagement of different stakeholders.

Some municipalities already seem to make this a strategic action for urban regeneration, either by building continuous structures – waterfronts, ecological structures – or by ensuring “adequate coverage” in different

urban centres (e.g. parks in Almada's municipality). So can we acknowledge that public space as a system is already part of urban design practice (see Table 1) with several systemic characteristics in place (Batty & Marshall, 2012; Marshall, 2012; McLoughlin, 1969; Morin, 1987).

These examples of the South Bank area multipurpose spaces illustrate the potential of sharing by public space systems to address some issues on how can population's basic needs and expectations be met. Together these public spaces already form a relevant system, linking different urban fabrics, activities and structures throughout different municipalities. Several urban areas are faced with fragmented or mono-functional structures: many incoherent and in-between spaces remain, but existent potential can be further developed.

This means there is a systemic potential that needs to be assessed and fostered, so as to enable spatial and functional interaction. A research based on a combined action "systems of collective spaces grounded in the interaction with landscape and infrastructural systems" (Portas, 2004) can frame methods and tools appropriate for specific contexts.

	Dynamic & synergy	Scale	Diversity of uses	Systems connectivity	Tools & strategies
<i>Almada's Civic Centre</i>	Structuring urban growth	City-wide attraction and urban link	Economic activities, commercial, nature, leisure	Infrastructure, ecologic, symbolic	Planning initiative
<i>Oliveira Salazar Park</i>			Ecologic	Local action (isolated)	
<i>Montijo's Municipal Park</i>					
<i>Moita's Municipal Park</i>			Nature, leisure, sports	Structural action	
<i>Nova Almada Velha</i>	Urban regeneration	Metropolitan attraction	Economic activities, leisure, commercial social	Infrastructure, communication	Integrated strategy
<i>Montijo's Downtown</i>		City-wide attraction	Commercial, leisure	Infrastructure, symbolic	
<i>Barreiro's central market</i>		City-wide attraction	Commercial, leisure	Ecologic, infrastructure	Private & public partnership
<i>Moita's waterfront</i>	Urban regeneration and natural environment	Municipal link	Commercial, leisure, sports, mobility, nature, heritage	Ecologic, infrastructure, symbolic, communication	Municipal strategy (long term)
<i>Seixal's waterfront</i>					City-connection
<i>Barreiro's waterfront</i>					
<i>Montijo's waterfront</i>					
<i>Alcochete's waterfront</i>					
<i>Almada's waterfronts</i>		Municipal strategy			
<i>Almada's Park systems</i>	Natural environment and ecological connections	City-wide attraction and urban link	Nature, leisure, sports, commercial,	Ecologic, infrastructure	Municipal strategy
<i>Paivas Park</i>				Ecologic	Structural action
<i>Quinta dos Franceses Park</i>				Ecologic	
<i>Barreiro's City Park</i>			Nature, leisure, sports, heritage, commercial,	Ecologic, symbolic	
<i>Saigueiro's green infrastructure</i>	Ecological connections	Urban link	Leisure, nature	Ecologic, infrastructure	
<i>Light rail network</i>	New transport connections	Metropolitan links	Mobility	Ecologic, infrastructure	Central & local government
<i>cycle path Trafaria-Costa da Caparica</i>		Inter-urban link	Mobility, tourism, sports, leisure, nature	Ecologic, infrastructure	Structural action
<i>C. Caparica urban project</i>	Urban regeneration	Metropolitan attraction	Touristic, Leisure	Ecologic, infrastructure	Central & local government

Table 1 – Public space projects and their systemic characteristics

5 CONCLUSION

Public space is produced by many reasons as a result of many urban policies, planning and design tools, frequently integrating different time-frame and multiple stakeholders. This immense diversity is a reason of its great importance within urban structures, but is also a matter of conflict and fragmentation. We can summarize some of these issues regarding public space production, that could benefit from a more interactive and systemic approach:

- Diversity of users: "(...) public is not a single entity, as it is composed of different social strata, each with a different set of characteristics, interests and powers"(Madanipour, 2010, p. 9). This heterogeneity adds complexity in reaching a common understanding regarding public space, dividing responsibilities or seeking accountability. Public interest management, or negotiation between different interests, is also not a given, but it is a continuous manifestation in the governance processes of the public space, be they political, social, economic or design related.
- Offer and production dynamics: mismatches between the provision of public spaces, the services they offer and existing needs are frequent, as space transformation and society changes may not have coincident rhythms. Achieving coherence is difficult, especially if it is not anyone concern. So to ensure that public space remains a durable and relevant element in cities, temporal and flexibility aspects have to take in account. These are matters of planning, programming and implementation, either in urban growth scenarios or shrinking dynamics.
- Regulation and disciplinary practices: despite interdisciplinary motivation, the existing body of knowledge regarding public space is still divided in "boxes" of professional or disciplinary knowledge, as a sum of elements that do not relate to each other. Codes and regulations focus on sectoral aspects (mobility, environment, signage, urban furniture) ignoring the complexity of the public space and its interactive character, not facilitating or encouraging innovation (Urban Design Alliance & The Institution of Civil Engineers, 2002).
- So to support and develop a systemic perspective of public space is not wishful thinking, but a real necessity that has to translate to urban planning, design and management practices, and tools to address the flourishing complexity of public space production and change. This is the work that PSSS, Public Space System Service research project is pursuing. Preliminary findings in this field can steer further work:
- Public space is by definition relational, so its primary role is to make contact, to ensure interactions, to allow and facilitates coexistence, diversity and overlap. An interactive urban element, it connects and coexists with other urban systems – infrastructural, ecological, communication – integrating hardware (physical) and software (social) features.
- Public space, seen as a system of spaces, to serve all common activities in urban environment and many interactions (social, economic, environmental, ...) is based on the assumption that urban phenomenon depends on relations of actors and agents, with increasing intensity, diversity and complexity. By mapping spatial service values, their potential integration becomes legible within systems structure.

So a systemic organization of public space can be a basis for evaluating urban values – from proximity to the larger scale, from meeting and interaction, to mobility and exchange, etc. – acting as a reference in transformation process, managing change and balancing changing needs, actor's roles and resources, integrating different urban ensembles and natural elements into a common frame of reference (physical, social and symbolic). Integration is promoter of value, boosted by the diversity and synergy between system elements.

1 INTRODUCTION

The present research intends to study and understand the problematic of the requalification of the public spaces in territories of high level of urban fragmentation. This phenomenon affects contemporary cities and takes place, essentially, by the forms of urban growth confronted with topographic factors and strong infrastructural presence. In this sense, we understand that the great advances of knowledge and technology, over the last two centuries, have caused profound changes in the urban landscape of the contemporary western cities. These transformations in the territory caused by the effects of the Industrial Revolution, mainly in 19th century, development of the railway systems which are assumed as an important socio-economic factor for the region they serve. However, its rigidity and low permeability has contributed to the creation of disarticulate spaces, only a few points of interface and relationship with the land crossing. On the other hand, the fluidity and permeability of road networks allow the rapid rise of these in the urban space. In the second half of the 20th century, it emphasizes a greater variety of functions at street level, where it reveals new ranges and road hierarchies. Thus, the street gains new meaning, assuming as a public space of greater complexity where there is a greater ambiguity of its areas and forms of control. The urban design trends have pointed to a broad and inclusive accessibility, masking many of the forces that promote arrays. It is therefore important to understand how the public spaces contribute effectively to social and economic cohesion. And, in this way, it appears the need to explore the boundaries and rules of use of these spaces beyond the constraints of their public / private control. It is this duality that we confront registration property, infrastructural barriers, difficulties in managing, sharing and overlapping of their areas. Thus, there is a need to increase public space requalification policies that consider systems of evaluation and project orientation supported by an operational sustainability. Where promote intervention strategies with interdisciplinary compromises and recognition of public space as dialog space and mediation of interests. In this way, a methodological support for research development is outlined, with a systematization of the theoretical problems of framing the design processes, the impact of accessibility infrastructures and the public space in fragmented territories. In this, emphasis is placed on understanding and critical reading on the operational capability of sustainability policies. For this, we proceed to historical cartography analysis, legislation and urbanization processes as key study and evaluation tools. In this context, it is assumed Campolide in Lisbon, as a territory test for defining a set of strategies that articulate the issues of urban fragmentation, with new types of public space and contemplating guiding factors for a sustainable intervention. In this perspective, a greater sensitivity to a landscape supported in various infrastructure systems is intended, which aims to better use of green systems and agricultural productivity by integrating them in urban renewal processes.

2 INFRASTRUCTURES, URBAN FRAGMENTATION AND SPACES OF OPPORTUNITY

The lack of enough road infrastructures and the consequent impairment of terrestrial mobility systems were, until the 19th century, a considerable obstacle to the growth of urban areas (Salgueiro, 1992). Only with the Industrial Revolution, it is that the street and the road had great changes, both at ground level and underground, gaining a scale and a completely new functional dimension. Thus, the introduction of industrialization allowed the rapid technological advancement and the development of accessibility of infrastructure, leading to the appearance of mechanical transport for public use in cities (such as tramways, electric cars, elevators and funiculars). At the end of the 20th century, a new revolution confronts the inactivity of urban forms and the organization of territories with the development of a huge network of infrastructures, information flows, goods and people. This was, in a way, advanced the concept of Plug-in City (proposed in 1964 by the Archigram group) that combined the architecture, technology and

Urban design should therefore be a process based on objective and well defined strategies, and its success depends on the consistency of the program, the degree of knowledge of the place, the methodology used, market analysis capabilities, as well as, the degree of involvement and community mobilization (Brandão, 2002). There are several authors who have been devoting himself to the study and design of public spaces, the main concern dialogue between the spaces and social life in cities. In *Life Between Buildings: Using Public Space* (Gehl, 1996) is presented to us the relationship between the usage patterns of spaces and spatial properties of physical environments, using the human dimension as the main analytical tool. And, later in *Cities for People* (Gehl, 2010), explains the methods and tools used in the conversion of certain urban public spaces, but always in a leisure and recreational perspective.

However, it is evident the need to improve the design and quality not only these spaces, as well as the introduction of components related to agriculture in an urban context (Lehmann, 2012). Thus, it is intended to introduce sustainability issues in cities. Rogers (1997) presents the fragility of the ecosystem in *Cities for a Small Planet*, highlighting the predominantly quantitative nature of the urban expansion process, to the detriment of the social quality aspect of the city's public spaces. Public spaces, according to the author, are the main urban elements from city reading, referring to public spaces where we felt like part of this, as is the case of Victorio Gallery Emmanuelle in Milan, the Ramblas of Barcelona, or the parks from London. Rogers also alludes to the importance of multifunctional spaces in intervention proposals in urban fabrics, since these are spaces that promote the coexistence of diverse activities and people. Also stresses the urgency of creating formal and informal venues, to ensure social interaction between people. And in this sense, become the fairest city, beautiful, creative and exposed to the open trial vision, as well as ecological and diverse.

3 SUSTAINABILITY AND URBAN PROJECT, CONTRIBUTIONS TO A PROJECTUAL OPERATIONAL

Over the past decades, the concepts associated with sustainability have revealed new approach places the issues of urban design and growth models and territorial development. The accelerated changes and speeds of communication and information about them have contributed to a greater awareness about their impacts and risks. This phenomenon leads to more critical reflection on the processes involved in the territory, especially for large infrastructure and forms of urban growth. The consumption of resources needed to support urban sprawl, especially after the energy crises of the seventies, has led to a greater sensitivity about the sustainability of our way of life (Rogers, 1997). Our cities represent some of the most extraordinary civilization achievements, but also weaknesses that demonstrate the risks of imbalances in relation to content and stakeholders that compose it. Not only the implementation capacity of buildings and infrastructure, but mainly to maintenance, monitoring use and even its transformation or demolition (Ferreira, 2016). Approaches to sustainability issues, although not new, gain new momentum in the 80's of the 20th century, the way they are currently framed. In this context, we intend to increase new insight into interventions in the territory, contemplating a more inclusive approach in the design process, reflected in lifestyle, considering the reference *Leading the Inclusive City – Place-based Innovation for a Bounded Planet* (Hambleton, 2015). Among the most basic pillars of sustainability are distinguished approaches on aspects of social, economic and environmental equity. However, despite the vast literature on the subject and even some reference legislation, there is a certain ambiguity and vagueness about the direction of change and the principles and policies operating of sustainability. In the perspective of the architect and urban planner matter consider, on the one hand, an integrated and generic view on the principles of sustainability. But on the other, establish a set of strategies and guidelines to report on the methodologies to consider the nature of a sustainable project. The concerns about some of the aspects of sustainability issues in the territory and the project are significant in historical references.

From the contents of the Vitruvius, considering the utopias of the sixteenth century, the social conceptions of the 19th century, where a community of Fourier, as Howard's Garden City, or even modernist avant-gardes of the early twentieth century, with a radiant city of Corbusier or Broadacre City of Wright, among others. In the late 20th century, other theories attempt to find themselves by evoking specific spaces on sustainability, with particular emphasis on neoliberal ideas through utopias like *Laissez-faire Town* and *On the City Celebration* (Roseta, 1999). In addition to the various theories, sustainability discourses have been accompanied by the growing importance of urban resilience, eco-development, and the creation of various certification systems, such as Leadership in Energy and Environmental Design

(LEED). The latter are a space of opportunity to guide a more operational character about the sustainability applied to the architectural project and with some expectations about the possibilities of extension for the urban project. Among various contributions in this regard, it stands out even contents of report Try This Way. A series of articulated concepts to sustainability, point to the growing social awareness of the forms and processes to design and manage the territory and its resources. The resilience emerges as the need to assess the responsiveness of urban ecosystems to adverse situations and injury of urban dynamics, aimed at creating a stronger society, secure and confident, particularly when it is systematically confronted with critical scenarios, either by direct experience or by widespread access to information in almost real time. The eco-development issues focus on the need to ensure the basic needs of the population through adequate and appropriate technology to each environment, considering the different levels of complexity (Filho, 1993). The various concepts show the concern for well-being and solidarity with future generations, with great relevance to the environmental dimension. Among the various dimensions of sustainability into the design process, the environmental issue is one of the most relevant, polarizing the main attention. Considering its importance, we seek, however, an approach that integrates a greater range of factors. In this sense, we identify issues that highlight the importance of local intervention, the recognition of their network of relationships, showing on the one hand, the environmental context and energy (wind, sun, water) and on the other, human dynamics, where functions and mobility are particularly prominent. The emergence of a multifunctional and multidimensional city (Ferreira, 2016) or encourage diverse urban form is an idea reflected by authors such as Wheeler in Planning for Sustainability (2003). The question of analysis and design of scales, highlights the importance of local and global relations, but also the human comfort of consciousness, from its communal existence the areas of privacy, this is from the region, city, neighborhood, home. With the growth of cities, and more than half the world's population living in urban areas also puts up the challenge of ensuring the supply of the companies of the future, changing the traditional dialectic of rural versus urban and appealing to new paradigms that show that urban issues such as urban rurality? or rurbanization ?. In this context, it is recognized the importance of works such as Food and the City -Urban Agriculture and the New Food Revolution (King, 2012), or trends in edible landscaping policies, the challenges of sustainable urban agriculture, and a new food culture. These approaches and new urban-rural commitments are explored in Food City (Lim, 2014) and Future Cities (Ween, 2014) stressing the possibilities of green scaffolding or vertical gardens (Birkeland, 2008). In this context, it is important to rethink the ways of allotment and registration. Since the knowledge and historical recognition of its transformation can be an essential source for new change tests. Among the most relevant aspects of the need to bring rural and urban, there is the route that foods currently make from the place of production to the final consumer. This factor is a sensitive point to the models and processes of urban and metropolitan growth (Steel, 2013) evidencing the emergence of new relations and conceptions between city, agriculture and landscape. There is a need to risk processes and methodologies that contribute to develop design guidelines aware of new commitments on an operational sustainability. It is the context of each project one of the key aspects to start equating the guidelines, case studies are particularly relevant compared to generic positions or sustainability policies. Within the main challenges is the awareness of the relations between local actions and their global effects. Thus, the means of production relocation decisions for large distances from urban areas, which concentrates the largest population percentages, is one of the key factors of territorial and human sustainability. The primary factor, directly related to environmental issues and climate change, mainly by energy costs representing the transport of goods, shows a large increase in ecological footprint. In addition to this, home -work travel and alternative means of mobility are also representative of environmental impacts, including the reduction of comfort and human well -being. In this context, the quality of public spaces, the relationship between the various transport systems and the quality of the forms of urban production are other factors to consider in territorial planning and design processes. Sustainability has a strong cultural component, which also highlights the issue of its relations with heritage, questioning both the sense of preservation and innovation. Thus, inheritances should be an opportunity to integrate heritage with new constructions, where the old and the new constitute a challenge and an opportunity to balance the times and their forms, with a view to improving public spaces and good Social welfare (Rodwell, 2007). The various places and their contexts are the result of interpretations and summaries made with looks that have not integrated the fullness of its construction and designed to meet requirements that are likely to be quickly overcome and it is in this context that should emerge a positive view of the value of sustainability -humility in relation to past and solidarity with the future. Starting from the construction of an interpretive basis of the surrounding territory to intervene and production of summaries of the most important elements highlighting the existing content in strategic and plan documents, it is essential to produce guiding elements for a sustainable intervention that emerges from a critical reading of the context of each place and the meaning of your

project. We propose a compromise between the existing elements and recognition of its book value, environmental constraints, the infrastructure systems, among others, such as mobility, transport systems and public spaces network in the context of the framework of climate zones and factors social and economic conditions. A set of several factors should contribute to increase the knowledge of the territory and report on the development of a sustainable design options.

4 THE CAMPOLIDE PLACE, OPPORTUNITIES AND INTERVENTION STRATEGIES FOR A SUSTAINABLE TERRITORY

The unique features and biophysical conditions of Lisbon, as the valleys, the hills, the presence of the river and the irregular topography of the city, has always marked its urban expansion, particularly for the northern area. Marked by the potential of its location and defensive and commercial offered by topography and by sea, Lisbon was conquering surrounding rural territory, to its urban expansion, transforming the old neighborhoods in new urban areas (Salgueiro, 1992). Among the various areas of the city, Campolide is an opportunity territory, highlighting features that reflect the constraints of the traditional models of urban sprawl. This area of the city is currently an urban area still keeping some traces of rurality, which testify to its importance in the supply of goods and water to Lisbon. Between the Parque Florestal de Monsanto (forest park) and the consolidated city, its morphological structure includes a significant diversity of urban fabric and some gaps still to be defined. Among the various forms of urban occupation, are distinguished neighborhoods of single-family houses -small isolated areas with identity and own urban design, in contrast, the great bourgeois avenues and highways crossing, crossing old to the center connecting paths of city and separating some urbanization polygons. However, it is necessary to go back a little in time to understand its morphogenesis and the opportunities that this territory offers. In the middle of the 19th century, this territory consisted of two more concentrated settlements -one near the Quinta de Estevão Pinto (Campolide de Baixo) and another on the Cruz das Almas (Campolide de Cima) -and another more dispersed settlement along the Rua de Campolide (FIGURE 3), as well as the remarkable presence of the Vale de Alcântara (JFC, 2017). This valley, characterized as the most important physio-hydrographic element of the present city of Lisbon (Magalhães, 2007), has always been a strong barrier to the continuity of its urban morphology.

Source: CML, LxLAB Adaptation

The first infrastructure that allowed the crossing of the accentuated slope of the valley dates back to the 18th century, with the construction of the Aquecido das Águas Livres (FIGURE 4) still today the main reference element of Campolide (JFC, 2017), and even the city of Lisbon. The boundary of this territory was created by the administrative reform in the early 60's, and covers an area of 2.77 km² where currently live 4,460 inhabitants. In 1960, Campolide had about 33,000 inhabitants, losing 50% of its population in 50 years (Censos, 2011).

FIGURA 4 - View over the agricultural fields of Campolide and the Ageduto das Águas Livres Watercolor print on paper, of English origin, from the 18th century - Source: JFC

This phenomenon relates essentially to the decay of the main income of the population –agriculture –in part by the great economic and industrial momentum in the middle of 19th century. This technological advance allows, therefore, the implementation of accessibility infrastructures, both rail and road, in most European cities. Portugal, after a period of political unrest that marked the beginning of this century, tried to catch up with other European countries by modernizing the country's administration and economic development. It called, therefore, the period of Regeneration, being created a new ministry, of Public Works, which Melo de Fontes Pereira took charge. This new government gives the main impulse in the transformation of the territory from its infrastructural dimension. The implementation of a specific ministry for public works provided an administrative reform based on the definition of municipalities where the municipal authorities now have greater autonomy and responsibility, in addition to increasing the number of roads. Throughout this process, it starts the construction of the first Estrada de Circunvalação (ring road) of Lisbon, associating two functions: fiscal and military. This would consolidate a new territorial scope that had long exceeded the boundaries of Fernandina walls, past physical expressions of an administrative and space limit. The creation of this road establishes a location criterion associated with areas of adjacency and transition, accommodating new spaces of industrial development and equipment, which were excluded from the old center of the city (França, 1997). A part of Campolide was within the city limits and another out of doors (JFC, 2017). The relationship between being inside or be outside the administrative area of the city was reorganized in terms of a progressive specialization and functional segregation, but also of hierarchy and social differentiation. The need to make the most of property, therefore, leading the 19th century, Bourgeois to open urbanization fronts that would respond to the needs of urban growth and value the peripheral lands. With the first attempt to legislate urban planning in Lisbon there is a need to draw up a Plano Geral de Melhoramentos de Lisboa (general improvement plan). This, despite not having immediate consequences, made it possible for the town interventions were seen as a set and influenced the urbanization of the late 19th century. Ressano Garcia, a Paris trained architect, thus defines a clear strategy for upgrading and expanding the city, defining the most comprehensive first plan for Lisbon (França, 2000). However, it is with industrialization and the great influx of people to the cities becomes an important business object. Land becomes a source of income and status (Salgueiro, 1992), and increases the value discrepancy between rural and urban land. The value of the latter results, essentially, from the relative location of the land and the type of activity (density and use) it may contain. However, it is the transformation of a rural land into urban land that generates substantial value added. Thus, the spaces along the Vale de Alcântara, until there intended to agriculture, are quickly transformed to supporting the implementation of a circular rail infrastructure in Lisbon, the Linha de Cintura. This converged on the valley territory (like Alcântara), not only because of the low value of land expropriation but also by topographical and hydrological facilities. This solution is recurrent in several European cities, where urban valleys and watercourses host major works of accessibility infrastructures (Rasmussen, 1967). In this context, relatively rigid design solutions are developed in the face of the slope and radius curvature limitations of the railway technology. The Linha de Cintura is, therefore, a disarticulate element of the surrounding and without specific preoccupations with architecture and urbanism. In the years of its construction, this element crosses lands outside the city still uncompromising urbanization and, with this, with a low social and economic dynamics. However, with the urban sprawl of Lisbon, this infrastructure has become an integral part of various planning areas and urbanization projects. Although there was a certain indifference to the presence of this new infrastructure in a space that would be crossed by the expansion of Avenidas Novas, functioning as a kind of dorsal, and not as a dorsal column, of the various

urbanizations at the time of development. A more integrated view of the various structural elements of the city is achieved with the architect and urbanist plan Étienne de Gröer which defined the major city development lines, with great emphasis on the area of Campolide. The landfill for the Avenida de Ceuta (where the Ribeira de Alcântara was developed, which was therefore converted into a caneiro), the Duarte Pacheco viaduct and the creation of a forest park in Monsanto with 900ha. These objectives defined much of what is now the city of Lisbon, although many have not been fully implemented, inducing new intentions and ideas for territorial planning. The works for the construction of the Avenida Gulbenkian, between 1960 and 1970, set out in Groër Plan, taking to population decline in Campolide, since they were evicted 540 families of the districts of Ribeira de Alcântara, part of the Calçada dos Mestres and Quinta do Tarujo. The intensity of urban expansion from Lisbon to the North is increasingly visible, but the projects for this are no more than utopias, some of them already since the time of the Marquês de Pombal, but have never materialized. Among the various proposals boldest reflected in this area, there is the extension of Avenida da Liberdade, understood as a process of building an identity for the new century Lisbon (Silva, 1931). The acceleration of urban transformation and social change, in large cities and towns, came to question deeply, methods and planning processes used in the 60s and 70s saw Lisbon thus its urban planning develop in witnessing proposals specific areas for the city with particular dynamics in the 1990s. These established the spatial organization model and the development strategy, as well as the classification of the soil and the rules and parameters applicable to the occupation, use and transformation of the soil (CML,1995). The infrastructural corridor present at the bottom and along the Vale de Alcântara, with emphasis on the North-South roadway and the railway infrastructure Linha de Cintura, on the one hand, has impacts on the population density of the parish; on the other, contribute to the modernization of a network accessibility that extends outside the city limits, allowing metropolitan and regional connections. Development of infrastructure, besides causing profound changes in the urban landscape and cause disruptions with older structural axis of the city is reflected in the identity transformation from places like Campolide, particularly fragmentation effects along the Rua de Campolide. In the late 20th century, began to develop in programs and cross-cutting urban projects that promote connection and mobility through redevelopment of public space and pedestrian accessibility programs, the introduction of energy efficiency programs in both public space as in municipal buildings and With urban projects, including green corridors (CML, 2012). One of the first references of a green corridor crossing Campolide, is a proposal elaborated by the Architect Gonçalo Ribeiro Telles (in 1976) denominated Green Corridor of Monsanto and, more recently, a complementary project that aims at the connection between the zone of Campolide and

Alcântara. However, it is important to note the lack of cohesion in the design of such projects, as for its long intervention area can create spaces dispersed and fragmented among themselves (Pereira, 2016). Campolide became thus a transition area with a high level of urban fragmentation and planning models scattered and disconnected, as are the plan of the layout of the cases of Avenidas Novas and development of the urban environment from Avenida José Malhoa, ending abruptly in the Twin Towers. In this territory, the diversity of planning processes and forms of urbanization that gave support to the urban expansion were also evidenced, considering the specificity of the geomorphologic context and the technological developments (FIGURE 5).

FIGURE 5 - Campolide framework in the city of Lisbon, with emphasis on the relation of accessibility infrastructures and public spaces - Source: CML, LxLAB Adaptation

In this sense, Campolide is assumed as an object of study and reflection for the definition of a set of strategies aimed at solving the problems mentioned above. Within the design and development of an approach strategy to project a sustainable aspect, we chose the environmental component in conjunction with accessibility issues, transportation and public space as the main guiding elements. These, however, are not dissociable from issues related to land use, heritage and urban regeneration, as well as the social component. The approaches to sustainable urban project necessarily include different content in functions of the scales of analysis. There is also the difficulty of transposing the policies and the principles of sustainability for the territory. In this way, the need emerges of a metodological construction adjusted to the specificities of each place. The place of Campolide, of great rural and agricultural tradition, shows the importance of its ecological structure due to the low level of edification in some areas of this territory, and

assuming as a strategic space for new models of urban-agricultural occupation. The proximity of the green lung of the city, the Parque Florestal de Monsanto in Campolide reveals the need to understand the meaning of these hinge green patches and its impact on the design of the territory, having regard to its peripheral nature (FIGURE 6). This has resulted in a network of green corridors that are based on the interconnection of various areas of the city, such as the Monsanto Green Corridor and the Alcântara Valley Corridor. This network, however, is subject to constraints of inherited urban forms and achievement possibilities of permeable areas, as well as, a vision on the relationship between ecology and landscape. The ecological system of the city (FIGURE 7), being a complex system, should look for new commitments between the natural environmental aspects and human activities. In this sense, the protection of environmental values and resources should point to the need for an integrated vision between green systems, humid systems and built urban structure, considering the natural and anthrop risks, namely, areas with vulnerability to floods, susceptibility to direct effect of tide, susceptibility of occurrences of mass movements in slopes and soil seismic vulnerability.

 Source: CML, LxLAB Adaptation |

FIGURE 7 – Detail of the Planning Plan - Natural and Anthropical Risks, Municipal Master Plan of Lisbon, 2014
 Source: CML

The geomorphology that synthesized one of the main orientations of the forms of human occupation constituted, on the one hand, a condition of urban expansion and, on the other hand, induced the technological development for its overcoming through new infrastructural systems. Thus, the use of soil (FIGURE 8) evidences successive achievements on geomorphology reflected in the different models and forms of structuring the territory. These processes are visible from the compact historical city to the expansion of the bourgeois city or to the diversity of the urbanization polygons of the peripheral areas. In the process of urban expansion there is also the proliferation of public recreation areas and landscape framing, without an integrated strategy of the ecological aspect. Among the values to be taken in the areas of sustainability, heritage is assumed as one of the very important factors for identity construction of communities. The heritage (FIGURE 9) is a key factor to be considered in urban regeneration strategies, considering the recognition criteria and the articulation between pre-existences and new intervention proposals.

FIGURE 8 - Detail of the Planning Plan - Urban Space Qualification, Lisbon Municipal Master Plan, 2014

FIGURE 9 - Classified and envisaged patrimony, in the Town Planning Plan - Qualification of the Urban Area, Municipal Master Plan of Lisbon, 2014
Source: CML, LxLAB Adaptation

The models of urban growth and definition of urban structure has implications for mobility and accessibility systems and impact on energy consumption and CO2 emissions. Thus, it is essential to an evaluation of the effectiveness of the integrated form of transport systems and the importance of it in the quality of urban life. So Campolide presents itself as an area of opportunity to promote a critical view of the relationship between urban form, mobility systems and human appropriation of spaces. This territory was established as a border area between various forms of urban consolidation showing significant levels of fragmentation. These are particularly relevant in the project of public spaces and their forms of connection and mobility systems, mainly due to the discontinuities of the human scale. In this context, we propose some urban project intervention strategies, with more specific implications for the accessibility infrastructure and the public space where the introduction of sustainable operational measures is foreseen. In this way, it is intended to increase the functional diversity at the street level, considering its crossing character or smaller flows, as well as the valuation of exceptional elements at the level of the building. In the specific case of Campolide, it is intended to introduce public space strategies that include greater coordination between various factors. Comparing the avenues Bordalo Pinheiro and José Malhoa there is, despite the similarities of their profile, highly diversified urban environments (FIGURE 10). This last has a lower functional diversity, as well as a lower permeability to the level of deployment. Another factor is related to the large scale of the building, which also dominates, in this last avenue, buildings of services and hotels.

Thus, it is necessary to promote the inclusion of various activities at the level of ground floors, achieved through financial incentives and qualification of public space in an integrated manner. The design process of these territories emerge in a way still very segregated and linked to a very narrow interpretation of zoning, and they lack some sensitivity on the borders of the various land use. Thus, the design of the green corridor takes refuge in reducing ecological argument, ignoring the complexity and diversity of

contexts that involve, particularly the relationship with the public parks south of Avenida José Malhoa with Jardim da Administia International. The very idea of continuity underlying a corridor is not recognized at the level of the environments it should provide, yet assumes itself as a forced connection of fragments of green spaces.

FIGURE 10 - Comparing Avenida José Malhoa and Avenida Bordalo Pinheiro
Source: LxLAB Adaptation

The vision of public spaces in the ecological character or landscaping in the city has raised new questions related to its productive potential. In this context, Campolide presents itself as a territory of opportunity to dilute the effects of urban fragmentation, through the use of accessibility infrastructures such as agricultural production corridors -green scaffolding. There are also possibilities for defining new forms of appropriation of the less compact spaces of transition, which are quite significant in Campolide, where the fragility of articulation in the mobility issues is greater. Here, too, there are some uncertainties in terms of transport interfaces, and there is a huge untapped potential for creating or optimizing distribution networks for products, services and people.

5 CONCLUSIONS

The issues of urban fragmentation highlighting the infrastructural support have been the subject of increasing attention. These, however, are faced with constraints arising from urban conditions underlying its nature, showing a certain segregation of uses, which include security issues. These areas are revealing, often as a corridor spaces, this feature has been made more as a constraint than an opportunity to establish relationships and intermediate connections in the various urban scales. The idea of territorial infra-structuring also often appears detached from the environmental issue, or even an integrated approach within the general and operating principles of sustainability. Many of the interstitial spaces of infrastructure corridors, assume a generic urban voids, urbanization of polygons, without a strategic vision that articulates the relationship of infrastructure corridors with areas of ecological value and agricultural, contributing to strengthening urban resilience and promotion an effective ecological development. Campolide, for their territorial nature, either as historic agricultural nature in the outskirts of the city or by the latest infrastructural crossing is a challenge to test intervention strategies and principles. The forms of urban growth in this area reflect the limitations of traditional models of territorial occupation when faced with topography difficulties, or with urban borders of a more dispersed nature or subject to the effects of infrastructural fragmentation, resulting from rail, road or even the establishment of large green spots as in the case of Parque Florestal de Monsanto – an urban park. In this sense, our central contribution, as well as critical reflection on the problems presented, focuses on a set of sustainable nature guidelines to consider in fragmented areas and imprecise uses, such as in Campolide, considering that these territories are an opportunity to rethink the urban design today.

ID 1441 | BRINGING LIFE BACK TO STREETS THROUGH LANDSCAPE DESIGNS: A CASE STUDY IN SUZHOU INDUSTRIAL PARK, CHINA

Miao He¹, Bing Chen¹

¹Department of Urban Planning and Design, Xi'an Jiaotong-Liverpool University

miao.he12@student.xjtlu.edu.cn

ABSTRACT: Previous research shows that the quality of street space would determine the outdoor activities, public health conditions and people's perception of place identity. This paper explores how the existing street landscape can be re-designed to bring public life back to streets – a concern arising in city regeneration. Due to the rapid urbanization in the last three decades in China, streets in major cities were often designed and built to prioritize and facilitate vehicular circulation. Although the well-known design principle – streets should be designed towards pedestrian-friendly – has been incorporated into textbooks and street design guidance. Less attention has been paid to the pedestrian's needs in practice. As a result, existing streets are often lack social activities. Public space design has now become a major concern of the Chinese public. How can existing streets be redesigned to bring life back to the streets in residential areas, especially in a given urban context with gated communities? To answer this question, a wide range of literature has been reviewed. Key factors that would contribute to a vibrant street life have been summarized into a design framework. Then a design research has been conducted to verify the effectiveness of these key factors, based on a case study in Suzhou Industrial Park, China. It is expected that the research findings would inform the retrofits of existing streets in the city regeneration process.

1 INTRODUCTION

This design research aims to explore landscape design strategies that can bring life back to the streets in residential areas, especially in a given urban context with gated communities. It is expected that some findings would be used to inform the retrofits of existing streets during city regeneration.

1.1 THE IMPORTANCE OF STREET LIFE

In this paper, street is distinct from road. Street with a sense of life leads to a livable, safe, sustainable and healthy city. Gehl (2011) highlighted the importance of the street life from a social perspective. His research showed that pedestrian-oriented street with mixed use frontage was safer than street with few people and activities. Wu (2013) agreed with this statement, and further explained that more people showed up and gathered on the streets would prevent criminal behaviors. Ashihara (2006) stated abundant street activities could be a substitute of physical wall in communities. Frequent meeting and occasional discussions on the street would allow inhabitants to be more familiar with their neighbors (Zayed 2016). Additionally, once walking become as a part of people's daily life, health related benefits would be brought to the public. As mentioned by Nieuwenhuijsen and Khreis (2016), strengthening outdoor

activities can address the health problems caused by car commuting such as obesity. Mentally, Harden (2014) and Wu (2003) summarized it up succinctly, vibrant street life can help inhabitants to get rid of the sense of loneliness. Besides, streets with place function always encourage people to choose travel on foot (Alexander and Tomalty 2002). Fewer cars on the roads will result in energy saving and fewer traffic problems (Wu 2013). Thus, sustainable and environmental friendly community would be achieved once more people are back on the streets.

1.2 BRING LIFE BACK TO THE STREETS

The loss of living atmosphere in urban streets now becomes the major concern of many local authorities worldwide. A UN-Habitat (2013) report showed that cities that failing to integrate the multi-function streets tended to have less infrastructure development, lower productivity and a poorer quality of life. In China during the past three decades of massive urban construction, human-related subjects have often been overlooked (Wang et.al, 2015). New urban areas in Chinese cities are characterized by systematic street networks, separated land use zones, big scale blocks, high-rise commercial flats, and huge open spaces between buildings (Wu and Huang 2013). The historical role of the street as a social communication place is vanishing. This urban form overlooks people's social needs because it puts a low priority on the role of the street as a meeting place. Jacobs (1993) and Gehl (2010) commented that great distance between people, events and functions promotes automobile dependence. To solve this problem, some pilot studies have been conducted to bring social life back to the streets. The municipal government of Shanghai issued the 'Shanghai Street Design Guidelines' in 2016, which showed an initial concern for pedestrian-oriented street design. However some questions remain unclear. For instance, how can the existing landscape be redesigned to bring life back to the streets in residential areas, especially in an urban context of gated communities? This paper aims to explore the key design factors that can bring life back to the streets. To achieve this objective, this paper will redefine the concept of 'vibrant street' based on literature review. A case study will be conducted in the Suzhou Industry Park (SIP), China. It is expected the research findings would inform the retrofits of existing streets in other comparable cities.

This paper includes three parts as shown in figure 1. Firstly, to answer the question 'what are the issues contributing to vibrant street life?' Literature on urban streets has been reviewed. As the outcome, key factors contributing to a vibrant street were summarized into a design framework. The second part identifies the main problems of the street in residential areas located in Suzhou Industrial Park. In this process, on-site observation, questionnaires and interviews were conducted. Direct observation is essential to study public life, and it is simple and efficient (Byman 2012, Gehl, and Svarre 2013). Through on-site observation, existing and non-existing activities were identified. Questionnaires and interviews were conducted to develop a deeper understanding of people's behavior. The third part provides re-design strategies for existing residential streets that can revive street life, incorporating the findings of the literature review and field research.

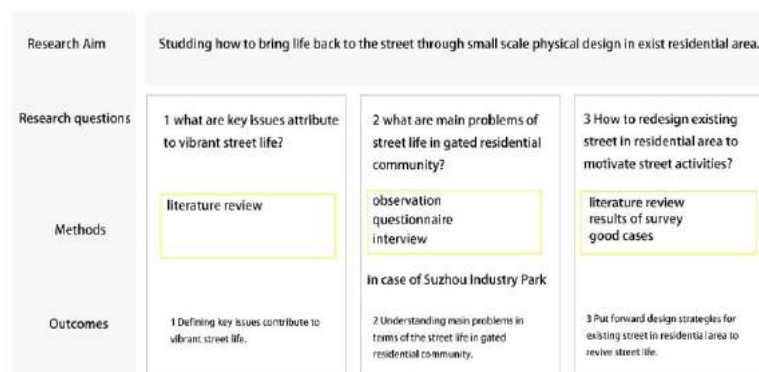

Figure 1. Research Framework

2 LITERATURE REVIEW

2.1 CLASSIFICATION OF STREET ACTIVITIES

Rebuilding street life is aimed at shaping a shared and integrated street environment rather than merely for circulation. Gehl (2011) divided street activities into necessary activities, optional activities and social activities according to the extent of the external environment requirement. Necessary activities happen with a kind of compulsion such as commuting, waiting for cars and buses. Optional activities are strongly associated with the condition of the external environment. For instance, sitting on the roadside or standing under trees only appear under certain desired situations. Social activities refer to activities dependent on the presence of others in public like children at play or greeting with acquaintances. Mehta (2013) further analyzed the behaviors occurring on the street from the perspective of social communication and sorted out the street sociability into passive, fleeting and enduring. Usually, passive sociability refers to individuals appearing in public space without any direct verbal contact with others. They appear street alone and focus on themselves, such as eating, reading, playing mobile phone or watching passersby (Mehta 2013). Subsequently, Mehta (2013) stated that fleeting sociability often happens in the neighborhood street with commercial functions. Greeting with an acquaintance, a short stop for a chat with neighbors, even a simple eye contact, a nod or a smile is the sign of fleeting sociability. Enduring sociability depends on more frequent and repeated contact among people. It is composed of weekly gatherings of intimate friends in cafés, or a family dining in the outdoors, as well as acquaintances standing outside to chat

2.2 RELATIONSHIP BETWEEN STREET ACTIVITIES AND DESIGN ISSUES

Necessary activities: As for the width of sidewalk, Whyte (2001), Mehta (2013), Marcus and Francis (1998) all agree that enough room for pedestrians is significant to support walking. Elevation treatment is another key issue. As Gehl (2010) pointed out people generally tend to avoid areas where level changes are large. It is noteworthy that frequent level changes in sidewalks produce problems for pedestrians, particularly for disabled people. Additionally, considering the situation of wheelchair users and people pushing prams, it is necessary to minimize obstructions on the footway. Meanwhile, planting (trees and shrubs) should not obstruct the sightlines of pedestrian. Pedestrian traffic is also quite sensitive to pavement. Jacobs (1993) and Gehl (2010) highlighted that the uneven ground surface is unsuitable for those with walking difficulty. Whyte (2001) also indicated that different pavement materials would be linked with various functions.

Passive sociability: As mentioned by Mehta (2013) and Whyte (1980), individuals seek relaxation in public spaces, and in the meantime, they do not want to be separated from city life. Even if they are temporarily alone, they still tend to pay attention to the streets where people hurry by since there is a feeling of liveliness and engagement. Just as indicated by Mehta (2013), businesses like bars, restaurants and stores are conducive to passive sociability. Admittedly, people are often engaged in some parts of the street where there are small businesses. Mehta (2003) argued people have more preference for small stores than large businesses in a community commercial street. Meanwhile, to ensure the environmental comfort, it is critical to provide comfortable microclimatic conditions, including temperature, sunlight and shade, and wind, for supporting outdoor activities. It also vital to set up enough seat places for both primary seats (chairs, bench) and secondary seats (stage, ledge) (Gehl, 2010; Whyte 2001 and Mehta 2003). Visual complexity is desirable for well-liked and well-used open space. An empty space without any interesting detailed design is hard to attract people for staying. It is vital to avoid a dull street view, which usually presents a clutter of elements of the same type (Whyte, 2001; Lynch, 1980; Marcus and Francis 1998). Animated edges of streets can catch the eyes of pedestrians and stop them.

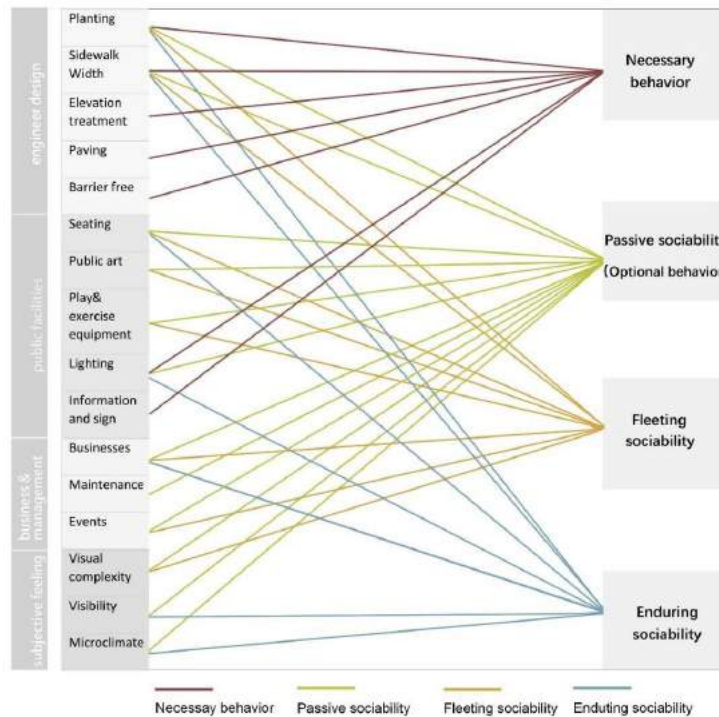

Figure 2. Relationship between design issues and street activities (Author 2017)

Fleeting sociability: First, the width of sidewalks should consider enough room for strolling, walking pets and children playing. Then, it is worth mentioning that street fronts with semi-enclosed sheltered space away from the pedestrian flow allows people to talk in a comfortable shade. To satisfy people who are staying on the street, sitting space should be provided. According to Mehta (2013), the street furniture should be designed and managed well, which sometimes supports casual forms of play. Playing in the street also produces opportunities for fleeting sociability since it sometimes attracts people to watch. The importance of play and exercise equipment has been stressed by Marcus and Francis (1998). Additionally, artwork and street events are very important. They can encourage people to stop and exchange comments Whyte (2001). External stimulus produces communication among individuals in various ways. Artwork can motivate people to stop or stay to promote social interaction (Gehl 2011). Triangulation can also be created by special events such as street parades, outdoor sales, festivals, and street musician performances (Mehta, 2003).

Enduring sociability: Generally, streets place which support enduring sociability are associated with space-fronting stores. It is crucial to have a certain proportion of businesses on the ground floor. Just as suggested by Whyte (2001), more than a half of frontage space in residential areas ought to be used to locate commercial services. Not limited to stores and open-air catering, businesses also refer to small stalls and handcarts. Informal businesses should be encouraged as well, which can both increase the vitality of a place and provide convenience for residents, thus improving the visual complexity (Whyte, 2001; Jacobs, 1998 and Gehl, 2010). Then, when finishing dinners in a restaurant, people may continue their talking and strolling along the street. According to Mehta (2013), an ample sidewalk space is obviously of significant importance in accommodating fixed activities (Ashihara 2006 and Jacobs 1993). The adjacent space on the businesses and the sidewalks as well as street corners must be equipped with safety and comfort to create an atmosphere for gathering. It is vital to design wide sidewalks with sitting places and pleasant microclimate. It is better to maximize the sitting places and fully use the secondary sitting areas (Gehl 2010, Whyte 2001). It is feasible to apply movable chairs because of their flexibility and comfort. In addition, to not disturb people standing outside for a long time, sheltered spaces are necessary to isolate the unpleasant environment condition microclimate. Marcus and Francis (1998) explain that, in generally, shade and shelter from the sun and rain are prerequisites for almost all sociable spaces.

3 CASE STUDIES IN SUZHOU INDUSTRIAL PARK

3.1 TARGET STREET

This part explores the problems in existing residential streets through a case study in Suzhou Industrial Park (SIP). XingDu Street is a secondary road through a residential area connecting the main avenue, which is located next to the central business district of SIP. Figure 3 shows the location and current images of the studied street. The distance between the central park and the studied street is just less than 300 m. The street is near the metro station within 5 minutes' walk. XingDu Street is a typical four-lane residential street in SIP, and problems on this street are typical of problems throughout residential areas in SIP. There are four motor lanes and two cycling lanes on this street. The motor lanes and cycling lanes are separated by 1-meter-wide green buffers. A 0.18m height difference exists between sidewalks and cycling lanes. In the 3m cycling lane, more than half the width is occupied by one-side parking. The space of street and community are separated by a 1.5m wide planting space and a 2m high fence. The width of the sidewalk is less than 2m.

Figure 3. Location and current images of the studied street(Author 2017)

3.2 PROBLEM IDENTIFICATION BASED ON ONSITE SURVEY

To identify the main problems of street life in the studied residential street, on-site observation, questionnaires and interviews were conducted. Existing and non-existing activities in selected sites are identified through on-site observation. The studied streets were visited at different times, during the night, day, working days and weekends. The visits took place between 9:00 am and 9:00 pm twice a week for a month by the author for an hour each time from May to April in 2017. Questionnaires and interviews were conducted to identify the reasons for the absence of street activity.. Residents were asked to share their opinions on activities in the street.

Figure 4 shows the category of existing activities on XingDu Street. The majority of activities observed are necessary activities consisting of commuting and waiting, which occur compulsorily. The quality of optional individual activities in the studied street is poor. Almost all individuals walk through the studied sites hurriedly without staying in the public space. Sitting on the roadside or standing under trees for a rest did not occur. Pet walking and kid playing occurred, but the frequency was low. Fleeting sociability occasionally occurred including children playing, greeting with acquaintances and short consultation of the house sale. As for enduring social communications, ambling and chatting with peers happened only occasionally. It is interesting that the lack of street facilities cannot support current requirement for enduring sociability. For example, although residents sit near the entrance of the community, they brought chairs by themselves.

Figure 4. Category of existing activities in the XingDu Street (Author 2017)

In the questionnaire, “enjoy the street view” and “sit & relax” are perceived as activities with the poorest environment design followed by “play”, “physical exercise” and “have a conservation”. The main reason for the low marks in optional and social activities like “enjoy the view”, “sit and relax” and “have a conservation” is the dull visual feeling delivered by the place. Then, “poor street planting” was regarded as a problem for both optional and social activity, especially for “have a conservation” and “sit and relax”. Poor design of sidewalk width and paving plays a key role in low satisfaction of all necessary, optional and social activities. Especially for “ambling & jogging”, “waiting,” “play”, and “physical exercise”. Inadequate street furniture negatively impacts the optional activities “sit & relax” and social activity “have a conservation”. Lastly, it is found that low outdoor comfort of microclimate decreased the intention of duration of social activities “play”, “exercise” and “have a conservation”. As for the expected street activities and functions in the studied streets, “street furniture” and “play & exercise facilities” are very desirable in the studied street. People in XingDu street also have a preference for work, venders, street business and street performances. Almost all respondents believe the current street does not have a pleasant environment for staying a long time. 80% of them agree that the street view is dull and lacks visual attraction. They have a strong feeling about the boring walking experience. Then, 90% of residents agree that car parking next the sidewalk is a serious problem as it often cause traffic conflicts and leads to a high safety risk. In term of the fence, around one-third of residents strongly approval of the statement that the fence damages visibility and visual complexity on street. 60% of them believe the fence should be removed or be designed in some other from.

3.3 RESEARCH-BY-DESIGN

3.3.1 DESIGN STRATEGIES FOR NECESSARY ACTIVITIES

Existing Problem: Walking is the fundamental street activity, but current street design gives the priority to traffic flow and car parking while the pedestrian is not the main concern. Present pedestrian circumstance is unfriendly to the disable or people with baby carriage or luggage. Improper paving, and height difference without slope will damage their walkability. One-side parking is an issue that impacts the safety of basic walking behavior.

Design strategies: Widening pedestrian zone by designing multi-functional buffer zone, eliminating height difference and changing paving.

Best practices: In the Street Design Guidelines of New Delhi (2010), multi-functional zones on a street should be a minimum of 1.8m wide, and may locate multiple functions. In the Shanghai Street Design Guideline (2016) proposes the combination of green buffer and street facilities with 1.5~2m wide. Multi-functional zone is a useful tool to maximize the space of pedestrian by overlapping green buffer and street facilities. Learn for the street renewal practice in Gevelsberg, Germany, the space of pavement can be defined by paving. Mittelstraße is Gevelsberg’s main street, the pedestrian way is defined by striped

paving which gives structure in a simple clear pattern. This slows traffic and creates even more opportunity for public activities.

Design proposals in the XingDu street: Enough room for pedestrian is a significant supportive point for street activities. As Jacobs (1993) mentioned a minimum of 35 % of street width must be dedicated to non-motorized transport. To widen the pedestrian zone, learning from Street Design Guidelines of New Delhi and Shanghai Street Design Guideline (2016), multi-functional buffer zone can be implemented in the XingDu street. A fully use of the buffer area between carriageway and pavement is a wise way to accommodate various functions consisting of tree planting, parking, street facility and furniture. Learning for the case of Mittelstraße Street in Germany, the different function of space can be defined by the paving material. Then, a shared space can be achieved by eliminating height difference between the sidewalk and bike path. Figure 5 shows the before and after section in the XingDu street. Figure 6 shows the before and after perspectives in the XingDu street.

Figure 5. Section of XingDu street before (left) and after (right) (Author 2017)

Figure 6. Perspectives of XingDu street before (left) and after (right) (Author 2017)

3.3.2 DESIGN STRATEGIES FOR OPTIONAL ACTIVITIES

Existing Problem: Current street environment cannot support optional activities such as sitting on the roadside or standing under trees. Most people said the street view is boring and they do not want stay alone. The poor quality of optional activities in XingDu street is closely associated with monotonous landscape (poor maintenance and useless shrub) and absence of visual attraction (fenced edge of communities).

Design strategies: Creating attractive street landscape by transforming fences of community into active edge.

Best practices: The strategy of active edge can learn from the new road project in Brighton. A new street decoration – a finely crafted, long wooden bench is placed along the edge of the street. The new paving and seating have invited people into the space, made interaction possible, and changed the dynamic of the street. Local citizens have been quick to embrace the change, generating a new urban culture in what has become one of the most popular places to spend time in the city.

Design proposals in the XingDu street: Current landscape in the XingDu street is featured with barren façade, fence and poor maintained shrub. Learning from the literature and New Road project in Brighton, the edge of communities can integrate street furniture or creative planting. By this design, a sense of joy of walking can be achieved. Using this design people on the street might be slow down and have an observation. The edge of community can integrate with the long bench. This design decoration offers

passersby a place to sit and relax while watching life on the street which is much-needed from people's opinion. Figure 7 shows the reference images of the active edge strategy in the XinDu street.

Figure 7. Design proposal of active edge

3.3.3 DESIGN STRATEGIES FOR FLEETING ACTIVITIES

Existing Problem: Apart from providing opportunities to greet with acquaintances, livable street provides opportunity for fleeting sociability between strangers. In XingDu street, fleeting communication merely happened occasionally and limited to in greeting with neighbors. Absence of commercial and recreational function decreases fleeting sociability in XingDu street.

Design strategies: Encouraging street events and temporary activities on the street.

Design proposals in the XingDu street: From the questionnaire and interviews, street events and temporary activities are desirable in the XingDu street. To stimulate fleeting social interaction, weekend market, outdoor sales, street musicians performing, movable and temporary stall supposed to organized as showed in figure 8. Triangulation communications can be produced by these special street events. These activities can also foster a feeling of liveliness and engagement that contribute to the passive sociability.

Figure 8. Design proposal of various temporary street events

3.3.4 DESIGN STRATEGIES FOR ENDURING ACTIVITIES

Existing Problem: From the observation and interviews, people in the XingDu street intend to stay outside and communicate with peers. However, current street furniture and facilities are insufficient, especially the lack of places for sitting, no pavement café and no shelter for bad weather. To support enduring social communication, a place must provide suitable physical conditions for meeting and chatting.

Design strategies: Adding street furniture, play facilities and art installation on the street.

Best practices: Parklet project was created in San Francisco in 2005. Converting parking spaces to a tiny public park is an efficient measure to create space for street activities. The designers put grass, turf, bench and potted tree in a parking space. The design of a Parklet is a platform that extends the sidewalk and provides amenities like seats, tables, bike racks, and landscaping. The parklet offers passersby a place to sit and relax while watching life on the street.

Design proposals in the XingDu street: To allow people to stay longer in the street and stimulate enduring social communication. Art installation and playing equipment play a main role since they sometimes attract people's attention. Learning from the good practices, the form of street furniture and playing equipment and art installation can be integrated with each other as showed in figure 9. Additionally, learning from the case in San Francisco, sidewalk can be extended by converting parking spaces to a tiny public park.

Figure 9. Design proposal of adding street furniture, play facilities and art installation

4 DISCUSSION AND CONCLUSION

To achieve a vibrant street life, a range of activities need to take place on the streets including optional individual activities and fleeting, enduring social communication and necessary activities. In SIP, the current condition of residential streets meets people's basic requirement for necessary activities, but does not easily accommodate optional individual activities and social activities. The quality of optional activities is negatively impacted by the monotonous landscape, the absence of visual attraction and the lack of street furniture.

There are no interesting or unusual activities get people to stop, look, listen and engage in fleeting sociability. Apart from greeting with acquaintances, few opportunities have been provided for fleeting sociability, especially occasional communication between unacquainted people. Ambling with peers is the only type of long time social communication. Although people have an expectation of meeting and chatting in the outdoors, the current street cannot provide suitable physical conditions.

To address the problems mentioned above, design proposals and strategies are generated for the studied residential streets. Firstly, ample space for pedestrians is the precondition of all street activities. To widen the pedestrian zone, sidewalks can be integrated with the cycling lanes. A shared street space can be achieved by eliminating height difference between sidewalks and lanes, together with a change of paving materials. In addition, multi-functional buffer zones (integrating green buffers and functional buffers) can be used. The second solution is to design the edge of communities in a creative way as a strategy to improve the quality of the street landscape. The edge could be integrated with street furniture or planting. Meanwhile, street furniture and facilities should be placed after widening the space of the pavement. Seats, play and exercise equipment, public art installations and shelter should be emphasized. The last design strategy is to encourage abundant temporary activities on the street. Diversity of temporary activities ought to be encouraged such as weekend markets, street performances, outdoor cafés and other events.

Current regulations of residential street design in SIP force a separation of pedestrian and vehicles by different height or by green buffers. To maximize the pedestrian zone and achieve a shared street space, this regulation should be altered. Furthermore, current regulations for street design in SIP require a separation of green buffers and functional buffers. To maximize the pedestrian zone, a multi-functional buffer zone ought to be encouraged. Meanwhile, in terms of functional buffers, the function of the cycling lane or pavement ought to be given priority instead of one-side parking. In addition, the rigid regulation of fence designs in residential areas should be altered. To create an attractive landscape, the edge of communities ought to change. The integration of a community's edge with street furniture or planting should be addressed. Lastly, commercial and retail activities are banned in the residential street. Regulation for temporary activities ought to loosen and encourage street commerce, outdoor cafés, temporary stalls and other street events.

Although the design strategies proposed here are based on extensive prior theoretical and empirical research in the case of SIP, the evaluation of design proposals have limitations. For example, even though users of public spaces were asked to share their opinions about current problems of street activities, the

choice of design strategies reflect certain values of the author. The public should judge the use of their own urban spaces. To verify the rationality of the design proposal, a second-round questionnaire and interviews should be conducted in the next step. By doing that, the design proposal could be further optimized with the help of the residents' feedback. In addition, although there is a feasibility analysis of the design proposal in terms of planning regulation and policy, the implementation of the design project must be considered through further research. Perhaps a public-private partnership can be used. For example, the cost of the project might be shared between the local government, the neighborhood committee, the property developer as well as other commercial sponsors.

ID 1448 | PUBLIC SPACES AS A PLANNING DIMENSION: MILAN CASE STUDIES AND POTENTIALITIES

Martina Orsini¹; Beatrice Galimberti²

¹Ibidem Research Group; ²Politecnico di Milano

martina.orsini@gmail.it ; beatrice.galimberti@mail.polimi.it

1 INTRODUCTION

After a long apathy phase, a combination of increased real estate pressures and international initiatives like Expo or the latest Triennale revival, heavily activated in Milan the realization of new public spaces and revitalization of old ones. Which include, among others, starchitects new inner city neighborhoods and landmark buildings, new design and fashion urban network spaces, car limitation policies to extended urban pedestrian areas. However, Milan urban renewal path is concretizing through heterogeneous results as they were the proceedings which inspired these transformations. Indeed, each of these modified areas has been individually conceived, being absent any meaningful high scale planning indication outlining an overall transformative vision of the city. This is clearly reflected in the Milan increasingly fragmented geography (Secchi, 2013), where the collective urban dimension has been often degraded to the rank of a public spaces collection to be consumed, rather than an urban structuring spatiality seeking connections. Such an attitude drives to the weakening of the heterogeneous but highly intertwined urban complex which has always characterized this city. The overlap of historical compact frames and contemporary fragmentations, as well as different densities, gave rise to the actual Milan spatial condition, where emerge considerable public spaces potentials that could lead to fertile experimentations. But if public spaces are trivialized, they end up becoming self-referential entities, missing the task to condense differences and relations of the city.

This paper will deepen some of these potentials from the consideration of public spaces as active devices within which to develop connective systems responding to contemporary urban complexity inputs (Mada-nipour, et al. 2014). Milan chosen case studies will be then investigated from a critical point of view, but also as an opportunity to activate vibrant and pervasive urban backgrounds able to react effectively to the incessant changes of the city. This required to go beyond mere voids furnishing design actions, which is the prevalent approach to the theme adopted in Milan since recent time. The proposed investigations, had adopted instead a structuralizing approach to intercept topics emerging from the many and different environments urban frameworks involved in the new or revitalized public spaces analysed and in some cases re-designed. The paper will thus draw on specific design and exploration experiences evolved at the Urban and Territorial Planning Lab and the Urban Studies Course of the Polytechnic of Milan which we've held, and in partnership with various stakeholders and scholars, to highlight interpretations, hypothesis and glances for a new approach to public spaces as a key theme within with to re-design Milan's contemporaneity. 'InFractures' is a design research in which are systemized and reconnected sets of empty in-between spaces at various scales innervating, through different intensities, areas from the city core to the eastern suburbs. Through 'TimeLapseCity' are investigated and interpreted new or deeply changed inner city public spaces, analysing their unexpected urban characterization in the light of everyday life uses, behaviours, practices, effects on the surrounding context. 'RipCity' deals with a globalizing real estate insertion in a crucial environment between compact core and urbanized Milan region, deepening public space design hypothesis with the task to reconnect clashing contexts. 'AgorUP' tests a public spaces network utilizing flat rooftop surfaces, so as to consider alternative urban landscape inputs in the collective dimension and fruition of the city. Selected key steps of these researches will try to advance new perspectives on the public space delicate role in the definition of the contemporary city, providing cues for its interpretation and design.

2 PUBLIC SPACES IN MILAN. SOME GROWING AUTARCHIES

The goals of the many and different actors involved in the development and renewal of urban environments in the contemporary city show to be increasingly indifferent of any enhancement of public spaces inherent values, nor the evolution which could reveal their urban structuring potentialities. To the increase over the last decades of wide real estate developments disseminated in every medium and large European city, to which are added the innumerable urban rebirth and district reuses, corresponds a widespread and deep banalization of the collective dimension. The impoverishment of its social, formal and cultural values, so as the incapacity to preserve or trigger relations between parts and elements composing the city, is now the dominant character of most of the new and revived public spaces in the western city (Tzonis and Lefaivre, 2013). Eloquent signs of this are seen in the loss of the plurality which should articulate their configuration, so as the self-referentiality it is usually conveyed. In fact, the research of predictability in the actions taking place in a public space had brought to a spatial overdesign to guarantee it, but also to globalization of the design to implement it. It is not uncommon to experience public spaces producing endless déjà vu of styles, patterns, materials, forms, conformations, so as starchy architect's spread design brandings. This flattening primarily coincides with the dropping of the public space from the interrelation domain to that of the consumption. A shifting which emphasised its increasingly autistic nature, together with the repetition as the preeminent identity device (Bauman, 2001). Indeed, the introverted character of many of the contemporary public spaces originates in an imbricated social, economic and cultural transformations weaving, of which the market rules are perhaps the most obvious inputs to be intercepted. Much more pervasive and subtle can be instead those linked to the people's behaviours, to the new social fears (Ellin, 1997), to the constantly changeable intolerances forms, to the expressions of individualisms and exasperated privatizations, to the growing social inequalities, and which have drained the public space since long. If today, the capacity of public space to be a powerful urbanity making is recognized by everyone, it must be also said that it is often conceived in a highly destructive manner both from design and urban policy points of view.

The following Milan's cases aim to highlight crucial fractures occurring on public spaces, and which spatial consequences reverberate at different scales in the whole city. One is the increasingly widespread prevailing of rigid borders on permeable ones, especially in recent public spaces designs. The growing design tendency to create enclosed collective environments, whether they are outdoor spaces like squares and other kind of urban surfaces, end up to frustrate the public space everyday negotiation aiming to inclusion and integration, rather than to the exclusion. This in Milan is achieved through barriers of various nature, ranging from the detachment of public soil from the city level ground (e.g. Piazza Gae Aulenti) to the dense buildings edges tendency with the purpose to hold the collective dimension, but with the effect of isolating it (e.g. Citylife recent urban project). In the same way, the compulsive filling of public space with shopping malls and globalized brands to economically support its existence, gives clear evidence of the deep deprivation of meaning to which is subjected, not to mention the retraction of the public financing which often lies behind that. The conceptual ground of this is also in a mix of real estate interests and convictions, which sees in the introverted public space a better housing market option to promote and develop. But also the just mentioned increasingly withdraw of Milan municipality from investing in public spaces making, thus letting the costs – therefore, their ideation - to the private investor and its beliefs, that are rarely sponsor of spatial experimentations, nor of meaningful dialogs with the urban context. Another fracture comes from the rigidity within with who is actively involved in urban transformations and implementations interpret the society. Indeed, there is a persistence of outdated and traditional views subdividing the whole citizens into sort of monolithic and opposed groups, when not classes, e.g. the resident and the users, the young and the olds, the families and the singles, the native and the foreigners, to name just a few of the categories to which a public space is usually referred to (Innerarity, 2006). This banalization often animates since the ideation and design phase, and in the dominant Milan urban policy debate, denoting the incapability to include the vast collection of pluralities characterizing any contemporary society and to go beyond rooted ideas (Breen, 2004). An attitude that in most cases produces disconnections between spaces and utilizers, revealing inadequacy to hold the social fluidity and its displacements, and ending up to bridle the innate unpredictability of public space, which is one of the necessary condition to trigger an authentic spatial vitality.

3 RESEARCH METHODOLOGIES

The following considerations emerging from Milan's case studies are the results of analytical and design kinds of academic research. But in both cases, a project glance has been used to interpret the urban areas in which the researches have taken place. In fact, from a methodological point of view, the teaching team, the students, and all the other subjects involved in the different case studies, have shared the belief that the interpretation of the city can be particularly fertile when is contaminated with design ideas, regardless of whether it is the final aim of the research. As a design idea here is meant not a specific solution for a given space, nor any hypothesis of an articulation of soils and volumes. Rather, it means a sensibility to perceive the potentialities of a place, its role if seen it from an extended urban prospective, its transformative capacities. The intersection between a design feeling and the analytical deepening of an urban reality doesn't mean to be trapped in a hypothetical and personal vision in-fluencing urban investigations. It allows instead to narrow the research field, to relate the work to a background of possible transformations as a creative selection for analytical choices avoiding to get lost in observations covering every aspect, dynamic and phenomena.

In addition to this, the research has followed common traces in the modalities through which investigate the different areas and urban themes, though leaving wide margins of variation to better consider the many heterogeneities characterizing them. A first framework of morphological reference consists of spatial types imagery to describe the relationship connotations at different scale between an object or an area and the context, e.g. clusters, bubbles, islands, threads, etc. But other morphological considerations emerged by the analysis and classification of the edges and described also their interchange status, e.g. the degree of porosity, permeability, continuity, fragmentation, spread. These morphological considerations were all related to different scales of observation, to highlight any variation when expanding or detailing the scale reference.

Finally, all the data collection, economic and social studies, including interviews and data variations over time, functions and uses detecting, other urban cases comparisons, have always been related to the aforementioned morphology considerations to validate or to question them.

3.1 INFRACTURES. URBAN RE-COMPOSITIONS

"InFractures" is a project investigation working on different scale urban void sequences identified in the north area of Milan tissues. This is an area of the city developed along three railway tracks and the city central station [Stazione Centrale], today still representing a very perceptible partition of the city. Even if it can not be considered a physical barrier, it generated recognizable spatial consequences. Indeed, the railroad embankment, however widely permeable by cars and pedestrians, acted as a strong three-dimensionality which had decisively influenced the urban morphology and framework definition, like urban snips, abandoned plots, rears and internal corridors, infrastructures remnants. Since the twentieth century and the post-war rebuilding period, the contact between the new city quarters and the sinuous shape of the railway had resulted in a series of in-between spaces characterized by rough geometries, and of which isn't easy to imagine re-uses. To a larger scale, the railway had instead provoked the succession of many residential introverted neighborhoods, added to the presence of high-speed infrastructure axis which historically led to the major urban factories on the northern edge of the city. This has determined the

Figure 1 - InFractures. Images by Stefano Manzoni and Mattia Santambrogio

tendency to divide the expansions of this part of the city following a large urban mesh partition, and giving rise to plots composed of extensive dense urban blocks. In many of these fragments are located the social housings, defined by mono functional articulations, as well as the absence of significant reciprocal relationships (Fig.1). Among them, in an ideal continuity with the nearby railroad, there are unused lots and large in-between spaces with a tremendous potential to insinuate a mixité able to trigger urbanity in areas that are to be considered Milan's almost central areas. But also to create urban dialogs to call into play new continuities, which are not those of unused voids sequences.

The teaching team and students have therefore investigated these open spaces sequences, considered together with the widespread structured and functionalized ones, trying to recognize in them sets of configurations that at the different scales could establish a fertile background for design experimentations. They have been identified different typologies depending on the dimension, spatial position, relationships with buildings or streets, visibility, potential connectivity, accessibility, and referring to spatial configurations like island, plug, linearity, dot. The abacus derived from it, highlighted above all a precious plurality to gather in urban systems apt to condense heterogeneity as an urban lymph (Fig.1). The interpretative and design work had the goal to transform urban disruption into new reconnection systems introducing through those large urban blocks new frameworks to activate positive tensions between fronts and rears, solids and voids. The innervation of alternative mobility through the enhancement of cycling and pedestrian paths also played a main role, well as generating a widespread public space system to counterbalance the introverted urban blocks and high-speed road combinations.

Figure 2 - InFractures. Images by Stefano Manzoni and Mattia Santambrogio

The projects have in particular worked on the continuity of bearing areas connecting well-established parts of the city and large green areas to the city's edges, thus acting both at district and town scale. In the design shown here (Fig.2) is perceptible this double spatiality, where different building typologies are kept together by a continuous public surface that as a linear plug relates one of the great urban axes leading to the north Milan's metropolitan area with an important urban park located on the east edge of the compact city tissues. The extensive permeability and porosity of this new urban configuration nullify the little significant rears sequence on the fragmented unused and empty spaces, so to sew the existing large urban blocks through specific typological and density choices.

3.2 TIMELAPSECITY. URBAN RELATIONSHIPS FRAMING

As mentioned in the introductory paragraph, since 2014 Milan begins to be considered a city again under the spotlight. Its preparation for the EXPO captures the world attention, although not only for the Universal Exhibition which is going to take place. Indeed, it is in the expansion of the city from the fashion and design field to the one of the so called “urban renaissance” that has been perceived a Milan’s rebound . This is evident when scrolling through the press review since 2014 of the most important newspaper in the world. If compared with the one of the previous twenty years, where fashion and furnishing designers city was celebrated, Milan suddenly reveals as a destination to experience great urban transformations. Which combined with a series of some historical districts gentrifications occurred since the end of the 80’s, giving raise to a new common perception of Milan as a city of vibrant and collective spatiality. The Boeri’s Vertical Forest, Hadid’s residential blocks, the Liebeskind’s and Isozaki’s skyscrapers, Koolhaas’s Prada Foundation Museum, Chipperfield’s Museum MUDEC, Sanaa’s Bicconi University Campus, the multi projected Porta Nuova District, the Foster’s new district Santa Giulia, undoubtedly testify of an urban rewrite of the city. However, far from the usual urban renaissance rhetorical within which such transformations are often described, it is equally undeniable that these projects acts as individualities in the urban tissues, constituting at most a sort of virtual architectural tourist itinerary. A prestigious assemblage but whose implications in terms of collective spatiality must be rationally examined. Many and articulate are in fact the forms of collective space individualism linked to these new urban appearances, as well as the public dimension forms of privatization they bring to light.

“TimeLapseCity” is an urban investigation experience characterized by an in-depth path about different collective spaces uses of some very thematised areas in Milan. Among these, three reveal to be particular useful to underline meaningful issues and dynamics of spatial exclusion. The re-composition of city maps returning implied, hidden, overlapped, excluded, mimetic, conflictual and contradictory aspects has had the purpose to provide new grains and glances to be juxtapose to more conventional images and representations. Holding this perspective, it has been experimented the overlay between different description, analysis and interpretation techniques ranging from interviews to data collections, detachment and re-design of constituent layers, behaviours studies, to re-determine some spatial interrelations and meanings.

3.2.1 GAE AULENTI SQUARE: BEAUTIFICATION AND EXCLUSION

The first case is piazza Gae Aulenti, a recently realized square in a new luxury settlement of 290,000 square meters of offices and residential buildings now fully owned by Qatar Investment Authority. It’s a square soon came to the collective imagination as a new centrality of the city, but which conformation represents one of the most contradictory and exclusive urban spaces that Milan has ever seen realized.

Figure 3 - Gae Aulenti Square. Images by Martina Orsini (left), Arianna Manzinali, Lorenzo Merigo, Matteo Pigni, Silvia Cassader and Stefano Iacolina (right)

The whole square is detached to any spatial dialog with the context. Indeed, the surrounding connections take place through gangways or stairs that are linked to what are considered to be strategic points, like the fashion and design district of Corso Como and the historic district of Isola, which in recent years has undergone a massive gentrification process. The beautification and overdesign to which the square was subjected, with intricate floorings, fountains and water games, so as shelters of every shape and style – but not a tree - can not mitigate the total sense of urban alienation and isolation that characterizes it. This segregating modality lies in real estate considerations, which saw in the choice to rise from the city the attempt to create a protected environment in the middle of the city centre. As a kind of gated community with a very selected permeability, it constitutes one of the broader examples of Milan's public space individualization, where the denying of the very essence of a square become the distinctive trait, as investigations and drawings of "TimeLapseCity" researches reported and analysed (Fig.3). They particularly focused on the lack of positive domino effects of this act of urban revitalization on the surroundings, and on the lost occasion that an intervention on such a delicate point of the Milan fabric it could have represented. In fact, this process of revitalisation in the dense city should not be limited to restricted zones but could spread to the whole area, bonding various parts of the city developed separately, due to the presence of the abandoned area on which this new district has been built. The new district could play a vital role in the creation of new active margins, and where some opportunities of urban re-signification could take place. Indeed, the need of public spaces capable of relating to other city areas, subjects and objects, and, as much as possible, being open to cross influences, clearly emerges from the opposite effect produced by the self-referential public space that have been finally realized. The diagrams produced by the research experience show instead the attempt to control through the design the realized public soil, depriving it of urban fertile opportunities. The whole new settlement and the square in it isolate themselves from the context through physical barrier of the elevation from the city soil, condemning the unwanted parts to isolation. Among them, a regional railway station, which instead of being considered an important connection with the extended urbanized territory, has been considered a point of possible social degradation from which to separate. To emphasize Gae Aulenti Square self-referential character, despite its being the core of a whole new district, it is a folding building like a snail that surround it, offering to the outside world a flat and impenetrable mirroring surface.

3.2.2 TORTONA DISTRICT: SPORADIC POROSITY

The second cases have focused on Tortona design district, a former industrial area originally located in what was the south margin of the historical city tissues beyond the railway belt toward the agricultural lands. Since the 1980's, advertising producers, fashion designers, photographers and artist's ateliers began to reuse abandoned factories spaces giving rise to one of the first gentrifications in Milan. It's characterized by of an urban plot originally mixing important manufacturing realities like steel, large scale porcelains furnishings, energy production, and with a consolidated network of supporting small manufactures. The urban grain is thus very discontinuous, with many scale shifting given by the interweaving of giant buildings with extremely wide outdoor storage surfaces and smaller buildings, often also mixed with residential, and with their smallest and intimate courtyards. To this was added an urban fabric made also of after-work spaces and union-workers headquarters innervating of sociality the large manufacturing urban blocks. In concrete terms, this size blend had made possible the many replacements while maintaining a strong space and uses differentiation. In fact, it wasn't necessary to subdivide the space, since larger spaces have settled major functions like MUDEC museum, the Scala's theatrical scenery laboratories, world-famous brand showrooms (Fig.4). The factory gates which for a long time had enclosed a feverish Milan's humanity, today are open to the world through the recurring 'something-weeks'. At the known in the world Design-Week and Fashion-Week, are now in fact to be added the Food-Week, the Music-Week, the StreetFoodParade-Week, the SkateFilmFestival-Week, the Spring-Week, etc.

Figure 4 - Tortona district. Images by Marco Attucci, Thays Colli, Goffredo Duranti, Matteo Paronuzzi, Pedro Petry Franceschini and Andrea Pirinoli (left), Matteo Baggiarini, Eleonora Catozzi, Giuseppe Rizza, Sara Barone, Heran Yang, Anqi Zhan (right)

A first crucial aspect emerged through the urban investigation is the massive gentrification to which the area has been subjected. Although it has not been promoted by real estate organizations, and the urban market has leaned on an already consolidated urban transformation, the self-definition and the pervasiveness through which the replacements have occurred haven't mitigated the effects of social selection and expulsions. In fact, this self-managed transformation promoted by some pioneers of the gentrification, had been so deeply influencing the collective imagination to become a kind of powerful social filter deciding between admitted and not admitted, and going well beyond the economic discriminant. This has had its concrete evidence in the management of revitalized space. In fact, in the early stages of this transformation process, large industrial enclosures were purchased and split by professional communities, and the introduction of new subjects was decided on a case-by-case basis based on social, cultural and identity affinities. Since the beginning, the large industrial courtyards became sort of gated communities, with locked gates and surveillance services. With this, the connective social fabric linked to work-manship disappears, being replaced by a plethora of restaurants supporting the 'something-weeks' visitors. It has therefore lost the enlarged meeting dimension of a social community, being substituted by very restricted ones (Fig.5).

The research has highlighted and schematized through diagrams these public and collective intermitten-cy modalities. Despite the dominant spatial and uses typologies involved, the flexuosity inherent industrial spaces themselves, their malleability and declinations opportunities, the district can't be considered permeable and porous. The many parcelling and mixed activities are accessible and connected by the large but extremely gated industrial courtyards. These surfaces are thus permeable for collective and public transit when they become a percolated ex-hibition space. In the everyday life of the city, apart great museums and art galleries, and some small injections of co-working spaces promoted by the municipality, they remain as secluded bubbles sequence. With the second wave of reuses, this stiffness has further accentuated. The establishment of luxury design and fashion brands headquar-ters occupying whole industrial blocks – e.g. Armani, Moncler, Fendi, to name a few – are ordinarily open to insid-ers only.

3.2.3 CORSO BUENOS AIRES: URBAN SCALE NON-LIEU

The third case proposes an investigation of Corso Buenos Aires, one of the longest shopping road in Europe (1.6 Km) and historically coinciding with a suburban axis connecting the inner city with the metropolitan-scale territories. Specifically, it was linking the Milan city core with Monza, home of the summer Royal Palace, as well as one of the most important industrialised region in Italy. When at the end of the nineteenth century, Milan planning extended to outside the city walls, involving pre-existing urban elements, this axis had been re-designed in a definitive way just close to Universal Exposure of 1906, thus localizing a dense sequence of new urban blocks. In what was a planning attempt at a cautious mixing, the road was split into two parts: on one side it was decided to locate the social housing, on the other the bourgeois one. It's a division today still alive, deeply marking the urban bands referring to this road despite its actual complete homogenization. In fact, since it has become a globalized shopping street, it no longer appears as a boundary/connection between two social spheres, but rather as a completely autonomous element inserted within two very different urban districts. If originally it was a mixed commercial space where elegant shops were coexisting with neighborhood stores, its progressive logo branding transformation made of it an urban scale non-lieu, a sort of alienating strip totally unrelated to its context. In the recent decades, the two urban bands developed along the commercial road have turned into two of very representative Milan contemporary urban environment. The one originating from social housing actually accommodates an extremely vital and mixed neighborhood, where different ethnicities, especially from North Africa, India and China, coexist with young professionals and retired employees. A very complex and stratified urban environment, where several generations and backgrounds identify one of the most intense area of urbanity in Milan. On the other side of the road, the large blocks of the bourgeois city are innervated with tree-lined boulevards and linear green squares, and in the recent times subjected to virtuous and experimental participatory urban actions involving residents and workers of the area. Here the social mixing is less varied, although in the years it has lost his prevalent residential connotation and has mixed with specialized professional offices and shops, well as users of its public outdoor collective spaces also coming from other urban areas. The investigation had focused both on the strangeness and contradiction emerged by the dematerialization of the road typical of urban scale non-lieux and its effects in relation to different contexts and urban scale. Three are in fact the dimension references at which it has been analysed. The first, deepens the road as a single urban component, taking into consideration its materiality, uses and users perceptions, the spatial organization, the transformation over time. From the spatial point of view, the original division has shifted in height. In fact, the incessant sequence of shops creates a sort of almost immaterial base on which lay the late nineteenth century architectures, like a fluctuating parallel city. The sense of detachment between the two sections is further sharpened by the fact that the base is the expression of a globalized repetition, while the city that overwhelms is a very local architectural mixing of Liberty Style and typical Milan's residential courtyard typologies. At this same scale, the relationship between the users and the space is exclusively based on the consumption, putting in the background its essence of being a public place (Fig.6). The road here is just a device leading from one inside (shop) to another (shop), to end in an under (subway), translating with great realism the Virilio's Ville Panique twilight of certain urban places. The second dimension of investigation, gives evidence of how variable in the contemporary city can be the concept of in-between space, which commonly is referred to unclassified and uncharacterized spaces of the city. Indeed, although apparently extremely vital, this long shopping road is like a in-between element, separating the late revolutionized bourgeois and working cities. But as other research diagrams emphasised, at the large scale Corso Buenos Aires also marks other boundaries, like the ones between the city core and the northern urban expansions and the other between the compactness of the ancient urban tissues and the increasing fragmentation of the suburbs. It is not then its boundary identity that has been questioned over time. Rather, the forms and the meanings through which it occurred. If in its first demarcation, this place was conceived as a margin in the sense of a place of mutual contaminations, today it represents a suspension, or also a cut, which interrupts the city.

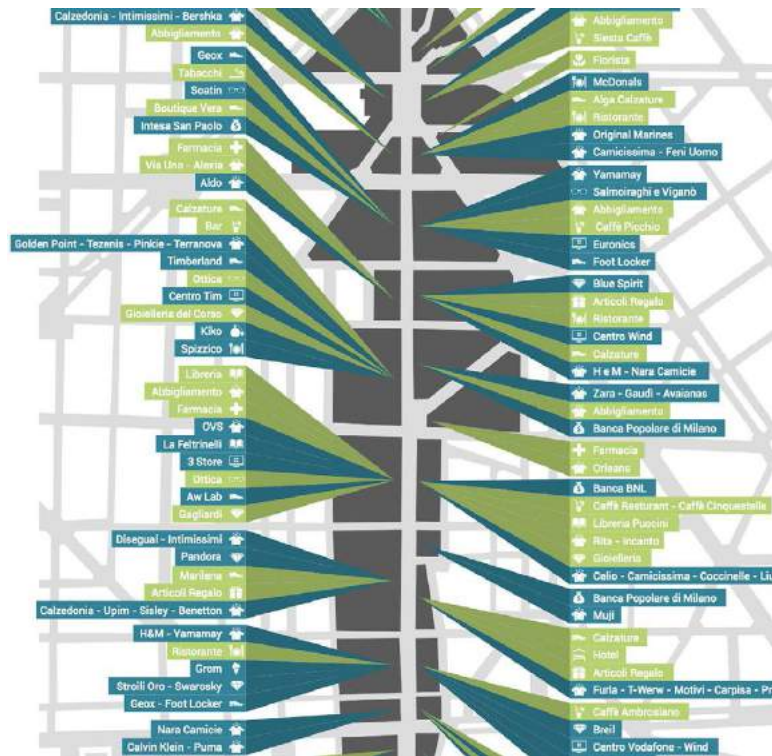

Figure 6 - Corso Buenos Aires. Image by Matteo Crippa, Jacopo Tassoni, Andrea Angiolini

3.3 RIPACITY. AROUND URBAN THINGS

Santa Giulia District is the redevelopment project of a former industrial area and for which deepening we have involved, in a very fertile dialogue, Risanamento Srl (the expressly established estate company), Foster + Partners Office Design, and a number of consultants, stakeholders, and public and private institutions. It is one of the biggest reconversion areas in Italy (land area 963,000 sqm; GFA 614,000 sqm) located between the consolidated Milan tissues and the margin of the sprawled city, overlooking a vast agricultural park toward the south limit (Parco Sud). The project site is currently under a slow realization due to the never ending economic crisis effects and related housings devaluation. The new district is part of a consolidated urban area consisting of public housings, disused industrial fabrics, agricultural residual areas, historic villages remains. The whole area is surrounded by an infrastructure system with high speed roads and railways connecting this place to the vast territory scale. However, such accessibility system produces a physical barrier at the everyday scale, making this place cut out of the corporal context perception and fruition. The prevailing characters of settlement is a spatial organization for enclave clearly distinguished by functions, but also by social belongings and cultural backgrounds, to which must be added disseminated empty plots waiting to be built. In such a context, the new Foster designed district fits un-critically this city area, sharpening the existing and poor urban relations due to its introverted and self-referential physiognomy.

The theme of the enclave as both specific typology and critical element of this area, has been explored and concretized in thematic maps with the aim to make evident the physical outcomes of immaterial dynamics, social and economic settings, spaces uses, but also potentialities emerging from these urban criticalities. Foster's project has in fact contributed to bring to the fore the properties of introversion common to the whole context. It had clarified the introversion as a settlement principle, but also as an individualism reaction to a generalized spatial identity lack, due also to the rarity of public and collective spaces. When we then explored and simulated through design scenarios and proposals to introduce some degree of porosity in such rigid morphologically situations, it soon became reasonable to figure that any massive intervention on the enclave - either old or new - not only was probably unrealistic, but seemed less effective than intervening from the outside inwards. Indeed, the space in-between enclaves has been ignored by both Foster Project when conceiving its edges, so as in the Municipality negotiations with the real estates developer. But if considered in a structural manner, it may constitute a new connective network within which restart a relationship-setting between fragments, to open to new orders and

combinations between them, to gather fluidity and plurality between the existing monolithic elements. And through this approach, it could be also overcome the common belief which supposes that to make trigger any urban vitality would be enough to scatter a plethora of collective functions and activities around. A tendency, this one, increasingly widespread not only among the great architecture offices, but also in the demands of the municipality when negotiating. The avoidance of useful dynamic dialectic with pre-existing small-scale urban milieu systems and with social, economic and spatial inequalities proliferation, is instead at the base of many agonizing urban contexts where new settlements are dropped, and with the bitter surprise of not being then able to trigger the imagined vitality so well represented in 3D images and simulations.

Figure 7 - Hinges, Circuits and Margins. Image by Martina Orsini

Figure 8 – RipCity Circuits. Image by Francesca Gervasutti

The re-design of soils and surfaces between settlements has been first of all a margins rewriting to include and to engage the constituent urban materials of this Milan's area in new configurations by which to define edges not anymore based exclusively on traditional antinomies. Therefore, the academic contribute to the enlarged dialogue has been the deepening of chosen design devices overcoming the enclaves separation, so to set up a spatial relation systems through which reorganize new and existing public or collective spaces and surfaces in a structural way. Circuits, margins and hinges (Fig.7) have been the references figures to diffuse and reorganize connections between enclaves, and to trigger a constructive and fertile glance.

The 'Circuits' have investigated the potential of continuous and organized systems of variable section of the soils considering enclaves as protected parts of a fluid and open system. The identification of potential continuous spatial loops composed of areas, filaments, empties of varying size and nature, has allowed to

experiment combinations of collective and public spaces in new urban geographies of support and connection between different fragments of this introverted part of the city (Fig.8). The 'Margins' have been instead tried to address and process the areas as complex places with a double value, where one can experience overlapping dynamics of belonging, but also conditions of strong autonomy. To organize them, they have been defined grids or linear devices based on the concept of parallel sliding, with the aim to shape the public space as a dynamic and autonomous entity, and as a support for cross-contamination between the new soil and the enclaves. Finally, the recourse to 'Hinges' spatial systems are to be intended as the juxtaposition between rigidities through flexible but solid connections, and around which the enclaves can rotate and ideally acquire the ability to recombine while maintaining a certain grade of individuality.

3.4 AGORUP. PUBLIC SPACES AS NEW URBAN VIEWS

"AgorUP" is a design investigation inquiring the potentialities of public space as a device to transform the underutilised supermarkets flat rooftops placed in compact urban tissues. Such a quite provocative issue has sprung in response to the observation of several recent public space arrangements in Milan that have been unsuccessfully designed –or overdesigned (Sennet, 2010)– as flat and smooth spaces, unable to permeate private spaces and to trigger connections between volumes and soils, dumping the dialogue with other urban materials to rhetorical diaphragms and transparencies. Contrary to Piazza Gae Aulenti's urban exclusion processes, AgorUP raised public spaces try to link roof surfaces to their context, establishing both physical and visual relationships between new public spaces and the urban landscape. Starting from these premises, the research fosters the design of public space urban systems located in areas already popular as supermarkets are, without producing any soil waste.

Figure 9 - AgorUp. Image by Beatrice Galimberti

A sheer number of supermarkets with highly underused flat rooftops is spread throughout Milan's urban tissues. Notably AgorUP focuses on Milan southern area, as it hosts a remarkable concentration of these rooftops typologies. Indeed the research site is a linear system oriented towards two parallel infrastructures (urban ring road and railroad) that crosses heterogeneous spatial conditions as compact residential tissues waved by a sequence of small green spaces, mixed-use fabrics without a predominant geometry, industrial sites under transformation, abandoned small scale craftwork platforms, Milan's Agricultural Park fringes, a scattered sequences of great urban voids as abandoned rail yards and high-scale building sites as Bocconi University Campus (Fig.9). In this composite area an almost isotropic carpet of flat roof supermarket is inlaid. Most of the time, these roofs are desolated non-lieux that people cross fast and unpleasantly, feeling an annoying discomfort in passing over. Although united by such a negative connotation, these rooftops presents different features. Indeed some supermarkets roof are big multistorey surfaces, while some others are settled in small areas; some are partially covered while others aren't; some are directly connected with commercial uses below (e.g. being mall parkings) while others are utterly detached; some are on the top of highly visible free-standing buildings while others are hidden in the heart of an urban block (Fig.10).

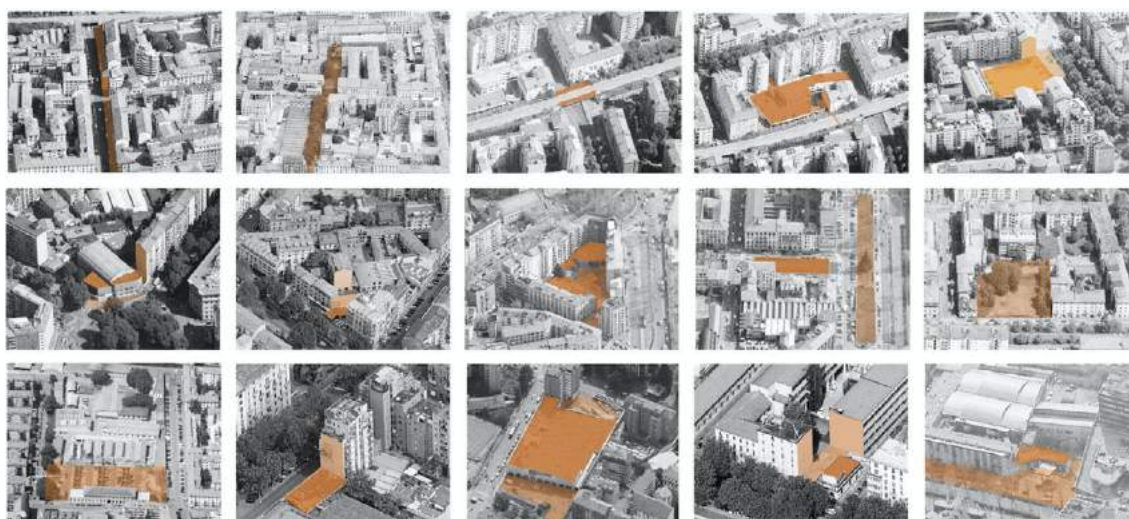

Figure 10 - AgorUp. Image by Beatrice Galimberti

Figure 11 - AgorUp. Images by Monica Bramanti, Beatrice Galimberti and Anna Rossi (left),

Starting from these variegated a context, students' strategies developed different public spaces typologies hosting various temporary or fixed uses (as neighborhood libraries, gathering spaces for associations and communities, recreational areas for elderly, playgrounds, and so forth) (Fig.11). The design outcomes deepened the issue of public use of space related to inhabitants' private and collective spheres (Sloterdijk, 2004). Furthermore, the investigation always deals with the challenge of defining public spaces that, even if raised from the street level, would be welded to their context by setting a continuity with ground level public spaces and building access, so to establish an urban loop of contemporary public uses.

AKNOWLEDGEMENTS

All the research described in this paper have been realised in courses held by Martina Orsini at Polytechnic University of Milan with the collaboration of Beatrice Galimberti and other subjects, namely:

-‘InFractures’: Urban and Territorial Design Studio A.Y. 2012-13 (professors Martina Orsini, Francesca Di Maria, Domenico Lungo; tutor Marco Baccarelli);

-‘TimeLapseCity’: Urban Principle course A.Y. 2014-15 (professor Martina Orsini; tutor Beatrice Galimberti); Città Metropolitana di Milano represented by Nausicaa Pezzoni;

-‘RipCity’: Urban Principle course A.Y. 2013-14 (professor Martina Orsini; tutors Beatrice Galimberti, Anna Rossi, Maria Zaghi); Urban and Territorial Design Studio A.Y. 2014-15 (professors Martina Orsini, Marco Baccarelli, Francesca Di Maria; tutors Beatrice Galimberti, Beatrice Valli, Maria Zaghi); Architect and Planner Paolo Pomodoro, Milano Santa Giulia SpA represented by David Albertini Petroni (AD),

Alessandro Meneghelli (Director of urban planning and programming), neighborhood and citizens associations:

-‘AgorUP’: Urban and Territorial Design Studio A.Y. 2011-12 (professors Martina Orsini, Camillo Magni, Franco Guzzetti; tutor Marco Baccarelli).

ID 1451 | CITY UNSILENCED: PUBLIC SPACE AND URBAN DEMOCRACY ON TRIAL SABINE KNIERBEIN

Sabine Knierbein¹; Jeffrey Hou²

¹TU Wien, Faculty of Architecture and Planning; ²University of Washington, Seattle, USA
sabine.knierbein@skur.tuwien.ac.at ; jhou@uw.edu

1 NEW PLACES OF URBAN SOLIDARITY AND RESISTANCE

Around the world, the shrinking capacity of (formal) democratic process has left protesters and ordinary citizens with no other resort than to take to the streets, the emblematic space of the publics, for reinstating democracy. Shrinking democracy, coupled with economic restructuring, constitutes an underlying challenge facing cities and communities around the world. Public space, as a building block and medium of political engagement and social interactions, may represent an alternative space and a vehicle of resistance against systems of shrinking democracy. In its capacity as a vehicle for active democracy, public space in contemporary society deserves greater care, attention, and critical reflection. As movements evolve to confront new challenges, explore new opportunities, negotiate with new actors and circumstances, and utilizing new technologies and platforms, our understanding of the role and agency of public space as lived and political space must also advance.

This is precisely the objective of exploring the linkages between urban resistance and public space in the age of shrinking democracy. With this work and others to follow, we continue to explore public space as sites of renewed hope and possibilities in the quest for a more just, enduring, and democratic urban(ized) society.

2 EXPLORING URBAN RESISTANCE TACTICS AND THEIR SPATIALITY 2.1

SHRINKING DEMOCRACY

It was not too long ago that (liberal) democracy as a political system and preferred form of governance seemed to be an unstoppable force around the world. In what he calls democracy's third wave, Huntington (1993, p. 3) estimated that at least 30 countries made transition to democracy between 1974 and 1990, "just about doubling the number of democratic governments in the world." Prior to that, 36 countries were governed democratically in 1962 (*ibid.*). By the mid-1990s, the triumph of democracy, and human rights around the world were celebrated by liberal political leaders, scholars and activists (Alagappa, 2004). With the collapse of Berlin Wall, Fukuyama (1989) famously declared the "end of history" suggesting that the advent of Western liberal democracy had marked the endpoint of the sociocultural evolution in human history.

Today, such a hopeful and partly romantic view of political emancipation and democratic governance seems dampened by the influence of technocrat governance regimes and multinationals without clear oversight and direct accountability (Wilson and Swyngedouw, 2015). Under processes of economic globalization, democratic states have succumbed to increasing global competition, transnational flows of capital and labour, and policies that steadily dismantled regulations and institutions that once provided necessary social support and stability for societies, as well as opportunities for democratic participation and political accountability (Peck and Tickell, 2003). At the supranational scale, global entities such as the IMF, World Banks, WTO, and myriad other such organizations have "uploaded various state functions from the national scale" (Smith, 2009, p. 6), thus weakening democratic control at the state. Under processes of globalization, Low (1997, p. 242) argues, "a politics of place no longer seems possible at the scale of the national state."

In the beginning of the twenty-first century, instead of traditional state institutions, cities and regions are now governed by what Swyngedouw (2010, p. 5) describes as "a proliferating maze of opaque networks, fuzzy institutional arrangements, with ill-defined responsibilities and ambiguous political objectives and priorities." Decisions affecting local communities are being made from an unknown distance, behind closed doors, by networks of actors and entities, under laws, practices, and loopholes beyond the comprehension of ordinary citizens. Local democratic processes are only as effective as electing politicians who have limited power under a system that operates above the local institutions.

Participatory democracy and oversight, to the extent that it has existed, is replaced or hollowed out by new alliances of political and commercial interests. Healey (2010, p. 69) calls this "a kind of network governance, in which linkages are developed between some key government arenas," which makes it much more difficult to identify where decisions are located, resulting in a loss of spatial transparency. Likewise, Swyngedouw (2010, p. 2-3) argues that urban governance has shifted so profoundly in the beginning of the 21st century that a new form of governmentality has risen, "one that is predicated upon new form and informal institutional configurations – forms of governance that are characterized by a broadening of the sphere of governing, while narrowing, if not suspending, the space of the properly political." Or, as Merrifield (2014, p. viii) has put it: "One of the defining features of democracy in modern times is its lack of democracy."

2.2 ARMAMENT OF PUBLIC SPACE

Cities have indeed become an important site in which processes and outcomes of de-politicisation can be witnessed, including shrinking democracy and evidences of restrictions for public life. Mayer outlines four dimensions of this new urban formation: (1) a process of urban upgrading driven by global developers and international investors; (2) gentrification-led restructuring of urban centres; (3) marketization of cities through branding, festivalization, mega events, and attraction of creative industries; and (4) the concurrent outsourcing of manufacturing to the Global South, coupled with the post-industrial cities of the North becoming "the playgrounds for the upper classes, serviced by armies of downgraded and increasingly precarious workers" (*ibid.* 2013, p. 9).

In the context of accelerating competition between city-regions and in effort to attract investment and capital, regulations have been relaxed and subsidies have been doled out to developers and investors. "Geobribes," Smith (2003, p. 80-81) argues, have been paid by the city to global corporations to attract

their investment. Healey (2010) notes that instead of responsible representatives of citizen's concerns, politicians are being "buttressed by self-interested officials and lobby groups, distanced from people's everyday lives." In some East Asian cities, including Taipei and Hong Kong, for example, city governments or redevelopment authorities have become complicit in expropriating properties for developers and bulldozing entire neighbourhoods under the banner of urban renewal.

In the decades since 9/11, the policing of city, cityscapes, and citizens has been further heightened by hyper-security measures including surveillance and control of both physical public spaces and cyberspaces that are meant to prevent and counter terrorist attacks (Low and Smith, 2006). In the United States, Europe and some Latin American countries, municipal police now increasingly resemble paramilitary forces with high-grade gears and equipment. In addition, zero-tolerance techniques have in turn been deployed by police forces around the world (Smith, 2003), and have been widely criticized by urban scholars for their ethno- racist bias and discriminative impact (Cahill et al., 2017). British police, for instance, has employed the use of drones to track down what they identify as "socially deviant behaviour", thus equivocally rendering any type of public encounter an eventual meeting of 'potential suspects' and perverting the original meaning of public space as a crossroads where an encounter in difference may take place every day. In times of shrinking democracy, security measures are increasingly used against not only potential terrorist threats but also political dissent as protests and occupation are quickly dispersed, or prevented in the first place. For example, anti- terrorist laws have been used against housing and anti-gentrification activists in post-Katrina New Orleans, environmental opponents of London Heathrow Airport expansion, and even Critical Mass gatherings (Smith, 2009). In Istanbul, many of the Gezi park activists face court trials, bearing firsthand the effects of the criminalization of active democratic practice.

So, are we not living in democratic societies anymore? Yes, and no. Democracy may still exist, and its formalities are perhaps no less than before, as evident in elections, council assemblies, public meetings, ballot measures, and other remaining institutional arrangements. The challenge before us is that such exercises, the actually existing democracy, appear to be empty, ineffective, and no longer sufficient or adequate in holding the hegemonic economic and political dynamics accountable at either the local, urban or state level. The clash between everyday needs and political systems which have lost a spatial connection to lived space or that manufacture new patterns of how everyday life should be enacted have become part of the problems facing urban societies around the world.

2.3 URBAN RESISTANCE AND PUBLIC SPACE

With communities displaced, jobs lost, pensions evaporated, cost of living rising, citizens harassed and killed by the police, and with no effective or available democratic process to hold back and reverse these trends, it is not surprising that communities in cities around the world are taking to the streets, squares, plazas, and other types of lived space to voice their grievances and to demand specific local policy changes in concert with global attempts to rearticulate general political mores. From mass assemblies in Brazilian cities, to occupation of the state capital building in Madison, Wisconsin, and protests in cities across Europe ordinary citizens have been engaged in a new wave of passionate protests and embodied resistance. Cities, it seems, have become again a catalyst for struggles to maintain, renew, and establish the democratic project, as it is here where the material impacts of abstract policies so viscerally materialize.

Public space, indeed, has been central to recent movements. But public spaces are also important in the recent struggles in a different sense as the public realm has been not only the site but also the subject of contestation and struggles against neoliberal development and policies. As Mitchell and Staeheli (2006, p. 144) note, "as cities redeveloped, public space has become a key battleground (...) over the homeless and the poor and over the rights of developers, corporations, and those who seek to make over the city in an image attractive to tourists, middle- and upper-class residents and suburbanites." Public spaces increasingly redeveloped to maximize values of surrounding properties. They are often privatized or managed through so- called public-private partnerships to offload cost of operations from municipalities strapped by austerity measures. As such, public spaces today face not only increasing control for order and security but also threats from financial interests from both municipalities and corporations.

As public spaces come under pressure, they also serve as a vestige of active democracy—a space of expression, mobilization, and contestation. However, the altering role of public space in the changing

urban resistance remains under-theorized and poorly understood. Specifically, for many movement scholars, space remains primarily as a backdrop to discussion of movement strategies, tactics and larger structural factors facing resistance movements. For planning and design professionals responsible for the making of contemporary public space, protests and resistance are far from their project focus. In the worst scenarios, their work is often intended to facilitate surveillance and control, if not to deter mass assemblies in the first place. For planning and design scholars focusing on public space, there remains much more work to be done in unpacking the role of public space in supporting and engendering active democracy, e.g. through understanding the connections between urban movements and planning, or between urban resistance and planning. Frank and Fuentes (1990, p. 142), for instance, argue, “[a]lthough social movements are more defensive than offensive and tend to be temporary, they are perhaps the most important agents of social transformation...” It is this capacity for social transformation that, we argue, suggest the direction for a new, emancipatory politics of public space, and a scrutiny of the role that planners and designers could contribute to support the spatial emergence of roots for emancipatory politics.

It was precisely with this in mind that this research has brought together a diverse group of scholars (marked in the reference list with *) from different backgrounds doing research on diverse cases of urban resistance and solidarity in South America, Asia, Europe and North America. The paper draws on empirical findings from 16 cities, analysed through the prisms of diverse disciplines related to planning theory and urban studies. We look for resistance movements that share a common struggle against neoliberal policies and shrinking democracy but with different linkages to the notion and material manifestation of lived space.

3 SPATIAL GROUNDS OF RE-DEMOCRATISATION

In this section, we specifically examine four aspects in which public space serves as nodes of critical actions and reflections: (3.1.) public space as sites of mobilization and negotiation, (3.2.) public space as spaces of contestation and learning, (3.3) public space as space of rescaling and re-politicizing, and (3.4) public space as grounds of alter-politics.

Although scholars tend to situate the ascension of global resistance to patterns of neoliberal urbanism in 2011, “the year of dreaming dangerously” (Žižek, 2012), urban contestations against modes of neoliberal urban restructuring have been unfolding well before then. In Athens, civic uprisings against the upgrading, commercialization and privatization of public space against the backdrop of beautifying the city for the Olympic Games 2004 were already visible during the 1990s. On the other side of the globe, Santos examines the resistance by citizens of Cochabamba, Bolivia’s third largest city where citizens successfully rallied against the privatization of water and the consequent increase in water consumption costs between December 1999 and April 2000. The five-month resistance involved tens of thousands of protestors who ultimately succeeded in the de-privatization of a World Bank concession that was issued with the municipality in 1997 (Santos, 2007 (2000)). In 2001, Argentina was heavily shaken by an economic crisis in which the Piqueteros movement of unemployed factory workers (now unemployed due to flexibilization of labour patterns, e.g. in the global car industry) gained momentum, leading to massive acts of urban resistance and to the first signs of horizontal and collective organization against a neoliberal regime put in place under the Military Junta in the 1970s and 1980s (Rosa and Vidosa, 2017, Lorey, 2014). In South Africa, the Western- Cape Anti-Eviction Campaign, initiated in 2001 served “as an umbrella body for a number of community organizations, crisis committees, and resident groups that emerge in Cape Town’s poor townships to resist [...] evictions and service cut-offs and demand their rights to shelter and basic services” (Miraftab, 2009, p. 36). These earlier sparks of resistance against discriminatory, exclusive, and often racialized practices under neoliberal policy regimes have been globally recognized. This scholastic blind spot regards large tracts has disregarded broad ranges of urban scholarship, empirical evidence, and theoretical framing for understanding grassroots insurgency against neoliberal governance and has (un)intentionally reified of such protest being ephemeral and episodic where challenges to neoliberal cultural or economic exports are diminished as growing pains to be overcome as a country or city undergoes neoliberalization, i.e. the introduction and implementation of neoliberal policy agendas. This two-pronged problem normalizes resistance in the context of a naturalized neoliberalism and significantly undercuts our ability to be critical practitioners and citizens.

In the light of these examples, 2011 can be conceived rather as a culminating point when resistance in the Global South spilled over to the North, reflecting the enhanced material inequalities related to the neoliberal policies. In particular, the global economic crisis in 2008 had further exacerbated the decline of employment, continued the decay of welfare states, and posed serious challenges to the dismantling of speculative housing investments all around the world. However, the impact of the neoliberal model cannot be framed in only economic or material terms, as its social, cultural and political dimensions have reached far beyond what is calculable and palpable. Contemporary interpretations of neoliberalism argue it has actively produced a political crisis where its capacity for economic predation has hindered civic control and responsiveness (Monbiot, 2016). Such mitigations can be seen in the reduced ability of voting to change political course, the conflation of civic advancement with capitalistic advancement, and growing acceptance of neoliberalism across the political spectrum, which further enhances voter disenfranchisement and the exploration of viable alternatives (ibid.).

As a result of fundamental social, economic and political changes, basic urban routines have become unsettled. Increasing urban inequalities in cities around the world is furthered by the de-politicization of politics through consensus-based liberal democracy; this has shut out citizens and left decisions to government managers, politicians, and specialists operating in a multilevel governance where actors who have not been democratically legitimated can increasingly assume power (Wilson and Swyngedouw, 2015). Meanwhile, as economic stability plummeted, discontent directed at the commodified nature of public life and public space has increased, as more and more educated, formerly middle-class individuals and groups joined the so-called urban subaltern (Bayat, 2010; Roy and Ong, 2011). But, is this the primary narrative to understand why we currently witness a new continuity of public space-based resistance? Hasn't public space always been a frontier between class interests, and a field for struggle against all sorts of inequality?

Public space has come into focus during recent struggles where the restructuring of multiple interrelationships between civil society, state, and markets unfolds. As part of this restructuring, we see increased attention to the roles that cities play, as the (conception of) modern nation-state faces a crisis (Appadurai, 1996). With focus on the crisis facing the modern nation-state, the political formation of many Western liberal democracies is receiving more criticism. As Mouffe (2000) has stated, liberal democracy has always been based on a democratic paradox between the liberal and the democratic strands of political thought: "On one side we have the liberal tradition constituted by the rule of law, the defence of human rights and the respect of individual liberty; on the other the democratic tradition whose main ideas are those of equality, identity between governing and governed and popular sovereignty. There is no necessary relation between those two distinct traditions but only a contingent historical articulation." (ibid., p. 2-3)

The paradoxical dynamic between freedom (liberal tradition) and equality (democratic tradition), which the Keynesian welfare state was still able to generally maintain, contributed to the fact that sporadic civil unrest would not gain global momentum or permanence during more recent welfare-state provisions, as the social material well-being was still secured in the Western world (Purcell 2009). This sustained paradox has been accompanied by another dilemma (cf. ibid., p. 144f), i.e., liberal democracies have long been adept at managing and legitimating social inequality. Their characteristic separation of the public and private spheres allows them to claim the existence of a formal political equality even when manifest social inequality is present. Under Keynesian policies, that equality deficit was mitigated by significant material redistribution and the meaningful inclusion of organized labour in public decision-making. Yet those accommodations were central targets of the neoliberal agenda and were significantly eroded. As a result, neoliberalism has increasingly exacerbated this democratic deficit that has long troubled liberal democracy (ibid.).

With the rise of neoliberal policies, an imbalance between liberty and equality has been created with a strong focus on liberty, while issues of equality have been increasingly neglected (Mouffe, 2000). In order to maintain its form of governance, the neoliberal political economy needs to actively modulate the political and social instability and crises it generates: That is why neoliberal policy agendas and their makers increasingly seek to link their goals and projects with democracy (Purcell, 2009). To solve this frustration, community development with a focus on public space—the 'soft spaces of neoliberalism' (Haughton et al., 2013; Lebuhn, 2017)—has in many cases operated as an essential enabling moment for neoliberal projects. In the field of planning and designing for public spaces in particular, formal participatory modes of communicative and collaborative planning have been applied that often tend to use consensus-building

and majority-decisions, while bearing the risk to (in)advertently flatten the contradicting voices (often of minority or marginalized groups) calling for a more radical and egalitarian democratic project and reality (Purcell, 2009).

As more economic and political pressure is put on public space, accompanied by social and ethnic polarizations, it comes as no surprise that the realm of public life is the territory where one can witness intensified class reconfigurations, discrimination, and societal struggles (Tyler, 2015). Tensions in public space, in this sense, need to be understood as seismographs of an over-accelerated and fragile neoliberal political economic model. This model has undermined the long history of urban commoning and has rendered public space a highly competitive field. In this field, political parties dominate representational space and access to voters; companies strive for higher revenues or civic legitimization; and civil society seeks reorientation in a landscape of power in which 'the political' tends to become absent. It is in this context that acts of public space based resistance need to be examined, as they not only disrupt the neoliberal taming of public life but also reinvigorate deep relationships between public space and lived democracy.

3.1 PUBLIC SPACE AS SITES OF MOBILIZATION AND NEGOTIATION

The use of public space as a site of mobilization and negotiation is one of the main processes that occurred in cases throughout our research. Cities are where the material impacts of neoliberal governance on the social lives of many dwellers becomes noticeable, as a critical mass of people not only take actions but also engage in a deeper understanding of the changes occurring in their society and ways to mobilize and find voice. Recent acts of urban resistance have brought a new generation of protestors to light, people who have never before been active in street (or other types of) politics, including groups that usually would have moral values and positions quite opposite from one another, e.g. LGBT representatives and conservative Muslims (Yiğit Turan, 2017) or left- and right-wing activists forming political coalitions (Kaika and Karaliotas, 2017).

These recent instances of urban resistance combine a place-based and context-specific approach to resistance with new ways of political identity formation through horizontal and worlded networks (Knierbein and Gabauer, 2017) and more global claims for egalitarian democracy (Kaika and Karaliotas, 2017). Meanwhile, a belief in the power of open dissent, civil disobedience, and active resistance against (quasi)authoritarian forms of governing is gaining force. Consensual solutions have found a smaller impact on changing the political landscapes as a new power balance between mainstream society and increasing minority power in diverse cities challenges consensual deliberation as hegemonic tool of majorities to govern minorities and marginalized groups. Within diverse groups consensus is practiced along with dissent as a valuable form of decision-making. In some cases, power structures inherent in the group (formation) are explicitly reflected and reworked, indicating the active presence of negotiation (Lorey, 2014).

Horizontality as a mode of mobilization, observed in the Latin American movements in 2001, has become a prevalent and effective strategy to self-organize and to develop new forms of resistance (ibid). It involves reflexive social regulations, new forms of organizing, and new modes of subjectivation, which might ideally lead to a collective and affective form of relations among protestors, while being used as an instrument for creating a social space in which participants feel empowered to speak and take part in common challenges. This is a space in which privileges and inequalities can be consciously addressed, and heterogeneity in the manner of speaking and in the opinions expressed has to be endured: Horizontal self-organization opens up a process in which conflicts and differences are not negated, but must be first recognized (ibid). It is important to note, though, that structural discrepancies are still enmeshed in these forms of horizontal mobilization. Specifically, there is a danger that horizontality and urban resistance mobilization might run risk of nurturing types of mimicry-resistance that are not progressive or striving for radical democratization at all, but try to interrupt communities and collectivization through pursuing a politics of fear (Knierbein and Gabauer, 2017). In these cases, urban resistance is instrumentalized by anti-democratic groups by fortifying boundaries between populations of different religions, cultures, ethnicities, classes, or gender (Chen and Szeto, 2017; Owens and Antiporda, 2017).

3.2 PUBLIC SPACE AS SPACE OF CONTESTATION AND LEARNING

The heartbeat of neoliberal governance is crisis produced through austerity mechanisms and processes of de- and re-institutionalization (governance). This model constantly (re)produces social, political and cultural divides, thus nurturing repetitive eruptions of urban resistance against increasing inequality, injustice and imbalances. Crisis is the seemingly inherent necessity through which neoliberal measures are legitimized and produced politically, thus rendering it a self-fulfilling prophecy. As crises and impacts of neoliberal governance unfold and threaten the public life and public spaces of cities, these sites are where the fissures and cracks of neoliberalism become visible and its continued evolution becomes contested.

The empirical case studies exemplify the power of public space scholarship that utilizes hybrid combinations of micro, meso, and macro analytical techniques to carefully analyse changing patterns of urban life at a local level within the context of macro neoliberal politics and economies, between formal policies and informal action. In the cases of Berlin, Tokyo, Warsaw and Poznań (Dimmer, 2017; Domaradzka, 2017; Lebuhn, 2017), for instance, activists have used formal means of participation and/or formal rights and law to claim a citywide or neighbourhood referendum, or to claim full information about legal and public authority-related legal procedures. Regardless of their results, the authors state that these processes have helped to facilitate learning in newly established political communities where the political claims had become more inclusive and focused, thus (a) trying to attract the wider city publics to engage with and support the activists' claim; and (b) to make a clear message possible during the referendum campaign.

Meanwhile, other resistance groups have not allowed parties or formal procedures to (entirely) co-opt and conquer their mobilization dynamics as shown in the cases of Athens, Istanbul, Hong Kong and Taipei, whereas in Vienna (Knierbein and Gabauer 2017), the emergence of a wider critique -and thus, of counter-publics- and more actively resisting groups was heavily supported by the more socially oriented political parties. The cases of Taipei (Chen 2017), Hong Kong (Chen and Szeto 2017), Madrid (Kränzle 2017) and Barcelona (Garcia-Lamarca 2017) show that activists have made their way straight into the political system during times of elections, thus renewing the governing bodies and challenging long-established political identities. In Barcelona and Berlin (Lebuhn 2017), activist groups have stated their goal to perform as an incubator for democratic control of the governance regimes in place, and have actively organized policy and legal recommendations to revert the legal and economic hegemony of existing governance networks.

3.3 PUBLIC SPACE AS SPACE FOR RESCALING AND RE-POLITICIZING

Chapters in this volume indicate that we are currently witnessing a moment in which the spatial scales of crisis require more complex ways to consider and engage the political through modes of urban resistance. Resistance tactics, goals, and claims need to connect and reorganize fragmented geographies of crisis, that is, resistance groups need to combine the quest for local human needs, urban equity struggles, regional justice mechanisms, national political contestations, supranational governance critique, and a struggle against the locally destructive impacts of global and virtual market forces, thus overcoming the "jumping scales of capital" (Swyngedouw, 2003, referring to Smith, 1984).

Urban public spaces are places where social densities and political identities meet, and where fragmented scales of resistance need to be reunited, from local solidarity with peers within one's comfort zone towards a much more global solidarity for egalitarian democracy. Contributors to our research have indicated that movements have occasionally shifted their focus from central public spaces to the neighbourhood scale (and narrow comfort zone), consequently risking to insufficiently address central political questions, and thus reducing the perseverance and impact of the movement (Kränzle, 2017). Certain local neighbourhood interventions can even serve as a pretext for cultural regeneration and symbolic capital accumulation, and thus gentrification. Others, however, have stressed that there are certain central and politically symbolic places in cities where the quest for more genuine political reform or revolution has been repeatedly posed over centuries. These squares and streets have witnessed a new spark of radically democratizing the urban, and inspired people to issue more fundamental political claims rather than narrow inquiries or local, interest-based issues.

Apart from this multi-scalar notion of resistance, and the potential of resistance groups to reconnect and re-politicize the "jumping scales of capital", we also find resistance as counteraction, response, and contestation against all types of unsettling: economic, cultural, ecological, social and political. Some of the

contributions emphasize attempts to re-politicize the many obvious and less visible relations between different scales and dimensions of crisis and resistance through radical dialectics (e.g. between housing and public space research in Barcelona). Several chapters highlight the vulnerability of younger generations to evictions and displacement from their everyday places either as a result of commodified public spaces (Maharawal, 2017) or through racialized broken-windows policing against communities of colour (Cahill et al. 2017; Owens and Antiporda, 2017). Such conditions provided in turn opportunities for engaged scholarship, participatory action research, and empowerment of disenfranchised actors to investigate and mobilize against such conditions and processes. Insights from Hong Kong, Taipei, and Vienna also leave us more hopeful, as the protests were mainly student-led, with an active and politicized student generation trying to push through social and political reform and change, while in the case of Vienna, a group of youngsters issued state critique through humanitarian aid for refugees, thus calling for global human rights and solidarity through local action in train stations. In times of a decreasing consensus about the prevalence of human rights, urban resistance struggles may become rooted in quite material and basic claims to guarantee the everyday survival of those who have been dispossessed, disenfranchised and disempowered (Knierbein and Gabauer, 2017).

3.4 PUBLIC SPACE AS GROUNDS OF ALTER-POLITICS

Cities have been historically understood as a collective actor, where different parts of urban societies constantly perform collaboratively, producing and using public space as urban commons. The neoliberal project, however, seeks to replace this collective and collaborative urban history with an economic narrative: the city as a competitive space. As a result, competition has been rendered as a key aspect of current democracies, as it is linked to appearance of transparency, efficiency, and so forth, even though the actual linkages are weak and superficially constructed. Furthermore, in the construction of an exclusive politics and a moral climate, the narrative of competition renders those that are not able to or do not want to participate in such competition as outcasts (Tyler, 2015). The various resistance movements presented in this book represent efforts to expose and intervene in the apparent cracks of this narrative and practice, not only to claim, but also to radically renew the democratic project.

As space is at the heart of the organization of changing political economies, it is worth reflecting on the spatial features of the acts of urban resistance. This work draws upon earlier thinkers who have articulated the collective production of spaces as truly democratic where constituents that previously had no part become now the key agents for renewing democracy (Rancière, 2010). Through the case studies from different cities and continents, we have gathered results that enable us to: (1) further differentiate those disempowered and disenfranchised and (2) to track how they relate (a) to public space and (b) through public space to make use of other spaces.

For differently-motivated resistance groups, public space serves as the initial sites where many try to make their claim or state their dissent within their field, and to expand their political identifications to others. That way, they enable the embodied realm of lived space to become the key catalyst for the emergence of wider political dissent and the generation of new and alternative democratic projects. Lived space is thus where the picture of multiple fragmentations, failures, and fractures of the current global capitalism become traceable, connected, and where the potential cracks and spaces that escape neoliberalism's spatial conquest can be analysed, and explored. It is here where different types of publics and counter-publics meet and collide in the accessible urban spaces in cities worldwide in order to achieve adequate living conditions, where they intermingle and develop solidarity across different(ly) affected groups. Public space, thus, represents both an opportunity and a threat, as on the one hand it makes their struggle become (globally) visibly to gain supporters; on the other hand, public space is where their vulnerability is exposed, with a high (bodily) risk of being further stigmatized, marginalized, dispossessed, criminalized, or menaced (de la Lata Gonzales, 2017). At times, this includes the risk of losing one's life.

Urban resistance tactics have connected public space assemblies with direct actions into the private, public, or hybrid territories of capital accumulation to disrupt, offset, or interfere with the productive space of the current neoliberal economy. The unemployed, for instance, have re-appropriated vacant factories, container terminals, and office space to set up self-organized labour markets or collective industrial cooperatives. The unsheltered have de-privatized and re-housed empty buildings or have de-commodified private property through land action and adverse possession. The indignant have blocked banks and reclaimed bank assets into public and collective property. The un(der)represented have blocked

parliament buildings and emblematic public squares and streets to go beyond mere discursive claims. The unattended have used train stations as local hubs to stand together in global solidarity and to self-organize humanitarian support. The colonized have occupied former prisons emblematic of long histories of colonialism, thus symbolically unchaining themselves from a colonizing genealogy of oppression and inferiority. The non-consumers have developed new alternative modes of being in common and sharing common resources, while using both private and public properties. These resistance tactics link public space with the workplace and labour markets; public space with housing and homes; public space with the places of resource transfer and (missing) material redistribution; public space with the places where democracy ideally should be made (e.g. parliament; fora, agora); public space with mobility hubs and transport infrastructures; public space with places of oppression, terror and imprisonment; public space with sites of non-consumption or commoning.

Urban research on these dialectical relations between the aforementioned fields can help to identify a shift from anti-politics (demonstrations against certain issues) towards alter-politics (Hage, 2012), the affective strive for a politics of change. Alter-politics aims at practicing a radical hope for a democratic project that is stronger than the weak post-democratic model we witness today. It shows affective action for a collective and passionate capacity to long for alter-modernity (Hardt and Negri, 2009; da Silva Andrade and Huguenin, 2017), to collectively produce the commons through an affective political project dwelling in present realities. Alter-Politics takes “us outside of ourselves to see how we can be radically other to ourselves.” It “aims at finding a possibility of a different life outside a given order of things,” “generating new alter-modern spaces lying outside existing governmentalities” (Hage, 2015, p. 294, 296).

4 UNSILENT AND SILENT FORMS OF RESISTANCE AND SOLIDARITY

Bayat has depicted public space in Western democracies as part of the institutions of the modern nation-state, to which many of the urban subaltern in the cities around the world have no access. “Because modernity is a costly existence, not everyone can afford to be modern. It requires the capacity to conform to the types of behaviour and modes of life [...] that most vulnerable people simply cannot afford” (ibid. 2010, p. 59). As a highly-institutionalized realm, public space is one of these institutions of the modern urban world. This is why many of the urban subaltern tend to avoid public expression wherever possible. That way, they seek to escape the modern legal structure, which does not offer any resources or opportunities but confines their realm of everyday action (ibid.). As we take a worlded, critical perspective in examining different forms of resistance, it is also important to consider that silent, individual resistance can contribute to an understanding of the city as self-organized political project.

This paper has been concerned with ways through which such silence has been dispelled, by seeing and using the city and public space as a site of resistance and a catalyst for political change, where people bang their pots and pans, use goggles, umbrellas, and flowers to disrupt political silence and renew —a democracy in which “the spaces of democracy (spaces for the practice of democracy) and the democracy of space (democratic relations in the production of space)” are inherently related (García-Lamarca, 2017, referring to Hoskyns, 2014, p. 4). As Ober has put it, the original term of democracy was meant to capture ‘power’ as the ‘capacity to do things’: “Demokratia is not just “the power of the demos” in the sense of “the superior or monopolistic power of the demos relative to other potential power-holders in the state.” Rather it means, more capacious, “the empowered demos” - the regime in which the demos gains a collective capacity to effect change in the public realm, “the collective strength and ability to act within that realm and, indeed, to reconstitute the public realm through action” (Ober, 2008, p. 7).

By better understanding the processes, actions, and implications of recent urban resistances, our research aspires to contribute to the renewed attention concerning the role and significance of public space in the practice of lived democracy and lived space. Specifically, we have argued that in the face of diminishing democratic institutions in cities around the world, spaces of political resistance have a greater role to play not only in holding the state and political establishments accountable to society’s interest but in renewing and reinvigorating democratic culture and pursuit for equity, difference, and justice. Without resistance and public space agencies, mobilization of the masses, and continued public debates and social movements, democracy is at risk of becoming stagnant, narrow, and obsolete. The continued presence, contestation, and discourse of lived space are fundamental to a renewed and lived democracy, a democracy that is fundamental to protecting and enhancing welfare of citizens and communities against the encroachment of neoliberal interests and all forms of increases in spatial patterns of social inequality.

ID 1454 | PERCEIVED QUALITY OF URBAN OPEN SPACE: A STOCKHOLM CASE STUDY

Östen Axelsson¹

¹Stockholm University

oan@psychology.su.se

1 INTRODUCTION

In investigating the quality of urban open space, it is important to investigate how the visual and auditory components contribute to the total quality. The majority of studies investigating audio-visual interaction in environmental perception have concerned how visual stimuli affect auditory perception, such as how vegetation affects the perception of the sound of road traffic from a motorway (e.g., Anderson, Mulligan, Goodman, Regen, 1983). In general, these studies indicate that how people perceive sound depends on the visual context. That is, some sounds are more appropriate in one context than in another, which seems to depend on the participants' expectations. For example, a city center is expected to sound like a city center, and not like a forest, and vice versa. Typically, a mismatch resulted in discomfort.

A handful of laboratory studies investigated how perception of auditory and visual aspects related to the perception of the composite of audio-visual information (e.g., Gifford & Ng, 1982; Kuwano, Namba, Komatsu, Kato, & Hayashi, 2001; Morinaga, Aono, Kuwano, & Kato, 2003). Chiefly, these studies showed that visual aspects of environments were more important than auditory aspects. However, how important the visual aspects were, was highly variable across different environments. This indicates that auditory information might dominate over visual information at some point (see also Gan, Luo, Breitung, Kang, & Zhang, 2014; Preis, Kociński, Hafke-Dys, & Wrzosek, 2015).

The present paper concerns a case study conducted in collaboration with the City of Stockholm, Sweden, in the summer of 2016. The purpose was to characterize and to investigate the potential for improving the quality of the environment in a centrally located park area in the city. Walks were conducted in situ together with 61 residents. In the walks the participants assessed five preselected sites in and near the park area, with regards to their perceived total, auditory and visual qualities.

2 METHOD

2.1 CASE STUDY AREA

The case study area consisted of 5 preselected assessment sites in and near a large urban park area in Stockholm, Sweden, located by a busy road. They were selected based on a planned intervention that might be implemented in 2017. Two of the assessment sites were selected as references where the planned intervention was not expected to have any impact. The other three were selected based on where the planned intervention was expected to have the greatest impact. Because there are plans to follow up the intervention, if implemented, the exact location of the case study area, or the nature of the planned intervention, cannot be revealed in this paper.

2.2 PARTICIPANTS

The participants in the study were 61 residents living close to the case study area (38 female, 22 male, 1 missing value), aged 15 to 77 yrs. (Mage = 54.6 yrs., SDage = 15.2). All households in the block of houses closest to the case study area, in which the oldest member was between 18 and 70 years old, received an invitation by post to take part in the study. In total, 1,583 invitations were sent out. For 17 of these the recipient was unknown, and the letter returned. Among those who received the invitation, 73 persons responded and expressed an interest to take part. The participants were informed that the purpose of the study was to investigate how residents in their area experience the outdoor environment, and to develop methods on how to assess the urban outdoor environment in general. The participants were reimbursed with gift certificates with a total value of 300 SEK per person.

2.3 DATA COLLECTION INSTRUMENT

The data collection instrument consisted of a pencil and paper questionnaire. It included three pages for every assessment site. The first of the three pages concerned the overall impression of the site, the second concerned the sound environment, and the third concerned the visual environment, in this order for all sites. For each of the three aspects of the environment there were three broad questions. The first of these three questions concerned what objects the participants perceived as dominant (artefacts, nature or people), the second concerned the perceived overall quality of the site, and the third concerned the perceived affective quality of the environment. To make it possible to compare the responses for the three aspects of the environment, these three broad questions were formulated to be as similar as possible for each condition.

2.3.1 DOMINATING OBJECTS

The first question for each of the three conditions was:

- "Overall, to what extent do you perceive that the following 3 factors (both auditory and visual impressions) dominate this site right now?"
- "Listen – to what extent do you hear the following 4 types of sounds right now?"
- "Look around – to what extent do you see the following 3 types of components right now?"

In the first case the three overall factors were artefacts, nature and people. In the second case the four sound sources were road traffic, other noise, sounds of people, and natural sounds. In the third case the three visual components were manmade structures, nature and people. The participants assessed how dominant these factors were on a 5-point ordinal category-scale with the verbal descriptors: "not at all," "a little," "moderately," "a lot," and "dominates completely."

2.3.2 PERCEIVED QUALITY

The second question for each of the three conditions was:

- “Overall, how would you describe this site as you experience it right now?”
- “How would you describe the surrounding sound environment right now?”
- “How would you describe the surrounding environment visually right now?”

For each of these questions, the participants provided an answer on a 5-point ordinal category-scale with verbal descriptors. The five verbal descriptors were “very good,” “good,” “neither good, nor bad,” “bad,” “very bad.”

2.3.3 PERCEIVED AFFECTIVE QUALITY

The third question for each of the three conditions was:

1. “Overall, how do you experience this site right now?”
2. “How do you experience the surrounding sound environment right now?”
3. “How do you perceive the surrounding environment visually right now?”

The participants responded on an 8-point semantic differential scale with the endpoints defined by:

“pleasant – unpleasant” (pl), “soothing – stressing” (so), “interesting – uninteresting” (in), “eventful – uneventful” (ev), “agreeable – annoying” (ag), “exciting – humdrum” (ex), “dynamic – static” (dy), “peaceful – restless” (pe), “living – lifeless” (li), “appealing – repulsive” (ap), “active – inactive” (ac), and “calm – chaotic” (ca), (abbreviations are used in equations below). These attributes were inspired by Axelsson, Nilsson and Berglund (2010).

2.3.4 OTHER QUESTIONS

On the first of the three pages for a site, the participants were also asked to respond on how they perceived maintenance as well as security/safety at the site. They responded on a 5-point ordinal category- scale of the same format as for perceived overall quality (i.e., good to bad). On the second of the three pages for a site, the participants were also asked to assess to what extent the surrounding sound environment was perceived as appropriate to the site. They responded on a 5-point ordinal category-scale with the verbal descriptors: “not at all,” “a little,” “moderately,” “a lot,” and “perfectly.” On the third of the three pages for a site, the participants were also asked how often they visit or pass by the site. They responded on an ordinal scale with seven response alternatives: “Every day,” “At least once a week,” “At least once a month,” “More seldom than every month, but at least ten times every year,” “At least once a year, but less than ten times,” “More seldom than every year,” and “This is the first time.”

At the end of the questionnaire, the participants were asked about their year of birth, their sex, their highest degree of education, and type of main occupation. Finally the participants were provided an opportunity to express other opinions on the five assessment sites, the study or the questionnaire, in an open- ended format.

2.4 PROCEDURE AND DESIGN

Walks were organized in August and September 2016, in which the 61 participants assessed the 5 sites with the aid of the questionnaire. The walks were conducted in groups, based on the participants’ availability. There were 14 groups with between 2 and 6 participants in each ($M = 4.4$ participants, $SD = 1.4$). All groups visited the 5 assessment sites in an irregular but sensible order, arranged in such a way that no group visited the 5 sites in the same order as any other group. In addition, the aim was to begin the walks from each of the 5 sites an equal number of times (in this case 3 times). Because there were 14 groups, walks begun at the last of the 5 sites twice. Chiefly, the walks were organized in the evening on working days — after working hours and before sunset (11 walks) — and during the day in the weekends (3 walks). The main criteria were that the walks were conducted in daylight, and during hours when the residents normally were at home. A walk took approximately 1.5 hours.

3 RESULTS

The results are reported for each of the five assessment sites separately. First, the site is described based on what objects the participants perceived as dominant at the site; totally, auditory and visually.

Arithmetic mean values are reported as the measure of central tendency among the participants, based on the individual responses, where 1 is the lowest and 5 the highest response. Second, the results of a set of hierarchical linear regression analyses (SPSS 22 for Windows) are reported, related to the perceived overall as well as the perceived affective quality of the site. Eq. 1 is used as statistical model.

$$Totalx = a + b1 \times Auditoryx + b2 \times Visualx \quad (1)$$

The subscript x in the equation represents the type of quality measure used in the analysis. The statistical model is used to analyze to what extent the auditory and the visual quality contributed to the overall quality of a site.

For perceived affective quality, the scores of the two underlying components Pleasantness (Pl) and Eventfulness (Ev) were calculated by Eq. 2 and 3, using the individual responses for each site.

$$Pl = (pl + ag + ap) + \sqrt{1/2}(in + ex + dy) + \sqrt{1/2}(so + pe + ca) \quad (2)$$

$$Ev = (ev + li + ac) + \sqrt{1/2}(in + ex + dy) - \sqrt{1/2}(so + pe + ca) \quad (3)$$

The square root out of a half in the equations is used as a weighting function to adjust the scores of the relevant variables, because they are assumed to be located at a 45° angle to the two main components (Axelsson, Nilsson & Berglund, 2010).

3.1 SITE A

Table 1 presents arithmetic mean values for how the 61 participants perceived Site A totally, auditory and visually. It shows that artifacts dominated the site, and that nature was not perceived at all. The participants perceived people at a moderate rate, but they could only be heard a little. Totally and auditory the site was perceived as bad. Visually it was perceived as neither good nor bad. On average, the participants visited or passed by this site every day.

Site A	Artefacts	Nature	People	Quality
Total	4.72	1.35	3.25	2.48
Auditory	4.62	1.07	1.87	1.85
Visual	4.75	1.39	3.31	2.69

Table 1 – Arithmetic mean values for how 61 participants perceived Site A totally, auditory and visually

Perceived auditory quality ($\beta = 0.416$, $t = 3.56$, $p = 0.001$) influenced perceived total quality stronger than perceived visual quality ($\beta = 0.321$, $t = 2.75$, $p = 0.008$), ($F_{2,58} = 20.46$, $p < 0.001$, $R^2 = 0.41$). On its own, perceived auditory quality explained 34% of the variance in perceived total quality. Visual quality added another 8%.

Auditory pleasantness ($\beta = 0.497$, $t = 5.21$, $p < 0.001$) influenced total pleasantness stronger than visual pleasantness ($\beta = 0.423$, $t = 4.44$, $p < 0.001$), ($F_{2,58} = 69.05$, $p < 0.001$, $R^2 = 0.70$). On its own, auditory pleasantness explained 60% of the variance in total pleasantness. Visual pleasantness added another 10%.

Auditory eventfulness ($\beta = 0.190$, $t = 1.19$, $p = 0.238$) did not influence total eventfulness over and above visual eventfulness ($\beta = 0.559$, $t = 3.52$, $p = 0.001$), ($F_{2,58} = 31.68$, $p < 0.001$, $R^2 = 0.52$). Auditory eventfulness ($\beta = 0.714$, $t = 7.84$, $p < 0.001$) explained 51% in total eventfulness, alone ($F_{1,59} = 61.50$, $p < 0.001$).

3.2 SITE B

Table 2 presents arithmetic mean values for how the 61 participants perceived Site B totally, auditory and visually. It shows that the participants perceived artifacts a lot, in total and visual terms. In auditory terms, artifacts (i.e., road traffic sound) dominated the site. The participants perceived nature a little in total and visual terms, and not at all in auditory terms. The same observation was true for the presence of people. Totally and auditory the site was perceived as bad. Visually it was perceived as neither good nor bad. On average, the participants visited or passed by this site at least once every week.

Site B	Artefacts	Nature	People	Quality
Total	4.25	2.15	2.51	2.23
Auditory	4.48	1.03	1.41	1.89
Visual	4.10	2.46	2.34	2.93

Table 2 - Arithmetic mean values for how 61 participants perceived Site B totally, auditory and visually

Perceived auditory stronger than perceived visual quality ($\beta = 0.243$, $t = 2.30$, $p = 0.025$), ($F_{2,57} = 31.91$, $p < 0.001$, $R^2 = 0.53$). On its own, perceived auditory quality explained 48% of the variance in perceived total quality. Visual quality added another 4%.

Auditory pleasantness ($\beta = 0.607$, $t = 6.78$, $p < 0.001$) influenced total pleasantness stronger than visual pleasantness ($\beta = 0.314$, $t = 3.51$, $p = 0.001$), ($F_{2,58} = 63.00$, $p < 0.001$, $R^2 = 0.69$). On its own, auditory pleasantness explained 62% of the variance in total pleasantness. Visual pleasantness added another 7%.

Visual eventfulness ($\beta = 0.147$, $t = 1.49$, $p = 0.142$) did not influence total eventfulness over and above auditory eventfulness ($\beta = 0.722$, $t = 7.29$, $p < 0.001$), ($F_{2,58} = 62.69$, $p < 0.001$, $R^2 = 0.68$). Auditory eventfulness ($\beta = 0.820$, $t = 10.99$, $p < 0.001$) explained 67% in total eventfulness, alone ($F_{1,59} = 120.66$, $p < 0.001$).

3.3 SITE C

Table 3 presents arithmetic mean values for how the 61 participants perceived Site C totally, auditory and visually. It shows that the participants perceived the presence of artefacts as moderate. The participants could see a lot of nature, but could not hear it. The participants perceived the presence of people as moderate. Totally and visually the quality was good. Auditory it was neither good nor bad. On average, the participants visited or passed by this site at least once every week.

Site C	Artefacts	Nature	People	Quality
Total	3.00	3.66	3.11	3.57
Auditory	3.21	1.36	2.79	3.11
Visual	3.11	3.70	3.02	3.83

Table 3 - Arithmetic mean values for how 61 participants perceived Site C totally, auditory and visually

Perceived visual quality ($\beta = 0.487$, $t = 4.88$, $p < 0.001$) influenced perceived total quality stronger than perceived auditory quality ($\beta = 0.373$, $t = 3.74$, $p < 0.001$), ($F_{2,57} = 26.13$, $p < 0.001$, $R^2 = 0.48$). On its own, perceived visual quality explained 35% of the variance in perceived total quality. Visual quality added another 13%.

Visual pleasantness ($\beta = 0.541$, $t = 7.43$, $p < 0.001$) influenced total pleasantness stronger than auditory pleasantness ($\beta = 0.465$, $t = 6.39$, $p < 0.001$), ($F_{2,58} = 105.26$, $p < 0.001$, $R^2 = 0.78$). On its own, visual pleasantness explained 63% of the variance in total pleasantness. Auditory pleasantness added another 15%.

Visual eventfulness ($\beta = 0.765$, $t = 10.13$, $p < 0.001$) influenced total eventfulness stronger than auditory eventfulness ($\beta = 0.189$, $t = 2.50$, $p = 0.015$), ($F_{2,58} = 119.38$, $p < 0.001$, $R^2 = 0.81$). On its own, visual eventfulness explained 78% of the variance in total eventfulness. Auditory eventfulness added another 2%.

3.4 SITE D

Table 4 presents arithmetic mean values for how the 61 participants perceived Site D totally, auditory and visually. It shows that the participants perceived artefacts a little. They saw a lot of nature but only heard it a little. They perceived the presence of people as moderate, and the environment as good. On average, the participants visited or passed by this site at least once every week.

Site D	Artefacts	Nature	People	Quality
Total	2.16	4.10	3.33	4.18
Auditory	2.56	2.25	2.89	3.80
Visual	2.12	4.18	3.20	4.18

Table 4 - Arithmetic mean values for how 61 participants perceived Site D totally, auditory and visually

Perceived visual quality ($\beta = 0.574$, $t = 6.00$, $p < 0.001$) influenced perceived total quality stronger than perceived auditory quality ($\beta = 0.296$, $t = 3.09$, $p = 0.003$), ($F_{2,58} = 34.21$, $p < 0.001$, $R^2 = 0.54$). On its own, perceived visual quality explained 47% of the variance in perceived total quality. Visual quality added another 8%.

Visual pleasantness ($\beta = 0.700$, $t = 8.32$, $p < 0.001$) influenced total pleasantness stronger than auditory pleasantness ($\beta = 0.235$, $t = 2.79$, $p = 0.007$), ($F_{2,58} = 88.20$, $p < 0.001$, $R^2 = 0.75$). On its own, visual pleasantness explained 72% of the variance in total pleasantness. Auditory pleasantness added another 3%.

Visual eventfulness ($\beta = 0.389$, $t = 2.76$, $p = 0.008$) and auditory eventfulness ($\beta = 0.397$, $t = 2.81$, $p = 0.007$) influenced total eventfulness almost equally ($F_{2,58} = 35.59$, $p < 0.001$, $R^2 = 0.55$). On its own, visual eventfulness explained 49% of the variance in total eventfulness. Auditory eventfulness added another 6%. The same was true in the reversed order.

3.5 SITE E

Table 5 presents arithmetic mean values for how the 61 participants perceived Site E totally, auditory and visually. It shows that the participants perceived the presence of artefacts as moderate. They saw a lot of nature but only heard it a little. They perceived the presence of people as moderate, and the environment as good. On average, the participants visited or passed by this site at least once every week.

Site E	Artefacts	Nature	People	Quality
Total	3.30	3.59	2.87	4.31
Auditory	3.11	2.56	2.49	3.52
Visual	3.44	3.49	2.70	4.08

Table 5 - Arithmetic mean values for how 61 participants perceived Site E totally, auditory and visually

Perceived visual quality ($\beta = 0.433$, $t = 4.09$, $p < 0.001$) influenced perceived total quality somewhat stronger than perceived auditory quality ($\beta = 0.402$, $t = 3.80$, $p < 0.001$), ($F_{2,57} = 31.23$, $p < 0.001$, $R^2 = 0.52$). On its own, perceived visual quality explained 40% of the variance in perceived total quality. Visual quality added another 12%.

Visual pleasantness ($\beta = 0.546$, $t = 4.78$, $p < 0.001$) influenced total pleasantness stronger than auditory pleasantness ($\beta = 0.305$, $t = 2.67$, $p = 0.010$), ($F_{2,58} = 49.30$, $p < 0.001$, $R^2 = 0.63$). On its own, visual pleasantness explained 58% of the variance in total pleasantness. Auditory pleasantness added another 5%.

Visual eventfulness ($\beta = 0.526$, $t = 5.51$, $p < 0.001$) influenced total eventfulness stronger than auditory eventfulness ($\beta = 0.410$, $t = 4.29$, $p < 0.001$), ($F_{2,58} = 94.93$, $p < 0.001$, $R^2 = 0.77$). On its own, visual eventfulness explained 69% of the variance in total eventfulness. Auditory eventfulness added another 7%.

3.6 AGGREGATED DATA

To explore the data further, it was aggregated by calculating the arithmetic mean value for each variable and each site. This resulted in a 5x53 data matrix, where the 5 rows represented the 5 sites, and the 53 columns represented the 53 variables. Pleasantness and Eventfulness were calculated for the total, auditory and visual aspects of the 5 sites, using Eqs. 2 and 3. To investigate under what circumstance the perceived auditory quality of a site influenced its perceived total quality more than the perceived visual quality, an index of Auditory Dominance was created by Eq. 4.

$$\text{Auditory Dominance} = r^2_{\text{Auditory}} - r^2_{\text{Visual}} \quad (4)$$

represent the squared Pearson's coefficient of correlations of perceived auditory quality on perceived total quality, as well as of perceived visual quality on perceived total quality, respectively. Thus, the index of Auditory Dominance is positive when perceived auditory quality explains a larger proportion of variance in perceived total quality than perceived visual quality, else it is negative. This new variable was used as dependent variable in a stepwise linear regression analysis with the other variables as predictors, except the three quality measures used for calculating Auditory Dominance. In addition, Pleasantness and Eventfulness were used instead of the 12 attributes of perceived affective quality. Consequently there were 23 predictors. The only predictor of Auditory Dominance was the perceived dominance of the sound of people, for which there was a negative relationship ($\beta = -0.959$, $t = -5.87$, $p = 0.010$), ($F_{1,3} = 34.46$, $p = 0.010$, $R^2 = 0.92$). Thus, perceived auditory quality influenced the perceived total quality stronger than perceived visual quality at sites where the sound of people could not be heard. Rerunning the analysis with this variable removed from the set of data revealed a more complex relationship.

Table 6 presents the regression statistics for the second regression model of Auditory Dominance. It shows that perceived auditory quality influenced the perceived total quality more than perceived visual quality when the sound of road traffic dominated a site. When controlling for this variable, the total perceived

The two terms r^2 and $r^2_{\text{Auditory Visual}}$ presence of people contributed negatively in the model. In conclusion, the sound environment contributed more to the overall impression of a site when it was poor, and where people appeared absent.

Predictor	β	t	p	$F_{2,2}$	p	R^2
Sound of road traffic	0.671	12.77	.006	217.72	.005	0.995
Total perceived presence of people	-.511	-9.72	.010			

Table 6 – Second regression model of Auditory Dominance

Using the perceived total quality as dependent variable and the other variables as predictors showed that the main predictor was total pleasantness ($r^2 = 0.999$, $t = 31.72$, $p < 0.001$), ($F_{1,3} = 1006.43$, $p < 0.001$, $R^2 = 0.997$). Table 7 presents the Pearson's coefficients of correlations between perceived total quality and all other variables with which it had a statistically significant relationship. The table is organized in order of the size of the correlations coefficients from the strongest to the weakest relationship. Pleasantness topped the table, followed by perceived quality. Thereafter the perceived dominance of the sound sources emerged as important predictors.

Variable	Total quality
Total pleasantness	.999**
Visual pleasantness	.988**
Auditory pleasantness	.986**
Auditory quality	.981**
Visual quality	.966**
Road traffic sound	-.948*
Natural sounds	.927*
Nature (total)	.899*
Sound of people	.887*

* $p < 0.05$ (2-tailed test of statistical significance)
 ** $p < 0.01$ (2-tailed test of statistical significance)

Table 7 – Variables with a statistically significant association with perceived total quality in terms of Pearson's coefficient of correlations

As evident from Table 7 above, on aggregated level, perceived auditory quality of the 5 sites influenced perceived total quality stronger than perceived visual quality. Together the perceived auditory quality ($\beta = 1.282$, $t = 1.34$, $p = 0.313$) and perceived visual quality ($\beta = -.304$, $t = -0.37$, $p = 0.781$) performed poorly as predictors of perceived total quality ($F_{1,59} = 26.96$, $p = 0.036$, $R^2 = 0.96$). They canceled each other out. Perceived auditory quality explained 96% of the variance in perceived total quality among the 5 sites, alone.

Using the perceived security/safety as dependent variable and the other variables as predictors showed that the main predictor was to what extent the surrounding sound environment was perceived as appropriate to the site ($\beta = 0.982$, $t = 8.91$, $p = 0.003$), ($F_{1,3} = 79.37$, $p = 0.003$, $R^2 = 0.982$). Table 8 presents the Pearson's coefficients of correlations between perceived security/safety and all other variables with which it had a statistically significant relationship. The table is organized in order of the size of the correlations coefficients from the strongest to the weakest relationship. Besides to what extent the surrounding sound environment was perceived as appropriate to the site, natural sounds or auditory pleasantness had positive relationships with perceived security/safety.

Variable	Perceived security/safety
Appropriate sound environment	.982**
Natural sounds	.929*
Auditory pleasantness	.893*

* $p < 0.05$ (2-tailed test of statistical significance)
 ** $p < 0.01$ (2-tailed test of statistical significance)

Table 8 – Variables with a statistically significant association with perceived security/safety in terms of Pearson's coefficient of correlations

The present study investigated the relationship between perceived total, auditory and visual quality of 5 sites in and near a large urban park area in Stockholm, Sweden, located by a busy road. Previous studies of audio-visual interaction in environmental perception has suggested that the visual aspects of a place dominate over the auditory (e.g., Gifford & Ng, 1982; Kuwano, Namba, Komatsu, Kato, & Hayashi, 2001; Morinaga, Aono, Kuwano, & Kato, 2003). However, there was a large variation in this respect, suggesting that the auditory aspects might dominate over the visual at some point. The present results suggest that the auditory aspects dominate over the visual when the sound environment is poor. This occurred when the sound of road traffic dominated the impression of a site, and other sounds could not be heard. The results also suggest that perceived auditory quality is just as important as perceived visual quality, at least under the present circumstances. It is particularly interesting to note how important the quality of the sound environment was to perceived security/safety. In summary, it seems as if previous studies of audio-visual interaction in environmental perception have used a rather restricted range of stimuli.

Potential limitations in the present study include the low number of sites in the study. The study was conducted in situ, and is based on observational data with low scientific control, as opposed to experimental data. Taken together, this means that the results cannot be generalized, and can only be taken as indicative.

ACKNOWLEDGEMENT

This study was sponsored by research grant (2013-03049) from VINNOVA – Sweden's Innovation Agency. Partners in the project are Chalmers University of Technology, Stockholm University, The University College of Arts, Crafts and Design in Stockholm, the City of Stockholm, Tyréns AB, Z-block Norden AB, and the artist Mikael Pauli. Special thanks go to Björn Lundén and Linnea Hamrefors for assistance with the data collection, and to the 61 residents who volunteered for the study.

ID 1455 | ASSESSING THE PUBLICNESS OF 'PLANNED' PUBLIC OPEN SPACES PROGRESSIVELY: THE AU MODEL OF PUBLICNESS

Lavanya Jothi Venkatachalam¹, Cho Im Sik¹

¹National University of Singapore

a0120152@u.nus.edu ; lavanya.jvks@gmail.com

ABSTRACT: Over the last three decades, public open space literature has been critical of the increasing involvement of private sector in contemporary practices of public open space planning and development. Critiques on private actors' involvement in public open space development are largely based on the notion of a 'highly public' public domain, argued to have existed in the public open spaces such as parks and squares in pre-WW II cities of Western Europe due to strong state presence in their development. However, as counter-critiques argue, the involvement of private actors in contemporary practices of public open space development is inevitable and could also be beneficial, particularly in emerging Asian economies whose cities are majorly built by private initiatives. And, as such counter-critiques argue, a reconceptualization of publicness as a phenomenon independent of sole state participation, and policies for public open space development based on novel combinations of state, civil society, and private sector participation are strongly warranted. Along these lines, this paper presents a model and method for assessing publicness of 'planned' public open spaces empirically – termed as AU model. The proposed

AU model is progressive, as a public open space is assessed in various stages of its development beginning from its planning - as part of an urban space - to its design, development, and management. Here, publicness is conceptualized based on two attributes – access and use, considered to be its core ideals and that the freedom of which makes a space public, and thereby the name AU. To assess the attributes of access and use, AU model is broadly conceived to constitute of two sub-models: quantitative publicness and qualitative publicness. While sub-model of quantitative publicness is conceptualized to measure the degree to which ‘planned’ public open spaces are developed into publicly accessible spaces, sub-model of qualitative publicness is conceptualized to measure the degree to which publicly accessible spaces - based on three dimensions viz., physical configuration, control, and civility - encourage use by the larger public of the city. Besides, sub-model of qualitative publicness is explicated furthermore into an operational model in which the above-mentioned three dimensions are measured and graphically represented through 14 indicators. Compared to existing pragmatic publicness assessment models, the proposed AU model is significant in providing a progressive, systematic, and comprehensive assessment of public open spaces and related policies. Primarily, it can be used to comparatively assess publicness of public open spaces that emerged under different planning policies, forms of provision, and management regimes. The paper is in five parts. The first part discusses the contemporary practices of public open space development and the associated debates on private sector participation. The second part discusses and then conceptualizes the nature of ‘planned’ public open spaces and their process of development. Third part conceptualizes publicness and explains the proposed AU model of publicness. Fourth part shows an application of the model to the case of parks in the city of Chennai, India. The final part discusses the model’s applications in urban design research and practice and future research directions.

KEYWORDS: Publicness, Public Open Space, Assessment Tool, Emerging Asian Cities, Indian Cities

1 INTRODUCTION

Public open spaces such as parks, plazas and squares are widely accepted as important for creating a safe, liveable, and sustainable urban environment (Thompson, 2002; Villanueva et al., 2015; Woolley, 2003). Conventionally, public open space development is the subject matter of the state. Recently, this scenario is changing in several cities around the world which are undergoing neoliberal economic transition with associated changes in spatial development and governance (Carmona & Wunderlich, 2013). In these cities, the state is slowly reclining due to shrinking municipal funds and capacity, and private sector is playing an increasingly greater role in public open space development (Madanipour, 2014). Such forms of public space development with private sector involvement have come under the scrutiny of several researchers over the last three to four decades, evolving into ‘the end of public space’ debate (Langstraat & Van Melik, 2013; Madden, 2010; Paddison & Sharp, 2007; Sennett, 1992; Sorkin, 1992; Tyndall, 2010).

While substantial efforts have been taken to understand the nature and implications of private sector participation in public open space development in the American, European, East, and South East Asian contexts (Dimmer, 2013), little effort has been taken with respect to the South Asian context. Such context sensitive studies are crucial for the future of public spaces as they can aid in elucidating how local histories, planning cultures, actor networks and spatial conditions have shaped the developmental process of public open spaces, and how such process have influenced the quality of such spaces under local geographical and socio-economic contexts (Dimmer, 2013). Along these lines, the present research aims to examine the developmental process of public open spaces in the context of Indian cities, to understand the nature of private sector participation, and develop a model to assess the extent to which private sector participation in local development processes have produced successful public open spaces in Indian cities.

The paper is organized in five parts. Following this introduction, the next section discusses the developmental process of public open spaces in Indian cities along with the ‘nature of’ and ‘debates on’ the emerging private sector participation. In the third section, a pragmatic model called the AU model is conceptualized and proposed to assess the publicness of public open spaces in the various stages of their development to understand the implications of private sector participation in the context of Indian cities. The following part shows an operationalization of the AU model with respect to public open space development in Chennai, India. And the final part elucidates contextual specificities in the nature of private sector participation in public open space development in Indian cities, and discusses the applications of AU model in urban design research and practice.

2 PUBLIC OPEN SPACES IN INDIAN CITIES – DEVELOPMENTAL PROCESS AND NATURE OF PRIVATE SECTOR PARTICIPATION

Public open spaces that are planned in Indian cities usually take the form of parks or playgrounds which occupy an important place in the public culture of these cities. In these megacities, which are fragmented by vehicle crowded streets and burgeoning shopping malls, parks offer a unique opportunity to socialize in a non-commercial public setting (Merchant, 2013) in addition to the facilitation of physical activity and engagement with nature (Choudhury, 2012). Parks also serve as a venue for several citizen-driven communal activities such as public speaking and visual arts (Hindu, 2016; TNN, 2016), which can hardly thrive in these cities otherwise. Park, as a spatial typology, was introduced in Indian cities, by the British colonial powers (Kaviraj, 1997). They established few parks in all major cities, many of which exist till date as important city level public spaces (Kalpana, Muthiah, & Schiffer, 2003). Apart from these, most other neighbourhood parks seen today have been developed in the postcolonial era (since 1947) due to the modernist town planning principles adopted from the West.

Typically, land for the development of parks is generated as part of the planning process through two approaches. In the first approach, land parcels are reserved in different parts of the city during the preparation of master plan for the purpose of public open space development. For example, the 1991 development plan of Mumbai has reserved around 2000 open spaces under the different categories of Gardens, Parks, Playgrounds and Recreational Grounds (Das, 2011). In the second approach, in the case of large planned spatial developments, a portion of the land in the development is reserved as public open space. For example, in the city of Chennai, India, any planned residential development with a land extent greater than 10,000 square metres, must reserve 10% of the land extent for the development of public open space. The land parcels reserved through both these approaches are subsequently designed, developed, maintained, and regulated by the respective local municipal authorities. Overall the development of these 'public' open spaces is the responsibility of the state, except for the designation of land parcel which involves the private sector who owns the reserved land or who is responsible for the large planned spatial development.

However, over the last few decades, especially after the adoption of neoliberal economic policies in India since 1990, this process of public open space development is changing. The private sector is increasingly playing a decisive role in shaping these open spaces, broadly due to two reasons. Firstly, due to budget deficits, the local municipal authorities are encouraging the participation of private sector in the development and management of public open spaces in most major cities such as Delhi, Mumbai, Bengaluru and Chennai through 'park adoption' or 'care taker' policies (Sripad, 2014; TNN, 2014).

Secondly, the broader pattern of urban development is changing to one driven by the private sector resulting in super block office complexes, gated communities and shopping malls (Banerjee-Guha, 2009). In these emerging fortified developments, the private sector plays a dominant role in the provision of basic services and security either formally or informally, which also extends to the public open spaces designated as part of these developments. In both these cases, the private sector is involved in the developmental process of public open spaces in varying degrees extending from design and development to undertaking management also. What is happening is a kind of gradual 'privatization of public open space' as coined by Loukaitou-Sideris (1993) who describes 'privatization of public open space' as the passing over of its production, management, and control to the private sector.

Review of media articles and research reports suggests diverse implications of such forms of increasing private sector participation in the development of public open spaces. On a positive note, private sector participation has led to the complete development and management of notable public open spaces in Mumbai which would have remained vacant lands otherwise, but are now freely accessible and usable open

spaces for the benefit of the larger public of the city (Deshpande, 2016). Likewise, private sector participation has contributed to the upliftment of the quality of public open spaces in the city of Bengaluru by providing financial support for the installation of special armature for play and physical activity (Hindu, 2012).

On the contrary, private sector participation is also seen to challenge the 'publicness' of public open spaces in Indian cities. For instance, in the case of public open spaces under 'care taker policy' in Mumbai,

several of them have been found to be restrictive due to limited opening hours, ticketed entry, and several other constraints which limit the use of open spaces (Rishi Aggarwal, 2015). Also, in Mumbai, several open spaces that fall under 'care taker policy' have been developed into clubs for exclusive private use with no public access (Manasi Phadke 2014). Likewise, several public open spaces developed as part of fortified developments in the cities of Bengaluru and Chennai are under the exclusive use of residents within the fortified developments with no access to larger public of the city (Patel, 2016; Raqshan, 2016).

The above-mentioned evidences of the diverse implications of private sector participation over the 'publicness' of public open spaces in the context of Indian cities, portray a scenario quite different from the popular 'end of public space' notion developed in the West. Review of Indian scenario shows both potentials and challenges of private sector participation in public open space development. Besides, it is also important to acknowledge the fact that much of the Indian cities or broadly the emerging Asian cities are built by the private sector either formally or informally (Hogan, Bunnell, Pow, Permanasari, & Morshidi, 2012) and therefore their participation in public open space development which is largely a derivative of the larger urban development dynamics is inevitable.

Therefore, the present research aims to approach the phenomenon of private sector participation in public open space development in the context of Indian cities from a unprejudiced position; so as to systematically understand the degree of its diverse implications and to identify opportunities to augment the positive implications; along the lines of De Magalhães (2010) who points out that "regardless of how one might position oneself in the debate, there is certainly an urgent need to better explore conceptually and empirically the risks and also the opportunities associated with these new public space governance practices". As a first step in doing so, a publicness assessment model is developed which is based on the process of public open space development and the nature of private sector participation in the context of Indian cities, and is discussed in detail in the following section.

3 ANALYSING PUBLICNESS OF PUBLIC OPEN SPACES IN INDIAN CITIES – CONCEPTUALIZING THE AU MODEL

Recent advancement in public space research has been the development of pragmatic or empirical tools to analyse the effects of privatization on publicness of public spaces. At least three models have been conceptualized so far: the 'tri-axial' model (Németh & Schmidt, 2011); the 'star' model (George Varna & Tiesdell, 2010); and the 'OMAI' model (Langstraat & Van Melik, 2013). All are based on a multi-dimensional interpretation of what 'publicness' necessitates in a public space; and provide a graphical representation of the same (Langstraat & Van Melik, 2013). But, all three models lack in the following ways to aid in assessing the effects of private sector participation in the context of Indian cities: publicness is conceptualized as the quality of publicly accessible space with a lack of focus on the availability of access which is severely challenged in the Indian scenario; and public open space development is conceptualized as a product of ownership and management and not as an ongoing process in which different actors are involved in the different phases of its development as in the case of Indian cities. This necessitates a broader conceptualization of publicness that moves beyond the notion of publicness: as merely a quality of publicly accessible space; and as an 'end-product' of specific forms of ownership or management of public space.

Overall, publicness is conceptualized moving beyond the common political and civic conceptions "as a state of thrown togetherness which consists of multiple actors, groups, and identities" as defined by Qian (2014). Such a conceptualization is based on the ideas of (a) 'public' referring to the larger public of the city (Iveson, 1998); (b) 'liberal model of public sphere' put-forth by Habermas (1989) referring to the political conception of 'openness and access to everyone'; and (c) 'public realm' suggested by (Sennett, 1992) as "not only a region of social life located apart from the realm of family and close friends, but also . . . [the] realm of acquaintances and strangers". Besides, the ideals of 'accessibility, inclusion and tolerance of difference' posited by Young (1986) in the 'unoppressive city' and the conception of public space as 'one which is not only accessible, but also usable by all' put forth by Arendt (1958) in *The Human Condition* – also shape the conceptualization of publicness in the present research.

Based on these notions of 'public', 'public sphere' and 'public realm', 'public open space' is understood as a space which is open and accessible to all and in which there is room for interaction and casual

acquaintances between strangers. And the publicness of a public space is conceptualized as put forth by De Magalhães and Trigo (2016) in terms of 'the access' it offers to the larger public and 'freedom' it offers with respect to their 'use of' and 'behaviour within' the space. Or quite simply, publicness of a public open space is understood as the freedom available to the larger public of the city to 'access' and 'use' the space. However, among the two attributes, 'access' and 'use' - as posited by Madanipour (2014), 'right of access' is considered fundamental.

A common criticism on public space research is that "often questions of spatiality are underemphasised by public sphere theorists while questions of publicity are underemphasized by public space scholars (Madden, 2010)". Moreover as Carmona and Wunderlich (2013) caution, "both approaches are equally troubling: the first advancing a space-less perspective and the second a place-less vision for a phenomena that will always be rooted in both place and space". To address this issue, a layered approach is adopted here wherein the fundamental ideals of publicness of public space is derived based on the theoretical concepts of public sphere and public realm, which is then translated to a spatial vision comprising of desired physical and organization qualities of public space.

To translate the proposed attributes of publicness, i.e., the freedom to 'access' and 'use' spatially and to overcome the limitations of the existing pragmatic assessment models, a progressive model is proposed here in which a public open space is assessed in various stages of its development beginning from its planning – as part of an urban space – to its design, development, and management. The proposed model is termed AU, denoting the fundamental attributes of publicness, i.e., 'access' and 'use', and to assess the implications of the developmental process of public open spaces over the same, the 'spatial' idea of publicness is differentiated into two viz., quantitative and qualitative publicness. Quantitative publicness refers to the degree to which 'planned' public open spaces are developed into publicly accessible spaces, and qualitative publicness refers to the degree to which publicly accessible spaces encourage use by the larger public of the city through their physical and regulatory qualities.

The proposed AU model is thus conceptualized as two sub-models: quantitative publicness and qualitative publicness elucidated in detail in the subsequent sections. Differentiating publicness in such a manner, not only offers the advantage of assessing the extent to which the basic right of access has been forbidden in public spaces, but also provides a deeper understanding of how publicness is affected in the various stages of the developmental process of public open spaces. It should also be noted here that this model conceptualizes publicness as constructed in the different stages of the developmental and operational phases of the public open spaces through the different actions of the multiple stakeholders and does not encapsulate the publicness as constructed by the perceptions of the users of the space.

3.1. CONCEPTUALIZING QUANTITATIVE PUBLICNESS

The quantitative model is developed to assess all spaces that are designated to be public open spaces in an urban area based on local planning regulations. Quantitative publicness is understood here as the degree to which all public open spaces planned in an urban area are developed into publicly accessible open spaces that are usable by the larger public of the city. Figure 1 shows the graphical model of quantitative publicness which is developed as a multilevel donut pie chart with concentric rings showing the different phases of public open space provision and management, i.e., designation, design and development, and use.

Centre of the graphical model represents the total extent of public open space that is planned in an urban area according to local planning regulations. In the case of Chennai city in India, 10% of large planned developments (plot extent exceeding 10,000 square metres) need to be designated as public open space as mentioned earlier. In the case of corporate buildings in the American cities like New York, San Francisco, and Los Angeles, provision of different types of public space entails additional floor space (Loukaitou-Sideris & Banerjee, 1993; Németh & Schmidt, 2011). Similar planning regulations aimed at provision of public open space is also evident in other cities like Hong Kong (Cuthbert & McKinnell, 1997). It is the total extent of these public open spaces that are to be provided as per the local planning regulations in an urban area – a district or planning region - that forms the centre of the graphical model of quantitative publicness.

Subsequent concentric rings in the graphical model of quantitative publicness represent the degree to which the planned public open spaces are public in terms of designation, development and use. The first concentric ring outside the centre of the graphical model represents the extent of the planned public open spaces that are designated in reality for the same purpose. For example, in the case of Indian cities, there are incidences in which the public open spaces are proposed in the planning schemes that are not designated.

The second concentric ring outside the centre of the graphical model represents the extent of the total planned public space that is both designated and developed as public open space. Here the development of the designated space into a public space is considered as publicness. This conception is quite similar to the notion of viewing the development of 130 new or refurbished public spaces in London as an expansion of public domain by Carmona and Wunderlich (2013). The possibilities for the designated public spaces to remain undeveloped is quite high in Indian cities due to the lack of municipal funds for the same. Such issues could also be expected in similar cities of emerging economies elsewhere. Hence, the development of the designated space into public space is also an important milestone in achieving publicness.

The third concentric ring outside the centre of the graphical model represents the extent of the total planned public space that is designated, developed and usable as public space, i.e., open to the access and use of the larger public of the city. Here, the designation and development of the planned public open space into a publicly accessible and usable open space is considered as publicness or precisely quantitative publicness. Empirically it is the extent of planned public open space that falls under the category 'Designated, Developed, and Usable by Public', which signifies the quantitative publicness of planned public open spaces in an urban area. All the remaining categories represented in the third concentric ring connote the challenges faced in the realization of 'public' public open spaces even though they are planned so, such as unavailability of funds for public space development, 'closing off' of public space due to exclusive private use and so on. To summarize, the proposed quantitative model of publicness captures graphically and assesses the degree to which public open spaces that are planned as per the applicable planning regulations are developed into 'publicly accessible and usable' public spaces in an urban area besides showing the different ways in which quantitative loss of publicness has occurred.

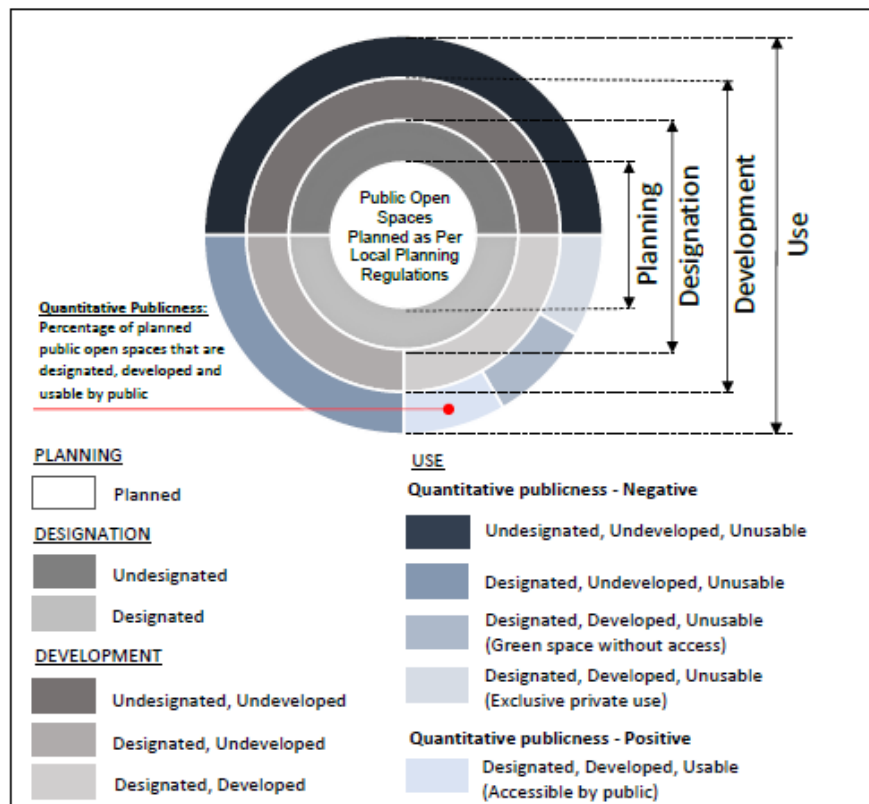

Figure 1: AU Model – Sub-model of Quantitative Publicness

3.2 CONCEPTUALIZING QUALITATIVE PUBLICNESS

The qualitative model of publicness is developed to conceptualize the quality of a 'publicly accessible and usable' open space, i.e., what is denoted as 'quantitatively public' in the sub-model of quantitative publicness. Even though public open spaces that are planned in an urban area are developed into 'publicly accessible and usable open spaces', they cannot be considered to be ideally public, as quite often a number of design and management techniques are employed in such spaces to discourage certain types of users, users and forms of behaviour in the name of sanitizing or securitizing such spaces thereby reducing their publicness (Németh & Schmidt, 2011). In such 'publicly accessible' open spaces, although access, i.e., the fundamental attribute of publicness is available, the other important attribute, i.e., freedom of use is challenged. Thus, 'freedom of use' or more particularly, the freedom the space offers with respect to their 'use of' and 'behaviour within' (De Magalhães & Trigo, 2016) that forms the focus of the sub-model of qualitative publicness. Specifically, the concern here is on how the developmental process of public open space has affected the qualitative publicness.

Qualitative publicness is thus conceptualized through three dimensions viz., physical configuration, control, and civility, which are further detailed out into 14 indicators, graphically represented as a pie diagram as shown in Figure 2. While the dimension of physical configuration and its set of indicators denote the design and physical qualities of the public open space, the other two dimensions and their set of indicators, i.e., control and civility denote the managerial aspects of the space. Conceptualization of the three dimensions is greatly inspired by the conceptualization of the Star Model by Georgiana Varna (2014). Together all three dimensions and their set of indicators assess the extent to which the design and managerial aspects of public open space encourage and do not discourage the larger public of the city to use the space.

Regarding the graphical model, each segment represents one indicator of qualitative publicness, which is assessed on a scale from one to five, represented through the five divisions of the segment. The colour of the segment denotes the dimension to which the indicator belongs to. The innermost division of the segment represents the value one which represents 'low publicness' and gradually increases to five in the outermost division which represents 'high publicness'. The higher the number of divisions is filled in each segment, the higher the qualitative publicness of a publicly accessible space. Representation of the model shown in Figure 2 represents an ideal public open space whose quality of design and management encourages the larger public of the city to access and use the space freely; and therefore, all the divisions in the segments are filled in the model.

As described above, the three dimensions are part of five dimensions of publicness conceptualized in the Star Model of public space by (Georgiana Varna, 2014). However, principles of the three dimensions as envisioned by (Georgiana Varna, 2014) are adapted in the proposed model based on the purpose, i.e., to assess the implications of the developmental process as manifested in the design and managerial aspects of the space, and local context, i.e., the socio-spatial context of planned public open spaces in Indian cities. Thus, based on a detailed review of international literature on contemporary practices of securitizing public spaces, relevant literature (including newspaper articles) on public spaces in Indian cities and a series of field observations on public open spaces in Chennai, India, a set of 14 indicators were developed in the present research.

Physical configuration: Physical configuration is conceptualized as both the quality of macro- and micro-design. Macro-design means the relationship of the space with its surroundings and measuring its quality is to assess whether "the public can reach and enter the place, and how much effort it takes (George Varna & Tiesdell, 2010)". The first indicator, i.e., centrality, connectedness and accessibility is concerned with the macro-design and assesses the degree to which the public open space is integrated in the surrounding public realm so that the space caters to a large section of people in the surrounding areas as noted by Hillier (1996). Micro-design denotes the quality of design within the space, and is measured as the "degree to which the design of the place supports and meets human needs in public space (George Varna & Tiesdell, 2010)". The other six indicators under the dimension of physical configuration viz., armature for basic use; opportunities for engagement, discovery, and display; favourable microclimate; lighting facilities; provision of restrooms and dustbins - assess the different aspects of the micro-design that encourage the use of public open space by multiple publics of the city. These sets of indicators regarding the micro-design are developed based on the highly important recommendations of key public space researchers such as Carr (1992), Gehl (2011), Gehl and Gemzoe (1996), Whyte (2012), and Tibbalds (2012) and are explained in further detail in the Table 1.

Control and civility: The other two dimensions of the proposed qualitative model of publicness, - control and civility - which are the managerial dimensions of public open spaces are conceptualized as a set of five and two indicators under each respectively. Control corresponds to all aspects of the management regime, which are aimed at restricting the 'use of' and 'behaviour within' the public space. Common control mechanisms in a public open space may include controlling through: presence - the physical presence of police personnel or

private security guards; ordinance – enforcing rules through security personal or other dominant persons; technology - surveillance through CCTV cameras; signage - imposing restrictions on the use of space through signage and timing – restricting use through limiting opening times of the space (Langstraat & Van Melik, 2013; Németh & Schmidt, 2007; Georgiana Varna, 2014) which form the five indicators of this dimension. Civility connotes “how a public place is managed and maintained and involves the cultivation of a positive and welcoming ambiance” (George Varna & Tiesdell, 2010). Civility includes both cleaning routine - the quality of everyday cleaning routines and physical maintenance - the attention to periodic maintenance and repairs and is emphasised by several public space researchers as one of the fundamental requisites that influence the use of public spaces (Tibbalds, 2012; George Varna & Tiesdell, 2010).

Thus, the three dimensions of qualitative publicness and the set of 14 indicators under the three dimensions cover some major fundamental and universal qualities of public open space design and management that can encourage the larger public to visit and use the space. The set of 14 indicators are further operationalized into several variables with an elaborate scoring criteria to aid in the empirical assessment as presented in Table 1 below and is explained in greater detail in the following section. Compared to the existing pragmatic publicness assessment models mentioned above, dimensions pertaining to the type of ownership and management are avoided in the present research as it argues against the normative notions that a certain type of ownership or management leads to more 'public' public space (generally believed as 'state' ownership or management), while certain other types may negatively affect the publicness of a space (generally believed as 'private sector').

Also, it is important to mention here that, in the context of emerging Asian cities, as observed in Indian cities, several times, public and private sector work in combination towards urban development and in turn public space development. Thus, reducing such complex partnerships of actors in public space development into few types and assigning them a value of publicness would be fundamentally flawed. Hence, in such conditions where the public sector and private sector work in combination towards urban development and in turn public space development, it is important to understand the implications of the different complex partnerships taken for public space development. In order to do so, the present research suggests a qualitative analysis that has to be carried out and correlated with the qualitative model of publicness proposed here. In doing so, conceptualizing 'type of ownership and management' as a normative is avoided, but a systematic understanding of the implications of the involvement of different actors is gained.

Overall, the AU model of publicness with the two sub-models viz., quantitative and qualitative publicness, conceptualizes the publicness of public open spaces as a progressive quality gained and augmented in the different phases of the developmental process of the space in which multiple actors are involved in each phase. The main significance of the model lies in discerning how publicness is affected in the different phases of the developmental process of public open spaces, which when combined with a detailed analysis of actor participation in the different phases of the developmental process can aid in systematically understanding the implications of complex partnership forms of public open space provision and management as evident in the case of Indian cities.

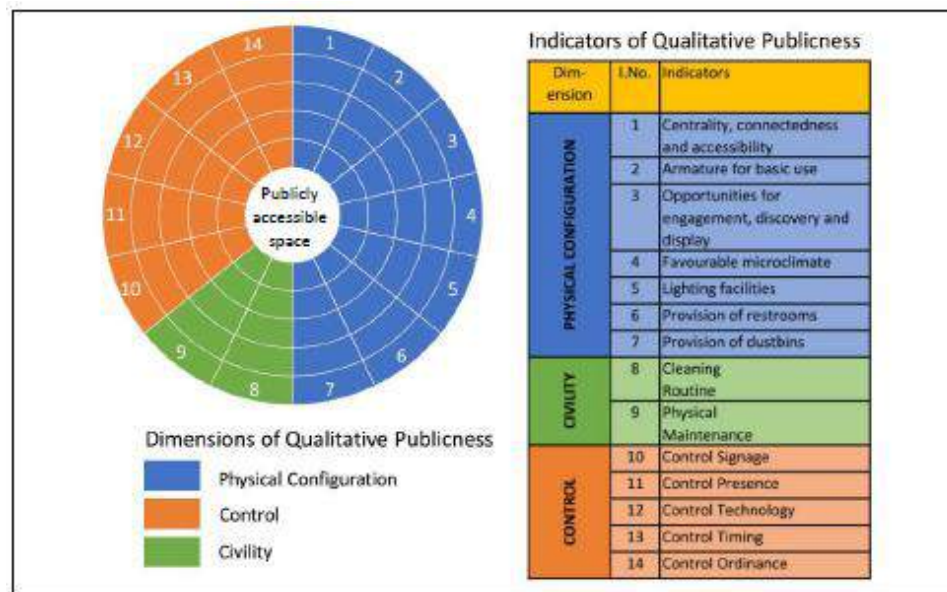

Figure 2: AU Model – Sub-model of Qualitative Publicness

4 OPERATIONALIZING THE AU MODEL: ASSESSING THE PUBLICNESS OF PUBLIC OPEN SPACES IN INDIAN CITIES

In the proposed AU model of publicness, the sub-model of quantitative publicness assesses the degree to which public open spaces that are planned in an urban area are designated and developed into publicly accessible spaces. Such an assessment is quite straight-forward and would mainly involve an audit of the present status of public open spaces that have been proposed in the planning schemes in an urban area and/or within a certain time-period, which can be conducted through several means such as field observation or through analysis of official data, if available.

However, the sub-model of qualitative publicness analyses the quality of design and managerial aspects of publicly accessible open spaces to assess the degree to which freedom is offered to the larger public with respect to the 'use of' and 'behaviour' within the space. Such an assessment, on the contrary, would require a complex understanding of the multiple qualities of the design and management of 'publicly accessible space', which contribute to its qualitative publicness both positively and negatively. Thus, as Kohn (2004) asserts, "publicness as a term has multiple and often contradictory definitions and the best way to approach it is to enlist a range of possible meanings or criteria which could then be grouped to form subsets that would then qualify a space as 'public'". The present research adopts such an approach and has developed an assessment framework that operationalizes the 14 indicators of qualitative publicness further to a set of variables each with a defined scoring criteria and is presented in Table 1.

The variables proposed in the framework are discernible or measurable qualities of public open spaces than can represent the 14 indicators. And the scoring criteria proposes the score of publicness to such discernible or measurable qualities and higher the score, higher the publicness of the space. The average score of variables under each indicator would form the value for the indicator and the total measure of qualitative publicness would be the percentage of the total scores under each indicator. The variables and the scoring criteria have been developed through literature review and field observations in Chennai, India, based on two premises: there are certain universal traits of public open spaces that make them highly public; and there are different shades of publicness that can be assessed on scale from low to high (Georgiana Varna, 2014).

Particularly the scoring criteria of each variable encompasses both qualities that encourage use and discourage use as suggested by (Németh & Schmidt, 2007). Qualities that encourage use are given the score of high publicness while the qualities that discourage use are given the score of low publicness. Besides, the scoring criteria includes qualities that represent both hard and soft methods of control, i.e., discouraging use, as posited by Loukaitou-Sideris and Banerjee (1998). Another key criterion that formed

the basis while developing variables and scoring criteria is the socio-spatial context of public open spaces in Indian cities. For example, under the indicator control presence, maintenance staff is included as a variable and the degree to which they exercise informal control is graded in the scoring criteria. Such a phenomenon has not been mentioned much in the international literature but is a common phenomenon in Indian cities. Overall, the operationalization of the sub-model of qualitative publicness can offer a more fine-grained understanding of the ways in which publicness is affected by the design and managerial aspects of public open spaces.

Dimension	Indicator	Variable	High Publicness	Scoring criteria	Less publicness
1	Control, connectivity, and accessibility (Heller, 1996; Laperriere & Van Marck, 2013; Loukaitou-Sideris & Banerjee, 1998; Nair, 2002; Varma, 2014)	1.1 Physical access - position of entry points in relation to the surrounding public realm	Strategically located entry points providing physical access to a large section of people in the surrounding area, well-integrated within the overall movement network	Mediocre location of entry points providing physical access only to a moderate number of people in the surrounding area, moderately integrated within the overall movement network	Poorly located entry points providing physical access only to a limited number of people in the surrounding area, poorly integrated within the overall movement network
		1.2 Physical access - barrier free design	Entry points designed to cater the differently abled - eg. Ramp for wheelchair accessibility	Signage showing public open space in all entry points	None present
		1.3 Symbolic access - signage recognizing public open space	Signage showing public open space in all entry points	Signage showing public open space in at least one entry point	None present
		1.4 Active footpaths	Large range of functions along the perimeter - highly active footpaths with a few passive footpaths and no blind facades	Medium range of functions along the perimeter - moderately active footpaths with many passive and blind facades	Little range of functions along the perimeter - highly inactive footpaths with predominantly passive or blind facades
		1.5 Treatment of the boundary of public open space	No physical restriction to access - no fences along the boundary of the public open space	Fence provided along the entire boundary of the site; Type of fence provided - see through and lower than the average person's height	Fence provided along the entire boundary of the site; Type of fence provided - opaque and higher than the average person's height
2	Amenity for basic use (Eck & Cohn, 2015; Goh, 2011; Gold & Gennep, 1996; Nair, 2002; Varma, 2014)	2.1 Facilities for sitting	Diversity of seating types (formal and informal) available; comfortable seating options (with backrest) available	Basic seating available but uncomfortable (without backrest)	No seating
		2.2 Facilities for walking	Even and non-slippery paved surface available for walking; paved walkways available for all activity zones; specially marked walking paths available	Even and non-slippery paved surface available for walking; paved walkways available for some activity zones	Most of the paved walking surface is uneven and slippery
3	Opportunities for engagement, discovery, and display (Kara, 1992; Varma, 2014)	3.1 Facilities for passive engagement	Art, cultural or visual enhancement opportunities for watching people, activity and active footpaths; diverse seating types well positioned to watch people, activity and active footpaths	Art, cultural or visual enhancement opportunities for watching people, activity and active footpaths; basic seating well positioned to watch people, activity and active footpaths	No art, cultural or visual enhancement opportunities for watching people, activity and active footpaths; no seating
		3.2 Facilities for active engagement	Diversity of activity and event spaces meeting the demands of all age groups for physical and cultural activities	Diversity of activity and event spaces meeting the demands of certain age groups for physical or cultural activities	No activity or event spaces
		3.3 Seating facilities for social interaction	Diverse seating options providing various opportunities for social interaction	Basic seating providing few opportunities for social interaction	No seating
		3.4 Facilities for discovery and display	Availability of flexible and uncommitted spaces that can support a variety of uses	Unavailability of flexible and uncommitted spaces that can support a variety of uses	Unavailability of flexible and uncommitted spaces that can support a variety of uses

Table 1 – Variables and scoring criteria for each indicator under the three dimensions of qualitative publicness

5 CONCLUSION

This paper has made two key contributions with respect to the issue of privatization of public open spaces in South Asian cities that formed the focus of this research. Firstly, this paper has brought out the characteristics of private sector participation in the developmental process of public open spaces in Indian cities along with the associated debates with respect to their influence on the publicness of such spaces. The nature of private sector participation in the case of public open space development in Indian cities is quite different from the Western context, as here private sector is involved in different degrees either formally or informally in the different phases of the development in a 'complex partnership form' of public open space development. Also, private sector participation has affected the publicness of respective open spaces both positively and negatively and therefore, more detailed research is needed to discern the specific reasons for the positive and negative influences.

Secondly, this paper proposes the AU model of publicness to assess the degree to which public open spaces planned in Indian cities according to local planning regulations are 'public'. The significance of the AU model of publicness lies in the progressive assessment, i.e., in the assessment of public open spaces in the different phases of their development, which can give a more nuanced understanding of how the developmental process of public open spaces affects publicness. Furthermore, the differentiation of the model into two sub-models aid in assessing both the fundamental attributes of publicness, i.e., 'the availability of access' and 'the quality of access and use'. However, the model does have its own limitations. Most important is that it relies on a qualitative analysis of actor participation to precisely understand how different actors' participation in different phases affect publicness. Future research could mitigate this by developing this model further to represent the nature of actor participation in the developmental process of public open spaces also graphically.

ID 1463 | THE URBAN DESIGN REVIEW IN THE PROCESS OF URBAN RENEWAL: A CASE STUDY OF ZHONGSHAN ROAD HISTORIC BLOCK

Benhao Xie¹; Yatong Wang¹

¹Tongji University

xbh79125@tongji.edu.cn ; wangyatong@tongji.edu.cn

1 INTRODUCTION

Historical districts are important components of urban image and urban quality carrying the core content and significant material of urban history and culture. As the policy Chinese Economic Reform: Reform and Opening-up is implemented for more than 30 years, accompanying with the blossom of national economy, the national government are attaching more attention to revitalising the urban cultural heritage, as evidenced by the continuous policy and fund support devoted to the protection and regeneration of historic blocks. However, in the process of concrete implementation, there are emerging some negative phenomena damaging urban image and cultural heritage such as excessive similarity in urban form and construction of fake relics, due to the deviations in the understanding of historical and cultural heritage protection, extreme market-oriented thinking and mechanised mode of operation and many other factors, resulting in the frustrating reconstruction of the historic railway stations in Qingdao and Jinan, which rebuilt the sites imitating the original architecture after the reasonless demolition. As a consequence, during the period of urban renewal, the historical characteristics of the neighbourhood should be taken into consideration, the precise analysis on the historical background and development pattern of the blocks is worth deliberating, and accurate orientation of historic districts are of vital importance as well, so that the

development of the traditional historic districts will be in better integration with the development path of modern city, for the sake of promoting the sustainable development of the city.

After the Opium War, Qingdao was transformed from the original uninhabited fishing village to the important coastal fortification of Qing government. Although Qingdao does not enjoy an immemorial history as long as it in other historic cities like Beijing, Xi'an, and Luoyang, but when looking through the sophisticated modern history of China, it is obvious to find that Qingdao, as a coastal city that has suffered from domination by many colonial rules for years, is tied up with many other major historical events like "The May Fourth Movement" (1919, an anti-imperialist, anti-feudal, political and cultural movement influenced by the October Revolution and led by intellectuals having the rudiments of Communist ideology). Consequently, Qingdao, as a key point in the collision and communication between China and the western world, has an irreplaceable special status in China's modern history. In different historical stages, there are a lot of planning practices for urban development and protection in Qingdao, and the relative planning researches for the protection of historical and cultural district are also in an endless stream, but there also exists some unsuccessful cases that failed to achieve the goals of reviving the state as before, the representative of which is the failing regeneration practice of Zhongshan Road Historic District experiencing four times transformation. Based on the characteristics of Qingdao, the institution of historic conservation planning in Qingdao should be combined with urban form planning, guides the urban design with the premise of protection, and on this basis, extends the concept of preservation from the protection of individual objects to related surrounding environment, anticipating making the protection planning more operational and implementable.

2 THE DEVELOPMENT OF HISTORIC BLOCKS IN QINGDAO

2.1 BACKGROUND OF URBAN DEVELOPMENT BEFORE LIBERATION

After systematic learning of the urban development history of Qingdao before liberation, we can divide it into four stages: German occupation period (1897 ~ 1914), the first Japanese occupation period (1914 ~ 1922), the Kuomintang reign period (1922 ~ 1937) and the second Japanese occupation period (1937 ~ 1945). In the early 20th century, the Germans formulated the earliest planning; the embryonic formation of the linear urban form was basically established during the first Japanese occupation period; The Kuomintang restarted the planning during its reign and determined to build Qingdao as The Portal of Yellow Sea in China's Five Major Economic Zones; during the Japanese occupation of Qingdao for the second time, the single-core urban structure in the German period was converted to multi-core layout pattern. Most of the urban heritage built before liberation remaining well now was German buildings, forming an urban fabric with red tiles, yellow walls, green mountains and trees, exploiting the advantages of altitude difference and combining the features of mountain landscape and ocean scenery. The well-preserved historic areas constitute a beautiful urban landscape of Qingdao.

2.2 CONSERVATION PLAN OF NATIONAL FAMOUS HISTORICAL AND CULTURAL CITIES, QINGDAO

2.2.1 PLANNING BACKGROUND

Qingdao was approved as the third batch of National Famous Historical and Cultural Cities authorised by the State Council in 1994. Witnessing the transition of Chinese society from feudal society to semi-colonial semi-feudal society and then, to the socialist society, Qingdao enjoys a valuable history deserving to be delved into. The protection of cultural heritage in Qingdao is always highly valued by decision-makers from government and the public. Accordingly, the Municipal People's Congress approved the execution of Qingdao Historical & Cultural Preservation Planning (2011 ~ 2020) in 2015, aiming at establishing the urban preservation system through overall consideration of historical & cultural heritage preservation with urban renewal, and forming a protection framework including natural environment, historic urban areas, historic blocks, cultural relics, industrial heritage, historical villages and towns, and intangible cultural heritage.

2.2.2 PRESERVATION REGULATIONS OF HISTORIC URBAN AREAS (28KM²)

- Preserve the current harmonious urban structure “mountain - sea - island - city” generally and protect the unique road network and urban fabric, so as to reflect the original living content, business atmosphere and cultural characteristics.
- Protect the landscape corridor, the scenic spots and landscape contours of historic urban areas and inherit the overall colour system of “red tiles, green trees, blue sea and blue sky”.
- Protect the intangible cultural heritage including folk customs and cultural characteristics, for instance, traditional crafts, traditional operas, traditional music and folk activities.

2.2.3 PRESERVATION REGULATIONS OF HISTORIC BLOCKS (13 DISTRICTS, 982 HECTARES)

1. Adhere to integrated conservation principles and maintain the authenticity and integrity of historic districts.
2. The construction of high-rise buildings is prohibited in protected areas, the height of new buildings ought not to exceed the height of the original historic buildings and the width of visual corridor should be controlled to sustain the original urban space contours.
3. Maintain the original road pattern and road scale in protected areas, control the authorisation of building large-scale centralised public parking, dissolving the parking problems through separating the distribution of vehicles.
4. Protect the traditional style elements like retaining walls, enclosing wall, steps, gates, corridors, road pavements, all the destroyed should be restored to their original appearance.
5. The construction and improvement of municipal infrastructure facilities should target at facilitating the living conditions of the residents, improving the environmental quality, and fulfilling the requirements of protected areas.

3 THE RENEWAL PLANNING OF ZHONGSHAN ROAD HISTORIC BLOCK

3.1 THE OVERVIEW OF ZHONGSHAN ROAD HISTORIC BLOCK

3.1.1 DEVELOPMENT HISTORY

In 1898, the Germans opened a commercial street named Frenndrich Street with a typical German style north to the Zhan Qiao Pier (the official symbol of Qingdao initially built as the first man-made military wharf in 1892), establishing the embryonic form of the present Zhongshan Road.

On the fundamental construction of Germans, Zhongshan Road became the commercial center of Qingdao gradually during the first Japanese occupation period. Meanwhile, in order to strengthen the cultural invasion and mind control, the south part of Zhongshan Road was renamed Shizuoka Street, and the north part was renamed Shandong Street or Shin Ze Street by Japanese.

In 1922, the sovereignty of Qingdao was taken back and the Qingdao authorities abolished all Japanese road names and renamed the whole Zhongshan Road into Shandong Road. Then on May 22, 1929, to commemorate Dr. Sun Yat-sen, the Qingdao authorities renamed Shandong Road into Zhongshan Road.

Before the full-scale war of World War Two, Zhongshan Road witnessed its last prosperity as a commercial centre with the financial blossom of many famous banks.

From the 1950s to the early stage of reform and opening-up, Qingdao government drew up development plans in 1950, 1957, 1960 and 1978, where Zhongshan Road Historic Block occupies a pivotal position in the commercial development of Qingdao.

After the mid-1980s, the commercial development of Zhongshan Road still maintained a relatively rapid pace.

In the early stage of 1990s, Qingdao government formulated a significant amendment to the urban development structure, resulting in the eastward removal of central city.

Since the 1990s, the traffic function of the block has been strengthened accompanying with the process of depression. The old block was calling for renaissance. (Figure 1)

Figure 1 - Current Aerial Photo (Source: Google Map)

Figure 2 - The Core Area of Zhongshan Road Renovation (Source: Tsinghua University)

3.1.2 THE PLANNING BACKGROUND OF URBAN RENOVATION

Zhongshan Road Historic Block is the birthplace of modern Qingdao enjoying a history of over one hundred years. From the beginning of the German occupation period in 1897, the area was becoming the irreplaceable urban centre and symbol of Qingdao. However, with the development and construction of the new town in the east of the old district starting up in the late 80s, the vitality and status of old district has been reduced ever since; then in 1994, the municipal government relocated eastward along with the transfer of financial centre leading to accelerating the further decline of Zhongshan Road Historic Block. In recent years, the Qingdao municipal government has put a premium on the fading trend of Zhongshan Road, taken positive measures to inject the vigour of the area. Unfortunately, there has not reached a comprehensive consensus on the primary problems and solutions of the renovation planning of Zhongshan Road Historic Block, which means the relative researches and program designs are still in urgent need. (Figure 2)

3.2 THE FIRST RENOVATION IN 1996

On May 3, 1992, The Decision on Speeding up the Development and Construction of Eastern Qingdao was launched, meaning that the municipal committee and government decided to take the lead to move eastward, affected by which the popularity of Zhongshan Road began to fall off a cliff. This is an irreversible historical tide. At the same time, the rapid rise of Taidong Commercial Pedestrian and Hong Kong Road CBD symbolising the low-end and high-end consumption respectively demonstrated that there left narrow path for old Zhongshan Road to develop forward, bringing about the gradual transformation from the past "City Centre" to the "Urban Fringe" today.

This version of renovation planning was to remould the Zhongshan Road according to the East Nanjing Road, Shanghai, the representative of commercial pedestrian street. For the purpose, the 129 oriental plane trees used to grow on both sides of pedestrian were moved away, and trolleybus route had to be bypassed and run along Henan Road. Nevertheless, the plan ignored the crucial role of Zhongshan Road as a traffic artery, the adjustment of trolleybus route paralysed the entire traffic. In conclusion, the idea of pedestrian street ended up with a complete failure.

3.3 THE SECOND RENOVATION IN 2003

In October 2002, Institute of Architectural and Urban Studies, Tsinghua University was entrusted by Qingdao Municipal Government and Qingdao Zhongshan Real Estate Co., Ltd. to assume the site planning and space design of Zhongshan Road Business District. The project started to carry out in 2003.

3.3.1 FUNCTIONS

Establish a liveable business and tourism complex with strong finance and social vitality, embodying local characteristics, and cultural landscape and integrating financial business, professional services, tourism, culture, and living.

3.3.2 TARGETS

- Excavate the historical and cultural connotation of Zhongshan Road area.
- Improve the urban landscape and infrastructure, and optimise the development environment.
- Redistribute urban residents appropriately, and conserve the historical features.
- Revitalise the economic and social development.

3.3.3 MEASURES

1. Measures to promote industrial development: coordinated development of business, tourism, cultural industry, modern service industry.
2. Measures to promote social development: population redistribution, community renewal, and justice security.

3.3.4 MEASURES

In line with the guidelines of the project, some old buildings such as Qingdao Hotel, Red Star Cinema and ancient bookstore were removed and new buildings with modern style arose, the purpose of which was to make Zhongshan Road advance with the times. (Figure 3~5)

Figure 3 - Aerial Photo before Renovation (Source: Tsinghua University)

Figure 4 - Simulative Aerial Photo (Source: Tsinghua University)

Figure 5 - Planning Range (Source: Tsinghua University)

After the implementation of this program, over 100 families who used to live around St. Michael's Cathedral had to bid farewell to where they stayed for many years. In the meantime, the demolition of many old buildings in Zhongshan Road Historic Block were wearing down the original sense of history, arousing extensive controversy, in addition, people did not catch sight of any essential improvement on the original chaotic phenomena such as massive gathering of transient population, poor quality of living conditions and stagnant business environment. Tsinghua University was the first outside planners involved in the renovation process of Zhongshan Road, although their planning professionalism and logical clarity excelled the works done in the previous projects, the lack of recognition for local characteristics like local history, culture and lifestyle declared the regretful failure of the urban regeneration emphasised by the public.

3.4 THE THIRD RENOVATION IN 2005

In 2005, the next round of Zhongshan Road renovation was put on the agenda once again. In January 2005, Zhongshan Road block was determined to transform to pedestrian street in accordance with The Commercial Development Planning, Shinan District (2005~2010). In August 2005, Shinan District government took back the command of Zhongshan Road renovation project from Qingdao Zhongshan Real Estate Co., Ltd. The Zhongshan Road Renovation Headquarter reset the project target to creating a leisure street with historical and cultural characteristics, besides proposed a slogan of "Restore the historic features, improve the living conditions and revitalize the commercial economy". On the basis of the targets, the headquarter confirmed a new renovation proposal with the concept of "Restore the antique as before" after summarising the experience of previous construction and came up with three principles of keeping the original street space, architecture texture and historic features unchanged. The operation of the policy measures taken in the renewal process was relatively conservative, laying the policy foundation for the following fourth renovation.

3.5 THE FOURTH RENOVATION IN 2009

On April 12, 2009, Pichaiyuan Area (literally: Axe Firewood Courtyard), the famous authentic cuisine street and the local cultural representative on Zhongshan Road, was solemnly opened after 15-months' complete reconstruction, gathering popularity once again. During the protracted period of reconstruction, there emerged an enormous number of social problems. The discourse from all sectors of society including the citizens, experts, scholars and officials exerted much influence on the decision-making, in the interim, the continuous emergence of old buildings with quality problems caused by out of repair for long years during the process of renovation also elevated budget of the project. Moreover, due to the misunderstanding of a small number of merchants, uneven technical level of workers made it difficult to interpret the design concept adequately, leaving a regret though it had already upgraded a lot compared to the past three renovation projects.

After experiencing four times of reconstruction, the disorder of shops and stores on both sides of Zhongshan Road was completely changed and the shopping environment improved significantly. But except Pichaiyuan Area reviving because of reconstruction, the operating conditions of the other shops were not all optimistic: many stores over-depend on tourism consumption and did not improve their service level and the supervision on commercial industry from authorities was not strict enough. At the same time, the population structure in the neighbourhood was imbalanced, the residents were almost composed of the native elder and migrant workers, most native young people had moved out to seek for opportunities. Without the inner development drivers, we could not see the possibility of ultimate renaissance of Zhongshan Road.

4 REFLECTION ON THE FOUR RENOVATION: DISCOVER THE URBAN DEVELOPMENT DRIVERS

Looking through the previous four renovation process, we could easily see that although there were a lot of magnificent objective ideas and strong policy measures proposed, the planning guidance on spatial level

and the government intervention on policy level could not fundamentally revive Zhongshan Road, we must dig out the primary reasons restricting the development of Zhongshan Road from social level to find out the urban development drivers to enhance the vitality.

4.1 EXCELLENT EDUCATIONAL AND MEDICAL FACILITIES HINDER THE BLOCK TRANSFORMATION

As the former centre of Qingdao, although the general development of business cannot be as prosperous as before, the educational and medical equipment in Zhongshan Road area is still much more outstanding than other districts. The Affiliated Hospital of Qingdao University and Qingdao Municipal located in the area are the few 3AAA hospitals (the most specialized hospitals in China according to Classification of Chinese Hospitals) in Qingdao, enjoying a wide recognition by the public. Even if these two hospitals have already opened new branches in eastern Qingdao with advanced hardware facilities and convenient transportation, but the abundant medical resources that the old hospitals have accumulated for years are still incomparable, as a result, the influence of the old branches of these hospitals should not be underestimated. The large influx of patients and their families into the surrounding areas are raising stringent requirements on traffic conditions, in addition, driven by the profits, the surrounding rental prices remain high though the quality of the apartments is in poor situation.

Apart from the best hospitals in Qingdao, the best primary schools in Qingdao are also concentrated in Zhongshan Road block: Qingdao Experimental Primary School, formerly known as the German Government Primary School founded in 1901, represents the pinnacle of fundamental education in Qingdao, in addition, Daxue Road Primary School founded in 1933, Jiayuguan Primary School founded in 1953 and Taiping Road Primary School founded in 1933 also have a high reputation in education field. In order to acquire the admission tickets of “elite schools” for their children, parents would not be held back before “school-choosing fee” of over 100000 RMB (equal to 13000 EUR). But in recent years, with the cancellation of “school-choosing fee”, ownership of housing in school district is the only way to have access to related primary schools. Therefore, the housing prices in the school district of former city centre are becoming an astronomical figure, the price of an old flat no larger than 20 m² is close to one million RMB, comparable to the luxurious flat with seascape in core urban areas. There leaves a tough challenge for investment in lands and compensation for demolition during block transformation.

4.2 EXTRAVAGANT PROFITS OF SCENIC AREAS UNDER THE PROSPEROUS BACKGROUND OF CLASSICAL ARCHITECTURE TOURISM

An important truth that cannot be neglected is that there are a tremendous number of landmarks located in Zhongshan Road Historic Block, the past core of the old Qingdao: Zhan Qiao Pier, the emblem of Qingdao first built in Guangxu 18, Qing Dynasty (1892); Pichaiyuan Area, the birthplace of Qingdao folk culture; the former site of Seemannshaus (literally: German Navy Soldier Club) with Renaissance Revival style; St. Michael's Cathedral, the largest Gothic architecture in Qingdao and also the only inaugurated cathedral in China; Jiaozhou Governor's Hall, the former German colonial government building and the largest and most expensive houses among all buildings in Qingdao The numerous classical buildings centred in Zhongshan Road constitute a stimulus to tourism development in Qingdao. Furthermore, in company with coast on the south and the old railway station on the west, Zhongshan Road attracts tourists from all around the world to gather here, but the grade of tourism still remains fast-food-style sightseeing, touring form stays in the one-stop visiting, dining and shopping. After satisfied by consumption of souvenirs, tourists would not have interests in visiting Qingdao for next time because there were not many worthwhile places for another tour. What matters most is that we cannot see the feasibility of launching in-depth travel tourism for the moment. The purpose of Zhongshan Road Renovation is to enhance the overall quality of the district, improve the quality of tourism, and spread the city culture, but as for the main tourism industry practitioners mostly composed of non-native merchants, Zhongshan Road block is an important security for their income source, which means thorough transformation of Zhongshan Road will seriously affect the income of these merchants relying extremely on tourist flows, though the overall tourism industry in Qingdao will only be slightly influenced in short term.

4.3 FLOATING POPULATION GATHERING AROUND THE OUTSKIRTS OF OLD RAILWAY STATION INCREASES THE PRESSURE TO TRANSFORM

On the west side of Zhongshan Road Historic Block lies old Qingdao Railway Station initially opened in 1901, although the surrounding Qingdao Liuting International Airport and Qingdao North Railway Station on the north of the old train built in recent years evacuate a lot of people, but passenger stream in Qingdao North Railway Station is mainly made up by citizens who prefer high-speed transports and live in other districts of Qingdao, besides, the commercial facilities and infrastructure construction around Qingdao North Railway Station are not complete. For this reason, most migrant workers taking the “green train” are flooding into the old railway station and taking root in the surrounding areas with low-quality housing, and they gradually control the business and market in this traditional business district. How to properly resolve the employment and housing problems of these non-native people and ensure social harmony and resident integration raise an intractable problem for the entire renovation of Zhongshan Road Historic Block.

5 CONCLUSION

5.1 DISCUSSION ON THE FIFTH RENOVATION LAUNCHED IN 2012

After four times of unsuccessful transformation four, the Qingdao Municipal Government set up the new Zhongshan Road Renovation Headquarter with highest specifications of all time, including 29 academicians and experts from China, Singapore, Germany and other countries to discuss the future regeneration of the site, proposing the following targets: promote the commercial environment, and improve the living conditions; preserve the traditional districts with historic characters and excellent historic buildings; revitalize the business vitality, and create a better tourist attraction with rich local culture characteristics and other elements like commerce, culture, tourism, leisure and living. The project is intended to transform the Zhongshan Road into a European Street, and the new turn of reconstruction is still on the march. Until now, we have not concluded a positive prediction about the project because we could not confirm whether the previous problems like blind westernization and misunderstanding of historical protection are solved or not.

5.2 EXPECTATIONS

The preservation of historic blocks should not only stay in the material level for the building, but also sustain the city memory and urban culture from the spiritual level. In the process of block renovation, we must make efforts to maintain an equilibrium of powers among government intervention, market regulation and social participation, taking full account of the implementation of various transformation measures, the long-term economic development and the vital interests of the residents. The planning projects taking into account of all aspects must be inefficient, but concerning too much for the interests of few is doomed to failure; at the same time, the transformation process must be combined with the analysis of the relationship between land and the city to explore the core drivers of urban development. We hope that the conservation planning of Zhongshan Road Historic Block could balance the interests of all respects, sweep away the obstacles limiting development of historic districts and revitalise the former central business district, directing to sustainable development of Qingdao.

1 INTRODUCTION

1.1 REAL ESTATE DEVELOPMENT WITH CHINESE CHARACTERISTICS

China started housing reform in 1992, abolished the welfare housing sharing in 1998, and ushered in real estate boom since then. China started housing reform in 1992, abolished the welfare housing sharing in 1998, and ushered in real estate boom since then. China's newly started residence area is 166.37 million square meters in 1998, 244.01 million square meters with residence complete achieving 2,139,702 in 2000, and 551.85 million square meters with residence complete achieving 3,682,523 in 2005. Under the state- owned urban land system and the land leasing system, large-scale demolition and construction became a common phenomenon. Taking Shanghai as an example, the quantity of residence expropriation is 386,430 with the area of 14.68 million square meters between 1995 and 1999, 359,545 with the area of 18.68 million square meters between 2000 and 2004, 317,176 with the area of 37.56 million square meters between 2005 and 2009, 138,708 with the area of 9.19 million square meters between 2010 and 2014.

This large-scale space production model caused spatial differentiation, which is one of the most important reason for gated community. From 1999 to 2004, 83% communities in Shanghai became gated communities (SONG Mi, 2015). Gated communities ensure the management and operation, while become isolations separated from the urban context. Meanwhile, with the development of technology, and the increase of land prices and housing prices, the residence development intensity showed an increasing trend.

Compared with the previous multi-storeys residence district, which floor area ratio is usually not more than 1.7, the floor area ratio of high-rise and high intensity communities, which is the mainstream now, is always more than 2.5, or even reach 4.0(LI Jiangyun & WANG Hongjie, 2015). But in fact, the floor area ratio of the residential area should not be more than 2.5 according to code for planning and design on urban residential areas(GB50180-93). In 2003, the fifth Shanghai planning meeting also suggested that the floor area ratio of residential area should be under 2.5 in central city. Newly built high-intensity communities meet people housing demand, but bring challenge to urban infrastructure and public service facilities. Higher intensity communities do not mean more liveable community life.

High intensity gated community as the main form of community now will exist for a long time in the city. It shows great significance to find the better way of public space construction to create better public life. The State Council pointed out in Comments on Strengthening Urban Planning and Development Control that urban blocks system will be promoted among newly built communities and gated communities will not be

constructed further in principle. The Quito Paper also appeal for transformation from gated community to open city. It's important to promote in at least two levels —— urban and community - to create better public life.

1.2 DEFINITION

1.2.1 PUBLIC SPACE AND PUBLIC LIFE

Public space in community is generally understood as what between the residential buildings, such as squares, green space, public buildings and every other thing considered as part of the built environment. In a board sense, public life is everything that take place between buildings (Gehl J, Svarre B., 2013, p.11). Tonnize suggested that there are four conditions for community formation: social network, relatively independent area, complete public services and the sense of value identity.

1.2.2 HIGH INTENSITY COMMUNITY

Floor area ratio is an important indicator of the development intensity of commercial residential area. The higher the floor area ratio is, the higher the intensity of land development. According to the Urban Residential Area Planning and Design Specifications (GB50180-93) in the high-rise residential area floor area ratio of not less than 2.0. In general, the higher the floor area ratio is, the higher the residential buildings are, and the lower the building density is. According to the Residential Design Specification(GB50096-2011), the height of residential buildings is always no more than 100 meters, or the design and construction standards will be stricter, because the building over 100 meters are defined as the ultra high-rise building.

1.2.3 GATED COMMUNITY

Gated community is 'walled or fenced housing developments, to which public access is restricted, characterized by legal agreements which tie the residents to a common code of conduct and (usually) collective responsibility for management' (Atkinson & Blandy, 2005, P.197). It's an important type of communities in a number of cities all over the world.

1.3 AN OVERVIEW OF ZHONGYUAN TWO-BENDS COMMUNITY

Zhongyuan two-bends community located along the Suzhou River in Shanghai, where used to be one of the largest shantytown. Shanghai started large scale transformation of old urban residential districts in 1992, aiming to finish 3.65 million square metres replacement before 2000 (Figure 1). Zhongyuan two-bend community was built in 1999, and was completed in 2005. The community covers an area of 49.5 hectares with a total construction area of 1.6 million square meters (1.4 million square meters' buildings are residential buildings) and a population of 35,800.

(a) in 1948 (b) in 1979 (c) in 1994 (d) in 2006 (e) in 2016 Source: Tiandi Map Shanghai and Google Earth

2 PUBLIC SPACE SHAPING IN COMMUNITIES

2.1 THE OVERALL LAYOUT OF PUBLIC SPACE IN THE COMMUNITY

2.1.1 SPATIAL FEATURE

As a high intensity community, Zhongyuan Two-bends Community faces the contradictions between living quality and high floor area ratio, public services and the population, design specifications such as the sunshine requirement and sum of buildings and so on. From the perspective of spatial arrangement, there three main feature: mix of building types, clear layout of open space and human scale space created by skirt buildings (Figure 2 and Figure 3).

Figure 2 - The Sketch Map of Zhongyuan Two-bends Community

Figure 3 - Photos of Zhongyuan Two-bends Community

It adopts the way of mixed arrangement, that is, instead of row-layout of board buildings, it combines board high-rise buildings with the point-type high-rise buildings to make the overall space well- arranged. The cluster of board high-rise buildings confines the important public space. It's a kind of transform of figure and ground, which is good for balance the building and the space outside. As for the layout of open space, there are three key open space: entrance square, waterfront space and green open space of residential group. From the perspective of spatial experience, the differences between urban space, community open space and more privacy residential group are significant. It ensures the quantity of public space and helps the residence to build the sense of identity. As for the quality of public space, both the green space and the construction of skirt buildings are helpful to assuage the stress from the board high-rise buildings. What's more, the design of skirt buildings, sky bridge, spatial corridors and so on enriches the spatial experience of pedestrians.

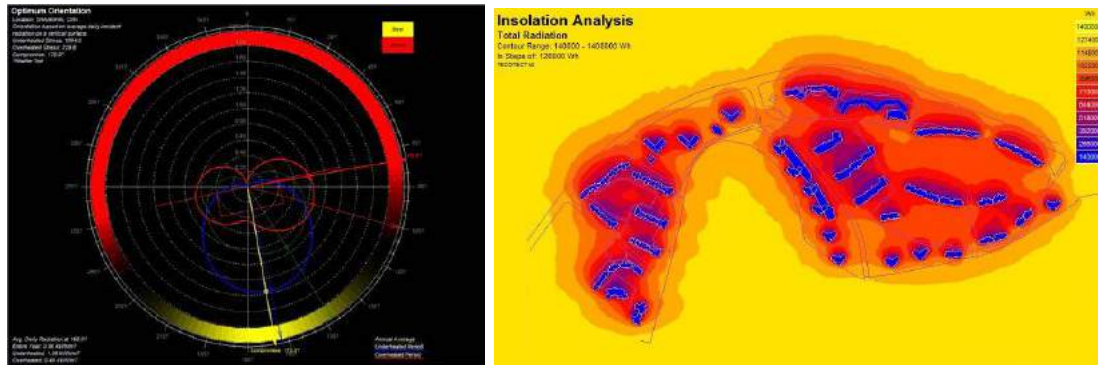

Overall, at least for physical space itself, there are public space design methods worth learning about. But the community itself cannot be separated from the whole city. Traffic problems and lack of public service caused by the high intensity still remains unsolved.

2.1.2 PHYSICAL ENVIRONMENT

Sunshine condition, nature ventilation and noise control are important factors that affect the physical and physiological living quality. Through modelling and analysing by Ecotect and Windperfect, this paper tried to find the physical environmental feature of high intensity community, wondering whether the high intensity will decrease the quality of physical environment.

Zhongyuan two-bends community is located in 121 degrees 20 minutes east longitude and 31 degrees 15 minutes north latitude. Shanghai belongs to hot summer and cold winter climatic region, whose summer is muggy, while winter is raw and wet. Favourable orientation helps residential lighting and natural ventilation. The optimal orientation of residential buildings in Shanghai is 10 degrees south by east, while the most unfavourable orientation is 80 degrees north by east (Figure 4). Thus there are lots of east-and-west facing residence in the community. And it's a common design method that turning the buildings at a slight angle on the plans will get richer open space. The residential in Shanghai need to follow strict requirements of sunshine, building interval and so on to ensure the physical environment of every apartment. As for the physical environment of the open space (figure 5), the total solar radiation is higher around point-type high rise buildings than around board high-rise buildings clusters. And the major open

space of the community has an appropriate amount of solar radiation. And trees and structures are used to provide shade for the residents.

Source: Provided by Yuhui LIN

As for the wind environment, Shanghai prevails southeast winds in summer, while northwest wind in winter. This paper calculated the air flow rate at 1.5 meters high of Zhongyuan two-bends community (Figure 6). The majority of the roads run northwest-southeast, which will force the wind through the community to lower the temperature in summer. And the board high-rise buildings in the north of the community will keep the northwest wind out of the community in winter. And the skirt buildings reduce wind speed at 1.5 meters high to make the public space of the residential group more comfortable. The overall layout of the community can have a great influence the microclimates. According to the interview with the residents, most of they are satisfied with the wind environment.

Figure 6 - Air Flow Rate of Zhongyuan Two-bends Community

As for noise control, it's north neighbourhood is the inner ring line and metro line 4, which can be an important noise source. The overall layout of the community intended to arrange board high-rise buildings in the north of community, acting as an acoustic barrier. This approach effectively guaranteed the acoustic environment quality of most area, but the residents living in the north of the community are living in a high level of noisy environment.

Overall, thanks to the design specifications, the physical environment in the communities can always be protected. What's more, it's possible to improve the physical environment by design methods such as ingenious skirt building design, reasonable green space layout system and so on.

2.2 PUBLIC SPACE DESIGN OF A RESIDENTIAL GROUP

As a super block community, there are several housing residential groups, which make it possible that it can make a compromise between super block mode and small-and-open block mode. Taking one of the

residential groups as an example (Figure 7), the methods used to create public space are worth learning. Five board high-rise buildings and their skirt buildings confine two main courtyard. The large courtyard, where the activities are concentrated, has plenty of gym equipment, benches and other interesting structures. Thus the interaction between green space and surroundings is positive. Although the buildings around the courtyard are almost 100 meters high, it does not make pedestrian stressful for the trees and other structures provide them with a better visual context. There is also negative space in the residential group. But the case of this residential group at least proves that it's possible to create high quality public space in a smaller block, while meeting the requirements of intensity at the same time.

Figure 7 - A Typical Residential Group of Zhongyuan Two-bends Community

3 PUBLIC LIFE CREATION IN COMMUNITIES 3.1 NEIGHBORHOOD COMMUNICATION IN PUBLIC SPACE

The boundary of gated community cut off from the urban fabric. In the gated community often causes the fragmentation of social space, while the space privatization often leads to the segregation of residents. What's more, the block scale can influence the interpersonal interaction. This paper tried to analyse neighbourhood communication in public space through behavioural observation, chat and analysis of social media topic.

What they care about on social network, is emotional expression of daily life, feeling of environmental transition of the block and time-efficient city event, such as dragon-boat racing on the Suzhou river around their apartment block and news events happened in the community. It has been more than 10 years since the community was completed, thus the residents have already created the feeling of identification and belongingness. As for the daily life of most residents, their activities are centred inside the community, and the entrance square, waterfront space and green open space of residential group are the most frequently used place. From 2 pm until 4 pm, there will be a majority of residents gathering around gym equipment or in the shade of trees and many public activities taking place in the public space (Figure 8). The residents who often stay in public space are primarily old people and children. And the interaction is limited among them for the limited form of activities. This meant that the design methods used to create public space in Zhongyuan two-bends community is effective. The comfortable open space indeed leads to spontaneous activities and social activities.

Figure 8 - Activities Happened in Zhongyuan Two-bends Community

During the last ten years, Zhongyuan two-bends community was well known for group-renting dwelling phenomenon. At that time, an apartment was divided into several parts and was leased to 8-30 tenants. And there were about 2000 tenements in the worst time. The reason is that investment-driven clients tried to shelter from risk in house pricing regulation and earn huge profits through group-renting dwelling. Group-renting dwelling phenomenon is not only a challenge to community security, but also harmful to the community identity and the community public life itself. Nowadays, after problem-addressing action took by resident volunteer, property management company and the police, group-renting dwelling phenomenon is almost disappeared from the scene. In such a context, entrance guard seems good for community governance. The community need a compromise to balance between community governance, security and urban vitality and publicity, which need a combine public space construction with building community.

3.2 DIFFERENT MODES OF PUBLIC LIFE IN LILONG HOUSING, WORKER HOUSING AND HIGH INTENSITY GATED COMMUNITY

There are three main types of residential area in central Shanghai, Lilong housing, Worker housing and what this paper mainly discussed—high intensity gated community, according to the time sequence. Different types of public life show in different types of community, for the differences existing in spatial organization and social organization.

After Shanghai opened as the treaty port, Lilong housing, which absorbed the advantage of row house in Europe and adapted to local lifestyle, became the mainstream type of residential buildings in order to intensively utilize land sources to deal with population explosion. Lilong housing is a kind of small and open block mode, which makes the residential area more harmony with the urban fabric. The spatial organization of Lilong housing is characteristic —— the density of buildings is high, the quantity of public space is low, the total number of piles of it is often 2-3, the passage between buildings is always narrow. Thus, the lines between private space and public space always blur. Because the area private space is not enough, the sharing of “kitchen” and “laundry” is a common phenomenon. This mode of spatial organization leads to frequent contacts among neighbourhood and the formation of “street eyes”. Put another way, the contacts are so close that sometimes cause neighbour conflict. What’s more, the quality of built environment in Lilong housing is indeed not good enough, lacking of enough open space, especially green space. The mode of public life in Lilong housing is worth learning, while Lilong housing is not the first choice to settle life now.

Worker housing played a vital role in residential areas in 1950s, based on special urban construction and institutional improvement background. Working housing was an important part of institutional improvement. It gave workers a strong sense of community identity and greatly improved the quality of living conditions at that time. Compared with Lilong housing, worker housing has a lager scale, with higher multi-storays buildings, lower building density and higher intensity. And a considerable amount of worker housing is gated. Its contacts with the surrounding environment benefited from the special social organization, cause the residents is kind of homogeneous groups. However, compared with high intensity gated community, which was gradually becoming mainstream in 1990s, worker housing has a smaller scale and lower

intensity. As a whole, the street, square and green space in working housing are important and vigorous place for public life. And actions like tiny-regeneration in communities are improving the environmental quality, the interactions between people and the environment and space utilization.

In a certain sense, high intensity gated communities nowadays won larger private space and per capita open space area at the price of losing truly community life. It's not mean high intensity gated communities is the history of regression, which is a preferred choice for many people, but it can be better.

4 DISCUSSION

4.1 FROM GATED COMMUNITIES TO OPEN CITY

The Athens Charter suggest that High-rise apartments placed at wide distances apart liberate ground for large open spaces, which is just the scene showed in most high-intensity communities. With the growth of gated communities and car-centric streets, people earned more space at the price of the lose of community life and street vitality. The New Urban Agenda suggested to support the provision of well-designed networks of safe, inclusive for all inhabitants, accessible, green, and quality public spaces and streets. Chinese government also encourages small- and-open block mode recently. Compared with the super block mode, the small-and-open block mode integrates the communities and the urban environment around it. Instead of cutting off the traffic connection, the road system of the community in small-and-open block mode will be connected with the urban road network, which may ease the problem of congestion. What's more, it will be help for the sharing of public service between the communities and the whole city. And the resources will not be privatization, but belong to the whole city. For example, the riverside of Suzhou River is occupied by lots of real estate projects, one of which is Zhongyuan two-bends community. It's a pity that the resources of waterfront is privatization. Although there will be lots of barriers before breaking down the bounding wall of the gated communities, and it's not a "one size fits all" way that is suitable for every community, once the communities become part of the open city, the situation will change so much.

4.2 FROM COMMUNITIES TO "OUR HOMELAND"

What residents want from the communities is not only material space one satisfied one's physiological needs, but also community identity to satisfied one's spiritual needs. On the one hand, the residents living in gated communities also need the interaction space to perceive others emotions and built community identity. During the process, different social roles are involved. On the other hand, the drivers of the cities are complex, including economic momentum, social dynamics and so on. The transformation from our community to "our homeland" need the integration of dynamics.

In 2015, Measures for the implementation of urban regeneration in Shanghai presented the concept "urban organized renovation", of which the core is people-oriented space reconstruction and activation of the communities. And the Shanghai Spatial art Season promoted the idea of tiny-regeneration, which combined the top-down and bottom-up mode of planning and involved governments, developers, planners and residents. It's an attempt to move up from public space construction toward building communities.

5 CONCLUSION

The production of space is one of the most important driver of urban regeneration, with it improving the quality of traditional urban space, enlarging the quantity of public space and promoting residential condition. But it's unavoidable that the super block created by the process of urban regeneration made the "community" too large for residents to feel and decreased the richness of public life to some degree. Taking Zhongyuan two-bends community as an example, the design methods it used did create the high quality public space, but it does not equal to high quality public life for it missing the social aspects.

When the designer or the developer focus on the comfortableness and beauty of the space, it's worth to take the people in public space into account. On the one hand, it's not enough to just focus on the

community itself, ignoring the urban fabric around. Small-block mode maybe improve the situation that the community itself is always separated from the city. It will help the community sharing the public service with the whole city, and strengthen communication among the people at the same time. What's more, from the perspective of urban planning system, adding directive criterions and leading design principles at the stage of regulatory plan will be helpful. On the other hand, the self-organization of the community is also important. Favourable operation organization will improve the public participation of community making and the richness of public life it self. Once the residents are the maker of the public space instead of passive participants, the public space will own the most powerful endogenous dynamic.

l.m.decarvalhofilho@tudelft.nl

1 INTRODUCTION

Brazilian cities have experienced several cycles of transformation, which ultimately altered these places from colonial fabric to modern agglomerations and metropolitan regions. Population figures are still rising and the urbanisation ratio as well. There is nothing particular about those processes; it is a general trend observed in most countries of the world. What typifies the Brazilian case is that the country has an enormous income disparity that results in different ways to deal with urbanisation and expanding cities network. Perhaps the most striking feature of the major Brazilian cities, in general, is the social and spatial segregation and its impact on street life.

This paper is based on research developed for a master thesis (Carvalho Filho, 2014) in 2014 , that currently is further explored in a PhD study. The research aims to explain the effect of the relation between private and public spaces on urban dynamics. In particular, it will assess to what extent the spatial configuration of this boundary contributes to street life and urban vitality. This study addresses the current set of formal and informal planning institutions to discuss the way plots, buildings and blocks incrementally shape urban spaces and on the other hand how space impacts on human behaviour. So far, the case studies will be in Brazilian cities.

The historical context in the use of public spaces of Brazilian cities and the ongoing debate about the extent of street life and urban dynamics currently observed are inherited characteristics of a colonial past (Leitão, 2009), add specific questions to the discussion about public spaces and public domain. Is it a process that goes beyond the reach of urbanism?

The first differential proposed here is that the research brings to light the processes behind the definition of city spaces, especially the border between public and private domains. The study follows a dual approach, integrating formal and informal institutions related to the development of the city. In that aspect, the study observes the relevance and reach of proper planning regulations and at the same time the role of the informal arrangements and non-regulated procedures that respond to the construction of large extent of Brazilian cities. Formality and informality in this research are considered as particular forms of practice and not necessarily types of territorial formation. There is a “need for further exploration of the ways in which different regimes of informal and formal practices take shape and impact on urbanism” (McFarlane, 2012).

Therefore the study sums to the debate about the role and reach of planning in the context of developing countries, namely Brazil, where economic growth and expansion of the cities are, in general, reinforcing existing divides and disrupting the conditions for street life.

‘The growth and development of several Brazilian cities during the past two decades was not just random or disorganised. It produced, predominantly, architectural typologies, spaces and transportation systems that favour a few ways of life over all others. This disurbanism has feedback loops that create physical structures that hinder other ways of life while resulting in cumulative advantages for the favoured ways, a spiral that continually produces new disurban trends’ (Figueiredo, 2012).

The research acknowledges both the relevance of urban dynamics as a way to counteract segregation in cities and on the other hand, that the patterns of urban dynamics in cities are not yet fully understood and therefore out of the reach of the planning institutions.

The approach of this research by combining spatial analyses to studies about planning instruments will cover a gap in current investigations that frequently focuses on one aspect only. The context of Brazilian cities and the comparative study of formal and informal settlements will reinforce the original character of this research. The research tools that will be used and developed in this study will provide urban planners and designers with instruments to evaluate and assess plans and existing spaces and to have a more accurate perception of the impact of individual spatial and institutional arrangements.

This article represents the initial stages of the research, and it is divided into two parts. The first section of the article reveals the history of planning instruments in Recife, a city in the Northeast of Brazil that is the first case study in the research, and the spatial parameters commonly regulated in these tools. That is demonstrated through a retrospective of the planning codes of the last decades, analysing and relating planning regulations to specific spatial parameters.

In the second part, a series of examples of implementation strategies used by real estate market in Recife will be examined. Connecting planning tools and the built configuration that results when these parameters are applied. The objective here is to identify elements embodied in these rules and somehow assess their impact on the use of public space. The method used is the analysis of development procedures, looking for elements sound enough to determine the role and reach of urban rules in the enabling of the vitality of city spaces. We expect, by identifying these strategies, not only to reveal the actual scope of urban rules when it comes to forging conditions for urban dynamics but moreover to understand what are the current restraints. The paper concludes with an attempt to point out possible contributions to urban rules in the context of Recife.

2 PLANNING INSTRUMENTS IN RECIFE

The review of the planning tools in Recife in the last decades that will follow intends to identify the mechanisms related to design control, whether it is explicit or not in the laws texts. It is an attempt to determine “the process of state-sanctioned intervention in the means and processes of designing the built environment in order to shape both processes and outcomes in a defined public interest” (Carmona, 2016).

Recife has to some degree experienced pioneer interventions in planning such as the partially implemented plan for the expansion of the city. It was commissioned in 1637 by Nassau during the Dutch domination of the region (1630-1654) and is regarded as one of the first urban propositions based on physical interventions in the Americas (Medina, 1997).

In general, planning in Recife can be organised into three main periods that somehow correspond to three main planning doctrines as pointed by Sarah Feldman when studying the evolution of planning practices in Brazil (Feldman, 2001).

In the period preceding the first two decades of the 20th century, there was a dominant European tradition in the formulation of laws and postures that governed construction in the city. These regulations were mainly focused on hygienist and aesthetics aspects.

The decades of 1920 – 1930 are a period of transition where there was a shift from the European tradition to the adoption of certain postures that referred more to American planning practices, such as zoning plans and parkways for example.

The last period proposed by Feldman, post 30's is the one under the influence of Modernism. The first shift was towards a higher level of flexibility in the planning instruments, greater involvement of architects and planners in the decision process and a following change in the urban fabric by the transformation of the parcels and land use.

2.1 THE PERIOD BEFORE 1920

As stated before, the regulations of that period are mainly addressing hygienist and aesthetics aspects of the construction of the city. That is evident in the importance given to the control of street alignments, in the location of different activities in the city and the regulation of built environment regarding open space.

From that period are the Municipal Law 4 from 1893 and the Law 1051 from 1919. The first one is a Municipal Code of Postures, instrument established in the country by federal law where planning tools were still part of the main body of the city regulations. The language and scope of the legislation from that period do not address specifically those involved in the design and construction of the city. It was a broader instrument to assess how the city should perform in general, addressing many aspects, not only those related to land use or typomorphology.

The second one, law 1051, shows already some degree of specialisation regarding the first, there was an overall conception of the city based on an underlying zoning plan that determined four perimeters in the city, main, urban, suburban and rural. In this first division of the city into zones, there was, as observed by Alves (Alves, 2009) a prejudiced organisation of the city by income and social level by defining what type of construction was permitted in each zone. For example, not allowing in the main centre of the city the building of the kind of dwellings inhabited by low-income population.

Regarding urban form, there was a clear connection and hierarchy between the building form and public space responding to the zoning. The spatial result of this instrument was a radioconcentric configuration where the density of occupation was higher in the centre and incrementally lower towards the limits of the urban area following the indications of the previous law.

The maximum height of the buildings was different in the zones and proportional to the width of the streets, ranging from 2 times the street width in the central zone, 1 ½ and 1 in the urban and suburban zones respectively. The minimum setback from the buildings also varied, from 0 in the centre to 3 to 5 in the successive zones. In the central zone, all constructions should be built observing the general alignment of the streets; there was also a minimum height limit and some artifices to allow taller buildings such as the introduction of arcades along the streets.

2.2 1930 – 1960

In Recife, that period is initially characterised by a revision of the law of 1919 in 1936 that introduces new subzones into the existing zoning plan. Functional subzones are created inside each of the first zones, defining different parameters for buildings according to their function. Another point introduced by this review was the introduction of the figure of coverage or percentage of the plot that could be occupied.

In the last years of this transition period, two new laws or decrees adjusted some of the parameters imposed by the law of 1936, the Decree 27 of 1946 and the Law 2590 of 1953. The first one changed the height limit in the city centre, aligned to the image of the modern city. The 1953 law changed the borders of the urban area, expanding it to the south following the expansion of the city observed along the beach front. It also increased the building coverage in that zone, maximising the construction potential.

In 1961, the law 7247 reviews the development regulation of the city that dated from 1936. This revision represents an expansion of the urban area towards the west and the creation of distinct zones regarding the port, commerce, industry, universities and nature reserves. Segregation of low-income residents of the urban area is still part of the law as it states specific conditions for the location of new developments targeted to that part of society. Those housing complexes could not be located close to public spaces or main streets.

2.3 1980 - 1990'S

The law 14511 from 1983 represents a significant shift in planning regulations in Recife. Such change is represented by the disconnection introduced in this act between public and private spaces in the formulation of the parameters to regulate construction. As pointed by Medina (Medina, 1997) the introduction of accurate and detailed parameters to control the use of plots, in a system of zones, represents the total inversion in the symbolic value of public – private domains, transferring to the individual plot and housing units the central role in the city regulations.

That shift in importance to the housing sector and plot scale is perceived in the zoning as higher allowed densities are now found in the city expansion in the south, no longer at the city centre. The detailed and specific parameters introduced in this law are not only related, like in previous instruments, to different zones but now they are dependent on the building function. That relation between parameters and function promoted an occupation of the city in a generic way; buildings are planned detached from the specific local conditions. Such aspect resulted in a reaction from inhabitants from certain historic districts that led to the establishment of more restrictive parameters, reducing maximum building height, in some of these zones.

In 1996, the law 16176 replaces the previous instruments and promotes a drastic revision in the zoning patterns and the construction parameters. It almost eliminated the relation between parameters and land use, and there is a simplification of the city structure.

The major differences between construction parameters in the zoning are related to coverage, initial setbacks and green ratio. In the areas where construction was expected to be less intense, the green rate reached 50% of the plot, and maximum coverage was of three times the plot area. Repeating a pattern described previously, the regulations in this law had unexpected results that generated a strong public reaction and had to be altered in a set of new rules.

The law 16719 from 2001 addressed the excessive construction density, and verticalization observed in some districts of Recife, mainly following the river. Maximum height for buildings was introduced in this area per a classification of streets. Height was restricted from eight to twenty floors and typically followed the location of the roads, proximity to the river or traditional areas.

2.4 CURRENT PLANNING INSTRUMENTS

In 1988, the Brazilian Constitution established the Plano Diretor as the core tool for development and city planning. Every city with more than 20 thousand inhabitants is obliged since then to have a Plano Diretor and to review it every ten years. After the implementation of the federal law 'Estatuto das Cidades' (2000), this obligation has been extended to cities that are part of metropolitan regions, conurbations and inserted in special zones such as environmental or historical. In the same federal law, it was also stated that Plano Diretor should be participative.

Recife latest planning rules are represented in the Plano Diretor of 2008. This instrument introduces a more detailed zoning system than the existing in the previous tools but remains connected to the urban plot as the core unit for planning. The figures regarding the potential for construction and maximum

densities are reduced overall in the city. However, there is a change in the way the area of development is calculated that minimises the impact of the lower constructive parameters permitted.

In previous regulations when it was stated the allowed maximum building intensity (floor area ratio) it meant that the permitted construction in a plot included both private and common areas. In the current instrument, parameters apply only to private areas. That fact, combined with the increase in the number of mandatory parking units demanded by the law contributes to the creation of massive street plinths, occupying ground floors of buildings mainly to house cars.

Another change regarding this instrument is the regulation of the frontage of buildings; it is stated now that 70% of the front of a plot must be transparent, not allowing anymore the long blind walls that characterise large parts of the city. It is also defined that the requested green area of a plot should also be in the front setback. That represents a change in the visual aspect of the border between private and public spaces, distancing the plinth from the street. However, this law hardly advances in providing the means to have a more active frontage.

2.5 HOW PLANNING INSTRUMENTS SET THE SPATIAL FRAMEWORK FOR URBAN TRANSFORMATION

The planning rules discussed here cover a relatively short time span regarding the history of the city. However, these rules have been responsible for controlling most of the formal urbanised area of the city. These instruments vary in complexity and scope. Still, some conclusions are possible, always trying to relate these plans or laws to their effect on the spatial configuration and restricting the findings to the most important aspects observed.

There can be identified a cycle of policies and legislation that go from a more generalist to a more comprehensive approach. That can be the result of the fact that more detailed and elaborated laws like the one of 1961, that had a very fixed setting of typologies and parameters somehow constrained the action of real estate market. That constraint was reduced in the successive plans by a more general zoning of the city and in a higher dependency on spatial parameters to regulate the construction in the city.

What can be understood primarily from the analysis of law 16176 of 1996 and the instruments that followed it is that these tools are generalising the different spatial features of the city and relying exclusively on parameters that are usually insufficient to deal with the city complexity. Even the more complex zoning plans like the new Plano Diretor of 2008 still lacks some instruments to allow a better negotiation between public and private sector.

In that sense, prior tools like the 1919 law were more efficient as they provided clear elements to the negotiation to mitigate the impact of constructions exceeding the limits stated in the law. Spatial solutions to deal with higher construction levels were embedded in the law; one example was the creation of public arcades to allow taller buildings. It is evident that the contemporary city and its scale of constructions involve much more questions than in the past, but modern instruments hand to private negotiations, and normally monetary compensations, the mitigation of projects with higher use than the parameters established in the law.

That is a clear result of what happened in a given moment when a dissociation was introduced between the instruments that regulate zoning and land use from those that deal with typomorphology. In short, more recent laws have set rules to be applied to the plot, restricting building capacities in an almost detached relation with the territory. Moreover, it is the result of the move from plans that envisioned a spatial configuration for the city, or at least to certain zones, to those that deal with the city based on the control of constructions in almost exclusively in a plot scale.

What has been described so far is that, in general terms, planning in Recife is reactive. The reading of planning instruments presented here shows that, in most cases, the tools could not cope with the pace that market operates and that the time necessary to adjust urban regulations leaves space for problems to persist even after their impact has been realised.

Most of the tools reviewed here deal with the allocation of different densities and functions in the city territory. However, the zoning of land uses was and still is to some degree more focused in the restriction of certain land uses than concerned in providing diversity in the city matrix of land uses.

2.6 PLANNING INSTRUMENTS AND THE DESIGN OF AN INTERFACE

“Urbanites experience their cities in what we call the ‘public realm’. It has a broader meaning than just ‘public space’; it includes façades of buildings and everything that can be seen at eye level” (Karssenber, Laven, Glaser, & Hoof, 2016). In this section, planning instruments will be codified using this notion of the public realm as a framework. The elements that compose this realm will be identified and observed in the different instruments that were employed in Recife in time.

Urban rules are in general associated with a design strategy. It is an attempt to codify concepts and delivery parameters that are sufficiently structured to guide the construction of a desired spatial configuration. “They represent creative acts that solve definite urban problems – and sometimes even create them” (Lehnerer, 2009). In the instruments analysed in the previous section, it was possible to identify the most common parameters used, how they have changed, have been simplified or made more complex, as laws were updated. In the table below, a synthesis of the parameters is presented.

Law	051	7427	14511	16176	16719	17511
year	1919	1961	1983	1996	2001	2008
Minimum setback (front)	null	null	3 to 7 m	3 to 7 m	5 to 7 m	5 to 7 m
Maximum height (total)	Related to street width	Related to street width	Defined per zone	Defined per zone	12 to 25 floors	Defined per zone
Maximum height (plinth)	Not informed	Not informed	6.0 m	7.5 m	7.5 m	7.5 m
Floor area ratio (FAR)	Not informed	Not informed	Not informed	1 to 5	1 to 5	1 to 3
Building coverage ratio (BCR)	Not informed	30 to 50%	30 to 50%	Not informed	Not informed	Not informed
Green coverage	Not informed	Not informed	25 to 50%	25 to 50%	25 to 50%	25 to 50%
Parking demand	Not Informed	Not Informed	01 parking at every 80m ²	01 parking at every 40m ²	01 parking at every 40m ²	01 parking at every 40m ²
Frontage	Commercial use in certain areas	Commercial use in certain areas	Not Informed	Not Informed	Not Informed	70% must be transparent

Table 1 Main spatial parameters identified in the laws. Source Author’s own

The application of the parameters has resulted in a series of different configurations regarding the building interface that is partially represented in Figure 2. As one can see in Table 1, the change in the parameters is apparently subtle in most cases, but the spatial result can be extremely various. It is therefore expected that each of these spatial profiles or different interfaces has a different impact on urban vitality. That reinforces the role of rules in the shaping of the urban setting and corroborates what Bernardo Secchi (Secchi, 2015) says about the role of urbanism and planning devices. “What changes down the history of the city is much more the regulatory sense and role of each device rather than the catalogue of devices, and it is through this regulating action that the city becomes a machine for social integration or exclusion as the case may be” (Boano & Astolfo, 2015).

Figure 1 Examples of the street interface, the ones on the left are frequently found in buildings built until the 1970's. The ones on the right are examples of the application of the current planning instruments. Source Author's own

3 URBAN CODES APPLIED AND STREET LIFE

The action of the construction market in Recife in the last decades has been so intense and at the same time mechanic and repetitive that particular operational modes can be easily identified and explained. The observation that construction market tends to follow few variables regarding building typologies can also be extended to methods used to make developments feasible.

One can see that in Recife, most of the new developments follow certain rules or steps that deal mainly with three aspects: to gain access to land, to achieve economic feasibility and to overcome restrictions or regulations given by the city planning instruments. Here to follow an exercise to confront the processes described in the analysis of planning tools and the role of the construction market. A critique on how Recife has been built that explains how insufficient regulations and aggressive action of construction sector currently undermines street life in Recife.

That critique resounds the process highlighted by Figueiredo (Figueiredo, 2012) as the causes for the denial of city life in Brazil. The author mention five processes that are, according to him, responsible for the destruction of urbanity in Brazilian cities: growing use of cars, lack of quality in public transportation, high walls and gated communities, loss of diversity and adaptability of buildings and segregation of people and ideas.

Here some of these processes will be further explained in the context of Recife, by describing in step by step way, how the construction market works within the gaps of planning instruments. The rules exposed here represent a critique of the modus operandi present in most of the recent production of new developments in Recife. The focus is to show how parcels and buildings are steadily transformed, what are the impacts for street life and moreover how planning instruments deal with that.

3.1 RULE 01 - UPSCALE PLOTS

Figure 2 - Upscale plots. Source Author's own

How does it work?

Recife's urban fabric is still mainly composed of small plots and built with detached houses. In the last decades, there has been sharp growth in the replacement of single homes by larger buildings. The rule here is straightforward; small plots are merged to allow the construction of taller buildings. Previously, construction companies would buy small plots and implement their development. Recently a more sophisticated method replaced this mere financial operation.

Currently what happens is that house owners are invited to be part of new developments instead of getting only money for their properties. What makes this change so appealing to homeowners, is the fact that they can receive from 15 to 50% of the number of dwellings of the new development, depending on the district where the house is located. Suddenly owners of a single house can have 5, 10, 15 apartments.

How does it affect street life?

One might expect that higher density in construction and population would be beneficial for lively streets; however, that is not the case in Recife. The result for urban dynamics is evident in the way it occurs here, upscaling properties contributes to reducing the interaction at ground level, as one gate replaces several front doors, and generally, no public function is provided at the base of these new buildings.

What is at stake here is the loss regarding adaptability and in the potential for street life that resides in a more fine-grained urban fabric (Jacobs, 1961). It is not that small plots built with houses has already a diversity of functions, but they are far more adaptable than a single building where the plinth is usually occupied with parking space.

How do planning instruments deal with that?

Planning instruments frequently, with very few exceptions in specific zones related to nature reserves or historic areas, do not pose any restriction to the merging of smaller plots. In fact merging and upscaling of plots is indirectly stimulated by regulations that make difficult to build on smaller plots. In the construction regulations, initial setbacks and demands for parking are rather constant regardless the dimensions of the plot, what restricts new developments in small parcels.

3.2 RULE 02 - SPEED UP OBSOLESCENCE

Figure 3 – Speed up obsolescence. Source Author's own

How does it work?

The previous rule is easily implemented, but what happens when it comes to medium size plots and buildings with multiple owners? And what if some of these owners are not seduced by the possibility of multiplying their assets? The procedure in these cases is more elaborated; it sometimes consists of buying units in buildings without necessarily revealing the intentions of replacing them with new developments. Gradually construction companies will gain control of the properties and start the replacement. The process is long and involves persuasion strategies that are at the limits of legality. Typically it is forged a process of fast decay in the buildings by the negligence of construction companies in the maintenance of their units, forcing the remaining owners to sell their properties finally or join the proposed development.

A more subtle but extremely efficient version of this rule is to force obsolescence by defining a model (Amorim & Loureiro, 2003) or standard for living that does not fit in constructions of a given period. Marketing of new developments and their standards of living are so well designed that fully functional buildings will lose their value in the market for failing to provide the same number of leisure activities present in the new developments for example.

How does it affect street life?

Again it is a question of replacing smaller units by individual developments, what frequently reduces the possibilities of interaction and mixed use at street level. The impacts of higher population densities are minimised by the loss of diversity in building age and construction types.

Several of these existing medium size buildings house different functions on the ground floor what is not observed in the developments that replace them.

How do planning instruments deal with that?

In a market economy, hardly anything can be done to prevent construction companies from buying units in buildings. What has been done in the last laws was to classify particular medium size buildings, that were not protected as heritage or national monument, with a certain degree of protection. It was an attempt to avoid their replacement by new constructions. But this instrument is limited as the number of buildings that can justify some level of protection is reduced when compared to the number of buildings aimed at by the construction market.

3.3 RULE 03 – HIDE THE IMPACT

Figure 4 – Hide the impact. Source Author's own

How does it work?

In the law 16.176 from 1996, it was established that any new construction starting from a particular built surface or plot size (20,000m² of construction and 3ha of plot area) should be considered as an 'impact development'. That classification demands, that to have a building permit, projects should be analysed in a broader way, assessing their impacts on traffic, environment and in the immediate neighbourhood.

That involves consultation to the local population and several studies resulting in extra time and cost before having clearance to start development; it also means typically that the developer should cover the

cost of the mitigation of these impacts. To avoid that, what happens, in most of these cases, is that a project that would be classified as impact is fragmented in smaller projects. After the completion of the construction, the limits between each project are erased, and the development assumes its initial characteristics of a single unit.

How does it affect street life?

Constructions that result from this rule are inserted in large plots that are not so permeable and constitute barriers in the city. This characteristic of being a barrier will remain even if the project has been fragmented into smaller plots.

They are also commonly represented by vast complexes of residential buildings provided with extensive leisure facilities; therefore, even if they will contain scores of people, the contribution to life in the streets will be very limited. In general terms, the impact of this rule is more related to loss of potential for street life then replacing an existing situation where there was a higher level of activities.

How do planning instruments deal with that?

Although it can be evident to those at public institutions involved in the analysis and approval of new developments that a series of projects in adjacent plots are in fact a single project, there are several limitations in the laws to prevent it to go further. Most of the planning parameters are based on the plot; there is hardly any instrument that relates construction parameters to the scale of the block or district.

3.4 RULE 04 – SAFEGUARD POTENTIAL

Figure 5 Safeguard potential. Source Author's own

How does it work?

It is determined in Brazil, by federal law, that local planning instruments should be reviewed periodically, every ten years for zoning for example. That fact frequently raises expectations that in these review processes new construction parameters will be more restrictive than the current ones. To deal with that, projects are approved and licensed even if there is not an intention to implement them soon. Construction sector builds in this way a stock of projects with more favourable parameters and can decide when to start development without the restraints of the current planning instruments.

According to the laws of Recife, once a project is approved, construction should begin in no more than two years, what has not been stated in these rules is how long a development should take to be completed. That rule is basically to safeguard more favourable construction parameters by approving projects before changes in the instruments and sometimes by realising just the foundations of the buildings.

How does it affect street life?

The impact of this rule has two sides, in one hand, plots will be left unoccupied for some time, depriving parts of the district or neighbourhood of life. On the other hand, there is the adverse effect on planning instruments, once this rule allows constructions with former legal parameters to be built in a time where they should no longer be permitted. The role and efficacy of planning instruments are questioned by this example, as the city image addressed in these tools is not necessarily accurate.

How do planning instruments deal with that?

This rule is the classic example of the opportunity given to the action of construction market by the limitations and inaccuracy of the planning tools in Recife. In a recent review of planning instruments, it was determined a period that precedes changes in regulations, where no new project could be approved, but this strategy only pushed back the deadlines for the production of new projects.

3.5 RULE 05 – INFLATE PRIVATE DOMAIN

Figure 6 – Inflate private domain Source Author's own

How does it work?

That is a general rule or procedure of the market that is mostly used regardless of the scale of constructions. It consists in bringing to the private domain the larger possible number of functions that are typically related to public spaces. This type of action takes advantage of particular characteristics of the society in Recife like the fear of violence, the search for personal status coming from exclusiveness (Amorim & Loureiro, 2005) and car dependency culture.

Buyers seem to be willing to pay more or to have their private areas reduced as long as they can count on the full program of leisure that their neighbours have. The question is much more related to the number of entertainment items one can have in their boundaries than the actual quality of spaces.

How does it affect street life?

The question for street life, in this case, is that this type of approach, bringing the focus to the private domain, reinforces the secondary character of public spaces in Recife and indirectly undermines their use. Currently, this phenomenon that is prevalent in high-income buildings has been reproduced, with the necessary adjustments on the scale, in developments targeted to medium class and even low-income buyers.

How do planning instruments deal with that?

Planning instruments in Recife do not regulate, at a higher level of detail, the uses one can house inside their buildings. As explained before, most of the instruments are designed to control certain parameters such as building intensity or green ratio, but they do not address the distribution of functions on the block or plot level.

4 CONCLUSION

During this initial process of study, especially when comparing the action from construction market with the mechanisms to steer the evolution of the city provided by planning instruments, the limitations of the planning codes to provide conditions, where street life can thrive, was reinforced.

To what extent planning tools can deal with the issues discussed here? Moreover, are planning tools relevant to the current development of the city that so far can be described as a city designed by the market?

From what has been observed here, the development of the city do not occur completely outside the domain of planning instruments, what happens, in fact, is that the city is built using the gaps in the instruments. These shortcomings are mainly the result of the detachment observed in the planning codes between the instruments that regulate zoning and land use from those that deal with typomorphology. As stated before, it is the result of the move from plans that envisioned a spatial configuration of the city, or, at least, to certain zones, to those that deal with the town based on the control of constructions almost exclusively in the plot scale.

The conclusion is that planning instruments are still relevant, although they may not be sufficiently elaborated to deal with the dimensions of street life. Moreover, planning tools are not able to deal with the formal - informal institutional action of the agents involved in the city development. In the next phases of this research, the connections between rules and street life will be further investigated to identify and locate spatial patterns and asses the levels of urban dynamics in this fragments.

1 INTRODUCTION

Emotional connections of people with their environment have been investigated in various disciplines and certain crucial constructs have come out such as place attachment and place satisfaction obtaining attention in environmental psychology. Place attachment was defined as an essential element of personal identity and it was associated with certain constructs which can be analysed in both personal and community context (Anton & Lawrence, 2014; Brown & Raymond, 2007; Jorgensen & Stedman, 2001; Proshansky, Fabian, & Kaminoff, 1983). Place satisfaction was defined as “multidimensional summary judgement of the perceived quality of a setting” which means it is a concept generated by assessing physical and social attributes of an environment in terms of fulfilling a person’s needs (Stedman, 2002, p. 564).

There have been multiple attempts to define place (Altman & Low, 1992; Easthope, 2004; Soja, 1998; Tuan, 1979). Place embraces the physical space through experiences and perspectives of the people (Relph, 1976; Sack, 1997; Stedman, 2003; Tuan, 1977). Spaces transform into places by use of meanings which are given to a setting (Tuan, 1977). Furthermore, Altman and Low (1992) define place as “the environmental setting to which people are emotionally and culturally attached” (p. 5). The construct of place indicates a space which is given meaning by way of individual, group or cultural approaches (Altman & Low, 1992). Moreover, Jorgensen & Stedman (2001) also proposed a framework of sense of place containing three constructs which are place attachment, place dependence and place identity.

Altman and Low (1992) define place attachment as “symbolic bonding which gives a sense to places culturally and emotionally” necessitates symbolic and affective connections with a number of environments (p. 6). It is also defined as an emotional tie between people and certain places (Brown & Raymond, 2007; Hidalgo & Hernández, 2001). Apart from these, Scannell & Gifford (2010) present a conceptual framework including three components to provide a definition of place attachment. This framework defines place attachment by analysing it in three dimensions which are person, process and place.

Place identity is defined as the cognitive significance of a place in terms of conserving experiences, emotions and relationships of people which gives a sense and purpose to life (Williams & Vaske, 2003). It is also defined as an element of self-identity which improves self-esteem and evokes a sense of belonging to a community (Williams & Vaske, 2003). The places which make people feel special, self-controlled and steady tend to be identified with the concept of identity (Anton & Lawrence, 2014). Proshansky et al. (1983) also claims that place identity is a cognitive base of self-identity including various cognitions associated with past, present and physical environments which describes the presence of individuals.

Place dependence originates from functional evaluation of a place in terms of satisfying a person’s needs by allowing them to reach their goals (Shumaker & Taylor, 1983). Place dependence is associated with the physical opportunities and characteristics of the place and it presents required conditions in order to fulfil and promote certain purposes (Mandal, 2016). It refers to how settings offer certain opportunities in terms of accomplishing the aims of individuals (Jorgensen & Stedman, 2001). Additionally, rootedness is another element which is defined as mental situation of being, a mood or a feeling in a certain place (Tuan, 1980). It can be stated that place rootedness is associated with certain feelings and behaviours which improve attachment to specific places. The concept of rootedness brings along increased satisfaction with a person’s present conditions where he or she lives in (McAndrew, 1998).

Place attachment can be investigated in environments of various scales such as homes, neighbourhoods and cities. The scale of place takes a considerable role in terms of influencing affective ties of individuals with their environments and the way they perceive (Casakin, Hernández, & Ruiz, 2015; Hidalgo & Hernández, 2001; Lewicka, 2010). Neighbourhood is one of the places affecting emotional bonds by creating sense of attachment especially in social context. Shumaker & Taylor (1983) define neighbourhood

attachment as “positive affective bond or association between individuals and their residential environment” (p. 233). It is a socio-psychological process creating individuals’ emotional bonding to their social and physical environment (Comstock et al., 2010) . In other words, neighbourhood attachment demonstrates a feeling of pleasure with the residential environment. In addition, the construct of satisfaction depends on physical and social features of environments which meet needs of individuals (Galster, 1987). Attitudes, meanings and knowledge related with cognitive evaluation of an environment take a considerable role in terms of determining place satisfaction (Stedman, 2002). Mesch & Manor (1998) define place satisfaction as an assessment of physical and social characteristics of a place. Place satisfaction in neighbourhood is related to residents’ evaluation of their neighbourhood environment (Hur, Nasar, & Chun, 2010). The factors affecting neighbourhood satisfaction can be analysed in three sections which are individual, social and environmental (Ibem & Aduwo, 2013). Individual factors are associated with personal or family attributes such as age, gender, income level and family size (Fornara, Bonaiuto, & Bonnes, 2010; Hay, 1998; Zhang & Lu, 2016). Moreover, social atmosphere of a neighbourhood is stated as determining. Social environment is perceived to be significant in terms of creating sense of place and place attachment. Social relations with neighbours, sense of community and sense of privacy, safety and local involvement can be presented as leading elements in order to provide satisfaction for residents in social way (Fornara et al., 2010; Sirgy & Cornwell, 2002; Zhang & Lu, 2016). The elements related with built environment are also considered to have an impact on neighbourhood satisfaction. Green open spaces, recreational areas, architectural style, building quality and size can be given as effective components (Sirgy & Cornwell, 2002; Zhang & Lu, 2016).

The current study aimed to investigate how neighbourhood location affects place attachment and residential satisfaction. We hypothesised that the residents living in the areas away from the city centre have higher level of place attachment compared to those living in city centre. It was explored by comparing two neighbourhoods; one in the city centre, the other away from the city centre. Moreover we expected that the residents living in the areas in city centre have higher level of residential satisfaction compared to those living away from the city centre. The relationship between neighbourhood location and residential satisfaction was analysed by assessing physical and social aspects of the neighbourhood which influence neighbourhood satisfaction. Apart from these, we examined if there is an association between residential satisfaction and place attachment or not as it was stated in the literature.

2 METHOD

2.1 RESPONDENTS

The respondents of this study were 135 residents from Ayrancı and Çayyolu neighbourhoods in Ankara. The sample group included 75 female and 60 male respondents aged between 19 to 85 years. Mean age was 47. Sixty-one respondents from Ayrancı and 74 respondents from Çayyolu took part in this study.

2.2 SETTING

The study was carried out in Ayrancı and Çayyolu which are two different neighbourhoods under the jurisdiction of Çankaya Municipality of Ankara. Ayrancı located in the centre of the city, surrounded by Dikmen to the south and Kavaklıdere to the northeast. Moreover, Turkish Grand National Assembly is located at the northern part of Ayrancı. This neighbourhood is divided as Aşağı Ayrancı and Yukarı Ayrancı. The socio-economic status of this neighbourhood is between upper middle and lower high classes; age distribution of the residents generally is between 30-34 years and 65 years above (“Ayrancı Bölge Raporu” (Ayrancı Region Report), 2017).

Çayyolu is in the southwest part of the Ankara. It located 17 kilometres distant from the city centre. It was settled down as a village then it was transformed to neighbourhood after 2004. The socio-economic status of Çayyolu is above upper middle class and age distribution of the residents generally is between 30-34 years and 50-54 years (“Çayyolu Bölge Raporu” (Çayyolu Region Report), 2017).

2.3 INSTRUMENTS

This study was assessed with two questionnaires which are Place Attachment Scale (Lewicka, 2010) and Perceived Residential Environment Quality and Neighbourhood Attachment Scale (Fornara et al., 2010). These scales distributed in Ayrancı and Çayyolu included 85 questions which were 7-point Likert scale (1=strongly disagree, 7=strongly agree). The first part of the questionnaire included questions related with respondents' demographic information such as age and gender, education level, length of residence and their neighbourhood. Place Attachment Scale (Lewicka, 2010) consisted of 12 items related with place identity and place bonding/rootedness. Perceived Residential Environment Quality and Neighbourhood Attachment Scale (Fornara et al., 2010) asked 66 statements related with physical and social features of the neighbourhood.

2.4 PROCEDURE

Two different neighbourhoods of Ankara; one in the city centre, the other away from the city centre were compared. Primarily, questionnaires were distributed to obtain data by using snowball sampling method. Respondents answered the questionnaires in their homes or workplaces. Then they were collected and analysed to reveal the influence of neighbourhood location on level of place attachment and residential satisfaction. Primarily, factor analysis was conducted for two scales to investigate which elements are the most effective on place attachment and residential satisfaction. Then, multivariate analysis of variance (MANOVA) was used to explore differences between locations and socio-demographic features such as gender on the level of place attachment and residential satisfaction. Apart from these, correlations were carried out to examine the relationship between the factors shaping place attachment and residential satisfaction. The statistical analyses were conducted by using Statistical Package for the Social Sciences (SPSS 21.0).

3 FINDINGS

Factor analysis on place attachment revealed the factors by investigating the most influential components on the level of attachment. It generated two factors and they were named as place identity and place bonding/rootedness. The first factor place identity emerged with an eigenvalue of 5.01 which accounted for 41,721% of the variance; the second factor place bonding/rootedness with an eigenvalue of 1.24 and 10,316% of the variance. The first factor consisted of three items about cognitive significance of a place associated with the construct of place identity. The internal consistency of this factor was 0,823. The second factor included five items which measure dependence of respondents by marking their positive and negative feelings about the place (see Table 1). The internal consistency for this factor was 0,813.

Statements	Factor 1	Factor 2
	Place Identity	Place Bonding/Rootedness
I am proud of this place.	0,885	
It is a part of me.	0,826	
I feel secure here.	0,694	
I know this place very well.		0,762
I don't like this place.		0,752
I miss it when I am not here.		0,721
I defend it when somebody criticizes it.		0,706
I leave this place with pleasure.		0,582

Table 1 - Items of Place Identity and Place Bonding/Rootedness and its loadings

For residential satisfaction fourteen factors were determined in first stage. In order to decrease the load generated by many components second analysis was performed and four factors were created by ranking in high order. The first factor was created with an eigenvalue of 3.73 which accounted for 26,670% of the variance, the second with an eigenvalue of 2.17 and 15,498%, the third with an eigenvalue of 1.3 and 9,523%, the fourth with an eigenvalue of 1 and 7,173% of the variance.

Items forming the Factor 1 were related with general evaluation of a neighbourhood in terms of external connection and transportation, educational services, neighbourhood attachment, upkeep and sociability (see Table 2). The internal consistency for this factor was found to be 0,818. Questions related with

external connection and transportation asked about the connection of neighbourhood with other parts of the city, frequency and quality of public transportation. Questions about educational services analysed the schools in terms of quality, availability and access. Neighbourhood attachment was examined by measuring place identity, bonding and dependence to neighbourhood. Questions measuring upkeep asked about maintenance of neighbourhood in terms of streets, roads and signs. Sociability was understood by questions asking about how easy to make friendship and social relations with others.

Elements creating Factor 2 consisted of five themes which are parks and green areas, social care, commercial services, social life and activities, parking and accessibility (see Table 2). The alpha level for this factor was 0,754. Relaxation spaces such as parks and green areas in neighbourhood were the first component creating Factor 2. Social care services such as health opportunities, nursing services and care for elders were also significant. Commercial services of neighbourhood were evaluated by diversity and arrangements of shops and stores. Social atmosphere of neighbourhood, relaxation and entertainment activities offered for residents were influential on Factor 2. Availability of parking areas for cars and comfort in accessibility was found significant in terms of satisfying residents' needs.

The third factor represented environmental health and aesthetics in neighbourhood (see Table 2). General environmental condition of neighbourhood was analysed in terms of environmental cleanliness, air purity and noise level. Moreover, appearance of buildings was evaluated by looking their colour and design. The internal consistency for this factor was 0,772. Apart from these, building volume defined the fourth factor in itself. Dimensions and volumes of buildings were found as effective in creating this factor. The alpha level for this factor was 0,815.

Statements	Factor 1	Factor 2	Factor 3	Factor 4
	General evaluation	Relaxation/care services and accessibility	Environmental health and aesthetics	Building volume
External connection and transportation	0,719			
Educational services	0,638			
Neighbourhood attachment	0,635			
Upkeep	0,607			
Sociability	0,603			
Parks and green areas		0,699		
Social care		0,690		
Commercial services		0,674		
Social life and activities		0,672		
Parking and accessibility		0,576		
Environmental health			0,826	
Building aesthetics			0,629	
Building volume				0,856

Table 2 - Items of Factor 1, Factor 2, Factor 3, Factor 4 and its loadings

One way multivariate analysis of variance (MANOVA) test was applied if there is a difference in the level of place attachment in Ayrancı and Çayyolu or not. Results indicated that there is no significant difference in terms of neighbourhood location between the residents' level of place attachment. ($\lambda=0,997$; $F(2, 132) = 1.539$, $p>.05$).

For residential satisfaction, one way multivariate analysis of variance (MANOVA) showed that there is a significant difference between two neighbourhoods in terms of level of residential satisfaction. The residents living in the city centre had higher level of residential satisfaction compared to those living away from the city centre. ($\lambda=0,449$; $F(4, 130) = 39.842$, $p<.001$).

Moreover, according to correlation results there is an association between place attachment and residential satisfaction (see Table 3). It showed that there is a statistically significant correlation between the all factors influencing residential satisfaction and place bonding/rootedness. (Pearson's r : 0,539, Sig. (2-tailed): 0,000), (Pearson's r : 0,228, Sig. (2-tailed): 0,008), (Pearson's r : 0,332, Sig. (2-tailed): 0,000), (Pearson's r : -0,255, Sig. (2-tailed): 0,003). Furthermore place identity was statistically significant correlated with general evaluation of neighbourhood, environmental health and aesthetics. (Pearson's r : 0,544, Sig. (2-tailed): 0,000), (Pearson's r : 0,381, Sig. (2-tailed): 0,000).

		Place Bonding/ Rootedness	Place identity	General evaluation	Relaxation/ care services and accessibility	E. health and aesthetics	Building volume

Table 3 - Correlations between place attachment and residential satisfaction

4 DISCUSSION AND CONCLUSION

In the current study, we examined the relationship between level of place attachment and residential satisfaction according to neighbourhood location. We hypothesised that there is a difference in the level of place attachment of two neighbourhoods; the residents living in the areas away from the city centre have higher level of place attachment compared to those living in city centre. However the results of analysis demonstrated that there was no significant difference in the level of place attachment in terms of neighbourhood location. Feldman (1990) conducted a survey in two different areas of city and found that the residents identified themselves with a type of settlement. Her other study also indicated that small part of the sample group did not feel attachment to any settlement type; the experiences, values and manners were significant in terms of creating attachment (Feldman, 1996). In this study living in the city centre or living from away the city centre was not found as influential on level of place attachment. It can be inferred that emotional ties, past experiences, memories and personal ideas are influential on creating attachment to places.

Contrary to place attachment, there was a significant difference in the level of residential satisfaction of the respondents in two neighbourhoods. As it was expected the residents living in the areas in city centre have higher level of satisfaction compared to those living away from the city centre. In line with previous studies the elements related with built environment such as building aesthetics, upkeep, external connection and transportation were effective on neighbourhood satisfaction (Sirgy & Cornwell, 2002; Zhang & Lu, 2016). Former studies also found that parks, green areas and social activities were also other significant factors on residents' in terms of satisfying their needs (Bonaiuto, Fornara, Aricchio, Ganucci, & Rahimi, 2015; Fornara et al., 2010; Sirgy & Cornwell, 2002). Apart from these, Bonaiuto et al. (2015), Hur and Morrow-Jones (2008), Hidalgo and Hernández (2001) stated that there is a significant relationship between place attachment and place satisfaction. Pearson's correlation results indicated that there was an association between place attachment and residential satisfaction as it was expressed in literature. Place bonding/rootedness factor creating place attachment was statistically significant correlated with the all factors influencing residential satisfaction. Place identity factor was also statistically significant correlated with general evaluation of neighbourhood, environmental health and aesthetics. In accordance with previous research satisfaction in physical and social opportunities of environment were found significant in influencing affective bonds of individuals in terms of creating sense of attachment (Fornara et al., 2010; McAndrew, 1998; Shumaker & Taylor, 1983; Stedman, 2002).

In this study housing type was not taken into consideration in terms of determining its influence on place attachment and residential satisfaction. However level of place attachment and residential satisfaction can be related to type of housing. There may be a difference between living in apartments and living in detached houses. For future studies influence of housing type can also be investigated. Apart from this, socio-economic status can make difference for level of place attachment and residential satisfaction. This study was conducted with the residents having similar income levels. Future research can examine if socio-economic status of residents affect level of place attachment and residential satisfaction or not.

ID 1497 | SHAPING PROCESS AND IMPACT MECHANISM OF THE THIRD SPACE UNDER BLOCK RENEWAL: AN CASE BASED ON KNOWLEDGE & INNOVATION COMMUNITY RENEWAL PROJECT

Bowen Chen¹
¹Tongji University
1967114471@qq.com

1 INTRODUCTION

In the rapid process of urbanization and modernization in China, many cities have made great changes in function, structure, space capacity, infrastructure and other aspects. (Tong Ming, 2014). However, as a public space for daily life, alienation has not brought into full play its social value. For example, privatization is serious, attractive and dynamic, loose in relation to the region. Compared with those of traditional city life is full of modern city, the trial in a rational level, but the life experience and cultural characteristics, is almost completely failure (Camino Sitte, 1990). As China's economic development has

entered the new normal, some cities have gradually expanded from denotative expansion to connotative upgrading, and entered the stage of urban renewal. But the social significance of public space has not been returned (Liu Jiayan, 2010). Urban renewal should be the unification of four dimensions, namely, the promotion of regional functions, the inclusion of vulnerable groups, the protection of historical threads, and the construction of site features (Tang Zilai, 2016). In the actual game of multiple interests, it often becomes a tool for market profit seeking. Many of the public and the diversity of the old neighborhood and Historic District, a closed area aristocratic commercial space or standardized in the renovation of the developers, single function, social exclusion, context and the lack of characteristic, exacerbated by the modern city life is dull and boring. At the same time, along with the development of industrial city some period after entering, become the new city of creative city development concept (Tong Ming, 2010). The relationship between innovation activities and urban space has attracted more and more attention. It is an important challenge for urban planning and urban design to create a new space to stimulate urban innovation in the new round of block renewal.

In 1982, American sociologist Ray Oldenburg put forward the concept of "third space" for the first time. He believes that the third space is informal public places except the family and work, is a kind of mixed function, enhance the vitality of the city to promote the spatial form of social interaction (Oldenburg R, Brissett D, 1982). Compared with the traditional public space, the third space emphasizes sociality (Oldenburg, R, 1989), which is beneficial to stimulate group activities and social interaction, and then to promote knowledge spillover and innovation. However, the related research has just started. Most scholars have made a qualitative description based on sociological perspective, and paid no attention to the spatial attributes (Feng Jing, Zhen Feng, Jing Wong, 2015). Specific empirical research, there is still room for further improvement.

Shanghai has taken the lead in the development of stock planning and even reduction planning, and the restoration and reconstruction of public space is the core issue. A new round of "Shanghai 2040 master plan" clearly puts forward the development goal of "more dynamic and innovative city". Creative activities and creative classes are calling the city's third space (Wang Lan, Wu Zhiqiang, Qiu Song, 2016). In this context, it is of great practical significance to rethink the material characteristics and social significance of public space in urban renewal. (1) is the process of shaping the third space happening in the neighborhood renewal around us? (2) what is the mechanism of influence on regional development and revitalization? In order to answer these questions, this paper uses and improves the theoretical framework of the third space. Then to Shanghai Yangpu District University City Central Community - KIC as a typical case. Combined with field research and interviews, this paper provides a theoretical and empirical basis for the third space research in block renewal.

2 FRAMEWORK OF THE THIRD SPACES

In 1970s, the traditional public spaces such as parks and parks in the western developed countries were declining day by day. Many shopping centers have become a new place for public life. This kind of consumerism and the public space produced by experience economy have some characteristics of privatization. In this context, Ray Oldenburg proposed the "third space". He called home and living space "the first space", the place where a lot of time worked was called "second space", while "third space" was an informal public place outside the place of residence and work place. Such as streets, community centers, beer gardens, cafes and so on.

2.1 ACCESSIBILITY OF THE THIRD SPACE

Third space is a public space with high accessibility, which is convenient for people to walk easily and become a regular guest in this public space (Li Qing, 2014). Accessibility has both spatial dimension and social dimension. The accessibility of physical space is directly related to the accessibility of people on foot. Through the integration of material space, the network of communication between people can be constructed (Tong Ming, 2014). Among them, the material space access needs to be realized by the road system, including cohesion,

cohesion and trunk area fast traffic and slow traffic convergence, bus station and walk line connection, subway and Commercial Street, and so on.

2.2 COMFORTABILITY OF THE THIRD SPACE

Third space gives comfort and ease of space, feelings and atmosphere. It encourages people to take the initiative to enter, and to produce social interaction, exchange of information and knowledge spillovers in a good spatial mood (Feng Jing, Zhen Feng, Jing Wong, 2015). Comfort has spatial dimension and social dimension. Whether the spatial scale is suitable or not is directly related to the personal experience of the people. Through the construction of spatial scale, it can affect people's behavior and psychology in the environment. Among them, the suitable spatial scale includes the walking distance, the friendly Street section and the traditional small block model.

Figure 1 - Framework of the third place

2.3 FUNCTION OF THE THIRD SPACE

Third space has a variety of functions, including mixed use of land and multifunctional buildings (Zhou Jian, 2015). These functions are not simply superposed, but interrelated and complementary. They meet the needs of people's daily activities and trigger a chain reaction in social activities". Therefore, the function has the same spatial dimension and social dimension, and whether the function is mixed is directly related to whether people's daily activities are rich or interesting. By linking different activities with different functions, the crowd produces a hybrid, dynamic, functional, sometimes changing public space (Tong Ming, 2014). As Jan Gehl describes it, some chain of activities mostly by the other two kinds of activities extend to people in the same space, "or are close by, or just now at a glance..... "People wander about in the same space and they start social activities" (Gehl, Jan, 2002).

2.4 SOCIALITY OF THE THIRD SPACE

Third space is more social than any traditional public space (Li Qing, 2011). It regards public space as the stage for people to realize their social communication needs. Just as the theory of "city man" (Liang Henian, 2012), rational city people pursue the opportunity of space contact so as to create freedom, choice and communication. Sociability also has spatial dimensions and social dimensions. Whether the communication space is recurring is directly related to whether people's social intercourse is aggregated or not. Through the reasonable spatial organization way, can realize the perfect construction of the city social network (Tong Ming, 2014). This means that in the overall level of city function and public space will continue to reproduce in the local level, creating space contacts at different levels and scales for the people, the formation of large and small, each linkage social stage. This kind of self similarity plays an important stabilizing role in organizing people's social activities.

3 OVERVIEW OF KIC BLOCK RENEWAL

3.1 SPATIAL LOCATION

KIC renewal project started in 2002, is located in Shanghai city of Yangpu District Wujiaochang City sub center, but also a key position in the University City of Yangpu District. Yangpu District was the Shanghai traditional industrial base in the early new century is put forward from the "University City" to "Knowledge Innovation Zone" strategy (Chen Bingzhao, Yang Fan, Wu Zhiqiang, 2005; van Junyong, Yang Fan, 2008), the use of university resources outstanding, actively carry out the adjustment of industrial structure and layout, implementation campus, community park, the "Three Zone interaction" (Zhang Shangwu, Chen Ye, Song Wei, et al, 2016). KIC is a demonstration project update the block. Its goal is to integrate the three district resources and create a knowledge innovation community which integrates learning, working and living together.

3.2 RENEWAL PROCESS

Since the KIC project started since the development of city space has been greatly changed. We can divide the update process KIC blocks into 4 stages. That is, the stage of industrial mixed living, the preliminary carding stage of space, the shaping stage of core space and the whole northward promotion stage. Specifically, (1) industrial residential hybrid stage (2000-2005) for industrial, warehousing, residential and a small number of commercial land mixed, interwoven, poor spatial quality. (2) space preliminary carding stage (2005-2008) in accordance with the planning and design of the demolition of most of the plant in Shanghai, on both sides of the road for new commercial office building. (3) the core space shaping stage (2008-2011) removal of the entire plant Songhu Road West of the National Road and to the west direction of new building, University Road, the basic form of the prototype. (4) the overall northward stage (2011-2016) to the University for reference, along the way to promote the construction of Shanghai north, the formation of today's kic.

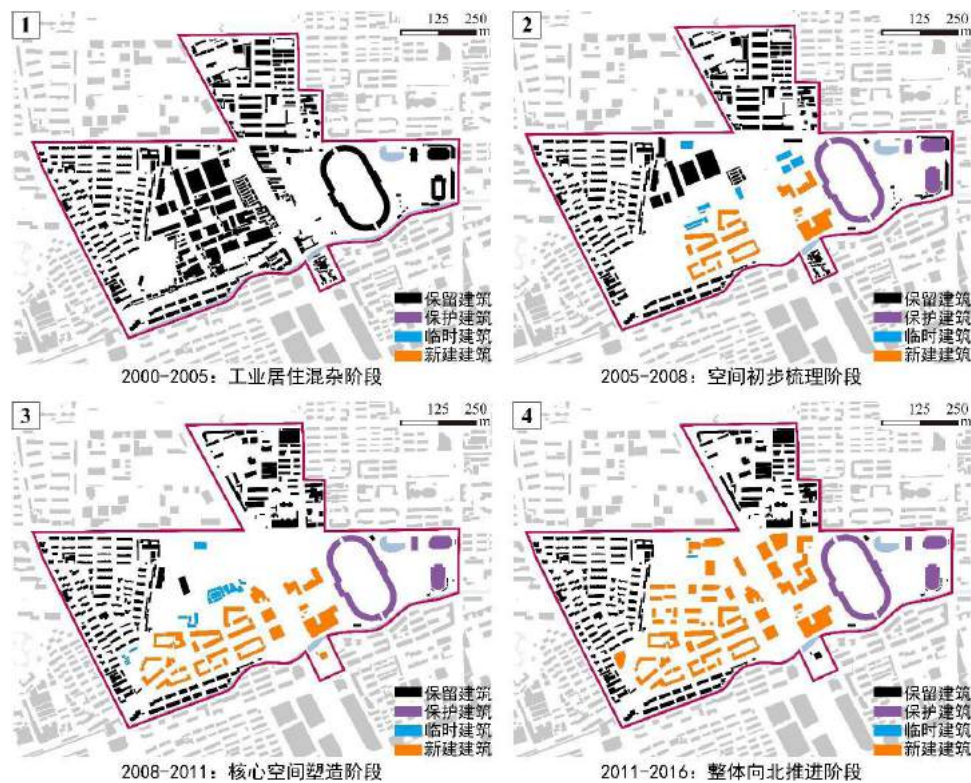

Figure 2 - Four stages of the renewal in KIC

4 SHAPING PROCESS OF THIRD SPACE IN BLOCK RENEWAL

4.1 SHAPING PROCESS OF ACCESSIBILITY

4.1.1 PHYSICAL SPACE: FROM CLOSURE TO FRAGMENTATION AND OPENING TO ACCESS

The accessible physical space can provide a material basis for people's walking and social activities. The connectivity of the road system, the connectivity of the road system and the bus station are selected, and the spatial accessibility changes before and after the block renewal are taken into account. Compared with 2000 and 2017, the overall road connectivity of the blocks did not change significantly. This is due to the formation of the urban primary and secondary trunk roads in the region. More than ten years, only a small number of branches and community roads have been added. By contrast, road connections within the block have changed considerably. In 2000, Shanghai Road West is a large building, only the main channel for the vehicles, cargo transportation, roadway is not continuous, the internal block relatively closed and broken. In 2017, with the Shanghai road to the west of Powerise square, KIC square, Jiangwan Hanlin commercial and residential real estate projects have been completed, and the community branch road density increase.

Figure 3 - Comparison in walking system of KIC between 2000 and 2017

KIC block is embedded in the region, residents not only to serve nearby and workers, and should pay more attention on the road system and bus station connection. From 2000 to 2017, with the overall improvement of public transport services in Shanghai, blocks and their surrounding areas showed a high degree of overlap between the bus station and the walking system.

The connectivity of the road system, the road system and the connectivity of the bus station were updated before and after. The car system has been improved by encrypting urban branches and community roads within blocks. Around the urban road, the construction courtyard, constructs two levels of walking streamline, has formed has the continuity and the hierarchical walking system. Roads and bus stations, especially rail sites, reinforce the overlapping relationship and generate more close spatial linkages with the surrounding areas. Therefore, before and after the KIC district renewal, physical space from the implementation of the transition to open closed fracture.

Figure 4 - Comparison of coincidence of road system and bus station in 2000 and 2017

4.1.2 ARRIVE ON FOOT: FROM NO ONE TO AN ENDLESS STREAM

The carding of the material space provides the basic condition for the shaping of accessibility. What is the actual walk of people in the block? In contrast to historical photos and photos directly reflects the status of KIC blocks changed from to pedestrians in a continuous line No one shows any interest in the. Originally closed inner blocks began to open their hearts and embrace "pedestrians", and the popularity of neighborhoods grew.

Figure 5 - Comparison of pedestrian walking environment in 2000 and 2017

During the working day (Thursday) to random street interviews, selected in the KIC blocks to work or business workers, ask the working day in walking street, and assist in drawing location and walking path. Local workers can be divided into two groups, namely, working here and living here, working here, and living in his land. It can be found that the walking line of people's working day has network characteristics, and most streets have considerable popularity. The pedestrian network mainly revolves around the University Road organization, and it is easy to arouse more communication and collision. The combination of the above material space reconstruction and the actual walking survey in two aspects, that KIC block before and after the update, the material from the closed space to achieve the transition to broken open, people's actual walk to become convenient and frequent, as in a continuous line blocks by No one shows any interest in. Whether spatial or social dimensions, the accessibility of neighborhoods is truly shaped.

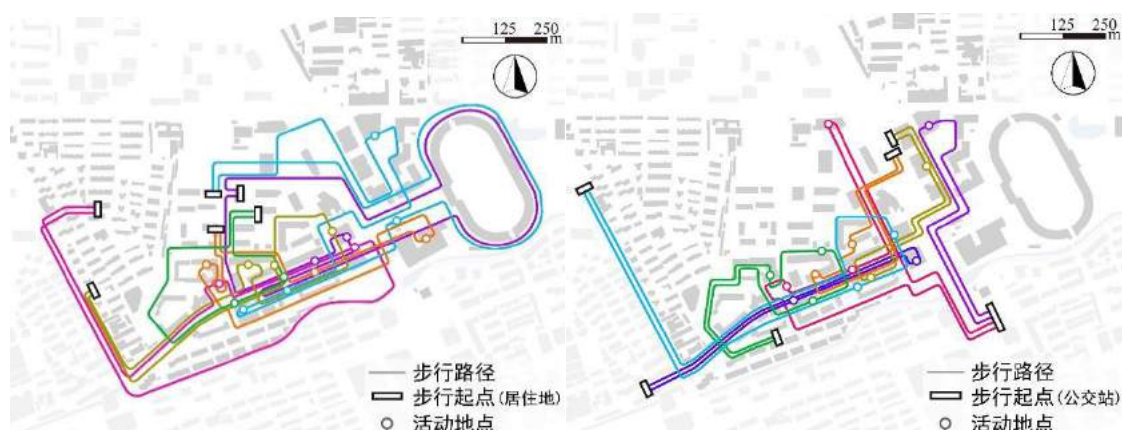

Figure 6 - Investigation on the walking route of workers in working days

4.2 SHAPING PROCESS OF COMFORTABILITY

4.2.1 SPACE SCALE: FROM BLOCK PARK TO SMALL NEIGHBORHOOD

The comfortable spatial scale can give people a pleasant experience and pleasant mood, and it is a necessary condition to attract people to walk, stay and communicate with each other in space. From 2000 to 2017, the neighborhood scale change Songhu Road East of the small, although there is a certain area renewal project is completed, but did not form a new City Road West of the road; Shanghai neighborhood scale is greatly changed, the city opened a new branch and community based road formed with a plurality of rectangular and trapezoidal blocks, the length and width of the the 40m to 120m range, and the city center area, San Francisco, New York and London neighborhood is a small scale similar to typical urban residents.

Figure 7 - Comparison of the interior courtyard space in same scale between 2000 and 2017

Deep into the neighborhood; consider the spatial structure of the compound. In 2000, the interior of the block was dominated by a large block of industrial buildings and storage buildings. These buildings form a narrow gap space and lack the inner courtyard space. In 2017, after the renewal of the neighborhood, the use of high and low, scattered, different sizes of building block combination, to eliminate the volume of construction. Enclosed in the interior to form a standard pleasant and pleasant courtyard space. In combination with the shape of the road network and neighborhood, the interior courtyard space is rectangular and trapezoidal, interesting and varied, and can accommodate a variety of outdoor activities.

4.2.2 PERSONAL EXPERIENCE: FROM MONOTONOUS TO FUN

Does the comfortable spatial scale really bring good experience and emotion to people? Choose between the road and the road of Wei a neighborhood in-depth investigation. Some university road, Wade road of social activities by local street building opening, from the street was introduced into the courtyard inside

the neighborhood, has formed a certain private public space, greatly enrich the experience of space, increase the interest through the. Ask in the neighborhood inside in the courtyard of several open their true feelings, some people think that drinking coffee here is relatively quiet outside, you can chat with friends better, but also to enjoy the outdoor sunshine ", some people think that drinking coffee in the yard can see the two floor of the gym and dance, this is very interesting, there are people that" if the day I love to sit in the evening more words may sit out, then the University Road, but one day the breath of life ".

Figure 8 - University Road and Weide Road between neighborhood inside courtyard building section

The combination of the above two aspects of spatial scale and neighborhood people's personal experience, that the KIC blocks have pleasant neighborhood scale and rich inner courtyard space, replacing the original huge volume, monotonous space. In terms of spatial dimensions and social dimensions, neighborhoods attract more comfort and interest.

4.3 SHAPING PROCESS OF FUNCTION

4.3.1 URBAN FUNCTIONS: FROM LOW-END INDUSTRIES TO MULTIPLE INTEGRATION

Only a variety of functions can stimulate diverse activities. The function is embodied in different dimensions. Based on the characteristics of the block itself, the changes of urban functions are analyzed from the aspects of land use, the combination of the functions within the land, and the combination of functions within the building. Land use situation comparison between 2000 and 2017, 2000, the block was mainly new Newworkshop factory, warehouse, the poor quality of the Old Homestead and 70s and 80s occupied two of industrial land, residential land, land for storage and a small amount of commercial land mixed arrangement. In 2017, the low-end industries were replaced by commercial, office and residential projects.

Figure 10 - Comparison of land use between 2000 and 2017

Further consider the functional organization within a single building. Among them, the function combination of the vertical buildings along the university road is the most typical. The first floor is mainly for people with greater traffic demand, higher rental capacity of commercial shops, including coffee shops, milk tea shops,

clothing stores, snack shops, convenience stores, bookstores and other formats. 2 - 4 layers for commercial office mixed use, including fitness clubs, education, training, study abroad consulting, law, accounting, dental clinics and other formats. 5 - 6 floors are mainly residential, office, mixed use, mostly using the typical form of LOFT residential units. A residential unit occupies two floors, partly single space, partly double deck space, which provides the floor height required for work activities. This semi work and semi residential space is used for small start-up companies, offices, couples, companies and even artists.

Figure 11 - Vertical function combination model of University Road building

4.3.2 DAILY ACTIVITIES: FROM INDUSTRIAL PRODUCTION TO COMMUNITY LIFE

A variety of hybrid city function enriches the KIC elaborate design of physical space, but this really inspired lasting vibrant community daily activities? With Baidu maps and API interfaces, thermal charts at different time periods on weekdays and Saturday (Thursday) are obtained to reflect the continuous change in population size and activity intensity. During the working day (Thursday), the activities of people from 8 began to gather, mainly around the Songhu road and College Road, when workers, entrepreneurs are hard to start a busy working day. From the point of the beginning of 18 has dissipated, then part of workers after work directly out of blocks, but there are still people in the night Everfount University Road shopping, consumption and leisure, added popularity and maintain night busy life. At the same time, LOFT residential, Jiangwan Hanlin area with residential function plots also hold a considerable part of the residents, together they support 24 hours a vibrant community life. In the rest of the day (Saturday), the crowd began gathering from 10 points, than working days later, the same is around the Songhu road and College Road expansion. In the stage of the young people in the hard pioneer weekend will enter in the office space, the surrounding area students, teachers, ordinary residents and tourists also have to take advantage of a short weekend leisure time to participate in social activities. They discuss topics in a coffee shop, shop on the streets, chat, or exercise in a fitness club, or attend training and salons in a workshop. These rich and interesting community activities did not dissipate until after 21, even in the early morning.

Figure 12 - Continuous change of Baidu thermodynamic diagram on working days and rest days

The combination of the above two aspects of city function and people's daily activities, that KIC block to achieve the fusion function, get rid of the low-end industrial area development to form. Relying on the function, people's social activities are also active, resulting in 24 hours of continuous vitality of community life. The functional dimension is well explained in both the spatial dimension and the social dimension.

4.4 SHAPING PROCESS OF SOCIALITY

4.4.1 COMMUNICATION SPACE: FROM NOWHERE TO REPEAT

Whether the communication space is recurring has a direct impact on people's social activities. Focus on the fractal characteristics of neighborhoods, to compare the changes in the communication space before and after the update. The so-called fractal characteristics, namely global and local existence of self similar characteristic, can be understood as some single building module, these modules constitute the module, and module group can progress the whole regional module group, the fractal characteristics have the stability effect on people's behavior (Tong Ming. 2014).

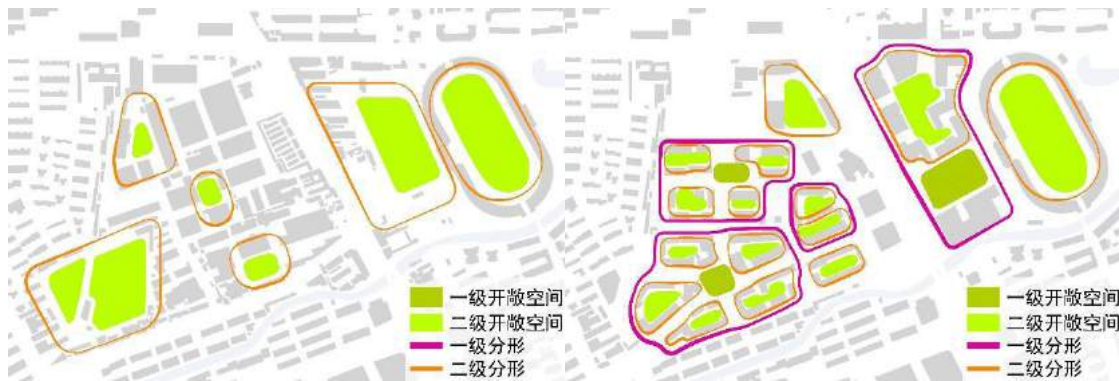

Figure 12 - Comparison of fractal characteristics between 2000 and 2017

Contrast the fractal features of public space in 2000 and 2017 blocks. In 2000 the district although there is open space, but the space is mainly used for loading, temporary storage, property does not have a public space, and combination of buildings are lack of coordination, lack of order, does not have the fractal characteristics of the scale of the communication space is nowhere. The 2017 block is the formation of fractal characteristics of closed, neighborhood buildings within the enclosed courtyard level of public space, the adjacent neighborhood is further formed larger around the square, combination of such lots in the updated constantly reproduce, constitute the different levels of the public, slightly outside the spatial difference between the system, people of different space shuttle, gain experience, prefer for the place to carry out social activities.

4.4.2 SOCIAL INTERACTION: FROM LACK OF DIALOGUE TO SOCIAL ADVANCEMENT

Has the rich and recurring communication space become the space catalyst to stimulate people's social interaction? On a Thursday afternoon in December 2016, a field survey was conducted between 5 and 7 p.m. to record the type and spatial distribution of people outdoors. All kinds of social activities in the block include chatting, walking, walking dogs, shopping, open-air coffee, square dancing and so on. Some of these activities are carried out outdoors in the open space, some in the gray space inside and outside the transition, forming a flow in the block, the sound of the landscape. Among them, the university road as the core to both sides of the infiltration of the formation of the central social vitality belt, is the most dynamic neighborhoods, social activities most intensive public space. In the late afternoon, commuting, commuting and passing crowds move together in different directions on the University Road, gathering together at different nodes and carrying out their own activities. The young man dispersed from the doorway of the SOHO building. Part of them left the block directly, and part of them poured into restaurants and bars on the University road. After a hard day's work, entrepreneurs leave the LOFT house and walk into the elegant coffee shop. Soon, the coffee chairs along the street were filled with guests.

5 INFLUENCE MECHANISM OF THIRD SPACE

5.1 REPLACEMENT OF LOW-END FORMS TO ENHANCE SPACE QUALITY AND ACHIEVE REGIONAL VALUES

According to the principle of neo classical economics, for a land mass, the timing of updating depends on the mutual change between the value of the building and the value of the land. When the value of the building is less than the value of the plot, the land will be updated. Because of the existence of the building hinders the realization of the value of land, the potential value must be reconstructed in order to realize plots (Feng Li, Tang Lai, 2013). The value reductions of different types of buildings vary with time, resulting in differences in the timing of land renewal. In the past the "industrial Yangpu" period, KIC of the block is a common space form section. Industry, warehousing, living and business are intertwined. With the construction of Wujiaochang City sub center, the block in 2000 has become an important section of the central city, and the regional conditions have changed. At the same time, in Yangpu District to create "Knowledge Innovation Zone" under the development goals, neighborhoods near the advantages of university resources are also increasingly prominent, potentially significant increase in value. The original industrial form obviously can not meet the new requirements of regional development and rejuvenation. In

time, the Yangpu District government and real estate developers, the KIC this renovation project, replacing the original plots of the low-end industrial form. They re comb the external space and optimize the quality of the environment, the university resources, new industries and community life organically combine to create convergence of popularity and creativity of the third space. In the process of district renewal, the construction of third space has a profound and positive impact on the regional space environment and economic benefits.

5.2 ATTRACT CREATIVE CLASSES, BUILD INNOVATIVE NETWORKS, AND LEAD CREATIVE CITIES

Creative classes seek vibrant urban life, especially those that can participate, experience, and interact in public space, not just a job. The updated KIC blocks Integrated University Road, street, neighborhood square courtyard, open-air coffee and other public spaces, they become common area characteristic and the symbolic significance of the third space. Entrepreneurs, engineers, designers, scientists, university students and other emerging creative groups from around the University and enterprises clustered around the blocks, matching the attributes of space with the needs of the community. They were able to facilitate social interaction in the third space. At the same time, the third space provides an interesting place for daily recreation for local residents, and also provides more job opportunities for service personnel. The creative class, local residents and service personnel to become the third space users, in the frequent face-to-face contact in the form of local integration of close and extensive social network (Wang Lan, Wu Zhiqiang, Qiu Song, 2016). Can produce production services, product development cooperation, outsourcing and other formal contact network in this process, also can produce knowledge sharing, chat leisure, emotional communication informal network (Zhou Suhong, Pei Yaxin, 2016). Social networks also need the support of government, venture capitalists and developers to produce synergistic effects of innovation.

6 CONCLUSION

Taking into account the spatial and social dimensions, from the accessibility, comfort, functionality and sociability of the third spaces, the development changes of the neighborhood from 2000 to 2017 are compared. Research shows that in KIC as a typical representative of the block shape update process happening in the third space, public space has third spatial attributes, encourage more people to walk, enjoy the fun of walking, experience the continued vitality of community life, development to stimulate innovation and social interaction. People arrive in the third space to find companions and social contacts, and social communication is also the essential feature and the basic purpose of the third space.

From the perspective of urban renewal, KIC updated to adapt to the changing relationship between city land value and the value of the building, to replace the low-end industrial form, the university resources, new industry, community living together, creating together popularity and originality of the third space, manifest the potential value of land, to meet the the new requirements of the development and revitalization of the area. In this process, the construction of "third space" has a far-reaching positive impact on the regional space environment and economic benefits.

From the perspective of the construction of Creative City, KIC through the integration of public space, the formation of distinctive and symbolic significance of the third space, not only to provide social places near the creative class, but also provide employment opportunities for service personnel for local residents to provide daily leisure places. Different social groups form a close and extensive social network in frequent face-to-face contact. Social networks, supported by related subjects, produce synergistic effects of stimulating innovation. The continuous synergy promotes regional innovation and innovation spillover, and finally leads to the construction of creative cities. In this process, the third space is both a catalyst and a carrier.

ID 1501 | A CONTRASTIVE STUDY ON STRATEGIC VALUE OF PUBLIC SPACE PLAN IN URBAN DEVELOPMENT FROM THE PERSPECTIVE OF SPACE PRODUCTION

Jia Geng¹, Bowen Chen¹, Meijie Wang¹
¹Tongji University
1505506201@qq.com

1 INTRODUCTION

1.1 THE TENDENCY OF PUBLIC SPACE PLAN AS A CATALYST

Public space is one of the most important elements to realize the concept of resilient city. Not only could it provide emergency shelters when disasters, it also could provide a flexible and sustainable development for industries as a macroscopic spatial strategy.

The value of public space has been rising gradually with calls for human-centered environment, after its concession for economic development in decades. Because it could beautify environment and promote social communication. What's more, it has a tendency from its own ecological, social and aesthetic value to strategic one as a catalyst in urban development.

Urban catalyst, means that a particular element has a positive influence on the external or internal conditions of the existing ones and causes a "chain reaction", promoting continuous urban development as arrangement (Atton W. & Logan D., 1994). There is no doubts that public space has a great potential to be a catalyst in urban development.

1.2 SPACE PRODUCTION VALUE OF PUBLIC SPACE

To realize the strategic value of public space as a catalyst, there is a main contradiction between high investment and low output of capital. Because the strategic value of public space is significant but abstract beyond capital, while the space production value of that is very low in fact, both of which disjoint to some extent. Therefore, it'll be a breakthrough to improve public value from the perspective of space production.

Space production, means the transformation from production of goods to that of space in a certain place, in other words, from usage value to commercial value of land measured in term of capital. So, what's the space production value of public space? Currently, it has presented mainly as the environmental improvement and a following increase of its surrounding land value. However, one-off land deal is not enough to support the long-term development of public space. So this paper take two cases to analyze their sustainable development and interaction with the surroundings from the perspective of space production.

2 CASE STUDY ON SKYLINE PARK IN DENVER, USA

2.1 BACKGROUND

2.1.1 URBAN DEVELOPMENT: URBAN SPRAWL & DOWNTOWN DECLINE

In 1890s, the downtown of Denver was the main commercial center in the Rocky Mountain Region. However, after 1960s, the urban sprawl started continuously with many shopping malls in the suburbs. Lots of citizens, especially the wealthy, and commercial activities moved to the suburbs, which made the downtown uninhabited and lifeless. The direct reason is private cars which reduced the distance between the downtown and suburbs, while the internal one is the decline of life quality in the downtown, causing the loss of economic vitality and social communication.

2.1.2 URBAN PLANNING: ACTION, INVENTORY & INTEGRATED PLAN

American system of urban planning consists of 2 sub-systems of Urban Planning and Urban Design, with 2 hierarchies of Strategic Plan and Implementary Plan respectively (Table 1). Because of the nearly finished urbanization in early 20th century, American urban planning has presented mainly as inventory and integrated plan.

	Urban Planning	Urban Design
Strategic Plan	Master Plan	Strategic Urban Design
Examples	<ul style="list-style-type: none"> ● American Comprehensive Plan; ● British Structure Plan; ● Japanese Area Division. 	<ul style="list-style-type: none"> ● American Urban Guide Plan; ● British Urban Design Strategy; ● Japanese Urban Institution.
Implementary Plan	Implementary urban development planning	Implementary Urban Design
Examples	<ul style="list-style-type: none"> ● American Zoning Regulation, Land Subdivision and Site Planning; ● British Local Plan; ● Japanese Land Use District Plan. 	<ul style="list-style-type: none"> ● American Special Urban Design Guidelines; ● British Development Brief and Design Guide; ● Japanese Planning Permission.

Table 1 - American system of urban planning and design

2.1.3 URBAN MANAGEMENT: PUBLIC-PRIVATE PARTNERSHIP

In the range of downtown, the Board of Directors of Downtown Denver, Inc (DDI), which has developed as Downtown Denver Partnership (DDP) nowadays, was established in 1955. As a leader, place-maker, convener, idea generator, facilitator, recruiter, team-builder and policy advocate, it guides some special projects to manage and develop the downtown as a unique, diverse, vibrant and economically healthy urban core of the Rocky Mountain Region (DDP, 2014). It also balances the benefits of partners and provides more opportunities for bottom-up projects.

In the range of city, the Denver Urban Renewal Authority (DURA) was established by the government in 1958 to assist in the redevelopment of blighted property in Denver, working with the residents, businesses, civic leaders, area developers together (DURA, 2016). Most of all, DURA has managed a portfolio of \$340 million in Tax Increment Financing (TIF) bonds and over \$166 million in outstanding TIF reimbursement obligations (Komara A., 2004). When these projects are fully built out, its investments will have leveraged an estimated \$8 billion of private capital in previously blighted and underutilized areas of our city (DURA, 2008).

2.2 DESCRIPTION

2.2.1 SKYLINE URBAN RENEWAL PROJECT & SKYLINE PARK

As a part of the renewal movement counteracting widespread suburban sprawl and autofocus retail, Skyline Urban Renewal Project was centrally approved within Denver's downtown in 1967 (Figure 1). Typical of urban renewal efforts, DURA's first jobs was to raze deteriorated structures so that the land could be made available to those interested in redevelopment. Ironically, historic resources were lost and it's the reason of the name "Skyline".

Skyline Park, a now-demolished park, was constructed in three blocks in the earliest stage of this program as a focal point. In 1968, Marvin Hatami was consulted by DURA to develop an original design scheme but it served as only a transitional space that would have given visitors little reason to linger. In 1970, DURA initiated a request-for-proposals bidding and finally selected Lawrence Halprin & Associates to refine and implement another scheme. The new concept introduced a formation inspired by the local natural environment into the downtown, because they noticed that rapid development was forcing Denver to lose touch with its vast and dramatic mountain landscapes. The Halprin firm requested they be granted design rights over the first storey of park-facing buildings in order to control their appearance, while there were also some other guidelines including height restriction etc. established in the reports based on Hatami's scheme. However, all restrictive guidelines were negated eventually, because it would deter developers (Hirsch P., 2006).

In 1973, Skyline Park was completed and opened to the public. However, Skyline Park Master Plan released in 1997 recommended its complete demolition. After the struggles in the later 5 years, DDP made the decision to demolition in 2002 and finished it in 2003.

Figure 1 - Map of downtown Denver illustrating Skyline Park's context. From Urban Strategies/Greenberg Consultants, Skyline Park Revitalization Initiative, April 2001, p. 17.

2.2.2 THE 16TH STREET MALL AND DOWNTOWN REVIVAL

In 1971, DDP proposed a plan of pedestrian-scaled development along the 16th Street but it was put off owing to the lack of capital. In 1980s, to meet the requirement of the commercial developers, the 16th Street Mall Plan was proposed again, then finished and opened to the public soon. It was not only a pedestrian-friendly plan but also an integrated plan including commerce and various transportations. It forbade cars and provided free buses as well as light rail connecting the two stations along the street, which was very effective to reduce 50% traffic jam. Most of all, the open street was expanding and forming a pedestrian system which was a new catalyst to promote prosperous commercial activities beyond expectation (Figure 2).

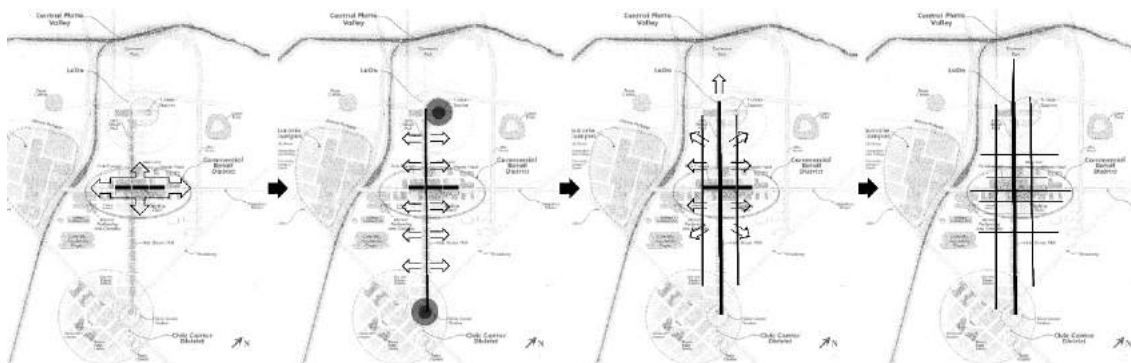

Figure 2 – The expanding process of 16th Street, From Urban Strategies/Greenberg Consultants, Skyline Park Revitalization Initiative, April 2001, p. 17, illustration by the author.

2.3 RELATIONSHIP BETWEEN STRATEGIES AND BACKGROUND

2.3.1 COINCIDENCE: REASONS OF ITS SUCCESS IN REVIVAL

From the perspective of urban development, it's a coincidence in content. The pedestrian-scaled block could promote social communication and commercial activities. Facing various problems in the city, pedestrian strategy has a positive and multilevel value. Its point in success is human-centered. As the only public space in the 16th Street, Skyline Park have induced the revival of the 16th Street Mall, although it didn't reach the arrangement. But it could be imagined that Skyline Park would play a much more powerful role in the public space system, if the government insisted the implement of those original guidelines. Anyway, the following expansion and infiltration of public space system was far more significant. Compared with the vertical space production of residences or commercial buildings, it's a kind of horizontal space production of public space. The primary value brought was the increase in the value of surrounding land, what's more, the continuous value was its support to the sustainable development of commercial area. Although it still couldn't be measured by money, it has already linked to the survival of commerce directly.

From the perspective of urban planning, it's a coincidence in method. American urban planning is more efficient and adaptive in process. Its Strategic Plan and Implementary Plan have a close connection and both of them have a dynamic interaction according to the situations and trends.

From the perspective of urban management, it's a coincidence in mechanism. Not only could Public-Private Partnership build an open platform, it also could regulate and control the market with some preferential policies. For example, TIF assistance is a policy to encourage the crowdfunding investment. To some extent, it's the key to the success of this project as the first Public-Private Partnership under the management of DURA.

2.3.2 CONTRADICTION: REASONS OF ITS FAILURE AND FINAL DEMISE

From the perspective of urban development, Skyline Park didn't solve the social interpersonal problems radically. On one hand, it rooted from the Hatami's design intention as the transitional space for more pass and less stay. He thought the accessibility of open space could promote the development of commerce, but he ignored the importance of communication. On the other hand, it's too hard to relieve race conflict. When the park became an insecure shelter for the poverty, it has been abandoned to some extent.

From the perspective of urban planning, the original purpose of Skyline Park is to entice private investors to buy the lands near this unique public amenity. So it's a balance between short-term capital absorption and long-term sustainable development. Finally, the inertial thinking of capitalist contributed to the choice of short-term capital absorption. It's a pity that DURA had to compromise under financial pressure and reduced the restrictive guidelines, making the walking system scattered and eventually depressed.

From the perspective of urban management, the primary cause of its demise is that both the government and developers emphasis on commercialism. In the letter Halprin sent to Cultural Landscape Foundation, he expressed his disappointment and helpless. It can be seen that the blindness of capitalism cannot be coordinated with the mind of planners as well as harmonious development of society.

3 CONTRASTIVE CASE STUDY ON RAILWAY PARK IN TIANJIN, CHINA

3.1 SIMILARITIES AND DIFFERENCES BETWEEN BACKGROUNDS

3.1.1 URBAN DEVELOPMENT: URBAN EXPANSION AND SPRAWL

The first similarity of Denver, America and Tianjin, China was the law of urban sprawl without the consideration of time dimension. However, during the implementation of the projects, Denver was at the late stage while Tianjin was at middle. As one of megacities in China, there was a great and continuous increase of populations and industries in its center in the past decades. Also, there was the following urban sprawl in the suburbs.

The second one is their intelligent and connotative development. But they were still at different stages of development. Tianjin was accelerating the transformation process from the secondary industry to service, from low value-added one to high. As a result, with the demise or removal of factories, industrial railways has been the useless and dusty city assets, blocking the traffic and leaving a negative image in the city.

The third one is the imbalance between demand and supply of social communication. In the both cities, urban expansion and sprawl has superficially resulted from the decline in quality of life, further internally caused the lack of social communication. Compared with America, the society in China is simple relatively without such ticklish problems.

3.1.2 URBAN PLANNING: BLUEPRINT, INCREMENTAL & SPECIALIZED

In fact, Chinese urban planning took American as a reference, so it is a derivative of American with some Chinese local characters. However, there are 3 differences between them. The first one is American action plan and Chinese blueprint plan. In America, the Strategic Plan is parallel with Master Plan as well as

corresponding Strategic Urban Design, both of which guide and control their parts in Implementary Plan. In China, on one hand, the Strategic Plan is much higher than Master Plan. It seems a blueprint to guide the national or regional development through some macroscopical and conceptual strategies and principles. On the other hand, Chinese system is lack of Strategic Urban Design. In other words, the urban design in China is just equal to Implementary Design in America, just submitting to the rules in Regulatory Detailed Plan and focusing on spatial forms, traffic organization and landscape, etc. without its own strategic value. As a result, there is always a long distance between Strategic Plan and specific urban projects. The second is the difference between American inventory plan and Chinese incremental plan. The main reason is their different stages in the process of urbanization. Because of the nearly finished urbanization in early 20th century in America, it has laid the emphasis on urban renewal of limited lands. Although the urbanization and urban sprawl has been still underway in China, there must be a tendency from quantitative plan to qualitative plan and from space capitalization to information capitalization. The third is the difference between integrated plan and specialized plan. Although the Chinese Master Plan seems cover all parts, they're not integrated as a whole and separate from each other in the next specialized plan.

3.1.3 URBAN MANAGEMENT: PUBLIC-PUBLIC PARTNERSHIP

Taking the full-developed Public-Private Partnership in America as a reference, China has been encouraging the cooperation between the government and private enterprises recently, though there is still a room to improve. In fact, the current practice is "Public-Public Partnership" to some extent, because most of the cooperation is between the government and state-owned enterprises which doesn't play a great role in leveraging private capital.

3.2 DESCRIPTION

Railway Park in Tianjin, China is a recent renewal project along the inner ring and the abandoned industrial railways in the center of city(Figure 3). It was just approved in 2003 and completed in 2016. It took full advantages of the cultural resources of railways and their surrounding industrial heritage. As a result, it has been a greenway with the length of 45 km, average width of 100 m and increase of green area about 123.5 hm². Its spatial structure has an integrated consideration of road networks, slow traffic system, public space system, river system and public service facilities, etc. It contains various functions, such as ecological conservation, industrial cultural education, entertainment and sports, etc. Not only could it provide citizens a low-carbon lifestyle, it also open up an industrial corridor in the city, both of which may be new name cards of Tianjin.

(a) Land use

(b) Location in the center

Figure 3 - Map of Railway Park in Tianjin. From Tianjin Railway Park Plan, 2016.

3.3 RELATIONSHIP BETWEEN STRATEGIES AND BACKGROUND

3.3.1 COINCIDENCE: REASONS OF ITS SUCCESS IN REVIVAL

From the perspective of urban development, it's a coincidence in context. With the concept of sustainable and human-centered development, public space could improve the quality of urban life, and further promote social communication. On one hand, it's a turning point to solve the previous urban problem by unblocking roads and reuse industrial heritage. On the other hand, it's a meaningful catalyst to induce industrial innovation and transformation through micro regeneration. As a result, it has been a spatial carrier of new culture and industries. The value of public space production here is not only increase the land value and expand public space system but also, what's more, get feedback from sustainable development of industries and life.

From the perspective of urban planning, it's an optimization in method, catering to the tendency of action plan, inventory plan and integrated plan. First, it provides a strategic action plan as an innovative connection between Master Plan and Regulatory Detailed Plan in China. Second, micro regeneration is a worthy exploration to take the advantage of inventory land and refresh disused but valuable heritage. Third, integrated plan, including open space, transportation, commercial and industrial development, etc. is the reason why it could play an effective role as a catalyst.

From the perspective of urban management, it's a breakthrough in mechanism. With the limited capital, the government would have too large pressure to pursue those expensive environmental projects. Bottom-up mechanism must be a key to relieve this difficulty. In this project, the planners shows their initiative and voluntary to pay more attention to urban development, although there may be some sacrifice. It realizes the real practice of Public-Private Partnership in China as well as the forth distribution – spatial distribution with the principle of space justice, which is a sublimation of public space production without any doubts.

3.3.2 RESOLUTION OF CONTRADICTION

Demise is not bad absolutely. Instead, the standards of judgement should be about their necessity of existence even if they have disappeared. Skyline Park in Denver is a typical case that ever had a positive influence on the urban development but went to demise, while Railway Park in Tianjin has been a sustainable spatial carrier to support the continuous urban evolution. Both of them are our references to think about the plans in the future.

4 CONCLUSION

In summary, there are 2 ways which can improve the value of public space from the perspective of space production. One is forming and spreading public space system, the other one is promoting the sustainable development of industries to feed back. So public space plan and design should not only shape space and beautify environment but also, what's more, plan in a large scale and play a significant role in cities or even regions. It must take local conditions into consideration and adhere to the human-centered concept absolutely. Meanwhile, our public space plan and management should run more Public-Private Partnership projects and go for more action plan, inventory plan as well as integrated plan.

ID 1516 | FROM INFORMAL TO FORMAL PUBLIC SPACE: THE ORGANIZATION AND INSTITUTIONAL TRANSFORMATION OF TACTICAL URBANISM MOVEMENT IN SAN

Hsiao-Yu Chou¹; Hsiu-Tzu Betty Chang¹

¹National Cheng Kung University

chouhsiaoYu@gmail.com

1 INTRODUCTION

Tactical Urbanism (TU) has become a force in urban design which cannot be ignored. Its representative is a new approach in requesting new types of public space which have changed the traditionally top-down, long-term planning process to bottom-up, action-oriented experiments to improve the public realm. TU is implemented by different sectors with different motives, but the ultimate goal of TU is the same: trying to improve the built environment with some low cost, fast, flexible installations to test the outcomes of the intervention.

There are growing attention on the social media and the internet about the transformation of the unutilized streets or spaces, such as the too wide sidewalks or vacuum parking lot. Through the simple intervention such as putting some tables and chairs for the public to rest, landscaping the parking lot to be an attractive site of the neighbourhood, etc. The collective name of these activities called "Tactical Urbanism." These small activities can enhance the people's quality of life and well-being. Its impact on urban design is increasing, and thus more and more people pay attention to this movement. Although the outcome of the TU is obvious (e.g. better public realm), few people know the mechanism of it and its background. TU is not a sudden occurrence but an outcome of some movements in the U.S. (e.g. Play Street, Open Street, Guerilla Gardening, Pop-up Retail, Pop-up Cafe). It has many different forms in different cities, but the spirit of it remains the same.

In this paper, we make a comparison between San Francisco's "Pavement to Park (P2P)" and Taipei's "One Day Street Life Experiment Activity (ODSLEA)". San Francisco's P2P program is regarded as the earliest and most successful development of TU that seeks to convert parking space into spaces for cyclists, pedestrians, residents, neighbourhood interactions, and local businesses. On the other hand, ODSLEA was a one-day activity held on September 15, 2013, in Taipei, which was highly similar with P2P on the surface. Here comes my question: What are the similarity and difference between these two tactical urbanism movements in essence?

Using a case study approach, this paper relies on first-hand interviews with key stakeholders and second-hand data such as papers, websites, reports, manuals, and promotional campaigns to study the history, organization, institutional arrangement, and the management dimension of P2P and ODSLEA with particular attention on the motivation of the initiators. This paper is expected to understand the motivations of the initiators of TU through the interview and second-hand data; it is important to know the motivation because it would lead to different results. Through the comparison between the P2P and the ODSLEA programs, this research aims to contribute to making a suggestion to all the TU initiators and participants to examine their TU programs that if they contain the TU spirits or not. If not, they are supposed to modify their programs to achieve their goals: to improve the built environment.

2 LITERATURE REVIEW

TU has become a global phenomenon in the last decade; its influence has reached the North America and the other countries around the world. It becomes a new approach to change the urban design decision-making process with some simple, adroit intervention. It's unique because it has broken the rules that the urban design decisions should be made by the planner, architects, designers, government officials instead of the citizens who live in there. The inefficient top-down approach has been gradually challenged by the bottom-up, citizen-led TU. TU not only represents the true needs of the citizens (physically, socially, economically), more importantly, it represents the true spirit of democracy. This movement is studied from different perspectives including both qualified method and quantified method.

Lydon et al. (2012) are the key writers to build the integral theory and the practices of TU movement. They elaborate the TU in their book "Tactical Urbanism- short-term action for long-term change". Lydon et al. (2012) list the following five key characteristics of tactical urbanism in their guidebooks: A deliberate, phased approach to instigating change; an offering of local ideas for local planning challenges; short-term commitment and realistic expectations; low risks, with a possibly high reward; and finally, the development of social capital between citizens and the building of organisational capacity between public/private institutions, non-profit/non-governmental organisations (NGOs), and their constituents.

Many papers about the TU movements would inevitably mention Lydon et al. (2012), such as Mould (2014) describes the importance between TU and Lydon that

The TU movement is attributed to urbanist and planner, Mike Lydon, who heads up an institution called the Streets Plan Collective, an urban planning-cum-activism group based in New York City. The growing popularity of TU, as promoted by Lydon and a growing cohort of devotees, has fuelled an interest in small-scale activities undertaken by local citizens that redesign their urban area to be more 'liveable'. (P. 529)

While the current model of what is generally known as tactical urbanism sprouted from the first Park(ing) Day in San Francisco in 1995, the movement can trace its roots as far back as 16th-century Paris with the pop-up book vendors along the River Seine and later the Play Streets of New York and London from the first half of the 20th century (Lydon et al. 2012). The key concept behind tactical urbanism is the idea that temporary interventions can help garner an understanding of what interventions might work in a particular context and lay the foundation for more permanent ones (Marshall et al., 2015). This ability for a city to learn can be linked to one of the most maligned names in city planning: Le Corbusier (McFarlane 2011). While many of LeCorbusier's designs have not stood the test of time, his theory that urbanism can and must be relearned fits with the creed of tactical urbanists (Marshall et al., 2015).

In recent years, there have been many academic papers to explore the phenomenon of TU, including: "how TU evolves from a short-term to long-term", "TU's history, prospects, impact and criticism" (Greco, 2012), "the relationship between TU and creative city" (Mould, 2014), "TU as instruments in urban design education" (Sargin& Savaş, 2012), "TU and the right to the city" (Alisdairi, 2014) and so on. The main focuses on these researches of TU are basically of its impact, prospects, critiques, and the relationship with other issues. However, there is no research currently trying to compare the similarities and the differences between Asia or Taiwan and the U.S. TU movements and the motivations of the initiators. This paper seeks to compare the similarity and the difference between the P2P program in San Francisco and the ODSLEA program in Taipei from different perspectives.

3 TACTICAL URBANISM 3.1.1 THE BACKGROUND OF THE RISE OF TU

There are several different versions of the context of the rise of the TU. Andres Duany (2015) argues that this is because the rise of the two most desirable urbanism in the 21st century: Tactical and XL (Extra Large), which represents the Rem Koolhaas' concept: S, M, L and XL is not complete, it lacks XS (Extra Small), and XS category is represented by TU. Gehl Studio San Francisco (2016) contends that TU is related to strategic planning projects and large infrastructure projects from the 1950s to 1980s. When the highway was expanded in almost all US cities and built skyscrapers, the top-down approach was gradually challenged and eventually replaced by community involvement from the 1980s to early 2000. It has been giving priority to human experience, and this change indirectly contributed to the new planning approach: TU.

It is also possible to analyse the causes of the rise of the TU from other perspectives, which are related to the economic recession, population transfer and the rise of Internet tools (Lydon, 2012). The North American recession has led citizens, municipalities and developers to take creative projects and focus on smaller scales and funding; the baby boomers have retired, and young people have entered the government to mark the transfer of population; web-based tools, blogs, Twitter and Facebook can share some of the content, in a few minutes the problem will appear in dozens of cities on the Facebook. It is clear that the emergence of TU in the United States is not a coincidence, but with a series of ideological changes, social change, population transfer and scientific and technological progress. Lydon (2012) also organised a series of activities that contribute to TU: from the NYC's Play Street program in 1916, NYC's Guerilla Gardening efforts in 1973, San Francisco Park (ing) Day in 2005, and then P2P began to expand within the United States and even worldwide as well.

3.1.2 INTRODUCTIONTOTU

Merriam-Webster's defines tactical as "of or relating to small-scale actions serving a larger purpose" or "adroit in planning or manoeuvring to accomplish a purpose." (Lydon, 2012, P.2) TU's ultimate goal is to enable these interventions to influence government's decisions and ultimately make these short-term activities part of a long-term policy. P2P is a case in point, from the park(ing) day one-day event to currently a long-term activity. As the result, most of these materials are affordable and low cost. "TU presents a palette of materials — a toolbox that can be used for rapidly deploying projects and testing ideas in your city's streets. They are grouped materials by their function, providing ideas for barrier elements, surface treatments, street furniture, landscaping elements, signs, programming, etc." (The Street Plans Collaborative, 2016, P.21). Most of the sites of TU occur in the unutilized public spaces, but not always. The famous Time Square in NYC is an example of situated on the lively street. Here are the common sites of the TU movement: open space, empty storefront, too wide streets, highway underground passage, highway underground passage, ground parking lot, etc.

Most of the TU movements are initiated by citizens rather than the municipal government. The citizens hope that through the informal expression of their views on the built environment, they would affect the government's decision-making, hoping that to become legalised and formalised. Just like the P2P from the beginning of the informal (two people rented a parking space and put some turf and a seat on it), to now become a formal, legitimate activity. The programs of TU vary according to its location and needs. "In most communities, Tactical Urbanism projects rarely fit the typical mould for permitting or installation. They are expected to have to troubleshoot and be creative in this aspect of your project planning." (The Street Plans Collaborative, 2016, P.18) Lydon (2012, P.3) also recommends that TU projects should be flexible and dynamic. "Because the places people inhabit are never static, TU doesn't propose one-size-fits-all solutions but intentional and flexible responses. The former remains the fixation of numerous and overlapping disciplines in the urban development fields, which assume that most variables affecting cities can be controlled now and into the distant future. The latter rejects this notion and embraces the dynamism of cities."

Despite its popularity, tactical urbanism has been mixed with other similar approaches to urban design, including DIY urbanism and action-oriented planning, which strategies and short-term actions are the essence of their philosophy. DIY urbanism contains the following terms: pop-up urbanism, user-generated urbanism, insurgent urbanism, guerrilla urbanism, urban hacking. It blends a spirit of entrepreneurial activism with public art, design, architecture, engineering, technology, and notions of progressive urbanism. Not all DIY urbanism efforts are tactical, and not all Tactical Urbanism initiatives are DIY (Lydon, 2012). The most significant difference between these two is that TU is intended to instigate long-term change, such as revising an outdated policy or responding to a deficiency of infrastructure and DIY Urbanism isn't. In other words, TU is highly related to the permanent improvement and DIY Urbanism mainly focuses on the temporary beautification or offering amenities. In addition, Action-Oriented Planning is distinguished from "Tactical Urbanism" by an increased emphasis on measurement and evaluation as the guiding star of strategy (see Fig.1). Pilot projects can be worthless without strategic vision or when support for iteration is missing. Measuring impacts is one way to stay true to a strategic vision and to engage many perspectives by telling stories through objective measures (Gehl Studio San Francisco., 2016).

Figure 1 - The process of Action-Oriented Planning (Source: Planning by Doing)

There are a range of forms of TU in the U.S. and worldwide as well and initiated by different stakeholders. Most of these programs are similar in essence but appear in different forms. The following are some programs of TU in different places: Open Streets (Bogotá, Colombia), Play Streets (NYC, London), Build a Better Block (Dallas), Park(ing) Day (San Francisco), Guerilla Gardening (NYC), Pop-Up Retail (Oakland, Melbourne), Pavement to Plazas (NYC, San Francisco), Pavement to Parks (San Francisco), Pop-up Cafes (NYC), Depave (Portland), Chair Bombing (Worldwide), Food Carts/ Trucks (Worldwide), etc. TU could be implemented by a series of actors with different intentions (e.g., governments, businesses, non-profits, civic groups, individuals). The following are the three typical types of actors of TU: “Initiated by citizens to bypass the conventional project delivery process and cut through municipal bureaucracy by protesting, prototyping, or visually demonstrating the possibility of change. This activity represents citizens exercising their “right to the city.” As a tool for city government, developers or nonprofits to more broadly engage the public during project planning, delivery, and development processes. As a “phase 0” early implementation tool used by cities or developers to test projects before a long-term investment is made.” (Lydon, 2012)

4 METHODOLOGY

This study is mainly based on the case studies and interviews to compare the similarities and differences between the P2P and the ODSLEA projects. On the one hand, due to the difficulty to get the first-hand materials from the P2P, all the materials of the P2P are based on second-hand materials. On the other hand, as part of case study examination, we conducted three different sets of interviews (see Table 1) to explore the ODSLEA. The interviews were held on April 14, 2017, the interviewees including several core actors in the ODSLEA such as Mr Tseng as the city staff representative (the official of the Public Works Department, Taipei City), Mr Liu as the site designer representative (Director of the Classic Design and Planning), and Mrs Kuo as the expert representative (Director of the Taiwan Institute of Landscape Architects).

Interviewee	Key Questions
City Staff	<ul style="list-style-type: none"> - Describe the history of the program including initial idea. - What departments are involved in regulation and development? - What is the intention of the city to hold this event? - Does the city have any plans to develop subsequent parklet or any other similar projects? - What are the successes, challenges and lessons learned for the program?
Site Designer	<ul style="list-style-type: none"> - Describe the history of the program including initial idea. - What is your role in this event? - What is the relationship between the P2P and the ODSLEA programs. - Is there any public participation involved? - How much time and resources did you invest in? - Are there similar events have been held in Taiwan? - What is the government's attitude from your perspective?
Expert	<ul style="list-style-type: none"> - What is your role in this event? - How do you weigh the values of this event? - How do you think the relationship between the P2P and the ODSLEA programs? - What is the government's attitude from your perspective? - Do you have any suggestions to the city government and the designers?

Table 1 – Type of Interview and Questions

5 SAN FRANCISCO: PAVEMENT TO PARK (P2P)

P2P contains three major parts: Parklets, Plazas and Prototyping. Parklets aim to transform all sidewalk-scale open spaces that repurpose the curbside lane. Plazas intend to use neighbourhood gathering places created by reclaiming underutilised street spaces. Prototyping is short-term tests of urban design ideas that are often portable, flexible, and relate to playing and performance. (Pavement to Parks website: <http://pavementtoparks.org/>) "Parklets and Plazas are a part of an emerging practice in Urban Planning and Design that goes by many names, and is characterised by inexpensive, temporary, adaptive, and grassroots strategies." (Stroman, 2016, P.8)

SF Planning Department (2014) elaborates the basic mechanism of the P2P project. "Through the program, parking spaces and street intersections have become the testing ground for new and easily reversible public spaces such as parklets and plazas. These temporary spaces are typically outfitted with amenities that enhance the quality of public life, such as tables, seating, landscaping, bicycle parking, and public art." Nowadays, there are more than 50 parklets and six plazas in the P2P program (see Fig.2).

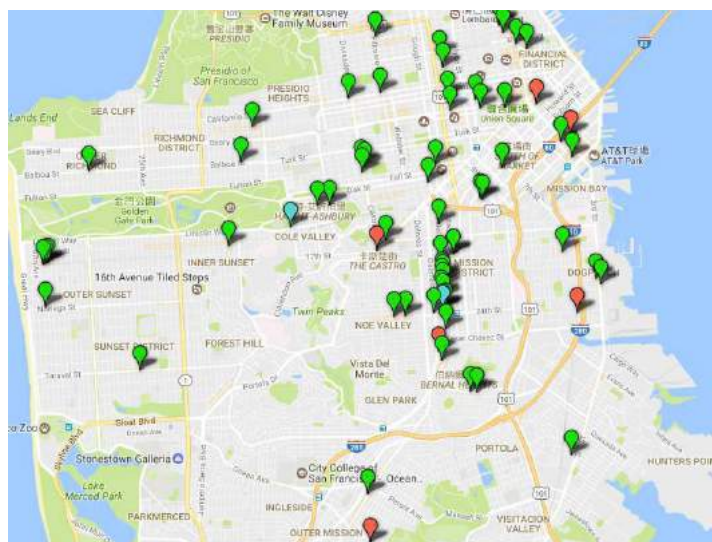

Figure 2 - Map of all parklets and plazas sites (Source: <http://pavementtoparks.org/>)

The term 'parklet' has heretofore been used informally to refer to a small urban park, 'mini park' or 'pocket park' (Gillool, 2010; Martin, 1998; The Washington Post, 1967; Z Waugh, 1947; Zion, 1962). This thesis recognises the Parklet as distinct urban design typology with specific spatial characteristics prototyped in San Francisco: the Parklet occupies a curbside parking lane, often reclaiming contiguous spaces, functionally expanding the pedestrian realm of the sidewalk. Ocubillo (2012) explained how parklets work: "Parklet installations are essentially temporary. Projects are granted permits on a renewable annual basis, which implies a limit to their lifetimes and their potential to effect – as individual sites or cumulatively – more permanent interventions and policies.

The creation of parklets and similar small-scale public open spaces has become a widespread effort across some cities in the United States. Since San Francisco's five pilot parklets in 2010, the local effort to expand on the successes of parklets is also growing. Currently, over sixty parklets have been installed across twenty different neighbourhoods, and more are being implemented as high public and business interest have resulted in an increase in parklet applications. The parklet program has evolved for more than a decade (see Fig. 3). It was initiated by two workers of the Rebar group. They rented a parking space and put some turf, bench and a tree on it in 2005. San Francisco government thought it was interesting and held Park(ing) Day in 2006. The parklet pilots started in 2009 and formalised by San Francisco government in 2015.

Figure 3 - The Evolution of the Parklet Program (Source: Planning by Doing)

The P2P program seeks to test the possibilities of these underused areas of land by quickly and inexpensively converting them into new pedestrian spaces. In other words, it tries to reclaim underutilised asphalt as public space without large capital expenditure. These spaces can become permanent public open space after an evaluation period. There are five principal goals of P2P: 1. Foster neighbourhood interaction 2. Reimagine the potential of city streets 3. Enhance pedestrian safety and activities 4. Encourage non- motorized transportation 5. Encourage non-motorized transportation 6. Support local businesses.

There are a number of sectors involved in the P2P program: San Francisco Planning Department, San Francisco Public Works Department, San Francisco Municipal Transportation Agency, Mayor's Office (the public sectors); Local Restaurants and Stores (the private sectors); Tunnel Top Park Steering Committee, Union Square Business Improvement District, San Francisco Beautiful, etc. (the third sectors) Each Pavement to Parks project is intended to be a public laboratory for the city to work with local communities to temporarily test new ideas in the public realm. Materials and design interventions are meant to be temporary and easily reversible. Meanwhile, the trial run demonstrates the need for design changes. After testing their performance, some spaces are reclaimed permanently as public open spaces. Seating, landscaping and paving treatments are common features of all projects (see Fig.4~Fig.6).

Figure 4 - Museum of craft and design parklet, Luna Rienne art gallery parklet
(Source: <http://pavementtoparks.org/>)

Figure 5 - Ocean avenue parklet, Simple pleasures parklet
(Source: <http://pavementtoparks.org/>)

There are many evaluation studies on the impact of the parklets. The positive impacts to the neighbourhood and the local businesses have been proved. The SF Great Street Project (2010) analysed the public use and the entire block as well as how business owners think it has impacted their sales. Their research reveals that the trial parklet has already increased pedestrian activity in the study area, the satisfaction of pedestrians in the area and people's sense of community character. Some businesses on the block have welcomed the increased foot traffic. For example, the greatest increase in activity was seen on weekday evenings when pedestrian traffic rose 37% from an average of 363 to 497 people per hour. The average number of pedestrians during all observation periods increased 13%. (SF Great Street Project, 2010)

ODSLEA was a part of the program of Taipei's apply for the 2016 World Design Capital City. To test the Boulevard pedestrian environment improvement program, the project is sponsored by the Taipei Public Works Department and hosted by Classic Design and Planning. It was an activity held on September 15, 2013, 05: 00-21: 00. The Taipei City government closed the Xinsheng South Road (86 Lane to 98 Lane) to utilise the parking spaces into a range of activities (see Fig.7). The use of the west side of the road about 165 meters long, 5 meters wide; east about 150 meters long, 3 meters wide. This period of the street is unique because it is close to National Taiwan University and surrounded by dozens of distinctive bookstores, cafes, restaurants and Japanese monuments. There is a strong local cultural organisation called "Wen-Luo-Ding" which is an alliance constituted by the local bookstores participated in the ODSLEA.

922

There were a series of public participation and propaganda involved in ODSLEA. Classic Design and Planning had held numerous public hearings to listen to the local residents', communities' and businesses' opinions on the impacts of this program. The propaganda was made up of a design competition of the parklets, a microfilm competition, website (<http://tgbdesign.4pt.tw/>), social media, advertisement, etc. The purpose of the ODSLEA concept is to use a more flexible and creative community participatory approach to invite students of the surrounding schools, communities and citizens to participate in the ODSLEA. Through the activities of the streets, so that the public experience and see the pedestrian environment widened, the street space use and activities of the more creative possibility. (Results report from the Classic Design and Planning, 2013) The real intentions of ODSLEA are 1. Taipei City government to test the impact of the widened road. 2. As the part of the propaganda of 2016 World Design Capital City.

The core sectors of ODSLEA are: Taipei Public Works Department, Taipei Transportation Department, Taipei Planning Department (public sectors); Classic Design and Planning, local stores and bookstores (private sectors); community college, Wen-Lou-Ding (a region surrounded by Wenzhou Street, Roosevelt Road, Dingzhou Road, an area about one square kilometer, there are thirty to forty bookstores distributed within this region) (the third sectors). ODSLEA used a variety of 1:1 models (bike lane, picnic area, wooden pallets area, street library, etc.) to enable participants to experience these street facilities with human scale (see Fig.8~Fig.10). Besides that, the project even included the experiencing Military Kindred Village culture, disaster prevention, hand-made crafts teaching, orchestral performances, etc., which were beyond the scope of P2P. The streets were not just becoming the social places but the places of education, performance and propaganda of the event. ODSLEA is a one-day activity which is not long enough to measure its impact. There was no official evaluation of ODSLEA. But through the informal interview with the participants conducted by the Classic Design and Planning, most of them held a positive attitude towards this event.

5.2 THE COMPARISON BETWEEN P2P AND ODSLEA

Although these two programs are highly similar on the surface, for example, both of them utilise the curbside parking spaces into different purposes and hold a range of public participation. Both of them have a series of local businesses and NGOs involved and aim to enhance the public lives. But as for the core essences, they are kind of different (see Table 2). First of all, formality. P2P was initiated by the individuals and gradually transformed into the government-oriented program. It applies to one of the feature of TU: From informal to formal. On the other hand, ODSLEA was launched by the government, and it lacked the civil spirit. Second, duration. P2P was a one-day event (Park(ing) day) in 2006 and has become a permanent program now. In contrast, ODSLEA was intended to be a one-day activity in 2013, and the Taipei government had no aspiration to make it a long-term program. Third, the attitudes between these two government. SF government supports the development of P2P, it even publishes manuals to the public and formulates policy framework. On the contrary, ODSLEA was just a part of the activities of World Design Capital Taipei 2016. In other words, it's propaganda to show the progressiveness and the openness of Taipei City. The government official said Taipei City government has no plan currently to formalise it or promote this program. Lastly, the spirit of TU. P2P truly embodies the true spirit of TU based on the reasons above. Unfortunately, ODSLEA had only little things to do with TU even if this program was so similar to P2P on the surface. It lacked the long-term support from the government and the comprehensive understanding of the meaning of TU.

	Initiating organization	Formality	Duration
P2P	From individual-led to government-led	From informal to formal	Short-term to permanent
ODSLEA	Government cooperated with private sectors and third sectors	Formal	One day
	Involving municipal departments	Involving private sectors	Involving NGOs
P2P	<ol style="list-style-type: none"> San Francisco Planning Department San Francisco Public Works Department San Francisco Municipal Transportation Agency Mayor's Office 	Local Restaurants and Stores	<ol style="list-style-type: none"> Tunnel Top Park Steering Committee Union Square Business Improvement District San Francisco Beautiful etc.
ODSLEA	<ol style="list-style-type: none"> Taipei Planning Department Taipei Public Works Department Taipei Transportation Department 	<ol style="list-style-type: none"> Classic Design and Planning Local Stores and Bookstores 	<ol style="list-style-type: none"> Community College Wen-Lou-Ding etc.
	Public Participation	Government's attitude	TU spirit
P2P	Yes	Positive	Yes
ODSLEA	Yes	Positive on the surface, negative in essence	No

Table 2 - The Comparison Between P2P and ODSLEA

If we visualise the transformation of the P2P program in the scope compass, the Park(ing) program in 2005 and the Park(ing) Day program are short-term and instigated by the users but gradually converted into long-term and managed officially (see Fig. 11). On the other hand, the ODSLEA was a one-day activity and initiated by the government and held by the private sectors and thus no motion of the cross (see Fig. 12).

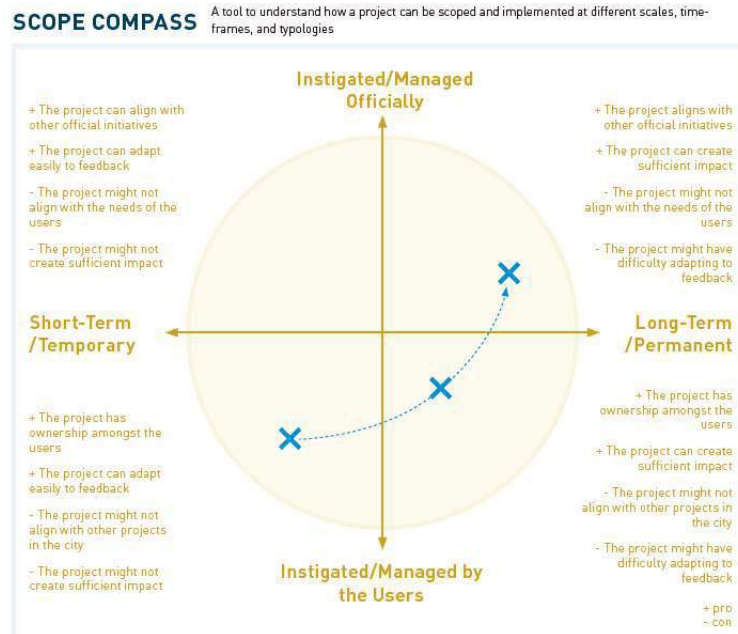

Figure 11 – The scope compass of P2P (Source: Planning By Doing)

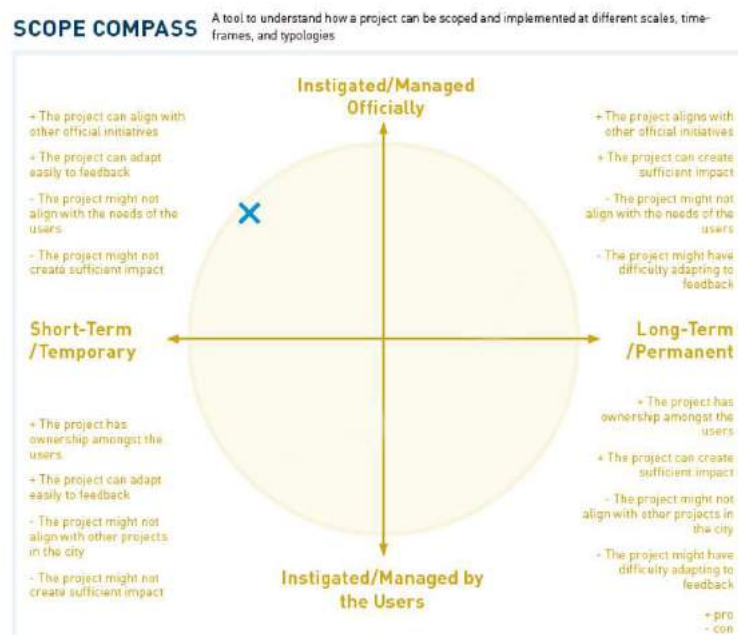

Figure 12 – The scope compass of ODSLEA (Source: Modified by the authors)

6 CONCLUSION

San Francisco's P2P movement from the citizen-led, informal, short-term evolves to the government-led, formal, long-term, which truly embodies the features of TU: low-cost, fast, low-tech actions to influence the government's decision-making process. Its influence is not only across the North America but also in the Central and South America, Europe and Asia. The P2P project has become an international city movements and attract more and more cities to engage in.

In Europe, there are also few projects of parklets, mainly concentrated in the UK, one in Sweden, one in France, one in Spain, so there is still much room for growth in the future. The European municipal governments, civic-groups, non-profits and individuals are supposed to make use of the unutilized public spaces into more appealing public realm to improve the life of the city.

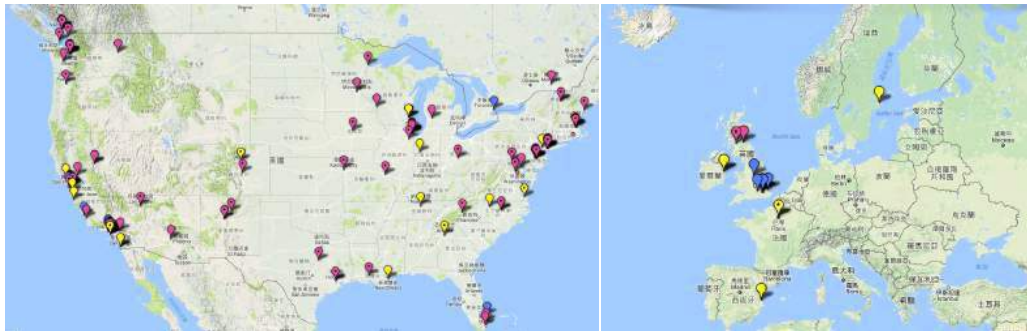

Figure 13 - The comparison between the parklet distribution in the U.S. and Europe
(Source: <http://pavementtoparks.org/>)

Although the P2P and the ODSLEA look so similar on the surface, they lead to entirely different results and influences. The P2P has been formalised and become a city feature and pride of San Francisco. This movement is still prosperous and improves every year. On the other hand, the ODSLEA was only a one-day event, and there are no subsequent plans to legalise and formalise it. The city government's attitude is crucial. The SF Municipal government is determined to offer the public more high-quality open spaces to enhance the public interest. It truly understands the meaning of TU and the benefit it brings. In contrast, the Taipei City government copied the form of the P2P in the ODSLEA but didn't understand the meaning and goals of the P2P and TU. The ODSLEA didn't have much influence on the government decision-making process and induced Taipei City government to offer more public space. To conclude, two similar TU movements with different intentions will result in totally different outcomes. Instead of imitating successful TU programs, the initiators should examine themselves if their programs meet the TU spirit and the local needs. That's the point.

1 INTRODUCTION

China has a vast territory in which the settlement areas, after more than 5,000 years of civilization development, have gradually evolved into the living environments with different characteristics, rich traditional oriental cultures and unique constructing methods and wisdom, showing their own styles in the history of city construction in the world. However, the rapid development of urbanization in China has posed a certain impact on the local traditional space, and the historical context and spatial features of many traditional settlement areas has been submerged in the tide of rapid urbanization. Under this background, it is somewhat unusual for Phoenix Ancient Town of Zhashui County located in the hinterland of Southern Shaanxi Qinling Mountains to retain the whole living environment of the traditional characteristics. Here the traditional street space is integrated with the surrounding landscape, which is a precious historical and cultural heritage, and implies the Chinese wisdom in the construction of the traditional living environment.

2 CHARACTERISTICS OF THE LANDSCAPE SPACE OF PHOENIX ANCIENT TOWN

Phoenix Ancient Town was originally built in the Tang Dynasty and flourished in the Ming and Qing Dynasties. Since the Tang Dynasty, it had experienced ten dynasties, including the Five Dynasties, Song, Liao, Jin, Yuan, Ming, Qing Dynasties and Republican Period, being more than 1,400 years old now. The Town started its development from Tang Wude 8th Year (A.D. 625) when the first batch of immigrants of 53 households from Wu and Chu states settled in the Town which was called "Sanchahekou" at that time. During the Ming and Qing Dynasties, the mule post road and shipping waterway were developed gradually, and the business began to boom here. Even in the Republican Period, the Town was an important commercial town. After that, the Ancient Town lost its former position and function due to the exhaustion of water transport and the improvement of highway transport, but its style and features, street spaces and ancient residential buildings have been preserved so far.

China has the cultural origin of advocating the natural environment from ancient times. And Confucius said: "The wise enjoy the waters, the benevolent enjoy the mountains." As affected by this thought, the construction concept of the traditional Chinese town advocates the integration with the natural

environment, and together with the limited ability to transform the nature, the construction of many towns shows a great dependence on the natural environment and is gradually integrated into the natural landscape along with the development and succession of the space. Phoenix Ancient Town is exactly an example which is constructed with dependence on the landscape.

Today, Phoenix Ancient Town of Zhashui County is located north of Daliang Mountain and south of Duchuan River. The Town is surrounded by mountains on three sides, forming a semi-closed plain. Duchuan River flows from west to east, the plain surrounded by the landscape features fertile soil and abundant water sources, Zhaohe River comes to a T-shaped intersection with Duchuan River on the north, which gives a picture of the gurgling streams, the green mountains and rivers silhouetted against each other, and the green gardens extending to the sidehill. In the view of Chinese traditional geomantic omen, the Town is a place where the mountains and rivers gather together to constitute a good geomantic omen, and also is a good place to live and work in peace and contentment.

3 WISDOM OF THE ECOLOGICAL CHOICE OF PHOENIX ANCIENT TOWN

As early as the Spring and Autumn period, the legalist school Guan Zhong made a wonderful exposition of the town location. As written in his works "Guanzi - Chengma", "A national capital must be built on the highland rather than under the mountains, and the plenty of water is available when living a highland away from mountains and there is no worry about the embankment work when living in a lowland away from rivers." In addition, "Guanzi - Dudi" also talked about, "The capital that is selected by a sage must be a unassailable place where there are fertile lands, mountains, rivers and lakes nearby." The location of Phoenix Town gives a full presentation of the concept mentioned above. The Town stays in front of Daliang Mountains, faces towards Duchuan River, and is connected with Phoenix Mountains across the river.

3.1 EVALUATION OF THE ECOLOGICAL SUITABILITY OF THE SITE

In order to explore the ancient's wisdom in selection of the site, ArcGIS system is used in this paper to analyze the topographical features of the Town site. And the terrain elevation, terrain slope and flood inundation line are selected as the factors to evaluate the ecological suitability (Figure 1).

Figure 1 - Ecological suitability evaluation chart
(Source: Author self painting)

Ecological suitability level	The most suitable area	More suitable area	Not suitable area	Prohibited area
Indicator range	1~1.8	1.81~2.6	2.61~3.4	3.41~5

Table 1 - Ecological suitability evaluation results

As indicated by the evaluation results (Table 1), the Town is surrounded by mountains and rivers, and the area suitable for construction is limited; within the range of 2.5 km around, the current site of the Town is the preferred area suitable for construction and can provide the spatial carrier required for further development. It is proved that ancient Chinese can, without the support of advanced technology conditions, select the construction site of a town by virtue of their unique historical construction experience, and the scientific and rationality in the site selection is not second to the judgment based on modern engineering technology.

3.2 SUMMARY ON WISDOM OF THE SITE SELECTION OF THE TOWN

The social productivity is very low in ancient times, the human survival condition is limited to local landscape and material conditions, and the people "live from what the land can provide" and fully benefit from the natural environment. As a result, the selection of the construction site always embodies the idea of advocating the nature, making a clever use of the natural landscape pattern.

The mountains surrounding the Town can, to a certain extent, reduce the monsoon and guarantee a good climate. The rivers nearby provide the necessary conditions for agricultural production, and the

convenient shipping waterway lays a foundation for the development and prosperity of business. At the same time, a certain distance is kept between the Town and the rivers to prevent flooding, and the higher terrain in the south than the north is conducive to drain water to the rivers in the north. The town site is exactly located at the "convex bank"(Figure 2), which refers to the inner ring zone of the river turn. Due to the physical inertia and centripetal force of water flow at the convex bank, the river water will flow slowly, the water level will drop, and the sediment in the river water is prone to settle here and causes the increase of the convex area and the land available, which proves the ancient's wisdom in the selection of the construction site.

Figure 2 - Location diagram
(Source: Author self painting)

As reflected in the site selection experience on the living environment of Phoenix Ancient Town, the ancient Chinese made a careful investigation of the surrounding landscape pattern at the beginning of construction of a town, exploring the link between the town and the natural environment. For example, Phoenix Ancient Town stays in front of Daliang Mountain and faces towards Duchuan River, the residential houses are constructed on the beach at the convex side of the river, and the surrounding mountains reduce the monsoon power in winter and summer and improves the microclimate here. At the same time, the rivers create good conditions for agricultural irrigation and water transport, and the fertile land on the bank side creates the basic conditions for agricultural farming. The site selection of ancients of great wisdom creates favorable conditions for the subsequent development of the Town. Except the influence of human factors such as war, the Town has never suffered any large-scale flood or other disasters, and to this day, the people still lives and breeds here.

4 WISDOM OF THE SPATIAL LAYOUT OF PHOENIX ANCIENT TOWN

The overall layout of the Town is a strip shape, the main axis of space is the historical street running from east to west, and the residential houses are winding on both sides. The traditional residential houses are characterized by front shop and rear house, in which the room facing towards the main street serves as the business facade, and the inside of the courtyard serves as the living space. On both sides of the main street, there are several north-south alleys leading to the house inside, and main streets and alleys constitute the transportation network of the Town.

4.1 ANALYSIS OF SPATIAL SYNTAX OF THE TOWN

Spatial syntax is a kind of theory and method used for quantitative analysis of the space, and the integration analysis can give a good expression of the relative accessibility of some nodes and areas. In order to probe into the spatial structure characteristics of the Town, UCL Depthmap software is used in this paper to analyze the whole integration of the space of Phoenix Ancient Town, and the result is shown below (Figure 3).

As indicated by the analysis results of the whole integration, the Town obviously features the single center structure. Main streets extends from east to west and runs through the whole town, and several south-north alleys go deep into the houses inside. The center area is of the best accessibility, and also is the area which witnesses the commercial prosperity with a number of shops in the history of the Town. Historically speaking, the Town just starts its history here and then grows into the scale today. The town center and the southern Dalian Mountain and the northern Phoenix Mountain stay in the same axis from south to north, and the concentrated construction area is located in the central position of the two mountain peaks, which reflects the “moderate thinking” (Figure 4) in the Chinese traditional culture. The east-west street serves as the main internal axis, and the residential courtyards are arranged on both sides in neat order. The layout of the ancient street is preserved today, and then the residential houses are built around, achieving ancient and modern compatibility. The ancient street, as the main development axis of the Town, is coupled with the surrounding mountains and rivers (Figure 5), and the rationally curved street in line with the trend of the surrounding landscape guarantees the accessibility, and also is full of fun thanks to its appropriate change.

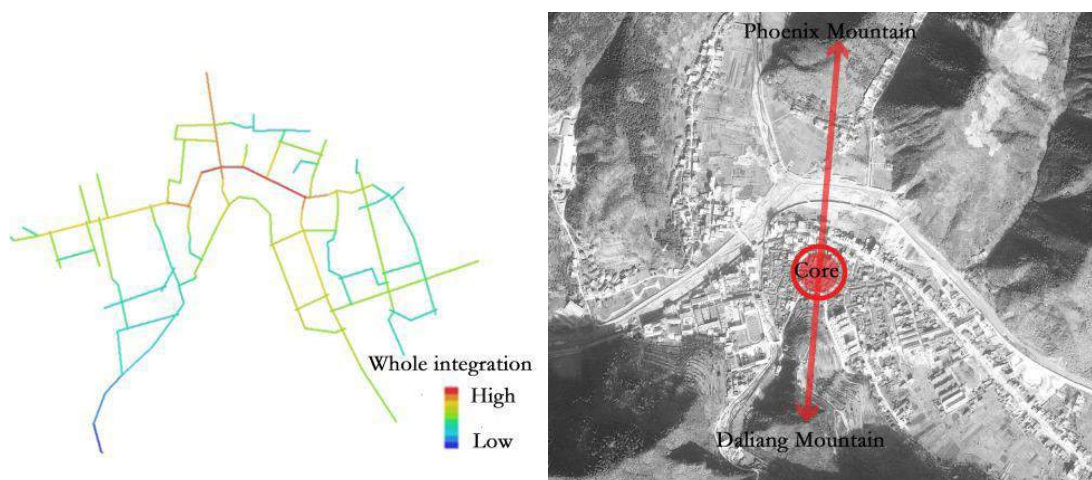

Figure 3 - Whole integration analysis | Figure 4 - Landscape axis relationship diagram
(Source: Author self painting)

Figure 5 - Analysis of street trends | Figure 6 - Building orientation analysis
(Source: Author self painting)

4.2 SUMMARY ON WISDOM OF THE SPATIAL LAYOUT OF THE TOWN

Influenced by the neo-confucianism thought, the space of Chinese ancient towns has a strong sense of order. Whether it is a large palace, a city, a small temple or a street, there is a definite axis relationship everywhere. At the same time, the mountains and rivers are linked organically with the axes of heaven and earth, and the mountain peaks are taken as the key factor in the construction of an urban space. "Axis of heaven and earth" and "centering and preserving" are the two basic cultural characteristics of Chinese ancient settlements, which gives rise to the axis relationship of ancient settlement spaces. In addition, the Chinese traditional thought attaches great importance to the ingenious arrangement of artificial construction in the natural order in line with the laws of nature, achieving the ideological realm of "harmony between man and nature".

The center of Phoenix Ancient Town is located in the center zone between southern Phoenix Mountain and northern Duchuan River, and forms an "imaginary axis" from south to north, which fully embodies the ancient traditional thought of order and centering thoughts. The east-west axis of the Town is coupled with the surrounding landscape layout, which complies with the trend of the mountains and rivers, and the residential building orientation is of the centripetal layout perpendicular to main street (Figure 3), which, on one hand, renders the leading position of the central ancient street, and on the other hand, creates the orderly plane form and integrates the space of the Town with the natural landscape, reflecting the Chinese traditional idea of "harmony between man and nature".

5 INSPIRATION AND INHERITANCE OF THE RESIDENTIAL WISDOM OF PHOENIX ANCIENT TOWN

The construction of the today urban living environment should draw lessons from the ancient living wisdom, keep harmony with the modern construction, carry on the historical and cultural context while guaranteeing the economic development, and avoid the elimination of the historical and cultural characteristics due to the neglect of the historical construction experience. The development of Phoenix Ancient Town can stand the test of time only by way of maintaining the historical characteristics of human settlements and inheriting the historical context.

5.1 INHERITANCE OF THE LANDSCAPE PATTERN

The main purpose of inheriting the landscape pattern of the historical towns is to keep harmony between the nature and manpower, emphasizing the integration with the natural landscape pattern. It is the primary living wisdom to be inherited by the construction of the today towns to integrate the construction of the ancient towns with the natural environment. The ancients make a reasonable selection of the urban construction site based on the overall landscape space environment, and the site selection is not only

consistent with the Chinese traditional concept of geomantic omen, but also is consistent with the actual urban construction requirements, which should be affirmed and inherited. With reference to the experience and wisdom of the ancient site selection, the construction and development of ancient towns should fully take into account the order relationship with the surrounding environment of the order, maintain the Chinese traditional "centering" thought, and pay attention to the overall pattern in which the urban construction keeps harmony with the surrounding landscape environment.

5.2 COMPLIANCE WITH THE NATURE PATTERN

Compliance with the natural pattern is an important principle for the spatial development of Phoenix Ancient Town. The street trend and building layout of the ancient towns should be integrated with the pattern characteristics of the natural environment, so that the artificial construction can keep harmony with the natural environment. For the construction of the ancient towns, the selection of the street space scale should refer to the scale characteristics of the historical ancient houses and streets, because the historical space is full of the ancient residential environment construction wisdom, is the precious wealth left in the history, and is in line with the space characteristics of the daily life. Furthermore, under the premise of ensuring the inheritance of the overall landscape pattern, attention should be paid to maintaining the relationship between the building and the streets and the nature, as well as the visual connection between main buildings within the town, the reasonable combination pattern of the architectural scale and space should be adopted so as to comply with the growth and development of the natural pattern. Under the background of the new times, the volume and height of new buildings around should also be harmonized with the style of the town, so as to avoid the destruction of the characteristics of the town space.

5.3 HIGHLIGHT OF REGIONAL CULTURE

The "location with mountains and rivers" is the spatial characteristic of Phoenix Ancient Town. The construction and development of the town should make full use of its own natural characteristics and historical and cultural relics, and continue and highlight its regional cultural characteristics. On one hand, it is necessary to improve and beautify the surrounding landscape environment and recondition the waterfront shoreline. On the other hand, it is necessary to meet the needs of the times, make a rational use of the historical and cultural heritage resources to develop the tourism industry, and embed the appropriate new tourism space, such as waterfront leisure business streets, ecological recuperation center, etc. The tourism industry can drive the protection and the development of Phoenix Ancient Town, and also can provide a broader cultural display platform to let more people understand the Town and experience the spatial characteristics of the Chinese traditional residential environment.

6 CONCLUSION

Phoenix Ancient Town that is constructed according to the natural landscape gives a full play to the Chinese traditional residential environment wisdom "living with mountains and rivers", and the historical spatial pattern pays attention to the integrity and order and inherits the historical context, which is an important carrier of the Chinese traditional culture. In this paper, the qualitative and quantitative method is used to analyze and summarize the residential environment construction wisdom of Phoenix Ancient Town, and the development strategy and suggestions are proposed for the inheritance of the landscape pattern, the compliance with the natural pattern, the highlight of the regional culture of the town, which can provide reference for the development and construction of the ancient towns in other regions. As a matter of fact, the general villages and small towns should also learn from the experience and wisdom of the construction of the Chinese traditional human settlements, and extract and highlight the regional characteristic culture, so as to avoid the situation of "the similarity of 1,000 villages and towns".

1 INTRODUCTION

The urban primary school travel in China is the necessary life behavior in the family daily life. For the adjustment of the urban population structure and the diversification of the transport means, as well as the unbalance public education resources and the school choice behavior, there are large spatial-temporal differences among the families school travel modes, all of the factors above cause the unsuitability of the urban primary school layout method which is only dependent on the service radius and the thousand people index. Combining the travel behavior with the layout of the urban primary school is one of the leading directions to improve the urban primary school planning (Zhang, 2014). Xi'an is the dominant city in the northwest area in China. The types of the urban primary school in Xi'an is multiple, and the city also concentrates more excellent educational resources and students enrollment. The paradox between the pupil number and the land area, and the spatial-temporal accessibility of the school travel issues become more fierce. This paper takes Xi'an as the example and analyzes the school travel constraint mechanism based on the summarization of the urban primary school travel characteristics, as well as doing the basic job for the future study which is to optimize the urban primary school layout from the perspective of the urban land and transportation integration.

2 RESEARCH METHOD AND DATA SOURCE

2.1 RESEARCH BOUNDARY AND THE SUBJECT SELECTION

School travel means school commuting of the pupil. The primary school travel includes 2 layers: the first layer is the school travel mode (which includes the go to school alone and picked up by others); the second layer is the school travel characteristics (which includes the travel subject, mode, time and distance). By comprehensively considering the conditions of the urban primary schools (establishment time, school scale, education quality etc.) in Xi'an and the city build environment, and this paper chooses 2 primary schools respectively from the 6 main administration districts between different areas within the Third Ring road in Xi'an. 6 in total, as the sample, which are Houzaimen primary school (A), Primary school attached to Xi'an Normal university (B), Primary school attached to the Xi'an Architectural & Science university (C), Cuihua Road primary school (D), Qujiang No.1 primary school (E), and South lake primary school (F) (table 1).

Table 1 - Basic characteristics of the sample primary schools

2.2 RESEARCH METHOD AND DATA

This paper takes the time geography as the theoretical base, the activity diary surveys of the school travel behavior and the families in-depth interview as the data base, and summarizes the family daily activity path; this research explains the constraint factors that affect the school travel behavior and proposes initial thought of the planning layout. The research group did surveys about the 6 sample primary schools within Oct. to Dec. 2013 and Mar. to Apr. 2016. The researchers observed and recorded the data of the 6 primary school commuting travel modes at the reasonable layout points of the school gates, as well as distributing the survey questionnaire about the family activity journal at each school based on the ratio of the 5-10% of the students numbers, the questionnaire content involves the family attribute, the travel mode of the pick-up subject, the travel satisfaction and the daily life record. 504 copies of questionnaires were recovered. Based on the questionnaire, this research did in-depth interview with 5-10 families for each school, and asked about the various activities within the daily life, behavioral habit and the family satisfaction in details.

3 SPATIAL-TEMPORAL CHARACTERISTICS OF THE URBAN PRIMARY SCHOOL TRAVEL IN XI'AN

The spatial-temporal characteristics of the urban primary school commuting travel include the travel subject, distance, time, mode and frequency.

3.1 TRAVEL SUBJECT: THE PARENTS AND GRANDPARENT'S PICK-UP SCHOOL COMMUTING, THE RADIO OF WORKING PARENTS OCCUPY LESS THAN 50%.

The urban primary school commuting travel subject is composed of the primary students and the pick-up parents. The proportion of the primary students travel alone is low, mostly are based on the parents pick-up. In term of the nature property of the pick-up parents, the mother occupy the leading position, meanwhile, nearly half of them are full time mother (or freelancer); secondary is the grandparents, then the father, others are the baby sitter or relatives. From the perspective of working nature, the pick-up subject is based on the non-working parents; the working parents only occupy a proportion of less than 40%. Among the working parents, the proportion of the female working parent is higher than the working male parent. The spatial-temporal characteristics of the primary school pick-up travel mode has large constraints to the working parents, especially to the working female parent (table 2).

Primary school		A	B	C	D	E	F	Total and total proportion
Pick-up parents	Full time mother(freelancer)	7/15%	2/2%	17/17.9%	12/11.4%	37/20.5%	5/9%	80/15.6%
	Working mother	10/10%	21/20%	50/51.6%	27/26.7%	31/17.0%	7/12%	126/21.4%
	Working father	12/21%	6/6%	19/20%	17/16.2%	27/14.8%	12/21%	95/16.8%
	Full time father(freelancer)	0/0%	3/3%	2/2.1%	4/3.8%	6/3.3%	0/0%	15/2.6%
	Grandfather	9/16%	37/40%	19/20%	20/19.1%	36/19.8%	16/28%	137/25.2%
	Grandmother	18/32%	25/26%	9/10%	26/25.8%	38/20.9%	16/26%	127/21.6%

Table 2: The travel characteristics of the primary school families in Xi'an city

3.2 TRAVEL DISTANCE: THE DISTANCE IS ENLARGING, BUT STILL HAS THE CHARACTERISTIC OF THE SPACE AGGREGATION

1) the travel distance for 27.6% families is within 0.8 kilometer, which reflects the special service enlargement trends of the primary school in Xi'an city. 2) about 73% families are distributed within 2.5 kilometers travel distance from the school, which suggests the families' strong demand to near the primary school space proximity. 3) while the family numbers within 2.5-3.5 kilometers start to decrease obviously, the constraint of the special and time distance is increased for the family travel. 4) 16.9% family travel distance is beyond 2.5 kilometers, which reflects the primary schools with fine teaching quality still have attraction for some families.

3.3 TRAVEL TIME: THE IDEAL UNIT TRAVEL TIME IS 15 TO 20 MINUTES, THERE IS CERTAIN SPACE AND TIME STABILITY

In terms of the family satisfaction survey results, no matter which travel mode is chosen, the ideal unit travel time for the family is 15 to 20 minutes, and the maximum tolerable travel time is 30 minutes.

There is a very large travel time difference among different means of transportation (table 3), the travel time for walk, electro-mobile(or bicycle) and private car is about 30 minutes; while, the average travel time for the bus is about 31 minutes, which is longest among all the travel modes. The travel mode of the electro-mobile (bicycle) is the point to point mode and the travel efficiency is relative high.

Primary school		A	B	C	D	E	F	The average cost
Means of transport								
Travel time	Private car (Sample size/minute)	14/26	9/19	19/18	14/21	54/17	16/15	106/18
	Bus (Sample size/minute)	12/33	19/56	16/26	15/24	9/56	5/27	72/51.4
	Non-motor vehicle (Sample size/minute)	10/15	15/15	24/16	11/10	10/10	4/12	74/16
	Walk (Sample size/minute)	14/11	60/21	36/11	40/11	74/15	26/15	209/14

Table 3: Average Time for Different Ways of Travel

3.4 TRAVEL MODE: BASED ON WALK AND PRIVATE CAR, THE BUS TRAVEL RATIO IS LOW

Among all the travel mode (in table 2), 1) Walk is still the main ways of travel, following is the private car and the non-motor vehicle; 2) the proportion of the motor vehicle is one third, but the travel is based on the private car, the proportion of the bus is very low; 3) the coverage of the school bus is very low, and the cost is high and paid by the families, therefore, only a few families choose the school bus. 4) Among the non-motor vehicles, the proportion of the electro-mobile is high because of its speed, flexibility and less time cost, while the travel proportion of the bicycle is low, etc.

3.5 TRAVEL FREQUENCY: TENDS TO 2 TIMES PER DAY, THE NOON PICK-UP CONSTRICTS TO A LARGE EXTENT FOR THE WORKING PARENTS

Among the 6 surveyed schools, 4 of them have lunch and noon break at school. The parents who choose not to pick-up the child occupy a large proportion (table 2). Most of the travel frequency for the primary school students is 2 times per day, which is going out at early morning and coming back at dusk. Interview shows that there is strong noon boarding appeal from the parents.

4 THE ACTIVITY PATH ANALYSIS AND BEHAVIORAL MODE OF THE SCHOOL COMMUTING TRAVEL

This research summarizes the activity path of the family school travel and finds there is certain regularity.

This paper classifies the family samples from the aspects of the pick-up parents(people), house-school-job spatical-temporal distance (space) and pick-up frequency(time), and gets 30 types of family school travel paths and 4 space-behavior patterns(figure 2).

The pick-up parents can be classified into 5 types, which are :full time parents (N-no job) , 2 working parents (F-full time job) , one of the 2 working parents has free working time (P-part time job) , 2 working parents +grandparents (G-grandparents) and 2 working parents +afterclass or education institutions (E-education) .

The space distance can be classified into 5 types, which are: job-school-house proximity, school-house proximity, school-job proximity, job-house proximity and the job-school-house is separation. The time can be mainly classified into 2 types, which are the not pick-up at noon and pick-up at noon according to the travel frequency.

It is needed explaining that the space and time path reflection is the school commuting situation of the one child family. In addition, according to the survey results, most of the pupils attend the after school interest class within the weekdays and on the weekends. The travel situation of the primary school students' interest class within the weekdays is included in Figure 2.

According to the time and spatial-temporal constraint , the school travel path can be classified as the following 4 types.(figure 2)

Mode 1—the time and space constraint extent are small, the ideal status

Mode2—there is time or space constraint, the most of the situation

Mode 3—there are both time and space constraint, extreme status

Mode 4—there are both large time and space constraint , no stable status

5 THE SPATIAL AND TEMPORAL CONSTRAINTS ANALYSIS OF THE SCHOOL COMMUTING TRAVEL

The core method of the time geography is to explain the human activities by 3 constraints, which are capability constraints, coupling constraints and authority constraints(Hagerstrand,1970).

5.1 CAPABILITY CONSTRAINTS

As the primary school students of the travel subjects, the capability constraints mainly derive from the physiology constraints and safety constraints.

5.1.1 PHYSIOLOGY CONSTRAINTS—THE TRAVEL DISTANCE IS SHORT AND THE SPEED IS SLOW

The walk speed differs with age. For the young, the walk speed can reach to 60-70 meters per minute, and the fatigue interval is 30 minutes; the walk speed of the aged and the child is 40-50 meters per minutes, and the fatigue interval is 20 minutes. In terms of physiology characteristics, the walk speed of the primary school student is slow, the fatigue interval is short and the travel distance is also relatively short [4].

5.1.2 SAFETY CONSTRAINTS—HIGH SAFETY REQUIREMENT, ACCOMPANY IS NEEDED

The school travel behavior has high safety requirement. The self-safety behavior awareness of the primary students is weak, the walk process of the primary students is often accompanied by running, jumping and playing, and they lack the pre-determination ability about the potential dangerous accident within the space, and there is certain safety problem.in addition, there are also some hurt accidents with extreme bad nature in the society. Therefore, the primary students commute to and from the school is certain accompanied by the parents, this has become the popular social phenomenon(Wang,2015).

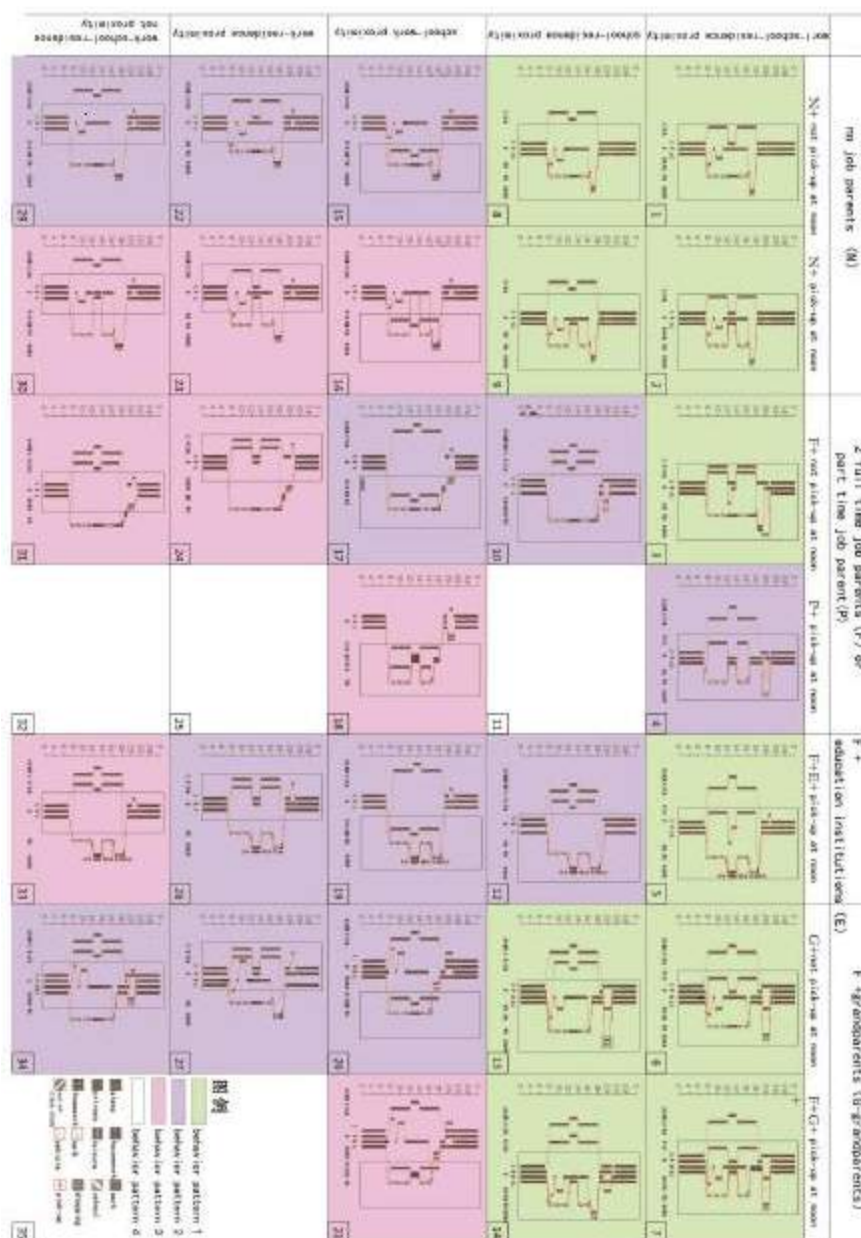

Figure 2 - 30 types of family school commuting travel paths and 4 space-behavior patterns

5.2 COUPLING CONSTRAINTS

Since the primary students commute to and from the school is accompanied by the parents, the parents naturally become the main decision makers about the school commuting travel. The pick-up time of the primary school and the distance between the school and home are the 2 most important influence factor of the school commuting travel.

5.2.1 THE PICK-UP TIME AND FREQUENCY HAVE OBVIOUS INFLUENCE ON THE CAREGIVER, ESPECIALLY FOR THE WORKING PARENTS

There are two factors that constraint the primary school family pick-up subject---time and space. The pick-up time of the urban primary school has the strongest time and space constraint for the working parents, and is the main factor for family to determine the pick-up subject.

If there is conflict between the primary school pick-up time and the working time of parents, it will constraint the pick-up behavior of the working parents; in this case, the pick-up subject is usually substituted, and the grandparents or the relatives will take the pick-up task. Besides, if the school provide the after school class or long-hour class, the pick-up demand of the working parents after work will be satisfied. The urban primary school teaching time management and space capacity support can ease the pick-up time constraint on the parents. For example long-hour class and the interest class after school in the primary school attached to the Xi'an Architectural & Science University make the working parent to pick-up possible, and the pick-up proportion of the working parents is high.

5.2.2 THE TRAVEL DISTANCE, CONSTRAINT WITH THE PICKER AND THE TRAVEL MODE , AND PRESENT CERTAIN TIME AND SPACE STABILITY

The family role, social and economic property of different pick-up parent will influence their pick-up travel modes. With the increasing of the travel distance, the constraint extent on the pick-up parents is also strengthened. The travel distance, pick-up subject and the travel mode also present certain regularity. The increased number of the aged have obvious negative influence on their travel time and space distance. The older the grandparents, the shorter the time and space distance. According to the survey date (table 6), the pick-up subject and the school commuting travel time and space distance present certain regularity: when the pick-up distance is within 800 meters, the proportion of the grandparents is highest; when the pick-up distance is 800--1500 meters, the grandfather and the mother are the pick-up subject; the pick-up distance exceeds 2500 meters, the pick-up proportions of the full time mother and working father increase obviously. The farer the travel time and space distance, the stronger constraint on the aged, and the pick-up proportion of the working father and full time mother increase greatly.

Space distance(m)	Pick-up subject proportion(the first 2)	Travel mode
≤800	grandfather<grandmother	Electro mobile(bicycle) <walk
80-150	Working mother<grandfather	Private car< Electro mobile(bicycle) <walk
1500-2500	grandfather<working mother	bus<private car<walk< Electro mobile
2500-3000	Working mother <working father	bus< Electro mobile <private
≥3500	Working father<full time mother	Electro mobile <bus<private car

Table 4: The Relation between Travel Distance, Caregivers and Travel Mode

5.2.3 THE HOUSE, SCHOOL AND WORK SPACE RELATIONS AFFECT THE SCHOOL TRAVEL MODES

The space constraint is embodied when the “house, school and job” distance is within the walk reachable range (as in figure 2 01~07), the constraint on the parents is least; when the “residence, school and work” distance is separated, the constraint on the parents is strongest (as in figure 2 029~035) . When the “residence, school and work” distance is in proximity, the pick-up behavior can be completed during the “family--work” travel process. As there is time constraint, the space link mode has great influence on the working parents, and the family travel cost will increased. According to the survey data, 39.2% of the families rent or borrow houses nearby the primary school, the “proximity enrollment” appeal is high.

5.3 AUTHORITY CONSTRAINTS

According to the regulation of the new Compulsory Education Law, the immediate school enrollment policy is implemented during the compulsory education period, the school is not allowed to choose the students beyond the school district, and the student is also forbidden to choose the school freely. In the actual practice the immediate school enrollment policy is implemented by the people (registered permanent residence)and the location(residence) related enrollment regime, the policy shall cover the immediate school enrollment according to the registered permanent residence as well as to the actual residence. The school district regime has been gradually implemented since 1996, which linked the education supplies with the “Hukou”. The unbalance in excellent education resource and the school district regime increase the threshold of the families’ school choice. There are differences in the space scales among districts in

Xi'an and the numbers of the primary school, the division of the school district range also has great differences and randomness(table 2), the family school travel which is within the school district range only occupies a small proportion.

6 CONCLUSION AND DISCUSSION

The family school travel mode is not only the subjective choice of the family, but also the result of the spatial constraint. It is found that the school travel still owns the characteristics of parents accompany, increased distance, space and time stability, motorization and multi-frequency by surveying the build-up area urban primary school space and time travel in Xi'an. The space and time can better reflect the reasonable space distribution of the urban primary school families. This paper summarizes more than 30 kinds of school travel paths by the constraint description method, 4 kinds of space behavioral modes can be classified based on the time and space constraint. Family school travel is the choice result under the individual, family, society and urban construction environment constraints. From the perspective of school travel, These aspects are necessary for the primary school layout to follow, and there are : the urban primary school extend needs the life care place; the formed community life unit taking the urban primary school as the core will facilitate the struction of the community; organize the urban primary school and the surrounding space layout from the perspective of satisfying the family travel demands. Based on the analysis of the school travel behavior, urban primary school layout from the perspective of integration of land use and transportation, can reduce the constraintans for family travel, improve the quality of life.

ID 1538 | WHEN TRADITIONAL AND CREATIVE INDUSTRIES BLEND: A CASE-BASED DISCUSSION OF THE IMPLICATIONS FOR URBAN DESIGN

Marijn van de Weijer¹

¹Universiteit Hasselt

marijn.vandeweijer@uhasselt.be

1 INTRODUCTION

As economic interests in an urban society develop, functionally determined zones of production become zones of transition and pose challenges to urban design as an instrument for organizing competing or contradictive spatial interests. This contribution centres on such a zone of transition, an industrial site in the Belgian city of Hasselt which is progressively enveloped by urban development. Interestingly, this area is part of a larger industrial area along the quays of the Albert Canal. This canal was developed in the 1930s to connect the Campine coal basins , the maritime port of Antwerp and the steel basin in Liège to one another (Van Acker, 2014). The Hasselt Canal Zone thus exists on the interstice between two very distinct systems: the radial-concentric pattern of the (medieval) city, characterized by two concentric ring roads; and the linear development of the Albert Canal, a national backbone for industrial and commercial development. Due to their subsequent development and saturation, these distinct systems increasingly influence each other here. Hence, the Hasselt Canal Zone demonstrates a gradual transition which includes the introduction of new programmes, creating a public and urban élan on the south bank of the Canal. This process has started in 1997, when the Muziekodroom, a local non-profit organization for

musical education, band practice and concerts, settled in a partly abandoned slaughterhouse. In the ensuing 20 years, other new users have followed by appropriating obsoleted industrial infrastructure: two shared office buildings, a college of advanced education in pop and rock music, a dance club, a repair service for electronics, and catering businesses. In branding the core zone of transition with the name Quartier Canal, this new generation of occupants manifestly propagate a cooperative and synergetic agenda. New occupants also coexist with traditional Small to Medium-sized Enterprises (SMEs), mainly light industries, building merchants and traders, which have not left the site, some still depending on the Albert Canal for transportation of building materials and petroleum products. Their interests are advocated by several public entities involved in maintenance and exploitation of the Flemish waterways, and entrepreneurship along its shores. As a consequence, very diverse spatial claims and expectations come together.

In what follows, I analyse this fragile equilibrium cultivated by diverse actors mediating between maintenance of the hybrid character and transition towards a more urban condition. The gradual, incomplete transition resulting from bottom-up initiatives, and the claims laid on the area by representatives of both industrial and creative economies render this a suitable case to expand on existing literature about urban regeneration and the role of both old and new economic pillars herein. Hence, it responds to a challenge of urban redevelopment raised by Madanipour centred on determining the performance of innovative clusters, and their part in “the wider urban society and economy” (2014, p.125). Projecting this challenge to this specific case study, it aims to establish in how far Quartier Canal is “embedded as an integral part of the local economy, establishing mutual linkages rather than hierarchical and disconnected relations” (Madanipour, 2014, p.125). It questions in what manner urban design actually manifests itself with regard to this fragile balance, and faces socio-spatial resistance.

1.1 METHODOLOGY AND STRUCTURE

The settlement of the Muziekodroom is the starting point of what in this contribution is considered as the period of transition for the Hasselt Canal Zone. This departure opens up a history of 20 years of endeavours to guide and propel transition – or to obstruct this, depending on the perspective taken. The focus of this paper is the south bank. Here lies an estate defined spatially by the figures of the Albert Canal, with a sluice to the east of the area, a bridge to the west, and the outer ring road of the city of Hasselt (figure 1). It is historically known by the name Trichterheide. Planning and design processes dating back to the completion of the Albert Canal in 1940 are included, because they explain the genesis of the urban framework at the basis of later transitions. This paper is hence primarily based upon a discursive analysis of planning documents and design proposals. Data was retrieved from the city archive of Hasselt, archives of involved planning and design firms, and from online repositories.

In addition, involved stakeholders were invited (by means of snowball sampling) to shed light on the recent history of Quartier Canal and to express their perception of planning and performance of the area. Respondents include traditional and new users of the analysed zone of transformation, as well as involved architects, urban designers and planners. With regard to the occupants, the balance of this sample is tilting towards involved representatives of the more recent creative enterprises: it proved difficult to involve the more traditional users of the industrial estate. Users were asked to explain the history of their presence in the area, as well as to articulate their evaluation of the performance of the area in terms of density, mobility, and functionality. Furthermore, they were asked to phrase their evaluation of implemented planning concepts and processes. Involved built environment experts and civil servants equally phrased their insight in developmental processes past and present.

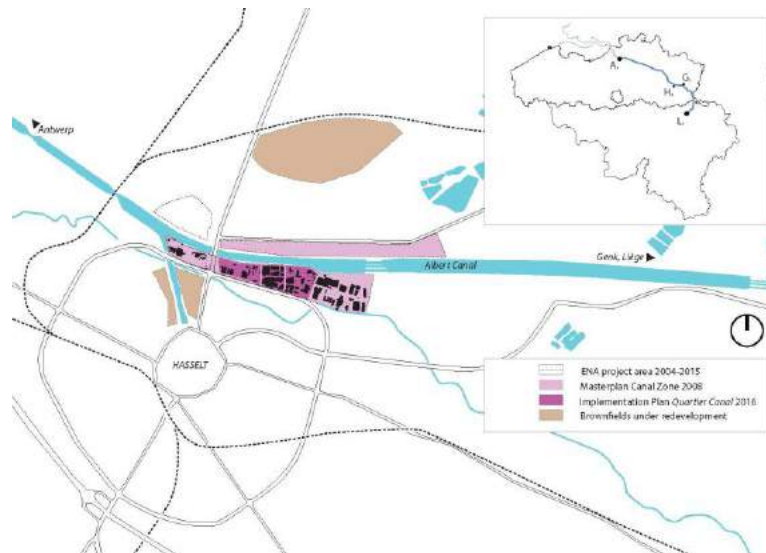

Figure 1 – The Canal Zone of Hasselt: linear and concentric figures intertwine

Hence, design arguments as well as economic and political decision making are interrelated. First, the main body of this paper synthesizes relevant economic circumstances and theoretical concepts to lay the foundation of this analysis. Secondly, the dynamics of using, planning and interpreting Quartier Canal, and by extension the urbanized area along the Albert Canal (figure 1) within the borders of the Hasselt-Genk conurbation, are discussed chronologically. The discussion extrapolates the local findings to the level of theory of urban design and redevelopment.

2 FROM TRADITIONAL TO CREATIVE INDUSTRY

This case study cannot be understood without framing the process of de- and reindustrialization of the province of Limburg, in which Hasselt is situated. Between 1966 and 1992, the seven coal mines, which had formed the provincial economic foundation in the 20th century, were gradually closed. Today, the province still has less economic resilience than the other Flemish provinces. Economic malaise has been battled by investing European subsidies in endeavours to increase labour participation, better education and economic diversification. two consecutive programmes for socio-economic restructuring were implemented, the first one between 1989-93 and the second one between 1994-98, partly funded from ESF and EFRD subsidies. Baeten et al. (1999) critically assessed the implementation of the second plan, which was characterized by fragmentation.

The Spatial Structure Plan Flanders (department RWO, 1997) selected the Albert Canal as an economic network (with the acronym ENA), which initiated a developmental trajectory to increase the economic significance of the Canal (figure 2). In 2004, the Flemish government effectively started to implement a 10-year plan for increasing industrial and transport activities along the Albert Canal (Flemish Government, 2004; Flemish Government, 2015; iris consulting et al., 2004). A “Limburg Plan” followed for the years 2006-09, which built on these ENA initiatives (Flemish Government, 2005). In addition, it emphasized strategic investments in other sectors to diversify the economic profile of the province of Limburg, stressing the opportunities of the creative economy. At that time, creative economies effectively sought and found a foothold in the Hasselt Canal Zone. Equally, prioritized investment in higher education directly affected this area. Responding to a new industrial crisis of the closure the ford Motor Company production plant in the neighbouring city of Genk, a strategic action plan for Limburg, known by the acronym SALK, was drafted for the province (Daems et al., 2013). SALK urges the traditional industry to distinguish itself based on local, sustainable and innovative production, and it highlights the significant potential the creative economy has for growth in the future.

Figure 2 – The Albert Canal between Hasselt (left) and Genk (right).

Hence, two pillars, of a creative and a more traditional industry, are drawn forward, which spatially come extremely close together in the Hasselt Canal Zone. Its developmental course testifies of influence from Richard Florida's (2002) notion of the Creative Class and of the notion of the Creative City (Landry, 2012), aiming for the stimulation of creativity as an economic driver. Evans warns that increasing examples of the implementation of growth models depending on the creative city thesis render this notion "a panacea for city and sub-regional economies" (2009, p.1005). Also, the vague definition of a creative class, which is exclusively assigned the power of creativity, has raised criticism (Markusen, 2006). Moreover, the contemporary production industry, with its innovation and smart city technology, is regaining its importance in contributing to a sustainable and circular urban model. According to the curators of the 2016 International Architecture Biennale Rotterdam (Brugmans et al., 2016), this is especially relevant for cities or regions dealing with an industrial transition.

Still, literature pertaining to the redevelopment of abandoned industrial sites demonstrates a hiatus with regard to productive urban estates where traditional users – industries, distributors and technical services – share a site with non-traditional users – creative industries and cultural institutions. Former industrial areas are exemplar of modernist dogma's and zoning practices, in response to which postmodern critiques formulate the importance of diversity as a "new orthodoxy of planning" (Fainstein, 2005). Most literature discusses former industrial sites as peri-urban transitional zones which have gradually been vacated, making room (after a certain period of vacancy) for urban programmes like service industries, arts and culture (Loures, 2015; Reicher et al., 2011; Stevens, 2015), often relating issues of heritage to urban planning and ambitious architecture (Oevermann and Mieg, 2015). Trip and Romein (2009, p.229) propose how "[e]xploiting its uniqueness could make a city's competitive advantage more sustainable, as it prevents quick imitation", and emphasize the importance of architecture and design in reinforcing local spatial characteristics. The blended use and interests proper to this case study define an arena of global interest and local intricacies (Larco, 2010), and the consequence for place-specific urban design proposals is investigated.

3 TWO INTERLACING PLANNING FIGURES

Plans for the Canal Zone dating back to 1938 already demonstrate diverse approaches to structuring urbanization between city and canal. The municipality sought to establish connection with the industrial area close to the city centre dating back to the 19th century, which became connected to the canal by an inner harbour. Its first plans for the Canal Zone also make a direct link to the centre via a boulevard, connecting to several educational institutes. Otherwise, the national Department of Bridges and Roads (Dienst Bruggen en Wegen) drew up grandiose urban development along the Canal in 1953, taking shape as a linear industrial city (Ryckewaert, 2011).

The final implementation of the ring road rather isolates the area from the city in the end. Ownership of the south banks by 1956 was divided between the Belgian state and the municipality, which is legible in the difference between urban patterns implemented. The Belgian state, represented by the department for shipping, centred on implementing a service road and rail infrastructure just east of the bridge, in support of provisioning and transshipment which would be developed there. The city architect designed an industrial estate consisting of six lots on the adjoining site. Some lots were joined during the development process (resulting in developable surfaces sized between 0,20 hectares and 1,05 hectares) and all became densely built over time. The municipality here built two generic warehouses targeting young companies. A flower mill, 20m tall, was also established along the canal in 1958. A second mill was established in the same year, more to the east. The building archive contains proof of many low-budget additions, like

offices, small garages, metal silos, and sheds, attached to the monumental industrial tower. Industrial and logistic SMEs developed the area clearly as a “backstage”. The organization into compactly built, small building blocks for which the city opted, would later form the prime foundation for its redevelopment. From 1964 onward, to the east of the municipal industrial estate, terrains were developed for industrial and commercial purposes, at lower densities and with bigger lots. On these lots, companies settled which were not dependent on the canal for transport. In 2000, the industrial zone was contracted, excluding the inner harbour which became an area for urban redevelopment. Simultaneously, to the west of Trichterheide, terrains were being developed for recreational and cultural purposes. These initiatives isolated the area from industrial networks and enveloped it with other programmes (BUUR et al., 2011b).

3.1 PIONEERING YEARS: NEW USERS ENTER THE FIELD

The 1997 Spatial Structure Plan for Flanders envisioned restructuring and intensifying existing business parks along the course of the Albert Canal, including the Hasselt Canal Zone. It had proposed to organize the spaces surrounding the Albert Canal as chambers, of which the conurbation Hasselt-Genk formed one, characterized by its urban character. At this point in time, the industrial estate Trichterheide was described in several planning documents as dilapidated because of its ageing road infrastructure, sewerage, non-existing green, and deficient parking system. It was at this time, in 1998, that the Muziekodroom started its gradual occupation of an obsolete slaughterhouse, which for several years had only served to stock old sports cars. First there was an insertion of a small concert hall and spaces for music lessons in an oversized building. An immediate problem was the fact that this function conflicted with zoning regulations, which was resolved before further colonizing the building. A lengthy legal process followed which ended in 2007 when, after facing severe protests from neighbours, the Muziekodroom was in accordance with zoning laws. Hereafter, the building exercised more influence on the public domain, as a large concert hall was constructed on the first floor, which required the placement of a significant fire escape on the side of the building (figure 3). Its effect of introducing a novel group of concert visitors initially was perceived with fear for burglary and vandalism by industrial occupants, but the Muziekodroom implemented good stewardship to prevent nuisance from its visitors to the neighbourhood.

Other entrepreneurs atypical for the industrial park followed by enrolling settlement plans in the two vacated flour mills. The tallest one was shut down in 2006 only to be repurposed within months by the architectural firm a2o, and was baptised the Silo (figure 4). The architects of a2o teamed up with a non-profit youth centre for cultural education called Villa Basta to fill in the large void at the site. The first task set by the architect was to demolish all secondary constructions not deemed fit for repurposing, opting for one clear and pronounced volume and diminishing the ‘backstage’ character of the site. What followed was organising representative openings and accesses in the former silo building, directing the “face” of the building toward the canal and to the heart of Quartier Canal. Retrofitting plans finally allow the current usage by a total of 13 companies. The terrains which were vacated were purchased by an entrepreneur in repair of electronics, who reused and expanded his warehouse on this terrain.

The smaller mill had already been repurposed in 2001 for a producer of jeans clothing, but was transformed in that period into a coworking space, under the name KAAI.16, housing about 15 companies in 2009. This building also was brought in connection with the canal by incising the brick structure with large glass planes. In 2008, a novel pop and rock academy, part of the provincial university of applied sciences, entered the stage. Its programmes were initially organized in the Muziekodroom, and after its first batch of professional bachelors graduated, the school started to occupy its own spaces within the same building.

Figure 3 – The retrofitted slaughterhouse, now a concert hall and rock academy (Hippo architecten)

Figure 4 – The retrofitted flour mill (a2o architecten)

All these “organizations and companies from the cultural, creative and innovative field” (a2o & KAAI.16, undated, p.1) settled here in vacated interiors, from which they started to exert influence on the use of public space by means of their architectural organization and because of the new audiences they attracted. There was no urban plan made for these novel activities, nor were these functions in accordance with the actual zoning regulations. As to the question why they opted to relocate to an operational industrial estate, respondents described how the process of gradual transition opened up opportunities of ample space and centrality in a dynamic location. Cultural organizations had been settled in the dispersed, isotropic urban landscape typical of Flanders, and took the chance to relocate to Hasselt where ambitious administrations sought to offer space for youth culture and innovative businesses in order to profile the provincial capital. Muziekodroom first benefitted from this central location, and ensuing organizations indicate that increasing presence of like minds and companies has been beneficial to their performance (e.g., students of the rock academy do internships at the close by cultural institutions). Architects working from Quartier Canal explained that this place outside of normality and top-down regulation, formed an attractive alternative working site compared to typical office parks which were sprouting along the outer ring road of the city. Municipal permit evaluations testify of the interest of the city to facilitate this “creative economy” in the Canal Zone (also see Arcadis, 2012), and respondents concur that the vision of the administration of the day proved essential to these dynamics.

3.2 CONSOLIDATING BOTTOM-UP EVENTS: PLANNING AND DESIGN

In response to changing functionality, the municipality took up the task to draw up a masterplan in 2008, which set as a goal to rethink the functionality of this area and its relation to the city. The implicit goal was also to negotiate a durable coexistence between traditional and new users. The Flemish urban design firm BUUR conducted research and design. They proposed three options for development of the Canal Zone: an “economic approach”, consolidating the original industrial and commercial purpose of the area; an “urban approach”, emphasizing the opportunities of its location to make an urban waterfront development; and an “integrated vision”, like option 1 stressing economic functionality, but going one step further in stimulating higher density, diversity and high-quality architecture. (BUUR et al., 2011a; 2011b).

Instead of continuing the discussion initiated in these design studies for the entire Canal Zone, the city opted to scale down to the acute issues of the south bank only. It initially sought to offer a legal basis for the cultural and creative economy and developed an implementation plan for those zones where these new users had settled. In a later stage the scope expanded to include the issues emerging due to presence both of a Seveso threshold 1 establishment, and public event locations. The complexity of expectations of roads and waterways, and the fragmented planning approach, led to the exclusion of the public domain from the planning process and product. The final plan provides guidelines for the kind of architecture which could be developed in the area, using terms as “front architecture” and “beacon” to define a level of ambition exceeding anonymous big-box architecture.

Before this plan in its final version was approved by 2016, the city was confronted with diverging interests (Arcadis and BUUR, 2015a; 2015b). On the one hand, the creative entrepreneurs and cultural organizations started to manifest their presence in the neighbourhood by branding it with the French name Quartier Canal. In a joint memorandum, entrepreneurs urge the city to acknowledge the Canal Zone as a “hybrid landscape where very diverse layers of usage are present simultaneously” and as “an area of expansion for the city of Hasselt” (a2o and KAAI.16, undated, p.1). In a strategic vision for the twin cities Hasselt and Genk, urban design firm BUUR (2013; also see Ruimte Vlaanderen, 2014) draws forward the opportunity to develop the Hasselt Canal Zone as a hinge between the city and the economic network of the Albert Canal. In this perspective, both cities possess structural elements linking them to the canal and which could make the Albert Canal one of the backbones for urbanization, and potentially include residential, economical and recreational programmes.

On the other hand, the municipality was led by advice not to hinder industrial occupation as present on the site. Government bodies such as the executive of the Flemish Waterways and Flanders Innovation & Entrepreneurship formulated such advice from their perspective on the Albert Canal as an Economic Network (Arcadis and BUUR, 2015a). In the ENA planning process, initiated in 2004, intensification of existing industrial estates along the canal is given priority, and is fitted into a vision stating that “[t]he diversity in working environments also needs to be translated into new industrial landscapes” (iris consulting et al., 2004a). The Hasselt Canal Zone is indicated as a key area for the ENA which is encapsulated by surrounding urbanization.

Furthermore, the agenda of ENA stakeholders manifests notably in their concern over what these proposals would imply for the petroleum company, and for the industrial sector as a whole (Arcadis and BUUR, 2015a). Urbanization, especially the introduction of residential purposes, would limit perspectives for this company, and this precedent was deemed by Flanders Innovation and Entrepreneurship to reflect negatively on all industrial SMEs present in the area. The executive of the Flemish Waterways in addition questioned the planning guides for new construction, wondering how industrial companies could keep up to the expectations of front architecture and (architectural) beacons. It protested against the designation of official cycling routes along the quays and towpaths, and against the idea to upgrade these quays as part of the public domain.

The result of the planning procedure was an implementation plan (RUP) which mediated between regulating the settlement of the creative companies, cultural organizations and the rock academy, and the continuation of the industrial activities which had been going on already for years without threatening their survival under the contemporary conditions. Outside these two groups, the process was occasionally interrupted by parties seeking to inscribe additional programmes into the area (for example, housing and wholesale business), in confrontation with the ambitions of the Cartier Canal Group, which frustrated the planning process. The plan did not make directive statements about the quality or character of the public domain.

3.3 EQUILIBRIUM OR STASIS? PERCEPTIONS OF USERS

While the implementation plan has facilitated the continuation of the equilibrium between new and traditional users of the Hasselt Canal Zone, concrete problems remain unresolved. The area still is indeterminate, which is also due to the priorities the city is setting for planning endeavours in other locations.

The indeterminacy coincides with lessened dynamics, in terms of the process of transition of the area. Overall, respondents share a sense of uncertainty about the direction in which the area will develop. Industrial occupants over time were concerned by the settlement of non-SMEs, and were surprised, stated the responding petroleum trader, about the support cultural institutions received from the city. He indicated how he has grown accustomed to the nature of coexistence, and learned to deal with the advantages as well as the disadvantages. From another standpoint, respondents pertaining to the creative sector lament the decreased dynamism driven by redesign of the public domain and attraction of additional players to strengthen the hybrid profile of the area. Actors in the cultural and educational sector perceived this negatively, as they have chosen wholeheartedly for a cultivated vision of an urban future of the area as a “creative site”, with which they interrelate the future ambitions of their organization. As one respondent from a cultural non-profit organization stated: “Underground is a thing that typically as a short-term effect.

After everybody knows it, the thing isn't underground anymore. Then, a comfort problem rises." The organization of the public domain, the perceived distance to the city core and the lack of parking spaces are seen as such comfort problems, which result in a limited attractiveness to cultural consumers. By organising (to some extent jointly) public events like theatre plays, concerts, bicycle drag races and temporary design & build actions, presence of the new users was felt stronger in the public domain, and the possibility of a fitting public urban space was probed (figure 5). With regard to the hybridity, respondents propose diverging arguments. The main characteristic of the area is one of "indefiniteness, [operating] under the radar, [working] bottom-up", thus formulated by the architect operating from the retrofitted flour mill. Actively engaged in the branding of Quartier Canal, he stated with regard to proposals for housing projects and a supermarket on the edges of the area: "people opportunistically interpret this [process of drawing up new plans for the area] and project programmes, to which we respond, that it has never been our ambition to do such a thing (...) The hybrid condition should remain." The director of the Muziekodroom, as the earliest pioneer of the area, acknowledges the aptitude of working self-sufficiently, as something which the site demands. He goes as far as to connect the "Rock 'n' Roll" identity of his organization to this condition. He refers to Berlin as an exemplary city where an innovative music culture thrives in retrofitted neighbourhoods (Bader & Scharenberg, 2010) and which offers an inspiring environment.

Respondents share a concern over safety of the area, because the public domain is not designed for the very diverse users passing through. Students face trucks crossing their path, and the roads attract cut-through traffic avoiding the main arteries. Concert visitors might wander off to the canal and fall in. On the other hand, industrial occupants seeking to keep the quays in use, plea for a clear separation of traffic flows. The consequence is that directors of the creative houses settled in Quartier Canal steal a glance at other developments in the wider urban environment, where actors in the cultural, technological and knowledge sectors are settled, or to the city centre. This poses a risk to the continuation of this urban experiment, as representatives in the cultural sector acknowledge the ongoing synergy as the main benefit of their presence in the area. Moving out parties is perceived as a negative game changer by those who would remain.

Figure 5 – An informal and temporary construction as a means to (re)appropriate the public domain

4 DISCUSSION AND CONCLUSION

Between the planning figures of the urban ring and the industrial Albert Canal, an experiment is being conducted of blending diverging economic and cultural interests. Early initiatives to inject the banks of the Albert Canal with a dose of creative economy were supported by local politicians and facilitated by the planning apparatus. The predominant perception among new users is that development of the area along this creative red line has come to a halt. It did so at a point where many issues related to urban design (the accessibility, the traffic safety, the quality of the public domain, the presence of a Seveso establishment close by semi-public facilities) remain unresolved and problematic to the functioning of cultural institutions and creative entrepreneurs. One of the instigators of the concept behind Quartier Canal has sold his company in a retrofitted flour mill after plans for expanding his business lost support at city hall. The faltering dynamic raises the question whether the concept of the creative city really is a panacea (Evans, 2009), one that neither fitted the persistent industrial interests materialized in this site, nor the ambitions of

a new group of users which colonized the area and faced its continued industrial usage. Based on the analysis presented in this contribution, I conclude by bringing both affirmative and negative arguments to the fore.

In a positive sense, the undefined nature allows the area to continue its manifestation as a zone of exception to the common rule, a counterweight to the very formal city centre of Hasselt – although it is questionable for how long still, given the concern over the perceived stasis among creative entrepreneurs. Its informal status invites bottom-up and temporary initiatives by its occupants to claim the streets of this hybrid industrial park. Many of the arguments in support of the settlement of new companies and organizations thrive on a shared notion of creativity which brings to mind Florida's "creative class" discourse. The notion of creativity cultivated here is however of a higher inclusivity: creative enterprises coexist with more traditional industrial and logistic SMEs and service companies which are not typically acknowledged as "creative entrepreneurs". Many of the occupants, across business sectors, identify with the informally organised network of Quartier Canal. There are signs of resistance against speculation and gentrification embedded in this cooperation. Moreover, in a region like Flanders, where urbanization has spread across the larger part of the territory and is best characterized as sprawl, shared usage of space is of increasing interest. The condition of living-apart-together proves a valuable demonstration of opportunities and pitfalls for a more intensive use of industrial estates.

But its resistance to continuing processes of urban development comes with very concrete problems of which traffic safety is the most pressing. The solution of connecting the university campus south of the outer ring road via a tunnel or bridge to cross the ring road to Quartier Canal is urgently needed. Alternative links between Quartier Canal and the city centre, via the towing paths and quays, have been proposed in planning and design documents as well as by local actors, but remain subordinate to the linkages in support of the Economic Network of the Albert Canal. Linkages between similar zones in the urban matrix consequentially remain too limited. It is on the level of infrastructure, that diverging interest come into collision most clearly. Diverging disciplinary frameworks and interests prevent discussion of potential interventions in the (semi-)public domain, if even on paper. Interestingly, in defending their cause, both traditional and creative industries support their viewpoint arguing for the sustainability of it: the industrial use of the waterway, for example, ensures a sustainable economic armature in relation to a transport sector offering alternatives for lorry traffic on the overburdened Belgian road network. From another perspective, creative entrepreneurs argue that new economic directions are needed in face of post-industrial developments. This condition curtails the role of a directive party (the city) to implement design concepts in response to acknowledged spatial problems.

This problem is centred on an indeterminacy between cultivating the state of exception of the area, and the resistance against developing its status and organization, thus sacrificing the origin and pole of attraction which led to the second colonisation of the site in the first place. There is a friction between the flexibility and consolidation allowed for in urban design: this affects both the interest of creative entrepreneurs in a perceived state of flux, and the freedom for traditional industries to develop their business unhindered by urban norms and standards. A spirit of DIY, Do-It-Yourself, remains present and is made tangible in the public domain, but requires a booster. While the municipality has defined its role mainly by consolidating the contemporary situation, most respondents are seeking for a clearer perspective on continued development, in order to determine their long-term ambitions on this site. Apparently, this legal consolidation is not enough to ensure sustainable coexistence of industrial, cultural and creative parties. This raises a new challenge with regard to urban design, namely to detect the common denominator for productive interaction in the public domain between involved actors, in order to start from here to bridge the gaps, and to maintain the continuity and communication lines in relation to the developmental process.

ID 1549 | SUPERBLOCK VS. TRADITIONAL GRID IN URBAN DESIGN IN BARCELONA: INTEGRATING SUPERBLOCKS WITH EACH OTHER THROUGH WALKABLE PUBLIC GREEN AXIS

Büşra Durmaz¹, Cihan Erçetin¹
¹Middle East Technical University
durmaz.busra88@gmail.com

1 INTRODUCTION

One of the most effectively working urban patterns is grid layout which has been worldwide accepted since the ancient settlements in history. Barcelona represents one of the most spectacular strict grid pattern since 1850s as a result of new demands in urban development in the city. This research will handle the grid pattern from a different perspective focusing on a transition from grid to Superblock and a simultaneous transformation in urban transport memory. Therefore, research question is to reveal what Superblock proposes in Barcelona as a change in urban transport memory. In this context, firstly, grid urban layout will be defined with its advantages and drawbacks in general. Afterwards, the historical being of Barcelona's grid structure and Superblock idea will be presented. Here the significant point will be touching upon basically the change in grid pattern and its prospective contributions on new urban transport memory. Finally, transition from grid to Superblock will be critically discussed by considering the aspect of expected transport memory reformation.

2 GRID PATTERN AND HISTORY OF GRID URBAN LAYOUT IN BARCELONA

In grid urban layout, roads create a rectangular network which creates identical building blocks having the opportunity to extend in any direction. This structure has been criticized due to its prodigality in terms of having all the streets with the same standard, excessive use of land, aesthetic monotony and lack of focus. However, creating hierarchical grid by diagonal arterials and minor grid streets seems to be solution for this critique (Lynch, 1985). This urban form does not have any definite edges or does not need to have nodes regarding its physical structure.

Grid pattern can be defined as a net of roads or diagonals without having a major spine in urban design of a city and without a certain boundary. The focal attraction points can be anywhere in the layout, which means the pattern does not imply the nodes or intersections. In this pattern, urban growth can occur towards anywhere inside or by extension to outside. The main advantage of grid is having high adaptability to growth and change, that makes the pattern flexible. Main disadvantages of grid also are lack of focus -in non-hierarchical grids-, waste of land and confusion of road network (Ceylan, 2003).

In Barcelona, Catalan civil engineer, Ildefons Cerda, prepared the first plan for the urban extension, which was considered as a revolution regarding its emphasis on hygiene, easy mobility and transportation on a modern grid-iron urban pattern. Living standards were optimized by creating 6m² volume of air per person within the structure of orthogonal city blocks with 113.3 m by 113 m (Figure 1). The pattern was supported with 35m large streets and big avenues. Cerda plan also proposed to increase green spaces and gardens in each block (Wynn, 1979).

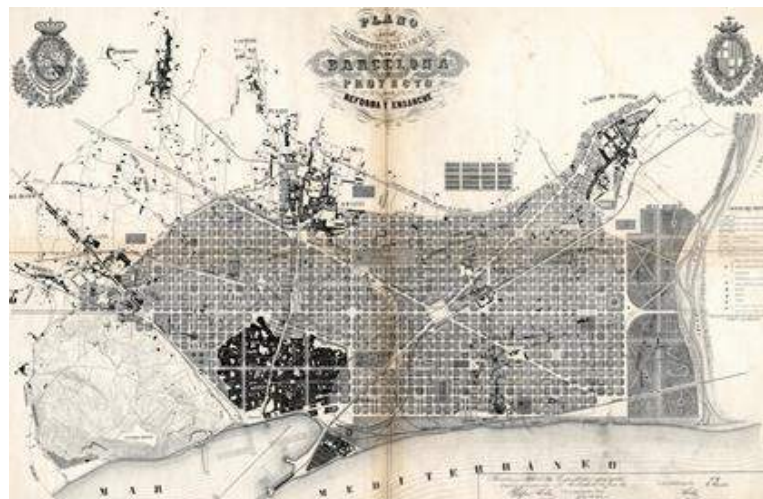

Figure 1. The Cerda Plan, 1859 (Source: Barcelona Municipality History Archive)

The Cerda grid plan basically depends on continuity of infrastructures and productive and residential forms. The main goal of this idea was taken as a new modern concept of the combination of multitude of movements between inhabitants and the elements of the contemporary city, which was thought to strengthen the relationship between human, economic growth and public space. In addition, within this grid layout local streets constitute the orthogonal grid layout and diagonal avenues create territories. The streets also create built and unbuilt spaces. Big building blocks between streets were assigned as industrial or non-residential, and other square small ones were as residential functions (Busquets et al, 2009). In Figure 2, the residential uses in plan can obviously be seen as mostly square blocks. Besides, main arterial diagonals and minor cross roads create variety in urban layout in Barcelona by the formation of different-size building blocks for today's current situation. However, some serious problems have started to emerge within this strict grid Cerda plan making policy makers take new precautions on urban transport design.

Figure 2. Solid-Void Relationship between Built and Unbuilt Spaces of Cerda Grid in Barcelona (Source: <http://tr.depositphotos.com/12853525/stock-photo-barcelona-plan.html>)

3 BARCELONA GRID WITH ITS PROBLEMS AND SEEKING A SOLUTION

Cerda grid plan emphasized mainly the fact that Barcelona city needed to breathe ideologically and physically, and to distribute the population in the area evenly together with enabling green areas within each building block. However, almost all the grid lines were dominated by cars which also triggered pollution and increase in noise levels. In short, the reasoning that made policy makers think about the solutions against the problems of greening and health in 1850s has emerged again as a tough problem in contemporary grid of Barcelona (Bausells, 2016).

According to a research carried out by Environmental Epidemiology Agency in 2015, if Barcelona performed the air quality standards of EU, it was seen that almost 1200 deaths could have been prevented in the city. The study also notes how the number of hospital cases increased in recent years in Barcelona due to air quality problems. Moreover, noise levels in the city become 61% higher because of city traffic and congestion levels (Trentini, 2016). In addition, air pollution in Barcelona itself has resulted in 3500 premature deaths in a year and also in detrimental effects on agriculture and ecosystems. Furthermore, some of the main reasons to generate a new Superblock grid pattern idea are excessive road accidents - 9,095 occurred in 2015-, sedentary lifestyles mostly effecting the future of kids who have not been got used to walking and sport, and scarcity of green areas in the city –particularly open public parks and green spaces-. According to World Health Organization cities need to own at least 9m² per inhabitant; however, the whole Barcelona city only has 6.6 m² green-spaces per capita -moreover, the pioneer implementation territory of Superblock project namely Eixample Neighborhood has only 1.85 m² per inhabitants (Bausells, 2016). As a result of environmental and health problems among inhabitants, policy makers of local government in Barcelona has decided to implement a new Superblock idea to decrease the occupancy of cars on urban space, increase the percentage of green areas and green streets and eliminate air pollution in the city. The specific project area in Eixample Neighborhood within one of the newly created Superblock basically focusses on formation of a continuous public interior connecting three Superblocks on one single green spine.

4 SOLUTION: ‘SUPERBLOCK’ RATHER THAN TRADITIONAL GRID

According to ‘Agencia de Ecología Urbana de Barcelona’ (2015), Superblock definition designed for Barcelona city as a new urban layout reforming the existing grid is mentioned as:

“The superblock (in physical terms) is composed of a set of basic roads forming a polygon or inner area (called *intervia*) that contains within it several blocks of the current urban fabric. This new urban cell has both an interior and exterior component. The interior (*intervia*) is closed to through vehicles and open to residents, primarily. The exterior forms the basic road network on the periphery, and is approximately 400 metres wide for use by motorized vehicles”.

Superblock consists of several building blocks in which traffic flow is reorganized around the outside of main roads. The priority inside part of a superblock belongs to pedestrians and bicycle users (Figure 3). Exceptionally, inhabitants in Superblock can drive inner streets with a low speed of 10km/h. those inner streets are also projected to fill with parks and recreational gardens. In addition, the new inner grid streets, left by cars, will become spaces of citizens for them to have new rights and functions such as commercial, culture and knowledge, participation and leisure time activity spaces in addition to use of inner streets as passageways (Peters, 2016).

Figure 3. Entire Superblock Design Layout for Barcelona (<http://www.barcelona.cat/ca/>)

The new Superblock renovation on Barcelona's grid will regain almost 60% of road space from car occupancy to citizens for different functions. Existing building blocks of the neighborhoods will be turned to Superblock which means joining almost nine building blocks into one continuing the orthogonality (Figure 4). The Eixample Neighborhood will be the first area selected for implementation. Main principles of Superblock design are humanizing public space, livability, sustainable mobility, green areas, biodiversity and local participation (Barcelona Architecture Walks, 2016).

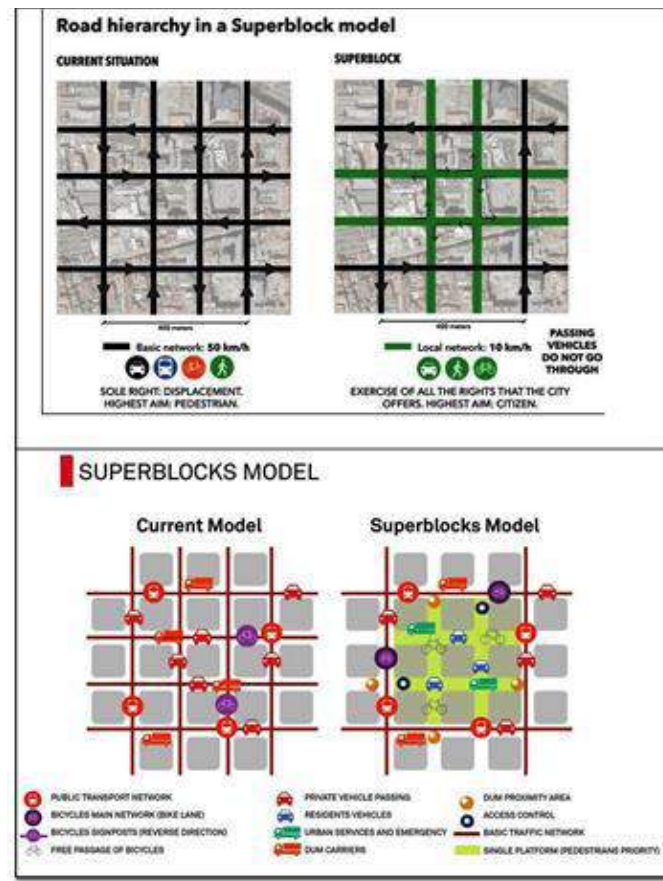

Figure 4. Functioning of Superblock Idea in Comparison with Current and New Situations (<http://www.barcelona.cat/ca/>)

5 WALKABLE PUBLIC GREEN AXIS TO INTEGRATE SUPERBLOCKS THROUGH DIAGONALS

The significant point in this research is to investigate ways to integrate these newly proposed Superblocks. The reason why there exists such a concern is that when new superblock structure is generated and applied to Barcelona streets and Avenues, there might be a concern also for disconnectedness between Superblocks in terms of social and accessibility aspects. Therefore, it is obvious that diagonals would be effective ties between Superblocks since they pass through the city as creating accessible central axes. In this research, an example diagonal green corridor will be investigated between “Parc De La Ciutadella” and the coast of Barcelona. The research interest of the research is formulated as: “How an old diagonal can behave in new Superblock structure of Barcelona as an integrative green spine of three different Superblocks” (Figure 5).

Figure 5. The Idea of Public Interior within Superblock Structure in Eixample (Source: Personal Drawing)

6 PROJECT AREA SELECTION, PRINCIPLES AND RESEARCH QUESTION

The Eixample Neighborhood is selected as the pioneer implementation of Superblock idea. The main research interest for the project area is derived from the issue of how an old diagonal can behave in new Superblock structure of Barcelona as an integrative green spine of three different Superblocks. The specific project area is called as a public interior (positioned in one of the Superblock) between two welcoming entries (positioned in two separate Superblocks) on an old historical canal, namely Av. De Bogatell Street today. Consequently, problems and potentials in the area, aim, vision, and finally design principles are noted as follows:

Problems

- The diagonal (old canal) has been used just as a passage and fragmented pedestrian way interrupted by many streets
- Entries into today's area are not clearly defined
- Problems in the organization of unbuilt spaces existing within the area to attract citizens into it

Potentials

- The area has a strategic position within Cerda Grid located as a diagonal
- It has the potential to integrate three different newly proposed Superblocks on a single green line
- The diagonal is an old canal which can be revealed as an historical attraction point
- Existing public programs in the area create potentials to enrich newly projected public interior (library, schools, and sport areas).
- Proposed Superblock urban layout perfectly fits into the strategy of creating public interior and its two welcoming entries

Aim

- Designing the area as an integrative green spine destination itself; not just a passageway together with the aims which are creating a public interior within Superblock structure and integration of public programs with public interior. In Figure 6, it is seen that existing situation contains fragmented grid streets on diagonal and strict property boundaries shown with red line. In design case, existing public program potential is used to create a linear pedestrian public interior inserting more public programs and open spaces. In prospective design aim, urban functions are flourished by the uses of residential, commercial, urban parks, school and library.

pedestrian line. The diagonal does not even work as an efficient, continuous pedestrian line. It is fragmented by streets of Cerda Plan and only small public spaces remained. Today, despite the existing public programs in the area, the diagonal cannot be counted as a destination itself; it is used just as a passage from one place to another. In the new design, east and west blocks of the project are kept as welcoming entries on different Superblocks, and in the middle, a public interior is created with new commercial activities, cultural uses, sport areas and green spaces to create a linear continuous spine on an historical old canal (Figure 6).

ID 1554 | STUDY ON THE OPTIMIZATION OF RESIDENTIAL SPACE IN RESOURCE-BASED CITIES - A CASE STUDY OF YULIN

Wang Tong¹, Chen Xiaojian¹, Hao Haizhao¹
¹Xi'an University of Architecture and Technology
1103544838@qq.com

1 INTRODUCTION

Resource-based city refers to the city, which is based on the formation and development of natural resources such as minerals and forests, and takes resource exploitation and processing as leading industry. According to the types of resources, resource-based city can be divided into coal city, forest city, nonferrous metallurgical city and oil city. According to development process, resource-based cities are divided into two types, one is "mine first then the city", the other is "city first then the mine". This paper addresses the latter one. City originated before the development of resources, and the exploitation and processing of resources which is situated in surrounding areas has accelerated the development of the city, and caused the rapid expansion of urban construction land, the rapid change of spatial structure. The urban residential space plays an important role in the spatial change of urban function, and its spatial optimization has become an important content of urban spatial structure adjustment. The paper, taking Yulin City as an example, studies the evolution of urban residential space by analyzing residential space of Yulin main built-up areas, and exploring the current situation of urban residential space and the factors that influence the spatial distribution of urban residential space.

2 RESEARCH OBJECT AND RESEARCH METHOD

2.1 OVERVIEW OF THE STUDY AREA

Yulin City is located in Northern Shaanxi province, and it sits at the border area of Shaanxi, Gansu, Ningxia, Inner Mongolia and Shanxi provinces (regions). It is a prefecture-level city of Northern Shaanxi province (Figure 1). Yulin City has two districts and ten counties within its administrative boundary. Its northern area is sandy beach area, accounting for 42% of the total administrative area, and the southern landform is the loess hilly and gully region, accounting for 58% of the total area. Yulin is a mineral resource enrichment area in China, especially for coal, oil, natural gas, rock salt and other energy and mineral resources. The study area is Yulin main built-up areas in the southern part of Yuyang District (Figure 2).

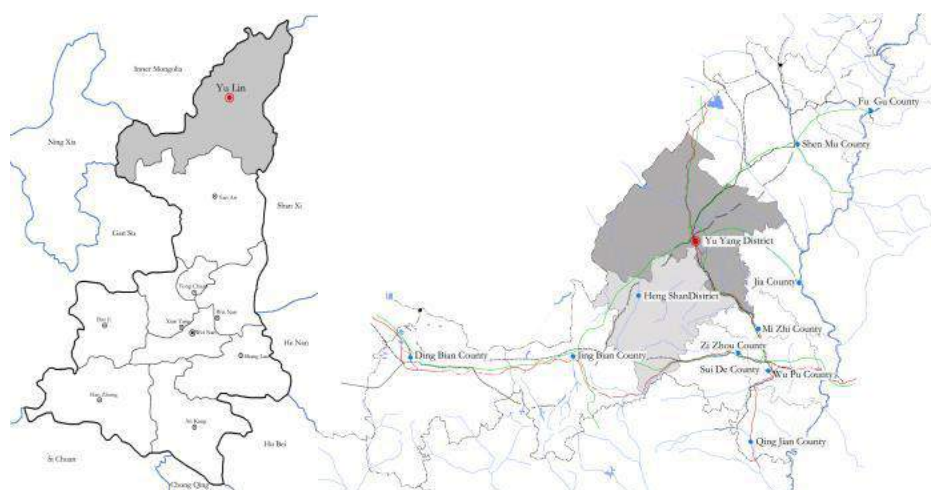

Figure 1 - Location Map of Yulin City | Figure 2 - Location Map of Yuyang District and Hengshan District
 Data Source: The graph is drawn by the author himself

terms of total population of different sub-district, the change of the population is different at different stages. The sub-district of Xin Ming Lou has greater population density distribution from 1990 to 2010. In 2010-2016, the sub-district of Chong wen lu has a higher population density.

Figure 5 - The proportion of the population changes in different sub-district over the years (above left)

3.2 THE EVOLUTION OF URBAN RESIDENTIAL SPACE

According to the relevant literature, urban construction is within the boundary of Lao Cheng, and the residential space layout along the axle from north to south before 1969; In the late 1970s, urban residential space expanded eastward with the increase of population and the construction of the industrial areas in southern suburbs. Industry and commerce development accelerated the increase of population growth, and urban residential space began to expand westward in the 1980s and 1990s. Urban residential land area reached 4.79 km² in 1988, and most of the urban residential space was still mainly distributed in Lao Cheng area. Urban economic development has accelerated and living standards has heightened since urban housing reform system in 1998. Meanwhile, residents pay more attention to living environment and housing location. The development intensity of Lao Cheng was controlled due to the protection of historical and cultural city, and urban residential land area reached 9.32 km² in 2003. In 2003-2006, urban residential land expanded southward rapidly because of the containment of the westward and eastward in urban planning, considering the ecological fragile and natural condition. While the western region develops westward further to XiNan new Area. Urban residential land area increased by 20.4 km² in 2006, and the Yuheng industrial zone, Qinhe new zone and Konggang ecological zone are constructed. The suburbanization of urban residential space was obvious. Urban residential land area reached 23 km².

From the perspective of the overall center of gravity change, the center of gravity of the residential space moved from north to south from 1988 to 2006, and moved from south to north from 2006 to 2016 in the central area of the east bank. The residential space center of gravity moved from north to south from 1988 to 2016 in the central area of the West Bank. The main built-up areas of the overall center of gravity presents from north to south movement from 1988 to 2006, and moved from south to north from 2006 to 2016.

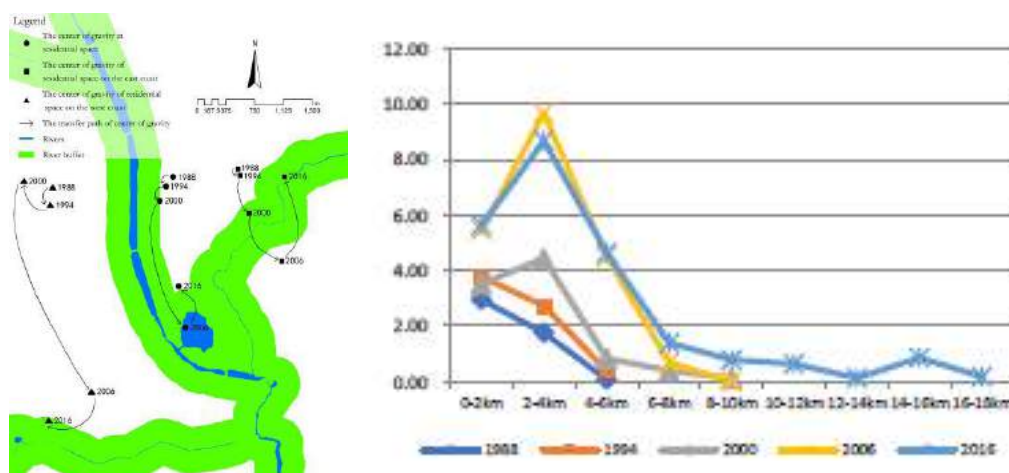

Figure 8 - Residential land center of gravity changes in the central area | Figure 9 - Residential area changes in each circle Data Source: The graph is drawn by the author himself

From the perspective of the change of the circle structure of the central area, the most of residential land is in 0-2 KM around the center, and the farer away from the core area, the smaller the residential areas from 1988 to 1994. The residential area reached a peak at the distance of 2-4 KM from 2000 to 2016. The form is similar to the shape of the parábola.

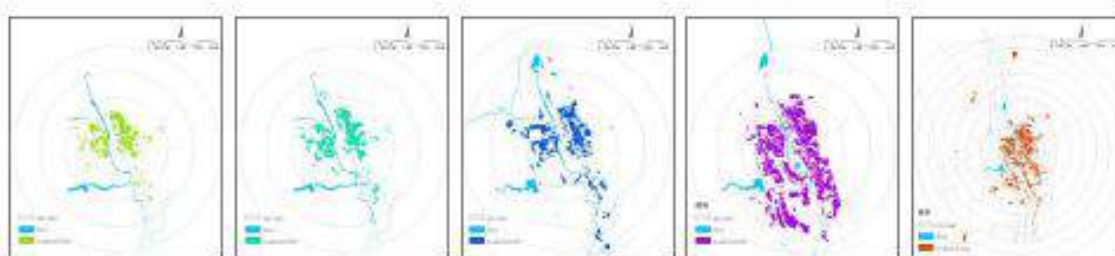

Figure 10 – The changes of the circle structure of the living space Data Sources: The graph is drawn by the author himself

3.3 THE RELATIONSHIP BETWEEN URBAN RESIDENTIAL SPACE AND RESOURCE MINING

Fig. 11 and Fig. 12 show that the industrial output of Yulin increase rapidly with the increase of coal production, and they show a strong linear relationship. In recent years, the built-up areas have increased rapidly, with the increase of industrial output value, and they also show a strong linear relationship. Residential land area also increased rapidly with the rapid expansion of built-up area.

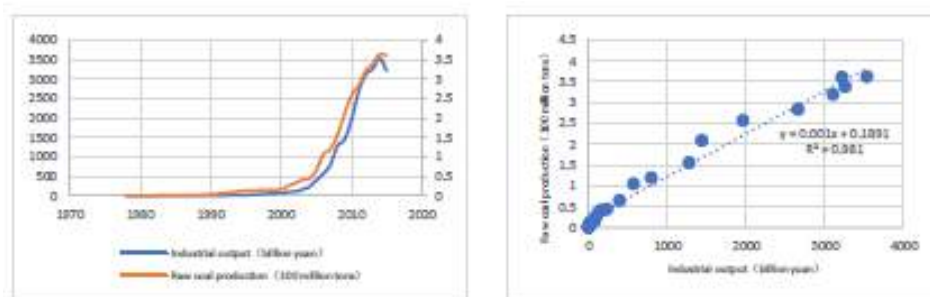

Figure 11 – The Relationship between Industrial Output Value and Raw Coal Production in Yulin City Data Source: Statistical yearbook of Yulin in 2015

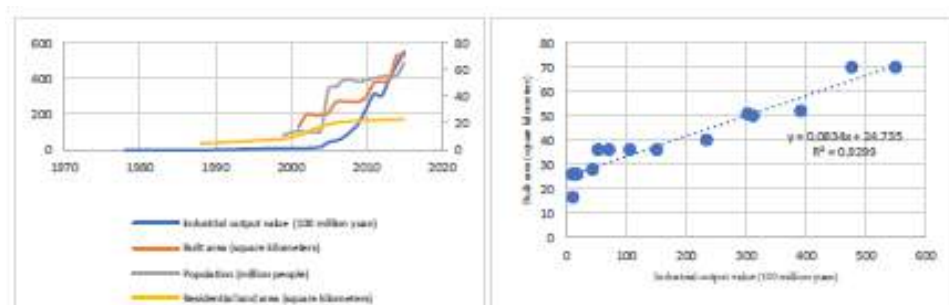

Figure 12 – The relation between industrial output value and built-up area is in Yuyang District
Data Sources: Statistical yearbook of Yulin in 2015

From the historical evolution of residential space, the original urban construction land is mainly in the Lao Cheng area, and the surrounding areas are mainly agricultural and forestry land and village land. With the construction of the surrounding mining sites, temporary residential areas have gradually been built around the mining sites and gradually transformed into a fixed community. The construction land expanded rapidly in the central area, and industrial areas formed gradually, and new areas built. With some mining plots immediate central areas exhausted, the mining points are gradually abandoned, and the temporary residential areas around the mining sites shrink, and the residents gradually migrate to other mining points or to the central area. From the point of view of the relationship between work and residence, the establishment of mining sites has brought a large number of migrant workers. They originally lived near the mining site. With income increase, more and more residents buy houses in the central city. They usually work in the mining area and live during the holidays in the main built-up areas.

3.4 THE CHARACTERISTICS OF RESIDENTIAL SPACE EVOLUTION

3.4.1 NEW RESIDENTIAL SPACE LAYOUT TOWARDS THE OUTSKIRT AREA

The main built-up areas are an ideal place for living with convenient transportation and better service facilities, so it is the earliest and most concentrated area for housing development [3]. Urban population increases rapidly with the development of economy after 2000, and the urban residential space couldn't meet the living demand only by renewing Lao Cheng area. From the point of view of urban residential land development over the years, urban residential land gradually expands to the surrounding area. The city periphery land resources are abundant, and land price is relatively low and has the good ecology condition. Therefore, the city housing expands gradually from the main built-up areas to the outskirts area.

3.4.2 LAYOUT ALONG THE TRAFFIC ROUTE

The distribution of traffic and urban residential space has the relationship of mutual restraint and interrelations. The distribution pattern of urban residential space affects the direction and flow of traffic lines [4]. The layout of traffic routes also affects the reorganization of urban residential space structure and the relocation of residential area. Especially for resource-based cities, transportation plays a very important role for the people travelling from mining areas to residential areas and vice. Taking the urban residential space in 2016 as an example, the 0.5 KM radius buffer zone analysis is carried out on the main road of the city, and the proportion and the results show that distribution density of the residential land in the statistical buffer area are accounted for 88.45% of the total residential land in the buffer area.

3.4.3 LAYOUT COMBINED WITH URBAN NEW AREA

With the exploitation of mineral resources, resource-based cities often form new zones or development zones in areas immediate mineral resources or cities to develop deep processing industries of mineral resources, and extend industries that do not rely on mineral resources further. New urban areas and development zones have certain infrastructure and industrial support, and new residential areas are closely related to the layout of new urban areas. Yulin has a state-level high-tech Development Zone, Xi

Nan Area, Yuheng Industrial area, Qin He Area, Kong Gang Area and Dong Sha Area. The development of new industry promotes the rapid expansion of residential space.

3.4.4 THE UTILIZATION RATE OF RESIDENTIAL SPACE IN OLD CITY IS HIGHER THAN THAT IN LAO CHENG AREA

Early residential construction is mainly based on low and multi-stories residential buildings, and the new ones in recent years are mainly based on multi-stories and high-rise buildings. From the point of view of the number of layers, the location of the residential area and the types of land use, the lower level residential areas are mostly located in Lao Cheng area, and are the three types of residential land. The quality of residential buildings is low and the environment is poor. The New Area mostly consists of one kind and two kinds of residence types, and the whole living environment is better.

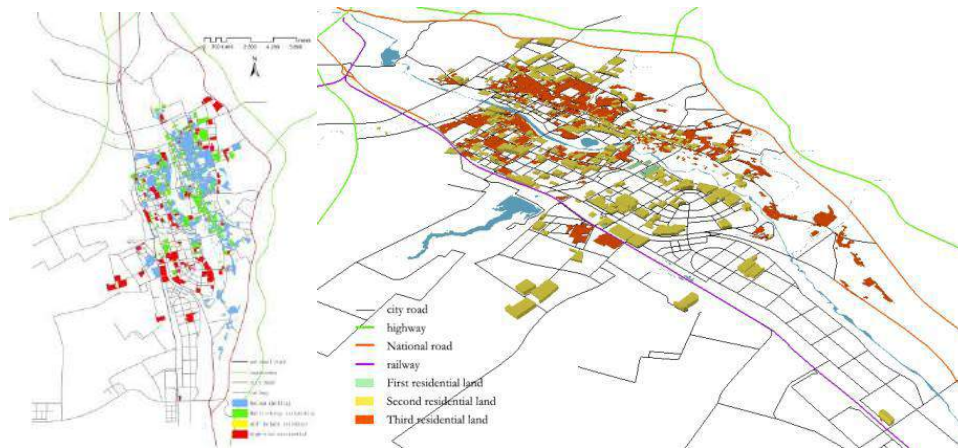

Figure 13 – Urban residential height map Figure 14 – Urban residential classification and living height map
Data Source: The graph is drawn by the author himself

4 THE PRESENT SITUATION OF URBAN RESIDENTIAL SPACE

4.1 THE SPATIAL DISTRIBUTION CHARACTERISTICS OF POPULATION

From the characteristics of the population space, the population density is higher in the sub-district of Chong Wen and Tuo Feng; The population in Xue Yuan community, Ba Shi community, Wan Fo Lou community is relatively higher than other places, and the population density reaches 265 - 437 people / ha. As a whole, the density of the Lao Cheng Area is higher, while the density of the new district is low.

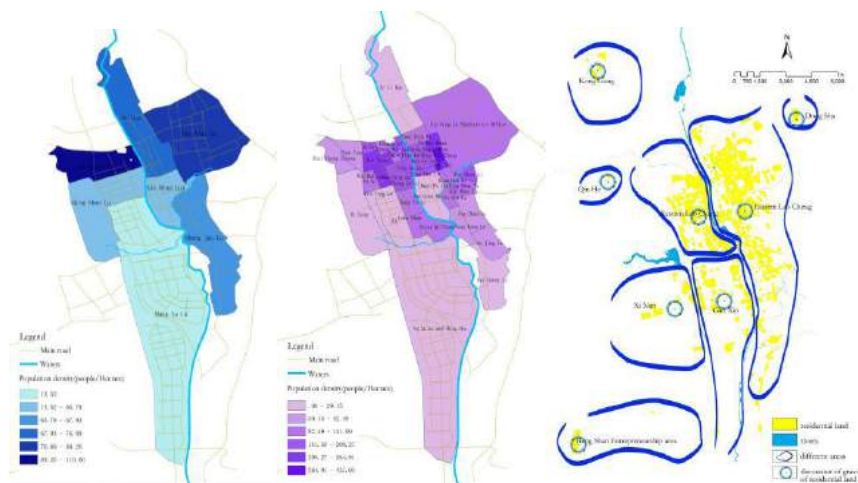

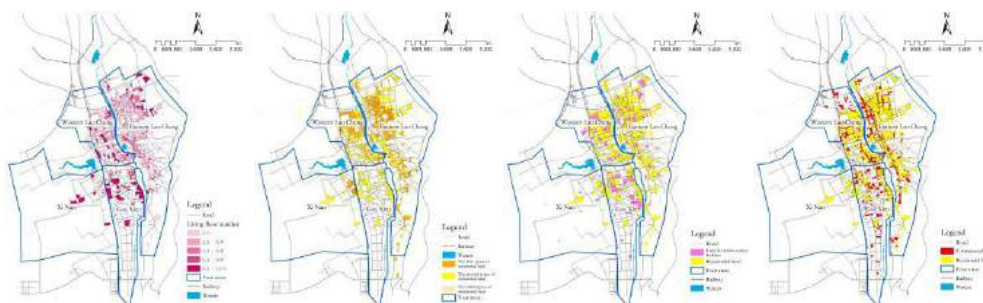

Figure 15 – Current population density distribution map Figure 16 – Residential land area
Data Source: The graph is drawn by the author himself

4.2 THE RESIDENTIAL SPACE DISTRIBUTION CHARACTERISTICS

In general, the residential land is mainly distributed in the Lao Cheng Area. In the east part of Lao Cheng Area, the number of stories in the house is low, and its living area accounts for 65.68% of the total living space of the area. In the west part of Lao Cheng Area, the urban area is still dominated by low rise residential land, accounting for 60.05% of the total residential space. Multi-stories and high-rise residential land has a similar proportion: multi-layer accounts for 21.57% of the total residential area and high-level accounts for 17.90% of the total residential area. As a new district is being developed in recent years, the distribution of residential land in Gao Xin Area is relatively scattered, among which the highest proportion of high-rise land use is 71.42%. In the Xi Nan Area, the existing houses are mostly low-rise houses, accounting for 41.58%. The newly built houses are mainly high-rise, accounting for 58.42%, and the living height difference in the whole area is relatively large.

From the classification of residential land, the proportion of the third types of residential land in Lao Cheng Area is relatively high. There are a small number of residential lands in Gao Xin Area, accounting for 8.39% of the total residential area. The residential land of the Gao Xin Area and the Xi Nan Area are mainly two types of residential land, accounting for 87.33% and 60.17% respectively of the corresponding residential areas. From the public facilities in the area of the layout, the layout of public service facilities of Gao Xin Area is the best. The administration and public services has a land area of 0.60 compared to the residential land area, and the commercial and business facilities has a land area of 0.63 compared to the residential area. The allocation of public facilities in Xi Nan Area is the worst, and the ratio of commercial and business facilities land and residential land is only 0.004. In terms of the traffic conditions of each area, the traffic condition of Gao Xin Area is optimal, and the density of road network reaches 3.65 km/km². The eastern Lao Cheng area is as good as Lao Cheng traffic condition in the west, and the road network density is 2.99 km/km² and 3.57 km/km² respectively. The construction of Xi Nan Area road network is not perfect yet, and the density of road network is 1.06 km/km². According to the housing world website statistics, function area prices ranging from high to low are Gao Xin Area, western Lao Cheng Area, eastern Lao Cheng Area, Xi Nan Area. From the distribution of present situation and residential land, the residential land is mostly distributed in the buffer zone of bus lines. The bus routes are mainly distributed in Lao Cheng and the northern part of Xi Nan Area.

4.3 THE PRESENT SITUATION OF THE RESIDENTIAL SPACE OF EACH AREA

4.3.1 THE LIVING ENVIRONMENT OF THE EAST LAO CHENG AREA IS POOR, AND THE LAND USE EFFICIENCY IS LOW

At present, the residential land in east Lao Cheng Area is characterized by high density and low volume, which hinders the improvement of the function of Lao Cheng. Taking residential space in Ling Xiao tower as an example, the whole area has a large number of residential buildings with high density and low floor space. Because of historical factors, the distribution of buildings is relatively messy and the quality of the environment is poor. However, the area is a famous tourist attraction in Yulin, and the disordered space hinders the development of tourism service function.

Figure 22 – East Lao Cheng Area residential space Figure 23 – West Lao Cheng Area residential space
Data Source: Google Official Website: <http://www.google.cn/maps>

4.3.2 THE FACILITIES ARE RELATIVELY PERFECT AND THE ARCHITECTURAL FEATURES ARE OBVIOUSLY DIFFERENT IN WEST LAO CHENG AREA

The residential space of the west Lao Cheng Area is relatively tidy, and the overall public service facilities are relatively perfect with convenient transportation. The quality of the low rise residential buildings is relatively high, and some residential sites are under construction immediate Yuyang district government and the Yulin Railway Station. The new residential buildings are in harmony with the surrounding architectural environment, and the residential buildings are obviously different in style.

Figure 24 – Gao Xin Area residential space Figure 25 – Xi Nan Area residential space
Data Source: Google Official Website: <http://www.google.cn/>

4.3.3 THE OVERALL QUALITY OF LIVING IS HIGH, AND COMMUTING FACILITIES ARE RELATIVELY PERFECT AND THE ARCHITECTURAL FEATURES ARE OBVIOUSLY DIFFERENT IN WEST LAO CHENG AREA IN GAO XIN AREA

The overall residential space building quality is good, and the traffic system is perfect in Gao Xin area. Residential buildings are mainly high-rise. Because the construction space scale is big, and some residents still work in the Lao Cheng Area, it is inconvenient for the residents to go to the work place. At present, part of the land mass construction is still imperfect, and the supporting facilities are still under construction, which results inconvenience to the residents.

4.3.4 THE LIVING SPACE HAS DIFFERENT FEATURES AND LACKS NECESSARY PUBLIC SERVICE FACILITIES IN XI NAN AREA

The residential space in Xi Nan Area was developed early on the basis of industry, and the scale was relatively small. However, the scale of new residential areas is relatively large, and the overall features are inconsistent; New residential areas often lack public spaces and have poor quality of life. New residential areas often lack public spaces and have poor quality of life. Although the southwest New District has been included in the main built-up area of the city, most areas have not been built. The whole urban road traffic and facilities are lack, and the separation of job and house is obvious.

5 SPATIAL DISTRIBUTION OF RESIDENTIAL SPACE AND ITS INFLUENCING FACTORS

Urban residential space distribution is affected by many factors. The resource-based city has its particularity. The urban residential space development not only has its own factors different from other cities, but also has the common factors same as other cities.

5.1 THE NATURAL ENVIRONMENT AND HISTORICAL FACTORS ARE THE BASIS OF THE LAYOUT OF RESIDENTIAL SPACE

Yulin is located in the ecotone between the Loess Plateau and Mu Us Desert, and belongs to the ecologically fragile and arid areas. The unique natural environment influences the development of urban residential space. The river passing through the city and the surrounding mountains become the basic elements that limit the layout of the residential space.

Yulin is a famous historical and cultural city with profound cultural background. The old residential buildings in the old city were built on the basis of the historical pattern. In East Lao Cheng, the number of residential floors is mostly low, and the living conditions are relatively poor, so that some residential buildings are in poor quality.

5.2 THE DEVELOPMENT OF MINERAL RESOURCES HAS A POSITIVE EFFECT ON RESIDENTIAL SPACE

From the evolution of the whole residential space, the exploitation of the mineral resources around the center of the city has greatly promoted its economic development, and further promoted the expansion of the residential space in the central city. The exploitation of mineral resources promotes a large number of population migrate into the central city. With the increase of the income level of the migrated people, most of them will buy houses in the central city, and even move the household registration to the central city, which will promote the development of the real estate industry in the central city. Because of the development of mineral resources, the ecological immigrants and mining immigrants will promote the development of residential space to a certain extent.

5.3 URBAN PLANNING HAS A LEADING ROLE IN THE LAYOUT OF LIVING SPACE

At present, four master planning has been compiled in Yulin. In the first edition of the master plan (1989-2000 years), the residential space was arranged and optimized, which laid the basic pattern of the urban residential space in Yulin. In the second edition of the urban master plan (1994-2010 years), the living space expanded to Gao Xin Area, and the living space scale was relatively large. In the subsequent third edition of the master plan (2000-2020 years), the urban space layout is "two axis, double cores, five clusters" pattern. The distribution of urban residential space shows a diffusion situation, and commercial housing rises in southwest New District and high-tech zone. In the fourth edition of the master plan (2006-2020 years), the residential space expands to Xi Nan Area, while the residential space in the east Lao Cheng Area expands further to the eastern region. The residential space in Lao Cheng Area has been gradually integrated, and the living environment has been improved.

5.4 THE MARKET HAS A CATALYTIC ROLE IN THE LAYOUT OF RESIDENTIAL SPACE

The development of the real estate industry promotes the distribution of the residential space in Yulin, and has a certain influence on the difference of the living space of each function area. Under the regulation of the market, it virtually causes the differentiation of different types of residential space. Commercial housing distributes in places with good conditions, public service facilities, and better living environment or urban road along the main road. However, most of the economically affordable housing is distributed in the outer suburbs of cities where the public service facilities and environmental quality are poor. [5]

6 OPTIMIZATION STRATEGY OF URBAN RESIDENTIAL SPACE

The differentiation of urban residential space is an inevitable phenomenon in the process of urbanization [6]. In the process of spatial optimization, on the one hand, the optimization of residential physical space is promoted; on the other hand, the living standard and living satisfaction of the occupants are improved.

6.1 IDENTIFY THE DEVELOPMENT ORDER OF EACH AREA AND PRIORITIZE PUBLIC SERVICE FACILITIES

Currently, the construction of the different function is under way, forming a multi group living space pattern. The construction of Gao Xin Area is relatively perfect, followed by the Southwest New Area, while the other new function and the main urban areas are far apart from each other and lack of infrastructure facilities. In the planning, high-tech zones and southwest New zones should be selected as the key areas for development. Other new districts will gradually develop according to the actual situation, and choose the advantage areas to develop, and improve the living space of the residents.

6.2 REASONABLE CONTROL OF THE SPATIAL INDICATORS OF EACH AREA, AND IMPROVE THE QUALITY OF THE LIVING SPACE ENVIRONMENT

In the process of renewal, the old city texture should be fully protected, and the space index of the area should be rationally determined from the point of view of historical protection; Different protection measures are taken for different building quality. It is necessary for us to fully improve the infrastructure, and create the old city landscape to enhance the environmental quality. In the newly developed residential areas, the development scale of residential areas should be appropriately reduced, and the residential areas with different levels should be set up in the same area. This kind of mixed arrangement can guarantee the safety and comfort of the living space of different strata, and can also realize the diversity of people in a large scale and narrow the differentiation of living space. It should avoid a single distribution in the suburbs for affordable housing, immigration, relocation, residential layout. They should gradually integrate into the city context and reduce the isolation of the living space of low-income groups.

6.3 THE FORMULATION OF PLANNING POLICY TAKES INTO ACCOUNT THE WISHES OF RESIDENTS AND COMPLIES WITH THE PRINCIPLE OF PUBLIC PARTICIPATION

In the process of planning urban residential space, it should listen to the public opinions through questionnaires, interviews and other forms. The Lao Cheng Area has a long history, and planning policy should be developed from two aspects, there are resident's satisfaction and historical protection. In the process of renewal of the Lao Cheng Area, the residents can make local arrangements as far as possible and settle the employment nearby.

1 INTRODUCTION

The bazaar is a social and spatial network, shaped through centuries of relations between the bazaar community, the states, the regular public, and other actors, such as the waqf endowment organisation and the religious clergy. As a commercial centre, urban heritage, and public place, the bazaar is profoundly influenced by the quality and quantity of the presence of regular public members.

By reviewing literature presenting empirical studies on the bazaars in Iranian commercial cities such as Tehran, Esfahan and Tabriz, this research has categorised the general types in the spatial, functional, legal, and social aspects of these bazaars (Yadollahi, 2017). Based on these categories and according to the literature on the methods of studying public places, this research has developed a method to study an Iranian bazaar as a public place. After documenting the aspects mentioned above in the Tabriz Bazaar, located in the north-west of Iran, this method is modified specifically for and applied towards this case. The present paper discusses the results of implementing the mapping method on the Tabriz Bazaar. The adaptation of the mentioned method towards the Tabriz Bazaar is based on the data collected through regular ethnographic research in the bazaar between March 2013 and September 2015.

Through mapping the functional, physical, legal, and cultural aspects of the involvement of public and private actors in the bazaar, this research addresses the following questions: How can we map the socio-spatial fabric of a bazaar as a public place? How can we discover the patterns of spatial distribution of public and private power in a bazaar, considering the four aspects mentioned above? Does crowdedness of a bazaar represent social diversity and equality of all public members in its use and control?

2 THE RATIONALE OF THE APPLIED METHOD

This method is designed based on the four factors that play a significant role in defining the public or private character of a place. Researchers such as Canter and Habraken have analytically studied the physical, functional, and social forces that shape the character of the built environment. Putting the categories introduced by these researchers and the corresponding attributes of Iranian bazaars together, factors of use, physical accessibility, ownership and local culture of territory-defining are suggested for studying the publicness of bazaars (Yadollahi & Weidner, 2017). Using these factors, it is investigated how different variations of the composition of these factors can influence the openness and accessibility of the spaces in a bazaar. The basic logic of the method is that if we can categorise the levels of publicity and privacy regarding each of these four factors in areas of a bazaar, we can explain how and why some spaces are (formally or informally) more public or more private. Accordingly, by means of these categories, we can illustrate the fabric of a bazaar in terms of the publicity-privacy of areas in it. It should be mentioned that this fabric is subject to change because, the physical, functional, legal, and cultural conditions of a bazaar is in continuous change.

To relate the mentioned four fundamental factors with the typologies of spaces found in a bazaar a matrix is used (Table 1). The openness-accessibility factors form the rows of the matrix and the columns indicate the degrees of publicity–privacy that can be identified in an area of a bazaar. These levels or types of publicity-privacy have a qualitative nature because they are defined mainly based on qualitative ethnographic fieldwork. So, this method does not have a deductive approach, which dictates or pre-defines categories and typologies. On the contrary, it follows a flexible, empirical and inductive way of studying the built space. The number of columns depends on the precision of the surveys and the numbers of identifiable categories of physical accessibility, use, ownership and the diversity of user groups in a bazaar.

After mapping the four factors in the bazaar and juxtaposing them with the help of the described matrix, the final map shows the publicity–privacy spectrum of the bazaar. The next section presents the results of applying this method towards the case of Tabriz Bazaar.

Level of Public /Private Control	The Spectrum of the Public - Private Control in the Studied Spaces		
Factors Defining Openness and Accessibility	Public		Private
Physical Accessibility	Spaces providing the highest level public accessibility		Spaces designed to ensure maximum private control on accessibility
Current Use	Uses attracting the largest volume of users with the greatest social diversity		Functions that mainly involve owners or limited (filtered) users
Legal Status of Land Ownership and Control	Public – State ownership		Private and vaqf ownership
Culture of Territory Defining	Places in which the highest level of diversity of groups, engaging in optional activities is observed		Places that are culturally considered as territories of certain groups or individuals

Table 1 - The publicity–privacy spectrum matrix for Iranian bazaars (Yadollahi, 2017).

3 RESULTS OF APPLYING THE METHOD TOWARDS THE TABRIZ BAZAAR CASE

Tabriz, located in Eastern Azerbaijan province in North West of Iran is one of the cities that have a long history of commerce. Tabriz is one of the largest commercial and industrial cities of Iran (Azerbaijan Governorship, 2013). The bazaar of Tabriz is located at the core of the historic centre of Tabriz. The historic city includes the area inside the former 18th-century city walls (Iranian Cultural Heritage, Handicrafts, and Tourism Organization, 2009) (Figure 1).

The Tabriz historical area, with the bazaar at its centre, is densely occupied with commercial areas. As the Detailed Plan of Tabriz Historic Area suggest, 50 percent of the trade in Tabriz took place in the city centre in 1995 (Aban consultant engineers, 1995). We should consider that this information is valid for 1995. But, the recent Master Plan of the city shows that the commercial character of the city centre has not changed dramatically (The Municipality of Tabriz, 2011).

The bazaar of Tabriz is located in the commercial centre of the city, it has several retail and wholesales units that offer various services. Architecturally speaking, there are numerous open spaces in the bazaar's spatial network that are accessible to the public. We should remind that the Tabriz bazaar is a crowded place, especially in its southern areas. However, our studies show that the public life in the Tabriz bazaar lacks social diversity.

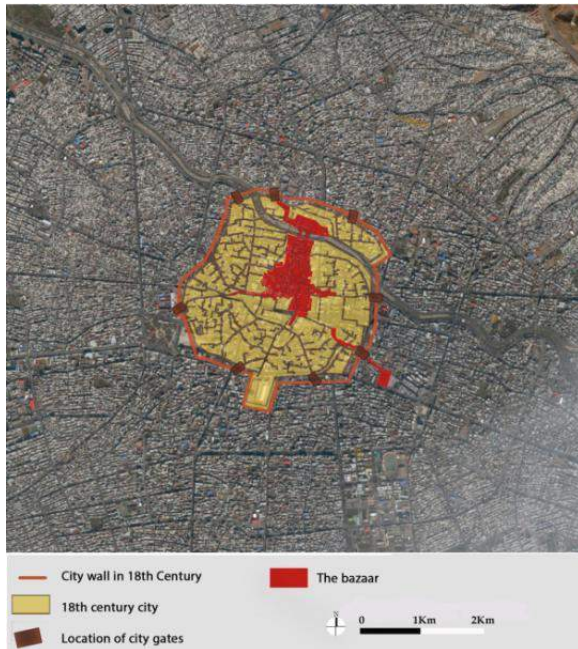

Figure 1 - The location of the bazaar in the historical city of Tabriz. (Yadollahi, 2017).

The national statistics show that the population of Tabriz in terms of gender, educational level and social class is diverse (Yadollahi, 2017). However, the results of the ethnographic research and quantitative observations in Tabriz bazaar between March 2013 and September 2015 do not show the similar diversity. The findings of this research show that most of the users of Tabriz Bazaar are from a traditional social background (Yadollahi, 2017). Furthermore, the quantitative surveys in the Tabriz Bazaar by Yadollahi (2017) show that the percentage of male users in the Tabriz Bazaar was observed to be between around 72.7% and 93.3% of the total users, including women and children. It is noteworthy that the number of children using the bazaar in relation to the adults did not go higher than 2.67% in the Tabriz Bazaar .

The lack of social diversity in the public spaces of the Tabriz Bazaar was a motivation to study the forces that influence and shape the public life in this bazaar. As the first step of studying the public life in the Tabriz Bazaar, the four factors of use, physical accessibility, ownership and local culture of territory-defining, mentioned earlier have been investigated and mapped (Figures 2-5).

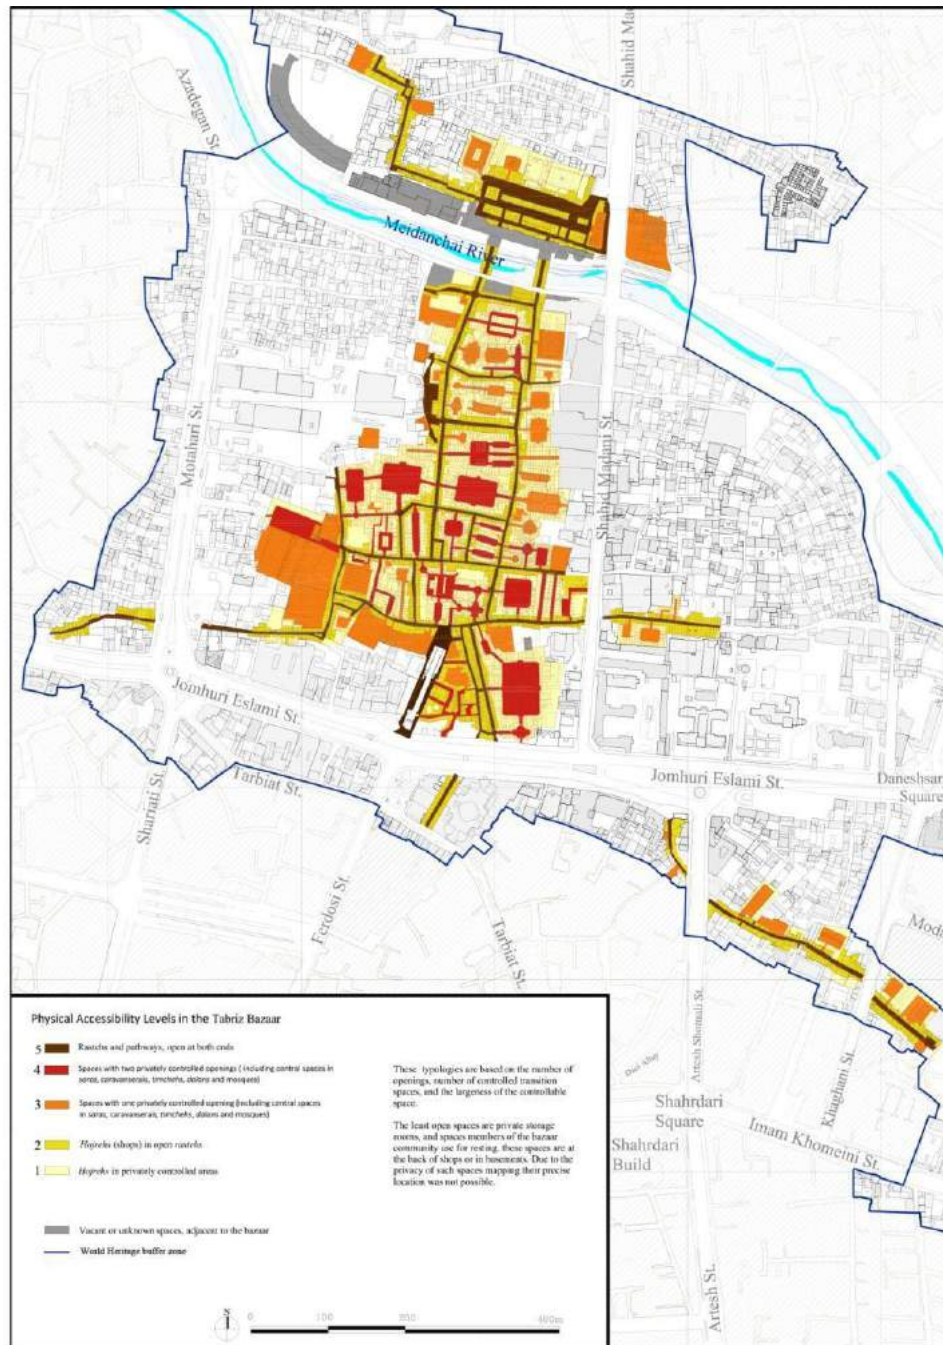

Figure 2 - Identified categories of physical accessibility in the Tabriz Bazaar (Yadollahi, 2017).

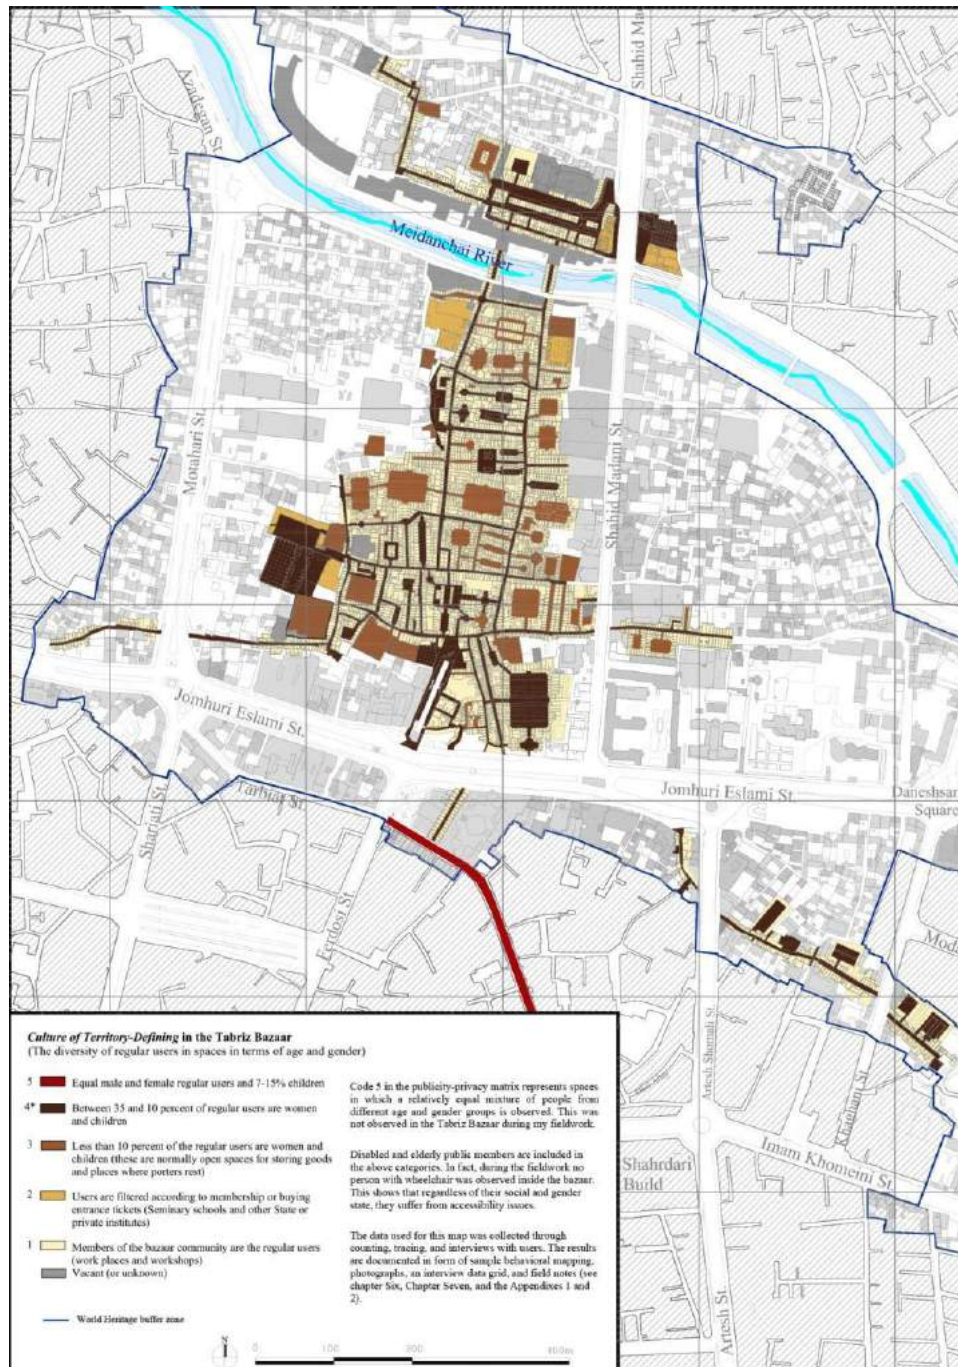

Figure 5 - Identified categories of the local culture of territory-defining in the Tabriz Bazaar (Yadollahi, 2017).

The categories found in the Tabriz Bazaar, regarding each of the factors mentioned above are briefly explained as follows:

- **Physical Accessibility:** The typologies of physical accessibility in the Tabriz Bazaar are defined based on the number of openings, their size, and the largeness of the area of privately controllable space. The privately controllable buildings in the bazaar are not accessible to the public before and after the working hours.
- **Use:** The capacities of each use zone to attract diverse user groups on daily, monthly, and yearly basis were categorised in the case of commercial areas. For defining use categories in non-commercial areas, the factor of membership or institutional control was considered.
- **Ownership:** Two types of public and private control were identified in the Tabriz Bazaar. The categories of properties that have a legal public or private ownership status are clear. In the Tabriz Bazaar, there are several buildings owned by the Owqaf and Endowment Affairs

Organization (OEAO). Regarding these properties, the extent and possibility of public control in them was considered in categorising them. Firstly, the head of the OEAO is not elected by the Parliament. Secondly, a Vaqf property is not legally considered a private or public property. Therefore, the regular public members are not legally involved in decision-making about the physical or functional changes in these buildings (Yadollahi, 2017). So, in terms of legal public and private control level, the status of Vaqf properties are considered closer to private properties in the bazaar.

- The Local Territory-Defining Culture: For categorising the local territory-defining culture in the bazaar, the regularity and quality of optional and necessary behaviours of the user groups were observed and recorded. The consistency of optional activities performed by a particular group indicates that they consider the public space their comfort zone or their cultural (although not legal) territory. Some parts of the Tabriz Bazaar (especially in the southern areas) can become overcrowded during the peak hours (Yadollahi 2017). Nevertheless, the patterns of optional and necessary activities of different users were observed to be remarkably different. Therefore, the factors of gender, age, and social class were highlighted in the ethnographic investigations.

As mentioned in the earlier pages, the number of male users in the bazaar is significantly higher than those of female and child users. The conducted research also shows that women usually use the public spaces only for the necessary activities. Those women who choose the bazaar for shopping are mostly from the traditional and religious social groups (Yadollahi, 2017). In addition to quantitative and qualitative observations, 35 users of the bazaar and a nearby shopping street were interviewed. Some female interviewees who had the traditional Islamic hijab stated that they felt welcomed and comfortable in the bazaar because they have a proper hijab. Most of the female respondents who had dress choices other than the preferable Islamic hijab complained about the dominant masculine and traditional ambience of the bazaar. The observation of both female groups shows that although most of them do not involve in optional activities in public spaces of the bazaar, the non-traditional group shows more interest and desire for having the possibility to enjoy such activities.

After categorising the areas of the bazaar in regards to the described four factors, the map of the publicity-privacy spectrum of the Tabriz Bazaar was prepared based on the presented maps. To be able to put together the mapping results of the four factors in the Tabriz Bazaar, the identified codes of categories were added to each other in each space. The final row in the matrix (Table 2) shows the possible results of coding.

Level of Public Control	5 (Public)	4	3	2	1 (Private)
Factors Defining Openness and Accessibility					
Physical Accessibility (perceived by the architecture, function of space, photography, and built conditions)	market	central spaces in apert, caravanserais, trekkers, dokbars, mosques with two and more controllable openings	central spaces in some caravanserais, trekkers, dokbars and mosques with one controllable opening	subject's private rooms used for various purposes in apert caravans	hotels in privately controlled buildings
Business Use (identified by field notes)	retail with weekly and daily shopping potential and	retail with weekly and monthly shopping potential	gold and carpet workshops, storage spaces and offices mixed with retail	non-commercial institutions (including schools) and workshops based on payment or membership	workshops and storage spaces (not necessarily having plenty of space)
Ownership (registered and/or unregistered)	public (state)	-	-	-	private and vaqf ownership
Culture of Territory-Defining (identified by observation, tracing, and recording)	relatively equal mixture of people from different age and gender groups is observed	10-15% of regular users are women and children	less than 10% of regular users are women and children (those are normally spaces for storing goods and places where people meet)	elementary schools and other institutions (owned mostly by certain users)	used primarily by staff, workshops and workshops
Score: The level of publicity-privacy in each zone	10-12	10-11	10-11	10-9	7-4

Table 2 - The publicity–privacy categories observed in the Tabriz Bazaar (Yadollahi & Weidner, 2017)

Although the method of adding the codes is used here as a solution for juxtaposing the four maps, the outcome will be more than a sum of these four factors. As explained in the previous section, the codes represent categories or levels that are defined based on qualitative contextual investigations in the Tabriz Bazaar. For instance, code 1 is considered to represent the functional category, which attracts minimum public users in the Tabriz Bazaar. As can be seen in Table 2, in other factors, these codes are defined

based on ethnographic fieldwork targeted on the four factors that affect openness and accessibility of spaces. In the case of the local culture of territory-defining factor, results of quantitative observations were triangulated with the results of qualitative observation and interviews to assure the accuracy of the judgments. In general, the results of the mapping method show the extent to which each of the four physical, functional, legal, and cultural factors influence the public or private character of spaces in the bazaar. Figure 6 shows the publicity-privacy spectrum map, resulted from the explained mapping process.

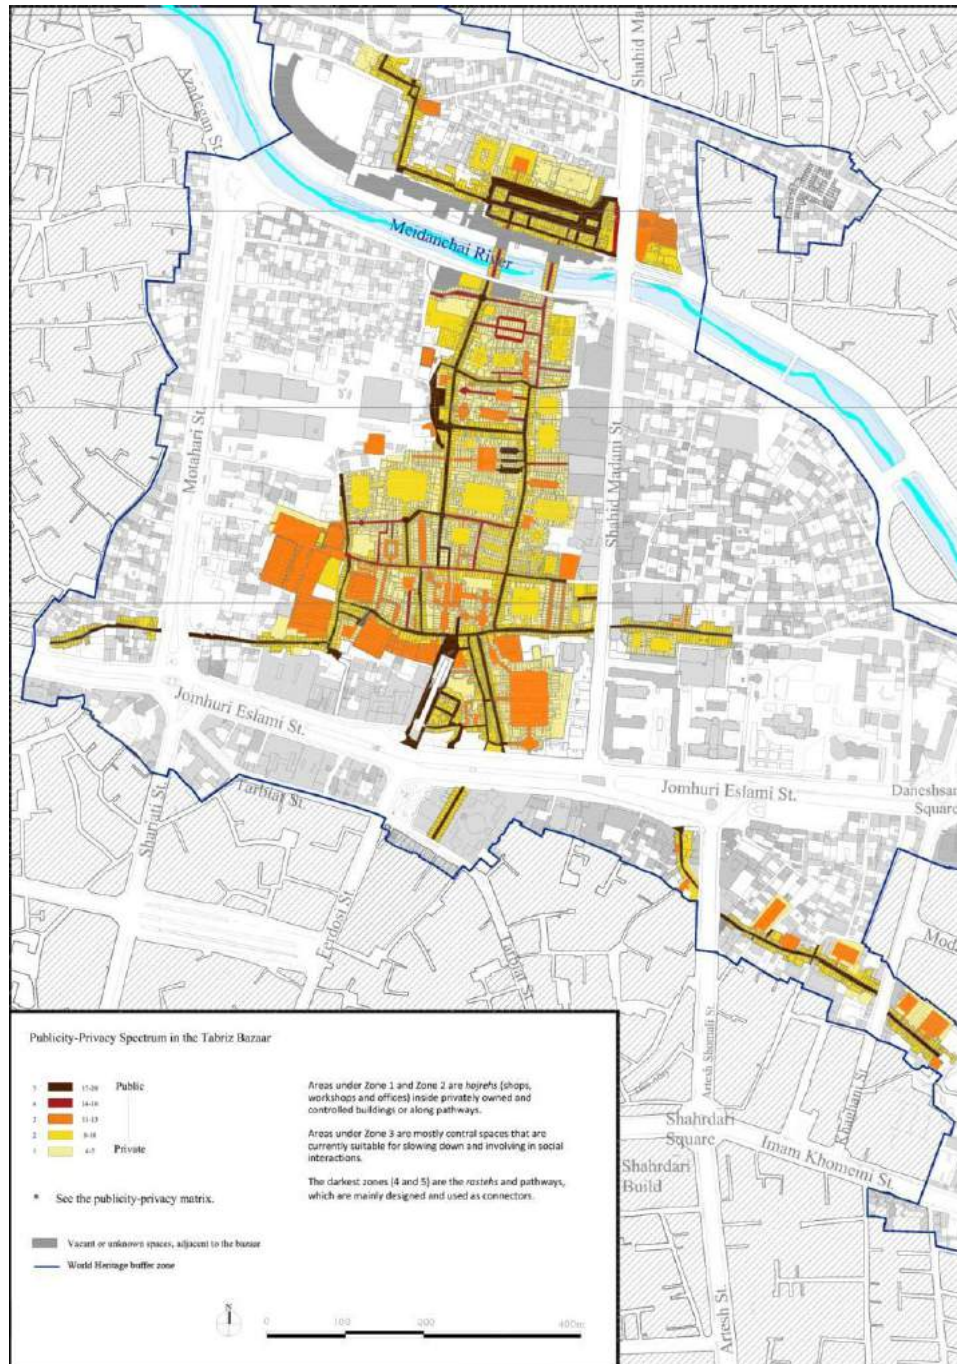

Figure 6 - The publicity-privacy spectrum in the Tabriz Bazaar (Yadollahi, 2017)

3.1 THE PATTERNS OF THE SPATIAL DISTRIBUTION OF THE PUBLIC AND PRIVATE POWER IN THE TABRIZ BAZAAR

The previous pages presented the method which was designed through the course of this research to map the socio-spatial fabric of an Iranian bazaar as a public place. This section discusses the patterns of the

spatial distribution of public and private power in the Tabriz Bazaar, considering the four factors of use, physical accessibility, ownership and the local culture of territory-defining. These patterns are revealed as a result of comparing the maps of the bazaar regarding each of the four factors and its publicity-privacy spectrum map. As the results showed, spaces in the Tabriz bazaar show three general characters. They are connectors, centres of public life, or private areas. The patterns of public life, observed in each of these areas can be summarised as follows;

- Connectors: As can be seen in the publicity-privacy spectrum map (Figure 6), the darkest areas (zones 5 and 4) form a spine, which keeps the public and private spaces of the bazaar together. So, spatially and functionally speaking, these connectors, which are mainly used by the regular public define the integrity of the structure of the bazaar. However, if we compare the publicity-privacy map with the maps prepared for each of the four factors, it becomes apparent that the strongest factor that defines the character of zone 5 as public spaces and main connectors is the use of their adjacent spaces. The high physical accessibility and public ownership in them are also effective but not determinative in shaping the public life in them.

Areas within the zones identified with code 4 can be described as secondary connectors. The factor which is mostly influential in differentiating them from 5 and zone 3 is their level of physical accessibility and the use of their adjacent spaces.

- Centres of public life: The Orange Zones (areas in Zone 3) are currently the middle zones regarding public and private control. Typically, these zones are the interior open spaces of the privately owned building in which an active public life was regularly observed. Comparing the presented maps with each other, we can observe that what makes Zone 3 different from Zone 4 and Zone 5 is the factor of use in it, which is less dependent on public users. Actually, the lower levels of the physical accessibility and the Territory-defining culture factors result from the more private uses in it. The architectural design in spaces within the Orange Zone allows free entrance on the one hand and makes private control of the openings possible on the other hand. However, because the uses of them do not demand high privacy, the private or vaqf ownership does not limit the public access to them, the Orange Zones have become the centres of public life in the Tabriz bazaar. Accordingly, the social diversity of the regular users who engage in optional activities in such spaces is higher than the other areas of the bazaar.

Areas in these Orange zones represent the centres of public life in the Tabriz Bazaar. Regarding the question of the relationship between crowdedness and social diversity in different parts of the bazaar, we should note two points. First; although the Brown and Red zones (zones 5 and 4) show a higher level of public presence comparing to the Orange Zone, they do not have the same level of publicness because they are mainly used for necessary activities such as passing by and shopping. Second; the stronger public character of the Orange Zones, comparing to other zones in the Tabriz Bazaar does not mean that they are equally open, accessible, and attractive to all people in Tabriz. As mentioned earlier in this paper, the results of the ethnographic research in the Tabriz Bazaar do not show a similar diversity, compared with the official population statistic in the Tabriz city. Therefore, the highest level for the factor of the Local Territory-Defining Culture in the Tabriz Bazaar is Four.

As we have briefly explained in Yadollahi and Weidner (2017), the Orange Zones offer an opportunity to the planners and managers of the bazaar for enhancing the involvement of women and children, because they have potential characteristics of successful public places such as safety, moderate crowdedness and good physical accessibility. Therefore, it can be said that if these zones start to attract a wider diversity of public users, they will influence their adjacent open spaces that are today classified under Zone 2. This will Consequently generate a growth in the density of the Orange Zones or the centres of public life in the bazaar.

- Private spaces: As we approach areas in zones 2 and 1, the character of spaces gets more private. These zones are mostly hojreh (small spaces in the bazaar) used as shops, workshops, and offices, located inside the privately owned and controlled buildings or along pathways. When viewing the presented maps, a meaningful shift from public to a private character can be observed in the interconnected factors of physical accessibility, ownership, and Territory-defining culture as we move from Zone 3 to in Zone 2. In Zone 1, the factors of physical accessibility, use, and Territory-defining culture have stronger private character, comparing to Zone 2. However,

due to the mixed use of some areas in it, even Zone 1 is relatively depended on the presence of the public user.

4 CONCLUSION

The presented results show how the level of public or private power and influence regarding accessibility, use, ownership, and culture of territory-defining of an area defines the quality of public life in it. Furthermore, the patterns of the interconnectivity of the mentioned factors with each other can be concluded from the findings. Understanding the revealed patterns of the distribution of public and private power in a bazaar helps us to explain the reasons why it is the kind of public place that we know today.

The first clear outcome of the described mapping process is that even in the highly private zones, the factor of use significantly depends on the presence of the public users. Nevertheless, the culture of territory-defining in these areas (Zone 1 and Zone 2) is clearly in favour of private control.

Maybe the most significant finding is that no space with a level of 5 for the factor of territory-defining culture was observed in the Tabriz Bazaar. Therefore, it can be said that despite the high level of their functional dependency on the public users, even the public zones in the bazaar are not welcoming to a broad range of public members. In other words, the power of public members in shaping territories in the bazaar is limited. Among the public users, women and children are the most marginalised groups. The State, the private owners, and the supervisors of the vaqf properties are the actors who mainly define the norms of public life in the bazaar. Considering the high dependency of the bazaar on the involvement of the regular public on the one hand, and the level of the social diversity observed in it, on the other hand, it can be said that as a commercial institution, the bazaar is making a strategic mistake regarding its approach towards the public users.

The idea of the „public man“ and „private woman“ is something that we have inherited from the past. So, one can argue that the way in which bazaars are used by the public members is also a heritage. But, the question is, do we have to apply all aspects of our heritage to our present life? This research argues that we have not only the option but the responsibility to understand and revise our heritage and contribute our creative solutions for integrating it into our present life. As Lowenthal (2000) suggests, heritage protection has to be a publically inclusive and creative stewardship, which encourages a prudent confidence for making careful alterations in the heritage. This research has provided empirical evidence, showing that there is a need for revising the Iranian bazaar as heritage and as a public place.

In fact, the aim of mapping the Tabriz Bazaar as a public place was to point out this problem based on empirically collected evidence. The ultimate goal of this mapping process is contributing to the enhancement of the diversity of the gender, age, and social class of the groups involved in the bazaar. These groups, which can be involved in the bazaar in the role of customers, investors, social activists or users of the bazaar's public spaces and institutions can enrich the bazaar with social capital. Once activated and generated, this social capital can reproduce itself and be passed from generation to generation. Through building strong connections with diverse groups of potential users, investors and custodians, the historical bazaar will have a greater chance to survive the consequences of rapid commercial and cultural globalisation.

Considering the current urban management system in Iran, the bazaar community and the State are the actors who should take the first steps to provide these connections. By highlighting the public and private levels of control and power in the Tabriz Bazaar, this research aims to offer a tool that can facilitate taking this first step. Although the results obtained for the Tabriz Bazaar do not represent the state of public life in other bazaars in the Iranian commercial cities, the presented method and its corresponding results in the Tabriz Bazaar can inspire our approach in studying and adopting conservation planning policies regarding the Iranian Bazaar.

Acknowledgement note: This article presents a section of the findings of a PhD research conducted by Solmaz Yadollahi (to be published in 2017) in Heritage Studies, the Faculty of Architecture, Civil Engineering, and Urban Planning at the Brandenburg University of Technology in Cottbus. The research is supervised by Prof. Dr.-Ing. Silke Weidner and Prof. Dipl.-Ing. Heinz Nagler.

ID 1589 | E-CAMPUS SPACE REVISITING THE LIFE AND DEATH OF THE CAMPUS URBAN LIFE

Sarah Abd Elmagid¹, May ElAdas¹, Ayman Abdellatif¹

¹American University of Sharjah

aabdellatif@aus.edu

ABSTRACT: How has Wi-Fi and smartphones changed the excitement of the Campus urban space? To what extent has it de-engaged students from themselves and their surrounding? How has the culture of smart phones affected the on-campus communication style in public spaces among the younger generation? The study is a continuation of the dialogue generated by Keith Hampton, Lee Humphreys and others on the impact of mobile phones in public spaces. However, it chooses to focus on ME Gulf City Campus Life. Campus life has traditionally been one of the most memorable and engaging experiences of student life. The common age-group, shared major of study, interest and common agenda has branded

the university life to become so memorable in the development and growth of a student, perhaps so much more than any other urban space in the city. Ever since the introduction of virtual space, that aspect seems to have changed. This study aims to investigate the effects of smart phones on how people interact, connect and perceive campus urban spaces. It investigates some aspects of the culture of smart phones on the design of urban spaces. These aspects of how people connect and perceive urban spaces, their cognitive abilities, communication skills, behaviour and face to face interactions are just few effects of smart phones in shaping the identity of people and places. The study finally investigates whether the design of the space affects how people use their phones or are there other factors that play a role in that. For this research, the students of the American University of Sharjah (AUS) are surveyed for the case study. The findings include insights about what motivates people to use their phones in public spaces and how physical elements of a space such as the provision of various seating options, soft-scape, good views, etc. would affect the likelihood of using smart phones.

KEYWORDS: mobile phones, social isolation, campus space, observation

1 INTRODUCTION

For a decade or more, the use of smart phones has been one of the popular acts throughout different societies attracting people of all age groups. The use of smart phones in public space social life became an undeniable phenomenon since about 2012 (Reisinger, 2013). Smart phones miraculously got people close to each other, they can now call, text, Skype and check Facebook posts from all over the world. Smart phones have changed from a simple communication tool, to a technological extension to our body (Lanier, 2010). Everywhere in the city, social life in public spaces is changing. Interaction and engagement seem no longer related to the confines of physical space and design. On campus too life is changing. We cannot leave a place without our phones. Walking around campus, students no longer talk to each other anymore while walking to classes. Even when sitting together on the same table, a short phrase when something pops-up, then each one goes back to their own digital world. Smart phones replaced face to face interactions. The use of mobile phones has turned public urban spaces into private ones where each person is in their own world with someone who is not in their same location. People move around with their own private bubbles, their own private public space. Therefore, as urban planning scholars, the question is posed: how does this behaviour affects how people perceive campus urban spaces? How do students interact with their campus environment within the dominance of non-physical engagement? Is there a new task for the campus planner/designer? The scope of this study is bound by the behaviour of users of the American University of Sharjah (UAE).

The time a person spends on smart phones is a lot more than what we spend on other life activities. Recent studies show that the average time an individual spends on a cell phone was about 4 hours every day (Emarketer, 2017, Flurry Analytics, 2017). Smart phones therefore affected the way people communicate and behave in outdoor as well as indoor public spaces. Many studies about the effects of smart phones -and their predecessors the mobile phones and PDAs -on social interaction and face-to-face communication in public spaces have been conducted. Lee Humphreys (2005) for example, performed a year-long observational study on how people's interaction changes in public spaces and how mobile phones became an anchor for societal relations. The behavior of people was examined when they were alone or with someone and how they used their phones as "defense mechanisms" to escape from "social vulnerabilities" (Humphreys, 2005). Keith Hampton's et al. (2010) looked at how social life took place in "wireless urban spaces". They observed seven public parks in four different cities in the US. The findings indicated three things: that people are attracted to public spaces that offer internet connection that they would not otherwise visit; that the location of seating that people choose depends on their usage of smart phones; and that users can be less aware of what is happening in their surroundings and are less likely to be engaged in in-person conversations. Ira Hyman (2014) compared the acceptance of cell phone usage among social groups. She found that young generation found texting and using smart phones among social groups to be more acceptable than older generations. Ling (2002) goes on to suggest that smart phones restrict the social interaction and nonverbal communication especially among the younger generation. While Irfan, Aqeel and others (2014) find the opposite -that owning a cell phone actually increases social capital and sense of belonging among university students.

Therefore, the issue of whether or not smart phones positively or negatively affect the campus life experience is still largely undetermined. This study uses different methodologies and in a different context and cultural setting.

2 LOCATION OF THE STUDY

For this study, participants are selected from one university, American University of Sharjah, in the United Arab Emirates (UAE). The United Arab Emirates is an Arab country located in the southeast of the Arabian Peninsula. The UAE is made up of seven emirates, Abu Dhabi, Dubai, Sharjah, Ajman, Ras Al Khaimah, Umm Al Quwain, and Fujairah. It is known to be one of the top countries hosting a wide diversity of cultures and nationalities which makes it an interesting field for social and studies. The city of Sharjah is the third largest emirate in the UAE. The American University of Sharjah was founded in in 1997 and is now a prominent all-inclusive coeducational university in the Gulf region. .

AUS is a huge 150 hectares campus with its acadeic core spreading across 18 hectares (550x360m). Academic buildings are symmetrically alligned along both sides of a north-south axis with the Main Building and Library (4) at its vista. The main gathering places are mostly indoors. The Student Center (2) has lounges, a food court, and Break Point restaurant. The Libaray building and its annex has the reading hall (4), the Sheraa Enterpeneurship Center and its infamous Belnds and Brew Cafe (3). Wifi servise covers the whole campus spaces both indoor and outdoor (figure 1).

Figure 1-American University of Sharjah Campus

3 RESEARCH METHODOLOGY

This exploratory study was conducted on three stages; online survey, recorded video observations and face-to-face interviews. In the first stage ; 35 students currently enrolled in AUS in different majors took the online survey. In this survey, campus spaces where student gather, use their smart phones and interact were identified. Students were asked 10 questions about their smart phone habits, technology dependency, reactions to their surroundings, their life before and after they own a smart phone and finally to rank the public spaces in the university where they use their phones the most to where they use it the least.3

Based on the survey findings, the second stage used unstructured observation technique (Gillham 2008) at those key locations around AUS during lunch breaks and campus peak hours. The main focus was on how students behave with each other and with their surroundings. The other motive was to understand the role of the space design on students' decisions to use or pay no attention to their smart phones and explore what other factors can play a role in that.

The third stage used in depth interviews with 16 students to find out about the motives of their behaviour and actions.

Figure 2 - Interview Analysis

The research took place during finals weeks. This caused the sample of our interviews to be smaller than what was intended. Not only this, but this might have also impacted the answers of the interviewees regarding their behaviour in the two spaces especially in the library cafe because all what they were thinking about is their studies. In addition, the findings might be limited to college students who are within a specific age group and not in public spaces in general. Therefore, the research is considered more exploratory in nature.

After the data collection, the analysis started with identifying trends and behaviour patterns. First, the scripts of the interviews were written, coded by their repetition and categorized into groups with different labels. From there they were prioritized according to their relevance to the study. The final step was to expand the understanding and explore the relationship between every answer and the other (figure 2).

4 FINDINGS

For the survey, results showed where students used their smart phones most and where they used them the least. Food Courts and Lounges ranked top in usage whereas Blends and Brews Cafe at the Sheraa Entrepreneurship Center has the least usage (figure 3).

Figure 3- Smart Phone Usage Ranking on Campus

During the observation, it was noted how students would react differently when they were alone or when they were in a group. When eating alone, they would be on their phones the whole time, while when they were with friends they would finish eating and check their phones immediately. Studying with friends or enjoying a coffee seem to drive students to abandon their smart phones for a long time.

Finally student interviewed results show that almost all the students agreed that food courts are the spaces on campus where students use their phones the most and that the library café is where they used it the least. When asked about their relationship with their phones, some people used the words “intimate”, “cannot live without it” and even “it’s like my wife” to describe this relationship. (see Appendix B for sample survey).

5 ANALYSIS

Upon review of the findings, it became apparent that certain factors contribute more than others to an attachment to smart phones. The following are some of these observations:

5.1 LONELINESS AND THE SURROUNDING ENVIRONMENT

Students seem more inclined to use smart phones when they are alone. Their frequency of use can be up to 10 times in an hour. Whereas when with friends, they tend to check them for a maximum of 5 times. This seems to indicate that the usage of a cell phone decreases when a person is accompanied by someone however, when alone and not concentrating in something such as studies, students tend to spend more time on their phones. This is compounded by another factor, the attractiveness of the surrounding environment. Students felt distracted and less connected to their surroundings when they use their phones. All participants stated that if they were not busy with their phones they will most probably enjoy the space and recognize its beauty and their surrounding environment generally.

The relatively low smart phone engagement rates at both the Sheraa Blends and Brews (Library café) compared to those in Break Point and lounges seem to further substantiate this fact. Sheraa – ‘Sail’ in Arabic (Sharjah Entrepreneurship Center) was launched in January 2016 to provide a launch pad for aspiring young entrepreneurs in the UAE. It is headquartered in AUS library and was designed to create an innovative, relaxing and comfortable environment that would aid in the flow of ideas. It has a refreshing mood with unconventional indoor stepped seating, swings, lighting fixtures that really seem to attract students to look around and engage. On the other hand Break Point is a classical restaurant with tables and chairs arranged in a conventional template manner. This goes to indicate that the physical elements and assigned activities of the space do have an effect on how people behave and interact. When asked about what would they do in this space we found out that people actually had clear ideas of things to do in the library café more than they could think of in break point. It supports the assumption that people were more engaged and paid attention to the space and thought well about enhancing their experience within the space than the restaurant area.

5.2 LIFE WITHOUT A CONNECTION

When asked what they would prefer to do in the space if they have no internet connection, students at Break point mentioned they would stare at the walls, have a meal then immediately leave after they finish or start a conversation with people sharing the space. While those at the library café students went for a wider variety of activities such as, listen to music, read, eat, grab a coffee or just approach others and start a casual conversation.

Figure 5 – Various views at the Blends and Brews Sheraa Center vs that of Break Point (lower right)

Noticeably, students would actually find something to do without having internet connection to kill their desire to interact with friends and with their surroundings. Also the common factor between the two spaces from the answers is starting a conversation with the person they are accompanied with. Therefore, an important question was asked, “How long would you stay in this space without checking your phone?”

Figure 6- Feeling without internet connection

For Break point students they said as long as it takes to finish eating, others stated they can't tolerate to spend more than 5 minutes. While this was an interview question, this is one of the behaviors documented while taking the observation videos.

While students answered positively that they would find different activities to do when there is no internet connection, this was contradicted by the survey responses. The question in the survey was to use a word to describe your feeling without an internet connection. Mostly used words were bored, normal, disconnected, lost and uncomfortable (figure 6). However, back to the previous point, people were can expressed their willingness to invest their time in other life activities. That means, the belief that we cannot live without our mobile phones is taking our minds off the things we can actually do and enjoy.

5.3 ENJOY THE VIEW

After observing and analysing the behaviour of people in these two spaces, the space design and physical character was investigated to study their effects on the behaviour of people. Physical elements in this

study include seating arrangements and options, lighting, landscaping as well as outdoor views. The analysis started by asking people in the survey about their first reaction when they stand in front of a very beautiful view. The answers revealed the participants' willingness to enjoy the view without their smart phones (48%) but almost the same percentage of people responded they will use their smart phones to capture the view (49%). Very few thought asking someone to share the moment would make them enjoy and appreciate the view (see figure 7). This might prove smart phones to be one of the factors that steal priceless moments and limit the joy of exploring life and adventures.

Figure 7 - Response to a beautiful view

Figure 8 - Willingness to spend time on phone

Not only this, but when asked during the interview about elements to add or remove to distract people from using their phones, most of the respondents answered that an outdoor view or wider windows to the outside would actually reduce the amount of time people spend on their phones. However, these answers were contradicted by a question that the students answered in the survey. The question was: how much of your time would you spend using your phone if you are in front of a beautiful view?

The responses show that while people claim that a beautiful view would distract them from using their phones and that they would just enjoy the beautiful view they are watching, they would spend more than 50% of the time on their phones.

Students in both places stated that their phones are the only source of entertainment especially if they are alone. Therefore they suggested some elements to make the spaces more lively and entertaining to take their eyes off their phones. Adding a source of entertainment such as TVs or activities was common in both places. Students thought of break point as merely a place to eat, they were not really keen about making it look better or change anything about it to distract them other than the three elements mentioned above. As for the library students were more open to suggestions and additions to the space as they can spend more time their studying or with their friends. They wanted to add elements of nature to the space and relaxing music in order to make them feel comfortable. A really good suggestion was choosing what types of tables are available to use in this space by making them higher for example to encourage studying rather than feeling like sitting in a lounge. This takes us to another important question that we asked during the interview. The question was "Why did you choose this particular place to sit while you have a variety of seating options?" Break point as apace does not really offer a variety of seating options; you either sit on the couch (figure 9) or on chairs, on a gigantic table for four (figure 10) or more or on a small table for two. Students' preferences were not varied according to specific factor, as mentioned earlier they just see it as a space that they will just eat their meal in and leave. Students chose the places they

want to sit in based on their needs at that moment. For example, needing a socket for the laptop, joining a friend or alone so a table for two is enough. Others were more concerned about their comfort and therefore they chose to sit in a more quite place or on the couches.

Figure 9 - Table for four people Figure 10 – Couches

For the Library Café interviewees mentioned that the seating selection depends on their planned activity. For example, students on the swings said it is fun to study there, some chose to set on the stepped floor to have the open view to the entire space, while others preferred to enjoy the view of the landscape so they set close to the large windows. Some student thought the excluded seating options are more private and cosy to study a way from other distractions.

On the other hand, the library café offered different seating options that are suitable for people who use the space for different purposes. These options make the space more attractive for students and more enjoyable for them when studying. Seating can be used by students who are just there to socialize, eat or drink (figure 11). They are also used by students who prefer to have tables in front of them while studying especially if the course requires solving (figure 12). The other seating options are different and more fun while studying such as the swings (figure 13) or the wooden steps shown in the pictures below (figure 14). However one disadvantage mentioned by students as to why they do not use the wooden steps is that it hurts the back. Moreover, seating options are also encouraging for groups to sit and study or do anything else together. As noticed in the observation, people sitting on seating designed for groups are less likely to use their phones than those sitting in seating designed for individuals or perceived to be used for people sitting alone or with one other person (figure 16).

6 LIFE BEFORE SMART PHONES

With all this being said, the authors wanted to know what people think about their lives now and before having mobile phones and we found out that peoples answers can be categorized in to three main categories (refer to table below). Some people felt that their lives were better before mobile phones in terms of their relationships and communication with people as well as enjoying the outdoors. Others did not feel there is a difference between that time and now in their lives and the third category of people thought that mobile phones were actually an advantage to their lives. They think that mobile phones enhanced and strengthened communication and relationships with family and friends. However, the majority of the surveyed students were more affected negatively by mobile phones.

NEGATIVE	NEUTRAL	POSITIVE
<p>Wasting more time (1)</p> <p>Life was meaningful, relationships were stronger, there was a dedicated time for hobbies and socializing physically</p> <p>Everything is different (2)</p> <p>Became harder to reach people unless you use a cell phone (1)</p> <p>I used to stay outdoors and not rely on it (2)</p> <p>I don't even remember how I was living (2)</p> <p>I used to communicate face to face (3)</p> <p>My relationships weakened (2)</p>	<p>Not different (9)</p>	<p>More and better relationships (3)</p> <p>Intimate communication (1)</p> <p>More connected (3)</p> <p>Had my phone since 7 or 8, so regarding my relationships with my family and friends I can state it increased and became better as I had more time with them through social media.</p>

Table 1 – People's view of their lives before and after mobile phones

7 CONCLUSION

To sum up, enjoying campus life has changed from a dependency on pure physical space design into a hybrid of factors that include both cyber and urban space. Design elements of a space still do matter and have an effect on how people use and behave in a particular space. What people remember about a space is affected by how long they spend on their phones but it is our duty to design spaces that leave a mark within each person no matter how long their use the smart phone in the space. The loss of connection is not because of one person but it is because all of those in a group. If you are with a group of friends who are busy doing something else or start using their phones, you are more likely to start using it to as a source of distraction or entertainment until you are given the attention once more from those sitting

with you. Student's face to face conversations are fading due to the presence of texting and when they talk to each other, they are often distracted by their phones. Moreover, we can conclude that people are aware of their actions and behaviour in public spaces and they know that they can live without their phones. However, people choose to live in it as they might convince themselves that it is the only source of entertainment. As future urban planners, our duty is not to force people to abandon their phones because clearly as they said in the interviews and as captured in the field observations this will not happen. So we should do our best to distract them as much as we can in order to strengthen the bonds they have with each other and with their surroundings.

APPENDIX A

PAGE 1

Q1: What is the first thing you will do when you see a very beautiful view?

Take a picture of the view

Q2: If you are in-front of a very beautiful view how much time will you spend on your phone?

40

Q3: When you need to locate a place which one of the following do you use? (please select all that apply)

Ask someone

Your phone

Q4: When you use your phone for navigation,how likely are you going to use it to go to the same place again?

Very likely (will use my phone again)

Q5: What word would you use to describe yourself when you don't have an internet connection on you cell phone?

Uncomfortable

Q6: How is it different between now and the time before you own your cell phone?(e.g. relationships with your friends, practicing your hobbies, etc.)

I used to communicate face to face more

Q7: Imagine if you do not have a cell phone, how would you spend your time?

I would go out more

Q8: Please rank in which part of AUS campus do you use your phone the most? (1 Most - 6 least)

Food courts	2
Library	5
Bus stations	3
Lounges	1
Blends & Brews (library cafe)	6
Classes	4

Q9: What is your gender?

Female

Q10: How old are you?

21 - 25

APPENDIX B

Interviewee 01 (Break Point):

Q1:

Answer: I think they use it everywhere, to take photos of their pictures and upload it on instagram but I do not think the space has an effect on how much people check their phones

Q2:

Answer: Alone- long time

With people- Rarely

Q3:

Answer: Does not get caught up when using the phone

Q4:

Answer: intimate

Q5:

Answer: half an hour

Q6:

Answer: stare at the walls

Q7:

Answer: fun activities, presentations but it is difficult to make people stop using their phones

Q8:

Answer: because there is a socket here and I need to use my laptop

1 CHILDREN, TEEN-AGERS, AND THE URBAN SPACE

According to Ansell and Smith (2008, p.1), children's position within a nation or culture holds an "immense symbolic significance". This is to say that how a society conceptualises and provides for its children represents a strategic domain in which complex social, political and moral agendas are mobilised (Freeman, 1997). Some childhood theorists go further and suggest that focusing on concepts of children and childhood is essential to understand a society or social context as a whole (Jenks, 1982; 1996; James & Prout, 1997; Corsaro, 2005). Nevertheless, however, even though children and kids are citizens to all intents and purposes (and with their own needs and rights), on the one hand, their mobility across the city – as non-drivers – is strongly reduced (Miere, 2008), so that their "right to the city" (Lefebvre, 1968) is denied in practice (see: Bozzo, 1998; Dolto, 2000; Moro, 1991); on the other hand, they usually are substantially excluded from decisions concerning the urban spaces of their daily life since they are considered as non-adults, 'still-in-progress entities' having no voice (Scoppetta, 2014a; see also: Alldred, 2000 as well as Spivak, 1994). But it is worth remembering that, after all, the well-known definition of sustainable development explicitly refers to "future generations" (WCED, 1987). Therefore, the exclusion of children and teen-agers from decision-making reveals the vagueness of such definition – "starting from how needs are to be defined and anticipated, and by whom" (Pellizzoni, 2012) – as well as the problematic character of sustainability itself.

Paradoxically, at a time of rapid demographic change, while in Western countries their proportion of the population is reducing more and more (Harper & Levin, 2005), children and teen-agers are experiencing "unprecedented" (id.) levels of intervention into their lives, for instance in the form of academic expectations, surveillance and restrictions on their already limited mobility. In this sense, it has been argued that this is an "era marked by both a sustained assault on children and a concern for children" (James et al., 1998). Many studies (see e.g.: Valentine & McKendrick, 1997), in fact, show that the presence of children and teen-agers in public space has become less evident due to an increase in parents' fears based on the perceived risks in public space from both strangers and heavy traffic (Gill, 2007; Lee, 2001) – where the former have a different and more relevant social meaning, but they often tend to remain hidden behind the latter. At the same time (and ironically), (especially male) children and teen-agers from about 9 to 13 years old daily walk across an immense virtual but extremely realistic Los Angeles – a landscape of advertising for actually existing products – by killing (or being killed) in all imaginable and unimaginable ways, by making robberies and illegally accumulating money in order to buy weapons, cars, apartments, drugs (to be sold) and various luxury objects (with well visible brand names) as well as female bodies (prostitutes) and by becoming familiar with thieves, fraudsters, (usually Mexican) prostitutes, drug addicts or dealers. This is the case of the widespread GTA V (5th edition of Rockstar's video-game "Great Theft Auto"), which cost about 256 million \$, has earned 815,7 million \$ in the first 24 hours after the listing, and has exceeded one billion in the first three days of sale and over 15 million copies sold (11,210,000 only the first day), with 75 million copies sold worldwide (until 2013) .

However, despite their virtual but daily experience, the relationship between children and teen-agers and the city is defined problematically in terms of the need to protect them against the city's perils (see: Valentine & McKendrick, 1997): following a more general trend (I refer to: Beck, 2006), the urban neighbourhood appears predominantly as a threat to their development and an undesirable socialising context. As a result, keeping children and kids 'off the streets' is assumed to serve their individual development, safety and wellbeing. Such an attitude reveals that what Zinnecker (1995) defines as the ideology of the "bourgeois childhood" has become a generalised pattern, an important condition in acquiring the necessary cultural, social and personal competencies and skills to be able to get on in society. This means that children and teen-agers are constantly involved in a broad range of pre-organised pedagogical settings and that institutional socialisation is seen as essential to 'normal' socialisation (Kampmann, 2004). Children's and teen-agers' everyday activities and spaces are therefore structured in a pedagogical sense: they spend most of their time in institutionalised settings such as home, school and recreational institutions (Kampmann, 2004; Rasmussen, 2004) providing them with well-controlled

developmental opportunities and preparing them for their future role in society. As a result, children's and teen-agers' use of time and space is dominated by a busy (institutionalised) leisure agenda, sometimes accompanied by leisure stress, leaving very little room for informal interactions (and for informal public spaces). This, moreover, also leads to the fact that many (not only urbanised) children and teen-agers currently live a spatially segregated life and the public realm is kept out of their everyday life as public spaces fall outside adult control and are therefore seen as a problematic influence on children's and teen-agers' socialisation. Despite the shift occurred in general planning theories and practices from Modernist 'rational' approaches based on zoning and functional separation to a more complex view of cities and societies, what concerns children's and teen-agers' urban space still remains anchored to the old logic based on separation and aimed at control. Such separate spaces clearly mirror the ways in which contemporary cities are organised according to a generational order, i.e.: the pattern regulating the relationship between adults and children, where childhood is represented in a double Apollonian-Dionysiac perspective, the former to be protected into 'safe' fenced areas; the latter to be tamed as it pretends to occupy adults' urban spaces (see: Harden, 2000; Holloway & Valentine, 2000; Valentine, 2004; Zeiher 2003; see also: Alanen & Mayall, 2001). In this sense, children may be seen as social actors provided with a "pre-determined spatiality" (Satta, 2012b; see also: 2010; 2012a).

More generally, on the one hand, we find the progressive reduction of public open spaces, where a worrying example in this sense is given by a series of regulations regarding public spaces promulgated within the frame of Tony Blair's so-called 'urban renaissance', all aimed at fighting youth crime, but actually including within the notion of 'crime' a wide range of behaviours (e.g.: skateboarding) (see: Charman & Savage, 2002; Flint, 2006; Flint & Nixon, 2006) thus revealing the (re)emerging of a sort of (neo-Victorian?) "moral panic" (Rogers & Coaffee, 2005) with a special focus on the young population. On the other hand, we find detailed designed age-based spaces devoted to children only, which are rhetorically promoted as giving them space, whereas, by contrast, such often fenced spaces – oases in the jungle of the city, safe heavens in dangerous public space – actually subtract them the city space as a whole.

2 THE MODERN DISCOURSE ON CHILDHOOD, AND PLANNING AS AN AUTONOMOUS 'TECHNICAL' DISCIPLINE

Following Hendrick (1997a), the children/adults divide can be interpreted as an inheritance of the radical economic/social changes due to the industrial revolution, when – although until then highly valued as unskilled low wage-earning labour force (see: Pollock, 1983) – children's and teen-agers' widespread employment started to be publicly opposed (mostly by the middle and upper classes) and working class children and kids became subject to a discourse that viewed them as worth protecting as future assets to society. A more skilled labour force, however, precisely was what industry needed. Aries (1962) underlines how, in the mid-19th century, European upper classes generated an age-based hierarchy which was institutionalised as a dichotomous power relationship between adults (rational, complete and superior by nature of being fully grown) and children (irrational, incomplete and inferior), which mirrored the existing divide between upper and lower classes. In addition, the notion that if left to itself the child would become feral and wayward was influenced by longstanding ideas about original sin that regarded the child as evil, base and corrupt (Cunningham, 2006). At the same time, however, the child was also described as innocent and pure. Such twofold notion of children's natural waywardness or goodness, representing negative or positive qualities lost by adults, still remains embedded in modern Western ideas of childhood (Lister, 2005).

Whereas, traditionally seen more like small adults, children and teen-agers of the lower classes had always worked amongst adults; with these shifting concerns, child labour suddenly started to become synonymous with exploitation: "children here are represented as the victims of super-exploitation who were rescued from the predations of capitalism by the combined influences of social reformers and moralists and by the certain economic transformations which shifted demand away from unskilled towards more skilled and educated labour". In this way, "children were relocated (displaced) in 'childhood' – an idealised and romanticised state" (James et al., 1998).

It is worth noting, however, that the modern discourse on childhood and adolescence has been developed precisely during the same historical period in which even urban planning emerged as an autonomous

'technical' discipline proposed as a "cure" for the "disease" (Calabi, 1979) of the "monstrous" (Munford, 1961) industrial metropolis and as bearer of progress and improvement of living conditions. According to Benevolo (1985), the new discipline, by self-representing itself as "a sort of St. George killing the dragon" (Secchi, 2002), was able to play a reformist role in-between revolutionary impulses and reactionary repression through the elaboration of a series of 'spatial devices' (such as social housing, schools, public open spaces) constituting the fundamental elements of a (public) "positive material welfare" (Lanzani & Pasqui, 2011, p.32) that, until then, had been entrusted to (private) charities. The emerging of both planning and the new understanding of childhood seem to be related to what Bernardo Secchi (2002) has defined as "one of the deepest anxiety of Modernity" concerning the worrying transformation of the 'common people' into a threatening 'crowd', within which it was no longer possible to clearly distinguish between "classes laborieuses" and "classes dangereuses" (Chevalier, 1958; more generally, see: Scoppetta, 2014a). Such an anxiety is clearly expressed by the flourishing of the 'monstrous' literature of the period – think of Sir Arthur Conan Doyle's, Oscar Wilde's and Stevenson's literary works – as well as Charles Darwin's evolutionary theories that fuelled concerns about both 'civilisation' and questions of mental and physical handicap, evolution and solutions to poverty, with a special focus on the effects of the environment on the development of child's mind, leading to further evidence for the distinctiveness of (working people's) child's 'primitiveness' with respect to the 'civilised' (middle class) adult.

Therefore, social reformers, who also theorised an educational role of planning, sought to remove working class children from the adult worlds of work, to 'civilise' them through education: schools would transform the wild nature of the working class child (often even through physical punishment) into a deferential being, by replacing child's familial and social knowledge with another one, more appropriate and worthwhile (Hendrick 1997b).

The idea of the urban fenced play-gardens emerged as part of modern concerns about childhood. It was strictly linked to both public health and educational policies. Both in the USA and Europe (Frost & Wortham, 1988), however, play-gardens were intended as constantly supervised by adults, mostly local residents and parents, but later also by professional supervisors, who also organised activities there: given the general focus on children's health and motor development, playgrounds were designed to make children exercise and develop their motor skills, while also providing them with fresh air within the city (see: Hartle & Johnson, 1993). It was just many years later that advancement in psychology, psychoanalysis and psychiatry as well as concepts from the field of developmental psychology – and particularly Piaget's (1973; see also: 1951) notion of the "naturally developing" child, i.e.: the assumption that children are 'natural' phenomena that implies a "figurative" thought as well as a distinctive "operative" intelligence – led to the idea of children and teen-agers as a class of being with specific needs, desires, rights and an innate potential capacity for reasoning, and of adult society as responsible for supporting their growing up. Such approach informed post-War attitudes towards children as individuals and concepts of child-centred learning (see. e.g.: Montessori, 1972), as "children [...] constitute an investment in the future in terms of the reproduction of social order" (James et al., 1998).

On the planning side, instead, in her seminal work, Jacobs (1961) marked a shift away from the idea of fenced playgrounds, as she underlined how children learn the fundamentals of social urban life by being able to live and play in the streets, as facing the unpredictable events taking place in the world is an essential component of children's and teen-agers' development (Hart, 1986). In fact, the separation of children's playground from the adults' urban spaces as well as the rigid division among different ages not only prevents lively inter-generational relationships, but this also denies the idea of spontaneous, creative and self-organised games in the urban space, being fenced playgrounds the sole place in which the right to play (for adults too!) is allowed. Furthermore, too often mass-produced equipments in children's gardens and playgrounds not only tend to influence their design but they also imply a passive idea of children's and kids' games as a monotonous unchangeable and mechanical practice that prevents children from experiencing an imaginative self-construction of their own space (for instance: based on the inventive use of objects trouvés). In this way, such kind of fenced and controlled children's gardens, where only pre-determined actions are allowed, keep them from autonomously managing their space and time and seem to be designed in order to construct passive subjectivities.

"continuous and durable reciprocity [...] objectified in unitary configurations" (Simmel, 1903) characterising what Alexander (1975) calls the "natural" historic city.

The second interesting aspect of Calzolari's and Ghio's work consists of an understanding of the proposed 'urban infrastructure' not only in terms of planning and design of physical spaces, but also in (immaterial) terms of highly inter-sectoral urban policies to be developed within a broader perspective that considers both the physical and social dimension as strictly inter-connected (in this sense, see: Ghio, 1964). But the most important aspect of their work consists of taking the point of view of the users of the spaces to be designed, i.e.: the future generation which the notion of sustainability (WCED, 1987) also refers to. Too often, in fact, the concept of 'urban quality' is emphasised, but it usually tends to be merely intended as 'quality of design', while it is rarely explicitly affirmed who such quality is for. Calzolari's and Ghio's child-based perspective has strongly influenced a still on-going action-research on the involvement of children and teen-agers in planning and design activities, whose findings are presented here.

4 MAPPING THE CITY FROM BELOW

Recent years have witnessed an increasing interest in planning processes based on the involvement of children in design activities (e.g.: within participatory workshops). Such involvement could be utilised as a sort of 'litmus test' to evaluate the sustainable perspective of the project, as it gives voice to weak actors. Children's technical contribution (see: Tonucci, 1996; Paba, 1997) to planning and design activities can be particularly fruitful as not only they "bear specific needs" (Paba, 2001b; see also: 2001a), but they are also provided with a 'different sight', which means a specific 'experienced knowledge' of urban spaces. Furthermore, they are also involved within the network of "weak ties" (Granowetter, 1983) of the neighbourhood level, where people are "within sights" (Mumford, 1968. p.35) and a "democracy of proximity" (Bracqu  & Sintomer, 2002) may be possible. Finally, children's distinctive spatial behaviour tends to be subversive since it is able to resist the usual "production of urban space" (Lefebvre, 1974) of late capitalism, and this fits well with a different and more political claim for sustainability. Thus, children's sight 'from below' can help planners in anchoring sustainable alternative visions to the local dimension of daily practices (Mc Kendrick, 2009). Especially if framed within and sustained by a learning path (e.g.: through workshops strictly inter-related with school programs, with particular reference to subjects such as geography, drawing and natural science, but also literature and music), their skilled involvement in planning activities can fruitfully contribute in re-imagining the city as an inter-active cognitive potential (see, e.g.: Sandercock, 2003) that lies within the daily social practices structuring urban spaces (De Certeau, 1990). In this sense, not only children's participation can force planners towards a more responsible approach to the resources and commons to be preserved for the future generations: their different sight can effectively help planners in placing "diversity as the cornerstone of their prescription for urban reform" (Talen, 2006a; see also: 2006b), i.e.: enabling diversity through planning and design.

A real and effective involvement of children in participatory practices, however, requires an understanding of their own distinctive language. In fact, as Poli (2006) underlines, space is usually thought as a real, objective and external construction, as a mere container of objects that exists in everyone's mind. By contrast, space actually is the result of a slow cognitive development that derives from perceptions, experiences, culture, individual and collective history. In this sense, the geographical Euclidean space, where objects are placed following an exact metric relationship, does not exist: it is nothing but a whole of logic calculations which are elaborated by our mind in order to organise our perceptions about the territory, where objects independently exist (Dematteis, 1985). Therefore, the ontological security of a map as a map cannot be automatically presumed, as its 'truth' mirrors the ideological frame of its creator, so that a place has a different meaning that depends on its uses and users: a non-cultivated field, in fact, has a different meaning for a developer who want to build or for a group of kids who want to play football.

Spatial concepts such as 'distance' and 'proximity' clearly show the ways in which space is a highly subjective social construct, as the former is related to notions of foreignness and the latter rather concerns familiarity: the distance from a place which is known as enjoyable will therefore be perceived as shorter than that from a sad place (e.g.: a cemetery). In the same way, the physical experience plays a relevant role, as a distance will be differently perceived if the street slopes downwards or upwards. Furthermore, although time plays a relevant role in the perception of space (a distance, in fact, can be measured by the time needed to cover it), geometrical maps usually ignore it as well as they cannot capture the complexity of real space, as what is represented of an object is nothing but its measure.

Figure 1 – Neighbourhood representation based on home-school daily route, with 'emotional landmarks' (school, friends' home ...) drawn in a different way

Historical maps were different: subjective perceptions, symbols and narrations were part of the representation of space. Ancient maps represented a "hodological space" deriving from the Greek *hodòs* ('path') (Janni, 1984), wherein the perception of spaces follows a line according to a 'route perspective', as in the case of the well-known *Tabula Peutingeriana*. Cadastral maps required the physical experience of walking across the territory, so that a variety of local measurement systems derived from human pace and eyesight (Farinelli, 1981).

Figure 2 – 'Roma in forma de leone' ('Rome in form of a lion'): a medieval symbolic representation of the city of Rome.

A 'genealogical' inquiry can clearly show how geometrical cartography has been progressively naturalised and institutionalised across space and time as a particular form of scientific knowledge and practice following the emerging of modern national states. Maps, as Harley (1989) suggests, are a tool for the exercise of external power, in which plans and intentions of powerful agents become realised. But maps are also provided with a power which is internal to cartography: it consists of the ability to categorise the world and normalise certain views of it, thereby influencing us at the level of meaning and experience. Many critical theorists from the Frankfurt School onward have echoed Weber's argument that the development of modern capitalism has been tied to that of an instrumental rationality in human relations and communication, with maps as one of the most powerful and pervasive tool. Spatial sciences, in Lefebvre's (1974) view, are primary agents in the reproduction of capitalism: as they interfere, through a

sort of inner colonisation, with the possibilities in everyday life through the use of space, by pre-judging the subjective world according to rational/bureaucratic typifications. According to Corner (1999), in fact, territory does not precede a map, as space becomes territory through bounding practices that include mapping. Thus, given that places are planned and built on the basis of maps, space itself is nothing but a representation of the map: the "differentiation between the real and the representation is no longer meaningful", as maps and territories are co-constructed, being the former not a reflection of the world, but its re-creation (see also: Baudrillard, 1994).

Analogies exist between historical and children's representations, as the latter do not imply Lefebvre's (1974) "espace conçu" ('conceived space'), i.e.: space as a mental construct, the space of "savoir" ('knowledge', i.e.: expert knowledge), the (abstract, geometrical) "representation of space". Children's representations rather refer to both Lefebvre's "espace perçu" ('perceived space') and "espace vécu" ('lived space'), being the former (real) space as (materially practiceable) physical form and the latter the space of everyday life and social relations, which is produced and modified over time through its use and whose understanding refers to "connaissance", i.e.: informal or local forms of knowledge (involving symbolism and meaning) that is gained through personal experience. In this sense, as it is at the same time both real and imagined, such "space of representation" is both the medium and the outcome of human spatial relationships (see particularly: Iori, 1996). Children, in fact, do not draw what they 'know', but rather what they daily experience, without a clear distinction between reality and fantasy, as their representations (especially at the level of nursery and primary school) consist of a non-structured non-hierarchical dis-homogeneous whole of objects and events – also including a dream or a nightmare, a desire or a fear, a sketch from a television program or a landscape from a video game – to be organised through a cultural process into their own 'mental archives' by using a non-detailed typological and often two-dimension representation, where the aim is to classify rather than to describe the real object (see: Pierantoni, 2001).

§

Figure 3 – The historical centre (of the city of Rome!) as seen by a teen-ager from the periphery.

In this sense, drawing is one of their own way for knowing the world by giving a name to each thing as ancient or primitive population did. In fact, as Chatwin (1988) tells us about Australian aboriginals,

"each totemic ancestor, while travelling through the country, was thought to have scattered a trail of words and musical notes along the line of his footprints [...] these Dreaming-tracks lay over the land as 'ways' of communication between the most far-flung tribes. A song [...] was both map and direction-finder. Providing you knew the song, you could always find your way across the country. [...] In theory, at least, the whole of Australia could be read as a musical score. [...] By singing the world into existence [...] the Ancestors had been poets in the original sense of poesis, meaning 'creation'. [...] Aboriginals could not believe the country existed until they could see and

sing it – just as, in the Dreamtime, the country had not existed until the Ancestors sang it".

Within such a framework, landmarks play a relevant role, as children's space is a sort of 'unknown archipelago' wherein some familiar 'islands', made by recognisable fragments, emerge.

As Lefebvre (1974) argues the more and more homogeneous and commodified space of our contemporary society is conceived before it is fully lived, and spatial practices, on which our knowledge of the world is based, emerge much more from representations and abstractions than from our daily experience, so that space itself becomes a representation – an overturning that Baudrillard (1994) calls "hyperreality" – by making us more easily manipulable by ideology. Differently, if space is constituted through mapping practices by weak actors, this means that constructing maps can positively 'activate' territory, by 'reconstructing' it over and over again. In this sense, understanding children's representational language through their involvement in planning activities could really help us to imagine smarter urban spaces that enable diversity and active citizenship.

ID 1606 | THE MORE COMMERCIAL, THE LESS SAFE? –IMPACT OF COMMERCIALIZATION ON STREET SAFETY IN REVITALIZED DOWNTOWN AREA

Sisi Liang¹

¹Department of Urban Planning, School of Architecture
liangsisi@tsinghua.edu.cn

1 INTRODUCTION

Urban safety is one of the most important issues among sustainable development challenges. Over the past decade, the world has witnessed growing threats to the safety and security of cities and towns. These threatens, in terms of traffic accidents, traffic jam, environmental pollution, crime incidents, etc, have all brought severe challenges to place-making and management on urban space. Streets, the public space where people commute, walk, go shopping, stay, and live, has played a key role in making our cities safe and secure for generation to come. Topics of street security cover a series of urban safety issues, such as transportation safety, defense and security, psychological security, and so on, which are worthy of attention by city planners and urban designers.

Streets are important elements in downtown revitalization. Among the globe, infilled development of commercial and retail functions in old downtown cities has being contested as an effective revitalization approach to promote the vitality of neighborhood with various functions, but also as a growing threaten to local safety as well as an overburden to streets according to increasing tourist and traffic flows. There are abundant researches on gentrification trends as well as discussions on urban revitalization approaches. As the basic demand of local residents and immigrants, the security issues, however, are in lack of discussion. Although there is common sense that the entering of immigrants, commerce, and tourists have increased unsafety risks to local neighborhoods, very few scholars have investigated this topic and make scientific verification.

Shi-Cha-Hai Lake District, a typical historical conservation residential area in inner city of Beijing, is an exemplification of downtown revitalization in recent decades with its typical fabric of streets and public space. Nowadays this area is mixed with local residents and a large amount of boutiques, bars, retails, and restaurants. Taking Jin-Si-Tao area (JST as abbreviation in following paragraphs) as example, this

paper analyzes and maps the impact of commercialization on streets safety in local community through exploring the following questions:

1. Within the dense footprint of residential blocks in downtown area, what are the major spatial characteristics of streets that affect safety and security issues?
2. How do streets change after commercialization and revitalization in terms of public space, public activities, and management? What are the subsequently impact on street security?
3. What are the implications on urban planning and street design?

This article is organized as follows. After this introduction, the second section makes an analytical framework of street security based on literature review, and introduces the research methodology of this article. The third section introduces the evolution of JST area in Shi-Cha-Hai Lake District, as well as research findings on changes of streets before and after commercialization. The penultimate section explores transformation of users' psychological impression on street security issues and street attribute. This article concludes with the future direction that street design in revitalized downtown may take.

2 LITERATURE REVIEW AND RESEARCH METHODOLOGY

2.1 AN ANALYTICAL FRAMEWORK OF STREET SECURITY

Streets are the backbone of urban experiences for users. The changes in different modes of transport have shaped urban form in history, as the impact of the motor car on the modern urban form shows. The modernist agenda of reshaping cities to accommodate the motor car, however, has come under pressure for a generation. Urban design is part of the campaign for pedestrian friendly urban environments, taming the cars, and support for the development of public transport. The order that the streets impose on the urban society, and the manner of experiencing it from inside a car, have been challenged by the meandering and free movement of pedestrians, who will have an entirely different experience of the city. Rather than a track for the fast movement of vehicles, the street is acknowledged as a social space, in which functional performance and social connections are reconciled.

Modern urban planning has proposed road hierarchy system, which raised transportation into an important topic in research of street security issues. The modernist ideas of movement, technology and functionality came together in the Charter of Athens. As the Charter writers argued, 'The street systems found in most cities and their suburbs today are a heritage of past eras... designed for the use of pedestrians and horse-drawn vehicles', and could 'no longer fulfil the requirements of modern types of vehicles' (Sert,1944). Alongside the phenomenal growth in the number and use of motor cars, these ideas were turned into manuals and policy documents to change the shape of cities. The conflicts between vehicles and pedestrians, between parking space and cycling routs, and the inadequacy of small blocks when facing rapid traffic activities, have all emerged with mobility. As a result, during that period, street security was nothing but vehicle and traffic accidents.

The pendulum, however, swung back, and the paradigm shift of streets-to-roads was reversed. Once again the urban street became the paradigm, where the speed of traffic could be managed and limited and where pedestrians were conized as a legitimate basis for design of the streets. The official advice from the Department for Transport now favored pedestrians and cyclists. As the preface to an influential document *Manual for Streets*, outlines, 'For too long the focus has been on the movement function of residential streets. The result has often been places that are dominated by motor vehicles to the extent that they fail to make a positive contribution to the quality of life' (Department for Transport,2007). The new emphasis now was on showing 'the benefits that flow from good design and a higher priority for pedestrians and cyclists' (ibid). Many cities around the world have now embraced this second paradigm shift, producing master plans for pedestrians and cyclists and creating pedestrian and bicycle priority areas. Rather than the segregation of cars from pedestrians, the idea of sharing space between them, which has been practiced in countries such as the Netherlands, has been widely adopted.

In the street networks of the city, some streets have become the central axes, finding a special local character, or becoming the concentration of the prominent activities of the city. Especially in downtown, streets are the center of activities in local communities and even cities. The social aspects of streets have played important roles in impacting urban safety issues with regard to monitoring, crime prevention, and

evacuating places. Jacobs used the phrase of “Eyes on the Streets” in her book “The Death and Life of Great American Cities” to coin about the crucial importance of a vibrant street life to neighborhood safety and community (Jacobs, 1961). She argues that if there are residents and retails locating along both sides of streets, they would play the role of monitors for activities on streets, which in hence largely improve the degree of safety. The criminologist, Ray Jeffery, has coined and formulated an approach of CPTED (Crime Prevention through Environmental Design), in which altering the physical design of the communities in which humans reside and congregate can help to deter criminal activity. A more limited approach, termed defensible space, was developed concurrently by architect Oscar Newman (1972). Newman's book, “Defensible Space: - Crime Prevention through Urban Design” came out in 1972. His principles were widely adopted but with mixed success. Later, Jan Gehl expanded the concept of “defensible space” into environmental field and practiced it in his urban design projects. Japanese scholar, Ito explored relationships between crime and urban environment and coined a series of specific strategies to promote urban safety (1988).

Since streets serve multiple functions involving transportation, location for social interaction, and public space for urban activities, this paper conducts an analytical framework of street security consisting of traffic safety, crime prevention, and psychological security. The conduction is based on the following assumptions: On one hand, users form their impression of street safety through physical environmental performance and spatial characteristics of streets. This impressions, such as whether they regard there is risk in crime, or whether they feel safe under monitoring, can lead to human-being activities. On the other hand, the physical road elements, such as cross-ways, pedestrian route design, and open space of corners, all affect traffic behaviors, which then lead to judgement of traffic security.

2.2 DATA AND RESEARCH METHOD

Our research case is located in Shi-Cha-Hai Lake District in Beijing. This district is a typical residential neighborhood in old downtown. Meanwhile, it is also a famous tourist attraction as well as concentration of commercial pubs and bars. One reason of why selecting it as the case study is that this district has well-preserved hutong-and- court-yard-fabric, and well-retained lifestyles for original residents. During the past decades, this district faces the same spatial challenges as well as other places in Beijing old city. Moreover, the gradually commercialization and infilled development process since thirty years ago have largely changed the phenomenon of streets. The case can serve as a great example in discussing impact of commercialization on old downtown.

In terms of impacts of revitalization on street security, this article develops a series of indexes on the changes of physical performance on streets before and after infilled development respectively. They include: spatial changes (such as number of retails, number of public space, etc), changes of lighting (elevation change, illumination, etc), changes of activities (local residents, tourists, shop owners, etc), and changes of management (on and off streets). The research data comes from following resources: ground survey on physical environment, questionnaire survey of residents and tourists, time-phased photographing, and traffic data.

3 CASE STUDY AND FINDINGS

3.1 SPATIAL EVOLUTION OF STREETS IN JINSITAO AREA, SHICHAHAI DISTRICT

The case, JST area, is located in Shi-Cha-Hai Lake District, which has the longest history during evolution of Beijing City. There is a saying that “Shi-Cha-Hai Lake comes first, Beijing City comes later”. In the historical planning of Jin and Yuan Dynasty, which is approximately 800 years ago, the water system in Shi-Cha-Hai Lake District is an important element in city layout. In Ming Dynasty (1368-1644), the area of water reduced, while courtyards, temples, and local dwellings are built around the lake. The commercial activities sprouted up at that time. As of Qing Dynasty (1644-1912), the local authority renovated and dredged the rivers. The JST area was formed as a peninsula surrounded by lake on three sides. More and more imperial palace were constructed during Shi-Cha-Hai Lake District. On the other hand, the emergence of Lotus Market, Yanday Xiejie Street in this area illustrated this area as a civic center in Beijing. During the period of republication of China, the lack of management has led to environmental

pollution of water resources, causing business decline till late 1980s, when Beijing Municipality set the entire area into Historical Cultural Preservation District. Since then, Shi-Cha-Hai Lake District became an important place of interest in old downtown of Beijing.

The street of bar in Shi-Cha-Hai Lake District is another leisure and recreational tourist area after Sanliten area in Beijing. The first bar emerged in 1997. After the year of 2003, the pubs and bars get a booming development. Many local residents changed their own houses into shops with frontage for rent or sale. Since then, the “street of bar” has become a well-known place. It is also one of the most welcomed tourist places in Beijing, as there are many important cultural heritages in this area, such as Prince Gong Mansion, Drum Tower, and Former Residence of Soong Ching-ling. Mixed people and traffic flows, rental cycling routes and pedicab have brought high traffic pressure on this area (Figure 1).

Figure 1 – Location of JST Aera in Shi-Cha-Hai Lake District

Jin-Si-Tao area, located in the middle of Shi-Cha-Hai Lake District, is a peninsula between Qianhai Lake and Houhai Lake. It occupied a 20-hectare area. There are 18 hutongs and 469 courtyards in this area, among which, Big Jin-Si Hutong, with its zigzag shape, has the most distinct character in terms of physical layout. The design of such distinct form is to guarantee each courtyard can have just north-south orientation. Along the periphery of JST area, three of four borders are streets of bars, with local dwellings located inside this area. Prince Gong Mansion is located to the west of this site, with only 200 meter distant, attracting a lot of tourists visiting this area.

3.2 CHANGES OF STREETS BEFORE AND AFTER COMMERCIALIZATION

For the sake of safety and comfort, traditional dwellings in China have relatively closed facades, such as folk houses in Huizhou, classic earth building in Fujian, and courtyard in Beijing. Usually, its facade facing the streets only has doors without windows or only small windows. The main living space in the courtyard inside. The lighting and ventilation needs of surrounding buildings are mainly solved through internal courtyards. The vertical and horizontal arrangement of the fish-bone-style of hutongs connect courtyards in series. The traditional hutongs have more trafficability characteristics than social interactions. The street safety relies mainly on relatively closed courtyards and walls for passive defense.

The transformation of lifestyles in modern society has increased both number and complexity of people in old city. Especially in JST area, the crowd and the influx of leisure tourists have brought large impact to original lives in this area. The original relatively independent space of the streets and alleys has also undergone great changes.

3.2.1 SPATIAL CHANGES OF STREETS

There are two types of commercial store transformation happening in JST area. First, some residents opened up the walls of their dwellings along the street and change some rooms into small retails. Most of the retails are owned and managed by local residents themselves. Second, the house owners rent their courtyards out to tenants, who are in charge of decoration and transformation. These courtyards are changed to restaurant, cultural and creative shops. The latter ones are always located close to the street of bars on the periphery of JST area (Table 1).

Subject	Security Factors	Changes after Commercialization
Some light	Light from lamps and houses	Increase lighting
Good view of street	Width, transparency of facades	More open facades
A lot of residents	Brightness	--
Buildings adjacent to streets	Emergency refuge	Retails as refuge area
Black area	Danger area	Reduce of black area
Width of streets	Awareness to dangers	--
Footstep of pedestrians	Pavement of streets	Increase of pedestrians
Unconnected alleys	Risky factors	--
Blind corners	Risky factors	Reduce of blind corners
Few open spaces	Potential risks	More open space for activities
View from home	Attention, monitoring	More windows for monitoring

Table 1 – Spatial Changes on Streets after Commercialization

According to the boom of bar streets, the hutongs adjacent to the streets also changed a lot. The traditional alleys used to be other hutongs deep inside the JST area, with quiet and tranquil atmosphere. The development of bar streets bring more commerce into this area, turning the adjacent hutongs into lively pedestrian streets. Correspondingly with the transformation of functions on street, the facade has become more open: most of the shop façade along the street are decorated with glasses and open shop doors. Compared to the traditional closed walls along the alley, open facade of street can promote the safety of the street.

3.2.2 CHANGES OF LIGHTING ON STREETS

Due to the business properties of bar street, the safety of the neighborhood night is more worth discussing. In the study of the Japanese streets, the consideration of defense safety is mainly evaluated by night lighting, sound, sight, and blind corners, among which the brightness and range of lighting has the greatest impact on nighttime safety.

Traditional alley lighting mainly rely on street lamps. Because the alley is narrow, the lamps are usually ranged in a single row. If there once is a breakdown of lamp, the street would in trouble of lacking light. Meanwhile, the shape of alley is complex, some part of the alley is very dark at night and lack effective lighting through public infrastructure.

The introduction of commercial shops has effectively improved the dilemma. The waterfront bar street, including many of the shops and restaurants, makes waterfront area brightly lit in the evening and thus largely improves the security in the neighborhood along the alley. Inside the blocks, the infilled small retails improve the alley night brightness through various lighting approaches and improve its safety accordingly. On the one hand, due to the placement of the store, its facade becomes open, the internal light can be revealed, which can enhance the brightness of the street. At the same time, shops always installed many kind of light boxes at the door for their own publicity effect, which serve as another source of night lighting (Figure 2).

Figure 2 – Change of Lighting Before and After Commercialization

Based on the investigation of current site, lots of shops are generally located at the corner of alleys. Fortunately, many hutongs in JST area have such zigzag shape. Thus there are several retails and shops at each corner. According to the research of Japan Lighting Association, the layout of light source has an impact on crime prevention and the improvement of the security of the neighborhood. The road intersection is the most important location for light source layout. Thus the light source density should be appropriately increased in the twisted streets, which can make the highest efficiently use of lighting. The lighting along zigzag hutong in JST area just meet this requirement, it can enhance the security of the neighborhood in terms of lighting.

3.2.3 CHANGES OF ACTIVITIES ON STREETS

The location nearby several famous historical heritage made hutongs in JST area also changed from the traditional residential community into a tourist attraction. In the daytime activities, there has been increased a lot of human tricycle for hutong and courtyard tourism. This caused a large security risk to pedestrians, as the tricycle driving may easily run into pedestrians in narrow alleys. Moreover, the investigation shows that the visit to private courtyard was welcome by local residents in the early days, but gradually turn to be refused by more and more house owners because of its disturbance to their daily lives and potential unsafe risks.

Research shows that the bar streets have transformed from semi-public alley space into a commercial and leisure space with completely public nature (Figure 3). Its citizenship increased, and nature of local community gradually weakened. Many local residents usually choose waterfront areas as a daily walking place. The study found that residents of different ages all like rambling along the waterfront alleys, together with the crowd here to form a very lively night scene.

Figure 3 – Cognition of Public Nature of Streets

As the bar street business hours are usually at night, the local residents living habits have also changed. The field research in the region founds that the active time in the block produced a significant extension due to the impact of the night bar. The increasing crowd and accordingly large sound and noise disturbed nearby courtyards and local residents. The shops in the hutongs adjacent to bar streets all postponed their business hours to meet local demands. In this situation, the active hours of the neighborhoods are different from those in other regions. With the postponement of the business hours of business shops, the complexity of the activities of the people in the night area has been significantly improved, forming the result of the common improvement of potential dangers as well as monitoring control in the alley.

3.2.4 CHANGES OF MANAGEMENT ON STREETS

With the transformation of street nature, people's awareness of safety depends to a large extent on the situation of regional management. During field investigation, we found that there were many people in the street who carried out security work in the area to patrol the duty. They also provide tourists enquiry and information. Their presence has a relatively large protection on both local security and the psychological awareness of residents.

Local authorities take charge of street security management in terms of the following two aspects: one is the requirement that all bars should close before 12am, which to some extent guaranteed daily work and rest time for local residents, and also ease the contradiction between the residents and the merchants. Another approach is to add a number of security personnel to the streets. Through the survey, both local residents and tourists generally feel that security personnel in the region have had a great effect on regional security. Therefore, the existence of these groups has a positive effect on psychological safety for the regional residents.

4 DISCUSSION

In the process of gradually infilled development of JST area, the introduction of new commercial formats has increased the number and proportion of tourist groups in the alley, as well as led to the removal of many local residents, making a significant change of the local population structure. Its safety considerations are no longer only for the residents but also for tourists and consumers. Accordingly, real estate developers bring street traffic and security management into the scope of business management. The street property becomes an open public space instead of traditional community space.

Changes in the properties of the streets have also changed the psychological awareness of the residents. The waterfront area of JST area is no longer considered as a typical local neighborhood-belonged alley, but completely become a pedestrian street with commercial services. People's awareness of the open area of the bar streets is no longer confused with the internal alley system as well. The clustering of the typed commercial formats has a positive meaning for the zoning within this area and is more convenient for the uniform management and business practices.

The public space in the streets has become an important part of urban life and has an important role in ensuring the security of the neighborhood. Shops on the streets do not only bring convenience to local residents, but also serve as "eyes on streets" through providing places for different activities. Some retails owned by local residents can not only provide necessary life services for local residents and tourists, but also serve as "information center" for foreign visitors, which hence is a great advertisement for local community. The owners and merchants also admit that travelling behaviors have brought more crowd into this area, thus they always monitor the street security through the windows and doors. Strangers will be inquired by shop owners. This undoubtedly has a positive effect on the safety of the entire neighborhood.

5 CONCLUSION

To sum up, the research finds that while the infilled development adds traffic pressure to inner city and increases complexity of users in this area, the retails and shops serve as monitors and guidance on streets for local communities by applying lighting, re-defining public space, well-organized management, and

remodeling users' cognition of this place. Besides the complexity of immigrant and its following crime risk, the commercialization of the JST area has had a positive impact on the safety of the neighborhood. The impact on the street security can be analyzed from two aspects in term of spatial transformation and psychological impression. From the perspective of spatial performance, commercial placement to some extent breaks down the closeness of original area and has increased a number of "eyes on streets". It also enhances the brightness of the street night and decrease crime risk in this area. From the perspective of crowd psychology, the introduction of commercial functions has changed the residents' cognition on local blocks. The most effective way to enhance people's psychological security is to strengthen the management of business behavior and to increase public security services.

Approaches of revitalization in inner cities has brought a series of changes to local communities with regard to activities along streets, daily lives in public spaces, social atmosphere in neighborhood, and transportation flows. The paper argues that these changes have transformed streets in local neighborhood from an original enclosed, reserved place toward an open, inclusive public place for both residents and tourists. A mix-use community environment that is both vital and livable is possible if planners and urban designers incorporate elaborated urban safety issues into street design guidelines and if local society can adopt new management approaches on commercial and public space.

ID 1620 | VISIBILITY OF TURKISH IMMIGRANTS IN AMSTERDAM

Ceren Sezer¹

¹Delft University Of Technology

c.sezer@tudelft.nl

1 INTRODUCTION

Throughout history immigrants have always played a significant role in shaping the streetscape of Western European cities through their amenities, which are characteristic for the immigrant neighbourhoods. Some of the oldest examples of these are the Jewish and Chinese neighbourhoods located in many of the major cities like London, Paris, and Amsterdam. However, it was after the 1960s that the immigrants influenced

and changed the cultural landscape of European cities the most. This was due to the arrival of labour migrants from Italy, Turkey, Greece, Morocco, Portugal, Tunisia and Yugoslavia to northern European countries as a result of trade recruitment. This happened to support the need of workers in labour-intensive sectors due to the developing post-war economies (Vermeulen and Penninx 2000). The arrival of guest workers along with the migration from the post-colonial countries, later on followed by migration from the cold war areas, made a significant change in the demographic and spatial organization of major cities (Vermeulen and Penninx 2000).

More the immigrants settled, stronger they became visible on the streetscape of European cities through their shops, restaurants, cafes and religious places. These amenities which have distinctive languages, signs, or ways of street uses that they generate, created characteristic immigrant neighbourhoods, recognized as, for example, African neighbourhoods, Turkish neighbourhoods, Surinamese neighbourhoods, and many others.

Amsterdam has changed along with the political and economic circumstances, and so have immigrant neighbourhoods. Since the 1990s, the trends in real estate market and urban renewal approaches have strongly influence the residential concentration of immigrant groups in central and suburban neighbourhoods. These trends also influence the observable features of immigrant amenities as they adapt to these changes.

The main aim of this paper is to identify and describe the immigrant amenities in Amsterdam. The study operationalizes the concept of visibility of immigrant amenities, which is understood as the physical features of the amenities observed through their distinctive signs, languages, products, as well as practices.

Visibility can provide a new perspective on the relations between immigrant amenities and the built environment, which is important to understand the processes in which immigrants settle in the city and shape the built environment. The study focuses on Turkish amenities in streets of Amsterdam. The leading question is: How does the location of Turkish amenities in Amsterdam influence their visibility in terms of physical features?

To answer this question, the paper is organized as follows. The next section introduces the concept of visibility of immigrant amenities and its significance. A section explaining research approach and methods follows this. The next section introduces Turkish neighbourhoods in Amsterdam and their demographic and locational characteristics. The following two sections identify and describe Turkish amenities and their location. The last section presents the findings and concludes by answering the main question and reflecting on the findings.

2 CITY, THE STREET AND VISIBILITY OF IMMIGRANT AMENITIES

The city has always been seen as a site of diversity of cultures, religious beliefs, economic status, professions, languages, practices and more. As Aristotle states “A city is composed of different kinds of men; similar people cannot bring a city into an existence” (Aristotle, cited in Sennett 1994:13).

Immigration plays a key role in promoting city diversity. People, driven by political, ecological, demographic pressures, move from their homeland and search for new opportunities (Sandercock 1998:14; Penninx and Vermeulen 2000:5-8). The city offers a plenty of opportunities for migrants, providing jobs, offering social networks, personal contacts or other associations for social and economic support (Blokland 2003). These opportunities help migrants settle in their new environment and establish their quarters.

Immigrant amenities are a manifestation of immigrant quarters. The shops with immigrant signs and products, culinary businesses from unfamiliar cuisines, religious places such as mosques, synagogues, and temples with special events characterize immigrant neighbourhoods through their physical features. These features are not only limited to the signs, languages, or products in these amenities, but also include their related practices. The distinctive time schedules of some of these amenities, such as praying time for religious places, religious events, or long working hours of shops in the weekends and evenings, enhance user diversity and influence user behaviour in the neighbourhood streets (Zukin et al. 2016; Hall 2015; Sezer and Fernández-Maldonado, forthcoming). These amenities’ observable features provide

visibility for the cultural characteristics of the immigrant groups on the public spaces, more precisely at street level. In other words, these amenities offer the general public the possibility to see, observe and experience immigrant cultural expressions.

The visibility of immigrant amenities closely relates with the diversity and vitality of the street. In terms of diversity it provides immigrants and other groups opportunities to interact with each other, or simply witness one another presence and activities. This is important to be able to appreciate distinctive group characteristics and cultures and helps for developing mutual respect and recognition among these groups (Young, 1990). The visibility of some types of amenities might be associated with fear and may raise unease towards certain groups. Public unease for communal amenities as mosques and tea-houses are examples of such situations in some European cities (Gole 2011, Wohl 2016), and might influence their visibility. This may be different for commercial amenities, more open for interaction with the general public. Nevertheless, in either cases, the encounters promoted by immigrant amenities might give opportunities to overcome prejudices and help to learn how to live in a diverse city (Sennett 1970).

The visibility of immigrant amenities also helps to stimulate vitality in street life, due to the variety of users, programmes, and functions (Jacobs 1961; Montgomery 1998; Gehl 2010). For example, the long working hours of restaurants makes the streets attractive to be used most of the day and binds people to the place (Jacobs, 1961; Young, 1990). It also increases the attractiveness of the street for visitors by giving the enjoyment and excitement of experiencing something new and unexpected; “a different atmosphere and a different crowd of people” (Young, 1990:239).

However, different streets have different abilities to accommodate diversity and vitality. Shopping streets, being the attraction areas of their neighbourhoods, are more likely to be open for diversity and able to have higher levels of vitality than backstreets (Zukin et al. 2016). There are also differences between shopping streets in the city centre and in the suburbs. The former are more cosmopolitan in character, because they are able to attract both residents and visitors, while in the suburbs shopping streets are more local by character. This implies that there is a connection between location and features, which is the matter of this study.

3 THE RESEARCH APPROACH AND METHODS

In this study, the visibility of immigrant amenities at street level is studied through their physical features in terms of signs and related practices. The amenities have been distinguished as communal and commercial. Since streets differ in their character according to their location, it was considered relevant to pay special attention to it.

The study focuses on the visibility of Turkish amenities in the streets of Amsterdam. For practical reasons, we call the study area Amsterdam, but it includes Amsterdam Metropolitan region. Amsterdam offers an interesting case study because almost half of the city population has a foreign origin. Turkish immigrants are one of the largest immigrant groups in the city, coming after Moroccan and Surinamese groups, with 53,948 people representing 5,5% of the almost 1 million inhabitants of the metropolis. Migrants from a Turkish background are considered to be poorly integrated to the Dutch society due to their low education profile and high dependency on the welfare benefits (Crul et al., 2008). Nevertheless, they are also known due to their entrepreneurship skills compared to the other immigrant groups (Rath and Kloosterman, 2000), which influence their visibility on the street.

The study collected data on the physical features of the amenities in terms of their visible signs and practices. The research is conducted in four steps:

1. Description of the context regarding the main changes in residential concentration of Turkish immigrants in Amsterdam in the 2000-2015.
2. Identification and description of the characteristics of Turkish amenities through data collection of the types, visible physical features and location of Turkish amenities in Amsterdam. The data was collected in April-June 2007. The observation during the fieldwork was carried out walking and cycling, and documented through field notes and photography.

3. Mapping of the location of Turkish amenities in central or suburban areas. For practical reasons, the clusters of Turkish amenities have been labelled as Street 1 (S1), Street 2 (S2), and so on.
4. Interpreting these findings regarding the cultural visibility of Turkish amenities by comparing the relations between their physical features and location.

Figure 1 shows analytical framework of this study and its relation with the research steps.

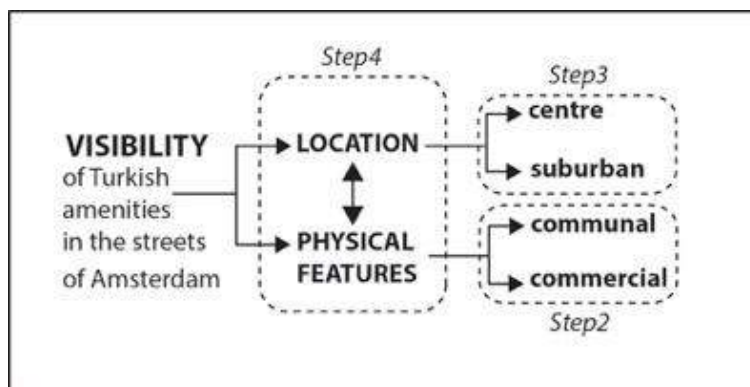

Figure 1 -Analytical framework and its relation with research steps.

4 THE CONTEXT: TURKISH NEIGHBOURHOODS IN AMSTERDAM

Turkish migrants arrived to Amsterdam as guest workers around the 1960s. After they received a permanent status and acquired the right to register for social housing areas at the beginning of the 1980s, the number of the Turkish migrants increased as a result of family reunification, marriage immigration or asylum. Recent demographic dynamics of Turkish immigrants show a steady increase until 2007 and stability from then on (see Table 1).

	Amsterdam Population	Amsterdam Population of Turkish origin	% of Amsterdam Population of Turkish origin
000	858,587	39,486	4.6%
007	884,472	49,007	5.5%
015	973,815	53,948	5.5%

Table 1. Turkish residents in Amsterdam 2000, 2007, 2015*

(Own elaboration with data from Gemeente Amsterdam, 2000, 2007, 2015; Zaanstad in cijfers, 2000, 2007, 2015).

*data valid for the municipalities of Amsterdam and Zaanstad

In their first arrival, Turkish immigrants settled in dormitory areas close to the harbour and industrial areas in Amsterdam North and Zaanstad. Figure 2 gives an impression of how these areas looked like. Otherwise, adult men settled in rooms in pensions or dwellings in poor quality located close to their working areas (Cortie and Van Engelsdorp Gastelaars, 1985). Figure 3 illustrates daily life in one of these pensions.

Later on, within the framework of the family re-unification, and the recruiting of brides and bridegrooms from home countries the demographic composition and the housing needs of Turkish changed to relatively larger households (Van Amersfoort and Cortie 1996). Almost in the same period there was an increasing suburbanisation process where lower middle class Dutch families were moving to the suburbs leaving houses in the lower end of the market available for immigrant groups.

During the 1980s, many Turkish households moved to the Western Garden towns, a large social housing suburb built in post-war period in Amsterdam West (Van Amersfoort and Cortie 1996). Figure 4 shows this area in its earlier phase. Other neighbourhood options for Turkish households were affordable social housing estates in inner city areas such as the Pijp in the Old South and the Indische Buurt in the East district.

Figure 2. Ataturk Turkish Village (Turkendorp) in Amsterdam North, NDSM Port area. Anonymus (NDSM Museum, n.d.)

Figure 3. Life in Ataturk Turkish Village (Turkendorp) in Amsterdam North, NDSM Port area. Anonymus (NDSM Museum, n.d.)

Figure 4. Social housing in Amsterdam West. Anonymus (Fotoleren, n.d.)

Turkish immigrants concentrated in two kinds of neighbourhoods: in those within inner city districts such as Amsterdam Old West, Old South and East; and in neighbourhoods located in suburban districts such as New West, Amsterdam North and the municipality of Zaanstad. Figure 5 shows the location of Turkish residential concentration in 2000, 2007 and 2015, illustrating the trends in these concentration areas: in the inner city neighbourhoods they diminished, while in the suburban areas they increased. Table 2 presents the differences in growth and decline of Turkish population in the two largest concentration areas in Amsterdam, Indische Buurt and Slottermeer in 2008 and 2015.

Figure 5. Residential concentration of Turkish immigrants in Amsterdam region in 2000, 2007 and 2015 (Own elaboration with data from Regiomonitor Groot Amsterdam, 2017)

		Turkish immigrants	Non-western foreigners	Total residents
Indische buurt				
2008	2	2770	13627	23243
2015	2	2145	11422	22824
Difference	D	-22,56%		
Slotermeer				
2008	2	3673	14218	25391
2015	2	4538	16570	26484
Difference	D	+23,55%		

Table 2. Turkish residents in the Indische Buurt and Slotermeer in 2008 and 2015 (Source: Gemeente A'dam, 2008; 2015).

The changes in residential concentration of Turkish immigrants should be seen within the context of the general urban development trends of Amsterdam. Two important factors are salient. The first factor influencing these changes has been the real estate tendencies in the housing market, by which house prices in Amsterdam inner city have vastly increased since the mid-1990s. The city has become highly attractive for tourists and young professionals, which has greatly increased the housing demand (Rath, 2007). Figure 6 shows the sharp increase in the price of houses sold in the period between 1995 and 2016 in Amsterdam (presented in red) in comparison to the national average.

Figure 6. Average price of homes sold in the Netherlands and the three largest cities, 1995-2016 (Source: Boterman, 2016).

Another important factor influencing the changes in residential concentration of Turkish immigrants has been the new policy approaches in urban renewal, aimed to promote socially mixed neighbourhoods. Since the 1990s urban renewal policies both at national (e.g. the Big Cities Policy) and Amsterdam level (Nota Stedelijke Vernieuwing) have aimed to avoid the residential concentration of low-income households in social housing areas (Beckhoven and Van Kempen, 2003). It was considered that the concentration areas create a negative neighbourhood image and limits the opportunities for daily contacts between different social groups. Urban renewal policies promoted social mixing to improve neighbourhood quality in these areas by creating differentiation in housing market through demolishing, selling and upgrading a part of social-rented stock and building expensive privately-owned dwellings (van Kempen and van Beckhoven, 2003; Kleinhans et. al. 2000). This provided new housing opportunities for young professionals, but also led to gentrification processes in inner city areas by displacing vulnerable households towards the suburban areas, where more affordable housing was available (Sakizliolu 2014; Uitermark 2009).

5 TURKISH COMMUNAL AND COMMERCIAL AMENITIES IN AMSTERDAM

The purpose of this section is to describe and identify the types and visible characteristics of the Turkish amenities in Amsterdam. This study found 456 amenities in 2007, which are mapped according to their visible and functional characteristics under two types: communal and commercial amenities.

5.1 COMMUNAL TURKISH AMENITIES

Turkish communal amenities include mosques, teahouses, and Turkish oriented organizations.

5.1.1 MOSQUES

Turkish mosques are places for religious practices, but they also function as places of social contacts, which provide a basis for informal exchanges about personal and collective issues, such as finding a job, an apartment, or raising money for charity purposes (see Figure 7). In Amsterdam, besides a main hall for

praying, almost every mosque buildings consist of a teahouse, a grocery, a hair salon, and even -in some cases -a billiard room.

In Amsterdam, we found 10 mosques which have different visible qualities, which in many cases, are not only associated with images of Islamic symbols, or signs, but also through their communal activities (e.g. street festivals in religious days). While in inner city areas, they are less noticeable from their architecture,

signs, and symbols. However, they are usually a part of a cluster of other amenities, such as Turkish shops, restaurants and cafes located in a close proximity, which provide them visibility. In suburban locations they are more noticeable, because they occupy larger areas, they extend their activities to the street, and use larger symbols, such as flags and name boards.

Figure 7. Wall board from a Turkish mosque with the announcements for job seekers, vacancies, houses for rent (Author,2009).

5.1.2 TEAHOUSES

A Turkish teahouse is a small café where men exclusively gather and drink non-alcohol drinks, mainly coffee and tea. Throughout history, Turkish teahouses have been places for social gathering where men chat, and exchange ideas, political views and practical knowledge (Wohl 2016). Teahouses in Amsterdam generally gather men from similar social status, political views, education, income, and even city of origin (Veraart 1987).

In 2007, there were 16 teahouses in Amsterdam, excluding those located within the mosques. It is difficult to notice teahouses at street level as they generally block the inside view with curtains, or frosted glass windows. Most of them are only recognizable by their names, generally referring to Turkish places. These characteristics make teahouses introverted places that do not welcome women or outsiders. In few cases, however, they extend the tables and chairs to the street, giving them a more open appearance.

5.1.3 ORGANIZATIONS

Turkish organizations in Amsterdam have many different interests, but most of them function as religious organisations, providing religious education for women and children and organising events to raise funding for the own organisation. These organisations are generally located in a close proximity to the mosques, but some of them are separate enterprises. Secular woman organisations occupy a small portion of all the organisations, which give language and health education programmes for women emancipation (e.g. Stichting ANDK). Another group of organisations function for secular educational purposes, for example, to teach Turkish language, musical instruments, or folkloric dances (e.g. Stichting Turks Onderwijs Centrum). Some organizations are also specialized in sport activities; giving training and organising sport competitions (e.g. Stichting Fenerbahce).

In 2007, 35 organizations with visible Turkish signs and marks could be counted in Amsterdam, almost one fifth of the officially registered number of organisations in the Amsterdam Chamber of Commerce. These organizations have a weak cultural visibility at street level, but a careful observer can notice them through their names. It is during the public events that they organize that they increase their visibility. Some of these events target large groups occupying parks, streets, and squares; while some others target

limited groups – such as wedding parties – holding these events in existing public buildings such as school halls.

5.2 COMMERCIAL AMENITIES

Turkish commercial amenities include daily food shops, eating and drinking places, service enterprises, and other type of shops.

5.2.1 DAILY FOOD SHOPS

Food shops are those, which sell daily food, such as bakeries, groceries stores, butchers, and supermarkets with distinctive visible signs of Turkish origin. Besides daily food, they generally sell Turkish products, which are not available in regular shops. They are mostly small-scale, labour-intensive and low-skilled enterprises, offering job opportunities for those who occupy the lower end of the social ladder. They mostly rely on informal economic activities to sustain their businesses, which depend on social networks among Turkish immigrants (Kloosterman et al., 1999:252). To survive in the city economy, they offer relatively cheap products, sometimes even cheaper than in the street markets, which may attract customers from beyond their own neighbourhood.

Turkish food shops have the highest number of visible Turkish amenities in Amsterdam, with 150 shops in 2007. They are visible through their names, colourful and rich display, and halal products. The long working hours of groceries stores and bakeries increase their visibility.

5.2.2 EATING AND DRINKING PLACES

Turkish immigrants enrich the food culture of Amsterdam with restaurants specialised in regional Turkish cuisine home-made products and street food (such as Turkish pizza). They generally offer economical options for lunch and dinner. The affordable prices of the Turkish food made these businesses attractive not only for Turkish, but also other Amsterdam residents. Drinking places, on the other hand are less specific with their specialities. They are mainly pubs, selling alcohol products open from late hours until midnights.

We found 128 Turkish eating and drinking places in Amsterdam, the second largest group of Turkish amenities. Many of them are highly visible due to their Turkish names and products. Remarkably, some restaurants have Greek-Turkish, or Italian-Turkish names, probably due to the similarity between Turkish and Greek and Italian cuisines, what has been used by the Turkish entrepreneurs to make their restaurants attractive for a wider clientele.

Drinking places are not very characteristic in their cultural visibility, except by their names and the advertisement boards of Turkish events in their front windows.

5.2.3 SERVICE ENTERPRISES

There are two types of service enterprises. The first includes tailors, clothing and shoe repair, automobile repair, and hair and beauty salons, and the second includes travel agencies, lawyers, architecture and engineering offices. The first type has the same features as food shops, being small-scale, labour-intensive and low-skilled enterprises, answering to the need to have a job in a very competitive job market. Many Turkish immigrants initiated their own businesses as repair workshops in Amsterdam. In such way, repair shops became an important part of the history of Turkish immigrants in Amsterdam (Rath and Kloosterman, 2000). Most clothing repair shops in Amsterdam are owned by Turkish immigrants, which make them very visible. Turkish hair and beauty salons are also popular in Amsterdam, especially among women customers. The second type of service enterprises is evidently more formal, with highly educated workers offering professional services.

In Amsterdam, we noted 46 service enterprises in 2007. Their visibility is characterized by their names, but also their long working hours and exceptional working days (e.g. Sundays). Turkish hair and beauty salons are visibly different from Dutch salons, also because they target exclusively male or female clientele.

5.2.4 OTHER KIND OF SHOPS

There are a large variety of shops with goods such as furniture, household products, clothing, souvenir, fabric, and music shops with Turkish visible signs in Amsterdam. Among these, furniture and household shops are the largest number. Some of them are branches of Turkish furniture brands. Household products shops are small-scale shops that sell a variety of products for domestic use, such as lighting, kitchen utensils and appliances. Turkish clothing shops are mainly specialised in Islamic clothing. There was one Turkish music shop in Amsterdam.

In our fieldwork, we found 76 of these amenities in Amsterdam in 2007. Without any exception, they have all Turkish names and products, which make them very visible.

6 LOCATION AND PHYSICAL FEATURES OF TURKISH AMENITIES

This section maps the location of culturally visible Turkish amenities and describes their observable physical features in relation to the locational characteristics of the streets in which they are situated. These characteristics are presented in relation to the residential concentration areas of Turkish immigrants in inner city and suburbs, and street types.

6.1 LOCATION

The location of commercial and communal Turkish amenities and the streets where they are clustered in Amsterdam in 2007 is presented in Figure 8. Most street clusters are located in inner city districts such as Amsterdam Old West, South and East. A third of them (approximately 35 per cent) is located in Turkish residential concentration areas outside of the city ring, suburban areas with an increasing Turkish population, such as Amsterdam North, New West and the city of Zaandam.

Turkish amenities are mostly located in Turkish neighbourhoods, but in few cases they are also located in areas with no significant Turkish population. Commercial amenities represent approximately 95 per cent of the total Turkish amenities, and are widely distributed across the city. They are generally clustered along the main or secondary shopping streets of their neighbourhoods (see S1, S2, S3, S4 in Figure 8). The rest is dispersed and located in busy shopping streets (see S11, S12) or in quiet neighbourhood backstreets (see S13, S14).

Communal amenities represent approximately 5 per cent of the total Turkish amenities. They generally cluster around mosques, teahouses and communal organizations, but the clusters may also include commercial amenities as grocery stores and eating places. Communal amenities are located in the inner city and suburban Turkish concentration areas, with the exception of the Fatih mosque, located in Amsterdam Old West. Within their neighbourhood, they locate at quiet streets, but in few cases they locate on main streets, as the Fatih mosque and the Sultan Ahmed mosque in Zaandam (see S6).

The different types of Turkish amenities according to their functions were mapped and are presented in Figure 9. Most commercial amenities located on main streets are daily food shops, eating and drinking places, and some service amenities such as travelling agencies, and clothing, souvenir, and furniture shops. Some food shops, such as groceries stores, and service amenities such as beauty salons, clothing or automobile repair shops, or shops with household articles are located on secondary shopping streets. Those dispersed amenities generally belong to the service sector such as clothing and car repair shops, but also some eating places such as snack bars.

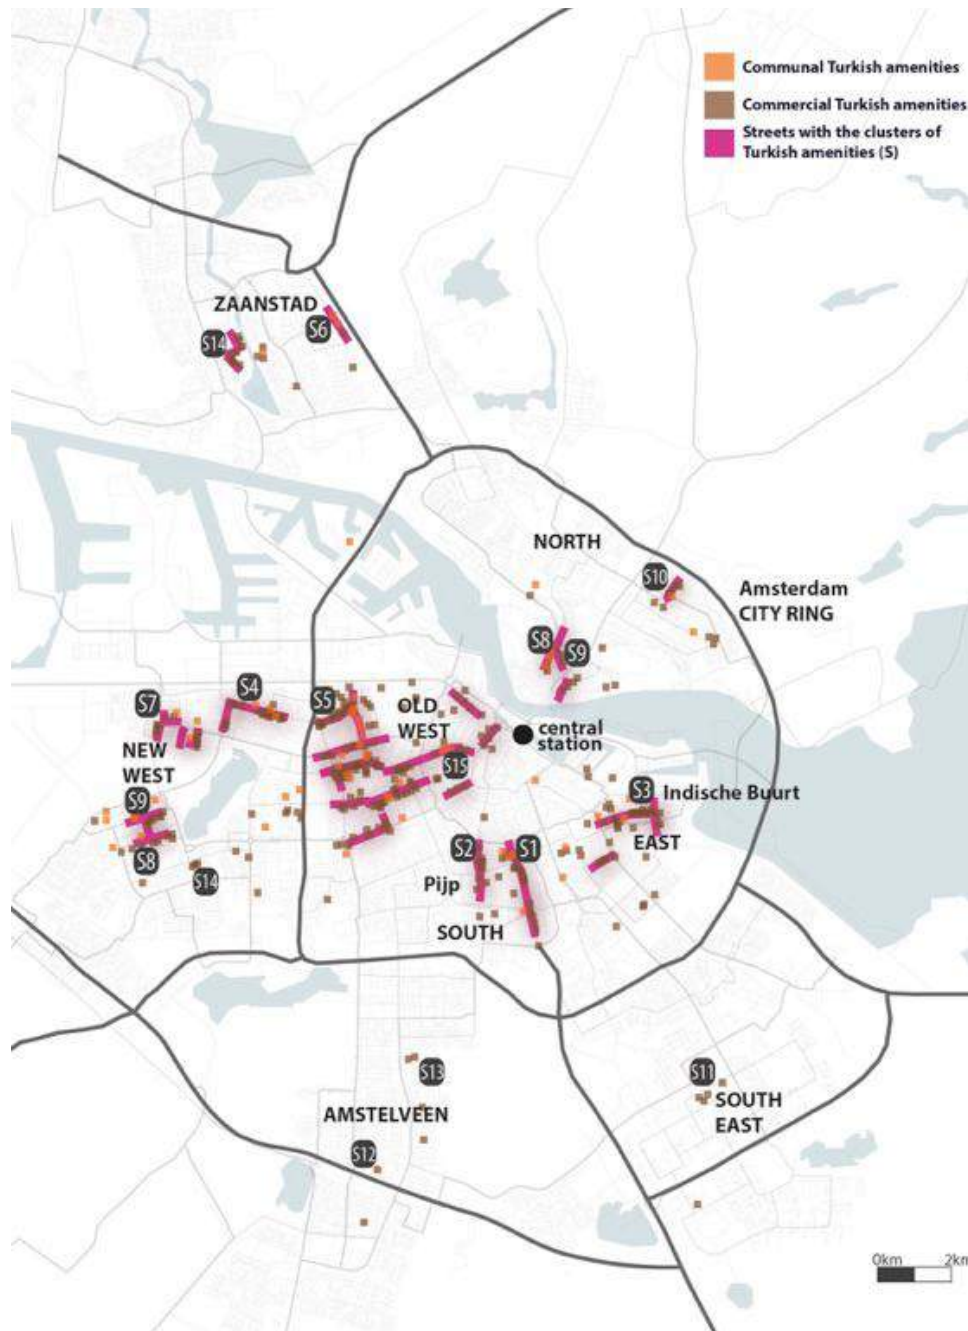

Figure 8. Streets clustering communal and commercial Turkish amenities in Amsterdam
 (Own elaboration with data collected by the author).

Figure 9. The types of Turkish amenities in Amsterdam according to their function (Own elaboration with data collected by the author).

6.2 PHYSICAL FEATURES

Turkish amenities, noticeable at street level through their distinctive names, have different physical features (such as size, window presentation, advertisement boards) and related practices (such as street use, working hours) depending on their types and location in the city. The differences between communal and commercial amenities are especially clear.

Commercial amenities are very visible at street level due to their window display, large name boards, and advertisements of events on their windows. But their visibility goes beyond their physical appearance and is also related to the practices and activities that they generate. Such amenities generally have longer working hours than the traditional shops that close at 18:00 hours. This is especially happening during the weekend and evenings, increasing the vitality of the street where they are located.

Commercial amenities in the inner city have different features than those in suburban areas. In the former, amenities offer a wider variety of products aiming to attract groups beyond Turkish residents. For example, eating places in the inner city generally mix Turkish cuisine with Greek, Italian, or Moroccan cuisines. Many Italian and Greek restaurants in the inner city have a menu with Turkish dishes and are owned by Turkish immigrants. On the other hand, commercial amenities in the suburbs are more exclusively oriented to the residents of Turkish origin.

Communal amenities have almost no visibility at street level. Since they specifically target Turkish interest groups, their window display and entrances do not clearly suggest their function for other residents. In some cases, even their entrances are hardly noticeable. The case of mosques is useful to illustrate the differences between commercial and communal amenities. Mosques are scattered around the city, and established in individual buildings or in part of a building. Those located in inner city areas are hardly noticeable, even for a careful observer, as they do not have boards with their names, signs or religious symbols, a common feature of mosques.

Since mosques are clustered with other communal and commercial amenities, they bring vitality to the streets where they locate, increasing their visibility. This is more obvious in the communal clusters located

in suburban areas, which often occupy a larger area with a garden, and extend the street use with tables and chairs, especially in the summer period. Figure 10 shows a cluster of Turkish amenities in Amsterdam New West which includes a mosque, a teahouse, a food shop, a sport centrum and a traveling agency.

Figure 10. A cluster of Turkish amenities in Amsterdam New West (Author, 2009).

The praying activities of mosques, dominantly by men, create a specific and rhythmic street use during the day, in the morning, afternoon and in the evening. In such way, the clusters surrounding mosques create a small niche for Turkish men and keep the neighbourhood active during day and night times in the week and weekdays.

7 DISCUSSION AND CONCLUSION

This study has been useful to verify a strong relationship between the location of the different types of amenities and their physical features, which in turn, shape their visibility. This is more obvious in commercial and communal amenities, particularly in those located within the Turkish concentration areas, which in the context of the general city trends in Amsterdam, tend to decrease in the inner city and increase in the suburbs.

How does the location of Turkish amenities influence their visibility in terms of physical features in Amsterdam? There are multiple indications of clear differences in the physical features of commercial amenities located in inner city and suburban areas, visible through their types, names, products sold and window displays. In the suburbs they are dominantly catering local residents. In the inner city, they target wider groups of people beyond the residents. This is particularly visible in the case of those neighbourhoods involved in a process of gentrification, which increasingly attract residents from the middle and higher income groups as well as visitors such as day-trippers and international tourists.

Studies on the gentrifying neighbourhoods of Amsterdam suggest that the residential gentrification goes hand-to-hand with the commercial gentrification (Zukin, 2012; Sezer and Fernández-Maldonado, forthcoming) and results in the displacement of long established specialized businesses or their transformation into other kinds of businesses. Commercial amenities in inner city areas are mostly adapting or transforming their businesses according to the demand of the new residents and visitors. However, not all the commercial amenities can modify their businesses following neighbourhood transformation processes. For example, those specialized on the needs of a specific target group (e.g. woman clothing shop for Muslim women) have difficulties to adapt to the changes and eventually may lose their businesses. This situation may have a negative effect on the visibility of distinctive immigrant amenities.

In regards to the physical features of the communal amenities, the findings suggest that communal amenities have a limited visibility, with some differences between suburban and inner city locations. In the suburbs, they are more noticeable since they use larger spaces and extend their street use depending on the availability of space. In the inner city, they are almost invisible because they mostly lack names, signs and in some cases clear entrances. However, the clustering of these amenities with some other businesses, for instance with shops and restaurants, provides them with an increased visibility. Additionally, the periodic use of some of the communal amenities (e.g. mosques) also increases their visibility.

The focus on visibility has been useful to give good insights into the practices performed by immigrants at street level. The concept of visibility appears as a valuable tool to get relevant neighbourhood data generally hidden from statistical and official data. The findings suggest that to study the visibility of immigrant amenities, not only their characteristic physical features matter, but also their location. They also imply that neighbourhood transformation programmes should be aware of the issues and assets related to the visibility of immigrant amenities to develop neighbourhood strategies that effectively improve the lives of local people. This would support the promotion of diversity and vitality of public life of the city.

ID 1633 | REPRESENTATION OF TERRITORIAL HERITAGE & DEVELOPMENT: CONJECTURED MAPPING TO UPDATE PORTUGUESE POSTULATES OF CITY-MAKING IN SÃO MATEUS, ES, BRAZIL

Sofia Simões Santos¹; Bruno Amaral de Andrade²

¹Federal University of Espírito Santo; ²Federal University of Minas Gerais

deandradebruno@outlook.com ; sofia.simoessantos@gmail.com

1 INTRODUCTION

This article is part of the state of the art regarding the methodology and technique of Representation of Territorial Heritage, capable of fostering reflections on heritage values through the elaboration of conjectured maps of four moments of the historical evolution of the urban heritage of São Mateus (1764, 1819, late nineteenth century, and early twenty-first century), in the state of Espírito Santo, Brazil.

Representation is one of the stages of planning, design and management for a self-sustaining local development, according to the Italian Territorialist Approach, whose research-intervention is directed to the overcoming of traditional analysis models, through: a theoretical revision, in which refers the enlargement of the concept of heritage, and an instrumental suggestion of geoprocessing and illustration production. The territorialist approach is a current of research-intervention thinking created and consolidated by the iconic figure of Alberto Magnaghi and the Society of the Territorialists.

This approach prioritizes the conservation and valorization of areas, figures and heritage elements in the territory, in the search for the widening of the concept of heritage, from the scale of the building to the scale of the city, the region and the territory. It questions the role of the territory, in the contemporary world, in the face of the problematic of political, economic, environmental and social unsustainability, and reveals technical and methodological paths for a local self-sustainable development.

The objective is the elaboration of conjectured mapping of Heritage Values of São Mateus, with support of geoinformation technology, as digital model synthesis in the iconographic ambit, identifying heritage elements, that can be point, lines and / or polygons materialized in the territory; and in the conceptual ambit, reflecting on the concept of territorial heritage and the relation with the local economy that provides a reproducibility of the Portuguese model of urban settlement.

In order to carry out the mapping, the method is based on the territorialist approach, concerning environmental, territorial and urban analyzes, and supported by georeferenced data; and of conjectural-cognitive analyzes, based on historical reports and iconography, to identify the main components of the place.

For the elaboration of the conjectural mapping elaboration, it is used a two-dimensional illustration program, which is constructed based on historical reports and iconography, in order to identify the main components of the site. And for the elaboration of the mapping of the graphic representation of heritage values, based on the Italian territorialist approach, concerning the analysis of weights of "values of use", "values of existence" and "values of actuality". The map of the representation of values is developed in the free and open source software QuantumGIS, whose graphic design constructed is georeferenced on the Orthophotomosaic basis.

The results obtained, in the state of the art, cover a discussion of methodology and technique of representation of values in heritage sites, when carrying out conjectural mapping, with geoinformation technology in order to reconstruct the evolution of the urban heritage of São Mateus, and to reflect critically

about the original Portuguese postulates for the contemporary moment of industrialization and of facing the risk of loss of tangible and intangible heritage; ie, one of the open discussion questions is related to if the original Portuguese urban settlement way of city-making in São Mateus has been reframed with the new socioeconomic dynamics and because of that a new way of thinking is still latent, or can it still be the answer to a self-sustainable local development?

2 CONTRIBUTIONS OF THE HISTORY OF URBANISM TO THE HERITAGE ANALYSIS OF SÃO MATEUS

The research of Simões Santos (2017) - São Mateus: from place to town - is within the scope of the History of Brazilian Colonial Urbanism, it is hypothesized that the settlement of the region of S. Mateus is of long duration, initiated in the 16th century, characterized by some (dis)settlements, and probably resulting from the need of proximity of larger urban complexes, such as Bahia's and Rio de Janeiro's. It begins with the recognition of the region - the place - between the captaincies of Porto Seguro and Espírito Santo, identified by Cricaré river or S. Mateus, which comprehend the territory adjacent to the river, with its own geomorphological characterization, which directly implied access to this region as a strategic settlement potential. It was concluded that there were difficulties of accessibility to the region, due to the proximity of the Abrolhos, significant shoals and sedimentation deposit at the mouth of the river, resulting from the joint action of the south-north sea currents and the strong seasonal winds that frequently changed the coast and river shores.

Historically this region was seen as a possibility of contacting the fertile lands of precious stones, abundant of the presence of the gentios, therefore, rich of woods and food from both forests and mangroves. However, it is not clear, based on primary sources, the exact origin of its settlement, nor the principles, strategies and actions, for how it would have started (Simões Santos, 2017). On the contrary, primary sources are presented which certify that in 1666 the river Cricaré was also identified by S. Mateus river; that in the first decade of the XVIII century sesmarias were given and that the settlement of S. Mateus had been (re)started in March 1716, by Domingos Antunes, captain of the eight men who accompanied him (Simões Santos, 2017, p. 150).

The Villa Nova de Sam Matheus is demarcated on September 27, 1764 (Amaral, 1927, p.278). From the Auto de Medição e Demarcação da Praça e Ruas da Villa Nova de Sam Matheus, it is elaborated a Conjectural Map of the probable urban area found by the Ombudsman Tomé Couceiro de Abreu, during his first visit to the town on June 16, 1764, by express order of the crown, in the person and authority of the Marquês de Pombal (Simões Santos, 2017, p.151-160).

Based on this information, it is evident the size of the village in the year 1764, which already has a main church and square, two streets that pass laterally to the church and which converge towards the west. The more extensive street has a curvilinear configuration, following the relief of the slope and receiving the largest number of buildings that lean over the river with the fronts facing the church square. This more extensive street is Rua Direita that starts perpendicularly to the Entrada da Vila, that comes from the port. At the same point it starts Rua da Aldeia, that follows the opposite direction of Rua Direita, and goes east, or towards the place of Pedra d'Agua.

The configuration of Rua Direita is curvilinear, to the north, tangential to the left side of the church, causes a strangulation of the west portion of the square, which never gets to be delimited or closed at that point, being able to enjoy the views to the river that is to the northwest, or more precisely to the sertão, and most likely with control of the church tower.

The measurement of the village began in the church square, which indicates that there were already houses on the street that intersect the right side of the church, followed by the measurement of the main street. From the north corner of the church, the Ombudsman determined the place and the marking of the rectangle of the Casa de Câmara e Cadeia, that will be built, on one side facing the square and the other side over the river. Next, the Pelourinho was erected and fixed of "Pão de Massaranduba, por ser pão tão forte que pode durar muitos annos" (Amaral, 1927, p.278), at the midpoint of the width of the Main Church Square. After that, it is determined the extension of the street that was already initiated by the right side of

the church, that is then called Rua Nova, containing information that from this street and the limit of the Barreira do Corgo, in a delimited quadrangular area, should be distribute the lands to whom wants to build.

It is known that the dock of the port is in the current port, for the information contained in the recognition of the S. Mateus river that the Ombudsman report of June 16, 1764, as "Porto da Povoação". It is also known that the population consists of 98 couples, with 98 children; 12 men widows, with 17 children, and 7 women widows with 15 children. In a total of 345 inhabitants, in which considered about 5 to 6 people per housing, results in an estimated of 57 to 69 houses. Furthermore, it is assumed that there were some houses of merchants and slaves near the port, because of the services necessary for the storage and transportation of cargoes. (AHU-ACL-CU-005, CX.35, D.6508, 16 de junho de 1764).

Then, the second mapping is elaborated and analysed, which is the Conjectural Map of 1764. It is possible to verify that the implantation of the S. Mateus settlement is in consonance and correspondence relation to the characteristics of the first Portuguese colonization formations of the Brazilian territory (Simões Santos, 2017, p.156-160). As the Portuguese architect José Manuel Correia Fernandes says: a Portuguese urban model was already present:

[...] o centro de vocação residencial é altaneiro, associando-se à elevação que guarda a memória do local de defesa colectiva; o centro de negócios e das trocas portuárias preenche o espaço de transição para o rio ou mar, em baixa e rasa superfície de aterros e praias. [...] Estas características básicas da cidade portuguesa - o pendor litoral e comercial, o sentido marítimo e trópico e a bipolaridade - tal como surgem pelos sécs. XIV-XV são adaptativas e vão enriquecer-se, sem se perderem, pelos contactos com novos ambientes, adquirindo se se quiser diferentes qualidades como mutações dentro do seu sentido inicial.(Fernandes, 1991, p.101-102).

With this study it is verified that the town of S. Mateus is developed next to the river, located in the highest quoted point of the region, rocky around wetlands, strategically protected with the control of guard both for the mouth of the river and to its sources, where the coming of the Gentio was frequent. A single access point to the village, in order to be easier to control the invader, with the very long Rua Direita that connects the Entrada to the place called Barreira do Corgo. In the middle of the extension of Rua Direita, tangentially, it's the Praça da Igreja. The Church faces the Rua Direita, located at the east end of the central square, parallel to the slope line and facing the valley that develops behind the Barreira do Corgo, therefore in the village spotlight, strategically beautiful, orderly and vigilant.

This structure refers to one of the typologies that Jorge Gaspar presents when he analyzes the adaptation of the D. Dinis villages, XIII-XIVth centuries, to military and administrative requirements, whether civil or religious, and which Paulo Ormindo de Azevedo makes known in this way: "[...] existe somente uma porta, com uma rua central que a liga ao castelo, situado na outra extremidade. À margem desta rua está, geralmente, o largo, ponto de reunião social, mas sem as proporções das praças renascentistas." (Azevedo, 1998, pp. 39-70). The Mother Church is the agglutinative element that defines the religious and urban center of the Vila, which will reinforce its role as a civic center, when surely in 1772, already has a Chamber House and Chain (AHU-ACL-CU- 005, Cx. 46, doc. 8553, de 1772).

From the notes made by the bishop of Rio de Janeiro, D. José Caetano Coutinho, who visited S. Mateus in 1819, it is known that he sent a letter to King João VI describing São Mateus in this way: "A freguesia de São Mateus já é considerável, porque já tem mais de três mil moradores, "[...] que exportam anualmente pela barra fora para cima de vinte mil alqueires de farinha em sumacas e lanchas próprias" (Coutinho, 2002, p. 123). Describes the village: "Esta vila está situada, elegante e alegremente, sobre uma cordilheira de montanhas que se levantam logo por trás do sítio da Pedra d'Água, e correm ao sul do rio para a parte do oeste" (Coutinho 2002, p. 63). He also describes the building and urban spaces: "[...] todas as casas de telha de duas ruas mui compridas, com outras atravessadas, duas praças, algumas dez ou doze casas de sobrado, bilhares, talvez lojas de bebidas, [...]" (Coutinho, 2002, p.63).

This description gives a notion of the economy aspects of the village, its population size and built area, which allows the elaboration the Second Conjectural Map, where it is observed that around the square is consolidating the construction of houses, reinforcing the priority vector along the slope, defense and connection to the east, in the prolongation of Rua Direita, which from the entrance of the village is called Rua da Aldeia. It is possible to observe in the analysis of the documents that the space next to the docks would already have a size and dynamism that was able to become a center of storage and commerce of a

considerable scale. Certainly it already had urban equipment to support the port, but there's not sufficient data to allow a precise representation on the map related to until 1819 (Simões Santos, 2017, p.161-165).

This statement is strengthened by the description of the geographer Hartt, who visits the city of St. Mateus in 1865: "é construída parte na borda das escarpas, parte no sopé da mesma, do lado do rio" and that "é uma localidade de certa importância, podendo ser avistada por vapores costeiros e pequenas escunas" (Hartt, 1941, p.149). Therefore, it is confirmed that in the mid-nineteenth century, there were already two urban centers in S. Mateus - the low and the high.

In order to confirm the consolidation of these two centers, especially in the port of the Vila, and if it allowed the evolution of the urban nucleus, we used the first photographs of S. Mateus, known from 1908, by Eutycho d'Oliver (Nardoto, 2016). It is a set of four photos: Two photos from the upper part of the city - Rua Direita and Rua de Baixo; Another photo of the Rua do Comércio and lastly the view of who arrives to the city by the river, visualizing the slope from the port to the high area.

In this map, there is a marked of buildings silhouette over the Praça do Porto and along Rua Direita / Rua da Aldeia; between the two squares of the Matriz and S. Benedito churches, resulting in the densification and emergence of a new parallel street to the south, called Rua de Baixo. It is also observed the consolidation of the block that develops immediately behind the Praça do Porto and along Rua do Comércio, revealing pomposity in relation to the Rua da Entrada da Vila, which traject is made by stairs whose paths intersect in the middle of the slope.

It is possible to verify in the photos the social and economic hierarchy of the streets by the significant number of houses, which predominates in Praça do Porto and Rua do Comércio; also in Rua Direita that has a house with three floors, another with two floors and the remaining majority with only one floor; in Rua de Baixo, all houses with one floor. The entire left-hand façade of the Praça do Porto is a unique one-storey building whose openings are all the same arched doors as if it were a storage place. (Simões Santos, 2017, p.166-171).

3 METHODOLOGY OF ELABORATION OF CONJECTURAL MAPPING

The central objective of Simões Santos (2017), whose research this article is based, is to identify moments of settlement of the region of São Mateus, between the XVI and XIX centuries, in order to arrive at an understanding of urban evolution of the town of S. Mateus, of which its consolidated urban center was raised to Vila in 1764, becoming urban nucleus, and for that reason, elevated the category of City, in 1848.

Based on the theoretical-methodological assumption proposed by Reis Filho (1968) on sociology, geography, economic and political-administrative aspects, with the aim to analyze the dynamic process of urbanization of the long duration, with mechanisms, actions and strategies, that allows the evolution of this smaller nucleus within the urban network that constitutes the history of colonial urbanism in the Portuguese America, aligned with the assumptions of researchers such as Cortesão (1965, 1971), Vasconcelos (1999, 2002), Araújo (2000), Abreu (2005) e Bueno (2011), regarding to historic cartography as an instrument capable of gathering information collected from primary sources, in order to understand the dynamics of the urbanization space in a remote period of scarce sources.

The methodology used is based on research of historical collections and archives, with a focus on colonial manuscripts, iconography and travel reports, as well as in the studies of geographers (Albino et al, 2001; 2006; Albino and Suguio, 1999), for the understanding of coastal geophysical morphology, and recognition of territorial changes.

Depending on the way in which these information relations are established, the results are obtained, which in this specific case allow determining the criteria for selecting the information; The criteria of the physical and temporal space to be represented; construct population and housing charts; calculate the percentage of probable spot built, etc., ensuring the reliability of the results that are the necessary elements for the elaboration of the conjectural maps.

The data is archived by topic, using EXCEL as a tool, because it allows the insertion of the information in a continuous way, with great flexibility of visualization in frames, or chronological grids/timelines. Hence,

grids allows establishing transversal and longitudinal relationships, diverse, in a specific context, or more comprehensive, as the research may require. Based on the objective of this research, the results are obtained in order to allow determining (i) criteria for information selection and hierarchization; (ii) criteria of the representation of physical and temporal spaces; (iii) construct population and housing graphics; (iv) calculate the percentage of probable built area, ensuring the reliability of the results that are necessary for the elaboration of the conjectural mapping method.

The Conjectural Maps are elaborated from the capture and conversion of the images of Google Maps in PDF, being constituted in matrices of scaled and referenced elements towards the space to be represented. Then, this matrices are inserted into Corel Draw where new images, now vectors, are created by overlaying them, to build each map simultaneously and independently, in which overlapping ones allows to evaluate the continuities guidelines of urban evolution. Finally, the images are converted to JPEG, so they can be pasted in the textual documentation.

In the specific case of Simões Santos' research (2017), the results obtained allows to construct conjectural mapping that represents three moments of urban consolidation of Vila de S. Mateus, covering an interval of 98 years, aiming to understand its urban evolution. The overlapping synthesis of maps allows analyzing the urban evolution of a place, or even a territory, if it is a set of settlements or urban nucleus (s).

4 THE TERRITORIALIST THEORY AND THE REPRESENTATION OF HERITAGE VALUES

The territorialist approach is a current of research-intervention thinking, created and consolidated by the iconic figure of Alberto Magnaghi and the Italian Territorialist School. This approach prioritizes the conservation and valorization of ambits, figures and elements of longa durata in the territory, and the search for the enlargement of the concept of heritage, from the scale of the building to the scale of the territory. It questions the role of the territory, at the present time, and its problematics of political, economic, environmental and social unsustainability, and proposes technical and methodological pathways for a local self-sustainable development (Magnaghi, 2010).

The core of the territorialists is the return of the place in the urban and regional project that, according to Magnaghi (2005, p. 7-8), is delineated by means of five movements: (i) definition, theoretically and methodologically, of the concept local self-sustainable development; (ii) methodology and technique of identity representation of the place, with focus on its testimonies, organized in an atlas of the territorial heritage; (iii) elaboration of the statute of the place, whose identity representation is the basis; (iv) elaboration of strategic scenarios based on the evaluation of the territorial heritage; and (v) evaluation of the concepts, the planning instruments and processes, from the knowledge gathered on the previous movements.

The goal of this article is to represent heritage values of São Mateus, in mapping format, with geo information technology software. The focus is on the use of the theory, method and technique of the territorialist approach towards the description, interpretation and visualization of the territorial heritage. Identity can not be described only objectively, detaching it from the processes of identification and appropriation, from the particular point of view of the architects of the territory, but also from the subjective elements, the original characters, the resistant historical and environmental references. It is possible to consciously use representation to describe the material history of an area, in whose challenge is how to use history to describe and draw the identity of the place (Magnaghi, 2001).

Relevantly, Vescina (2010) points towards a crisis in representation studies, as a problematic of the contemporary city design, in its physical and cultural structures, concerning how to observe and interpret the values that a society establishes in a given historical moment. It highlights the active role of representation, as a construction process, according to the point of view that maps represent and model reality.

Magnaghi (2005, p.10) argues that the motivation for the study of identity representation is of strengthening the hypothesis of wealth production by the sustainable valorization of the territorial heritage of each place. The author defines territorial heritage as a system of relations between physical environment, built environment and anthropic environment. To research the territorial heritage for the use

of values as resources requires the construction of an inventory in order to interpret in an integrated way the three environments that compose it.

In short, the method for representation encompasses transcalar and transdisciplinary characters, which are fundamental in the studies of the science of the territory, reasons for the incursions in other disciplines, besides architecture and urbanism, to describe a more complex image of the territory. Hence, in order to draw a territory, it is necessary to adopt a synthesis instrument, that reproduces the heritage narrative, evidencing long-standing structures, making it possible to reveal the personality of the place, its biography. (Magnaghi, 2005).

According to the territorialist approach, the territory is heritage, the essence of the temporal construction of men, the result of accumulation of stratified cultures, the act that plays a central role in planning, design and management for a sustainable development in the contemporary world (Magnaghi, 2001, p.3). Therefore, from representations of heritage values, in mapping format, it is possible to reveal the multidimensional character of the territory, and, thus, the enlargement of the concept of heritage.

5 ELABORATION OF HERITAGE VALUES MAPPING

The map of the representation of heritage values aims to provide bases for analysis of the physical and anthropic aspects of the territory, and its relation with the cycles of long term territorialization, as a basis for interpretation of the territory and landscape identity. Cartographic pre-analyses of the physical components of the territory and of the landscape are developed, framing themes of geomorphological, hydrographic, climatic and vegetative character. The analyzes performed were made through the data construction of mapping use georeferenced data, historical documents, historical iconography, and, mainly, aerial photographs.

The heritage approach of the territory and the landscape discusses cultural and technical bases related to cartographic description and representation, considering the historical moments in which the territory is stratified as a palimpsest. It is proposed, therefore, a reading that sees the landscape in its complexity as a legacy element together with the ecological, structural and, mainly, perceptive dimensions. It is discussed issues of territorial scale related to the description of morphological, typological, and structural articulations of the built environment. The final product is a map that evidences the territorial heritage of the place, as a presupposition to understand the relationship developed historically between the environmental structure and the built structure, and therefore socioeconomic.

This understanding shows the logic of the nature of urban occupation, consolidated throughout history, and the (dis) equilibrium between the settled society and its living environment, which (does not) guarantee the durability and sustainability of the settlement. Thus, the nature of the urban space is characterized from such relations, to be then reinterpreted from the point of view of contemporary society.

With the methodology of representation with technology of the geoinformation proposed by Poli (2012 and 2013), which focuses on the two-dimensional mapping QuantumGIS, already applied for the case of Santa Leopoldina, in Espírito Santo by de Andrade (2015), and with the possession of the methodology proposed by Simões Santos (2017), with references to the Conjectural Maps of São Mateus, there's an effort to combine both methods in order to gather theoretical and practical elements necessary for the mapping of São Mateus heritage values (Figure 1).

The territorial area adopted for the mapping of the representation of values also refers to previous heritage protection regulations, such as the São Mateus Municipal Master Plan, concerning to the item Historical Heritage (Figure 2), whose preservation area validates the adopted to this study. The mapping of high, medium and low values makes reference to the three territorialisation cycles of the conjectured maps proposed by Simões Santos (2017), whose argumentation and methodology of elaboration is present in the aforementioned section of this article, which is in line with the concept of the territorialist theory.

The gradation of values should not be understood only as a socio-temporal hierarchy of the local heritage, relative to its value of existence, but rather it is articulated with other variables related to the current state of conservation, use and appropriation, that is, its value of use and value of actuality, in the face of contemporary socioeconomic dynamics. The analytical combination of the value of existence, use

and actuality, endow the set of gradation of low, medium or high heritage value. In this way, the value endowed with a patrimonial asset, will dictate the intervention addressed to it.

As an example of high value, the “First Cycle of Territorialization” from the first Conjectural Map reveals an important heritage production moment for the historic center of São Mateus, as it is given a higher gradation when compared to other elements due to its value of existence, containing aspects of memory, identity, and aesthetic-formal as a parameter of evaluation.

As an example of medium value, the “Third Cycle of Territorialization”, whose maintains its value of existence, lose weight in terms of use and actuality, by the transformation of the architecture in contrast with the previous cycles, and also facing a new urban socioeconomic dynamic, which could trigger a new program for a reflection and compatibility on the new demands of use and appropriation of the land. The intention of the gradation as a medium value is that the analysis favor projects of valorization and requalification of these area to increase its gradation to a higher value. There are no examples of low value, as there are no elements whose combination of values of use, existence and actuality makes it an urgent intervention needed. Although there are some punctual inferences related to the new architecture and the expansion of the city, in total contrast and low quality specially related to the three cycles of territorialization present before. Other than that, another inference is need concerning the actual value of the port, that is deactivated, and although the place remains memorial with this high value, it no longer has the same value force of the previous use and situation, therefore this opens up intervention opportunities towards the revitalization of the port, harboring the new dynamics of everyday life in São Mateus.

6 RESULTS AND DISCUSSIONS

The representations narrate, evocatively, the character of the place, its configuration, and transmit a language that satisfies criteria of replicability and reproducibility of method and technique. The method proves to be able to be used to identify patrimonial values in the Brazilian context, provided that the adaptation of concepts to the local reality, such as long-standing heritage, citizen participation, space clippings (scope, figures and elements), Understanding of the territory as an organization that has layers (environmental, built, socioeconomic), and the geoinformation technology to be used.

The tool used for the construction of models, QuantumGIS software, has ample capacity for analysis and synthesis of the territory. It responds effectively to analyzes of heritage approach, as well as the work with existing georeferenced data created for territorial and urban analysis. It is a top two-dimensional representation tool, where it is possible to later explore three-dimensionality.

It proves to be a tool with potential in terms of information capacity to coalesce; Updated as one of the first tools of analysis, that is, a platform on which to make as considerations, together with the survey and recognition in place, and above all able to dialogue with several technicians of different specialties, But are complementary to the heritage approach, provided that a matrix of criteria for a gradation of value is safeguarded.

The effort to overcome the challenge of fine-tuning criteria between the conjecture map methodology and the methodology of value representation in which the very precision of the data and historical sources in articulation with on-the-spot data checks are essential. For the transposition of conjectural polygons to the map based on a georeferencing system, as to the agreement with respect to the gradation of values. Therefore, as a result of this study, it is proposed (i) in situ verification of spots from the conjectural maps; (ii) improvement and evidence of the value-gradation matrix, determining and justifying weights, in order to develop a qualitative-quantitative synthesis; And (iv) progress in the elaboration of a database of patrimonial values in São Mateus, with possibility of expansion to other localities, as is already the case of Santa Leopoldina (de Andrade, 2017).

Territory is heritage, but heritage may not always be the territory, unless a relationship of recognition of identity, local environmental, urban and economic values is established. The work of representing values has importance in building knowledge of the local culture, while proposing models that conform as project directives for the territory. In this sense, there is a contribution to the state of the art for the urban planning of patrimonial contexts, and indicative for research developments in the elaboration of digital models of the territory with a core in the identification of the Portuguese urban settlement model, whose system can be used to reflect on a Development.

In addition, the Municipal Master Plan of São Mateus opens a participatory process to contribute to the revision of the plan. With regard to the preservation of historical heritage, it is suggested as a provocation, in the universe of approach of this article, the elaboration of detailed studies about the representation of patrimonial values of São Mateus, whose syntheses can be used as guidelines for participatory pathways related to parameterization Based on the patrimonial approach of the territory. And, therefore, constitute theoretical, methodological and practical postulates for overcoming the conservation and development dichotomy.

ID 1638 | EVERYDAY NATIONALISM AND URBAN CULTURE – NORMALIZING NATIONALIST REPRESENTATIONS, DISCOURSES AND PRACTICES IN PUBLIC SPACE

Elina Kränzle¹

¹Interdisciplinary Center for Urban Culture and Public Space, TU Wien

elina.kraenzle@skuor.tuwien.ac.at

1 INTRODUCTION

Public space research has engaged in depth with progressive social and political movements which have appropriated and reframed public space as a political sphere and a space for local, lived democracy. However, urban public spaces have not only been the place of these progressive movements' protests and occupations in the face of crisis and austerity policies. I want to briefly sketch some of the different phenomena that show that public space has also become the place of anti-pluralist, xenophobic and nationalist protests: The Brexit-vote, a result of anti-immigrant sentiments and Euro-skepticism, brought increased xenophobic violence to public space. When the unleashed violence of terrorists has disconcerted public space yet again, the French government has extended the state of emergency curbing citizen's rights such as the right to assembly and protest. Another example of urban space being used for rightist and nationalist strategies is Turkey. After the failed coup in Turkey, thousands followed the call of Erdogan for a "Democracy Watch" in Taksim square, re-appropriating the symbol of the 2013 Gezi Park Protests against the government with national symbolism. In 2015 the rightist movement Patriotic Europeans against the Islamisation of the Occident (PEGIDA) came to a head with 10.000 citizens protesting in Dresden (Zeit.de).

These observations point to the relevance of urban public spaces in the operation of rightist political organisation. They postulate a closer look at urban public space as a central arena of the right's anti-pluralist, xenophobic and nationalist agenda. Furthermore, they expose the city a contested space of both progressive and rightist appropriations. The aim of this paper is to pay attention not to the overt protests and demonstrations but to expose everyday and popular nationalism in public space. It seeks to address the representations, discourses and practices that normalize nationalism in public space. The research therefore challenges the notion of rightist spaces as rural phenomena as well as it challenges the notion of urbanity at the heart of inclusive and cosmopolitan societies. Based on Bulut's (2006) definition of popular nationalism as "the exacerbation of nationalist feelings and the increased attachment to the idea of the nation in everyday representations, discourses and practices" (p.125) this paper points out the return of nationalisms to public space, drawing on the democracy watch protests and the popular festivities of the Austrian National Day. It aims to present first explorations of rightist appropriations and nationalism in public space to develop future research propositions.

2 EVERYDAY COSMOPOLITANISM

In the prevalent discourse on life in multicultural global cities, the mingling and mixing of diverse and different urban dwellers is often described as a huge potential to establish a cosmopolitan attitude. Many urban studies authors have underlined how the complexity and lived difference of urban life transforms us into cosmopolitan citizens, as we are confronted with various cultures, religions, ethnicities and lifestyles in our urban everyday life (Amin and Thrift, 2002; Caglar, 2002; Sandercock, 1998). To live our life in global cities we need to deal with this difference, and thus national or religious, essentialist notions of the city and its spaces are upset. Instead of building community and citizenship based on national, religious, or ethnic identity, the city becomes a possible contact point of shared identification across dividing lines (Caglar, 2002). These assumptions on urban societies' capacity of inclusion though have rarely been grounded with empirical research. As Müller (2011) points out, "academic interest has mostly focused on postulating an abstract ethics for an as yet unrealised cosmopolitan society" (p.2) instead of analysing the ordinary citizens' extant cosmopolitanism.

Cosmopolitanism is mostly explained in a normative approach, delineating a philosophy of world citizenship on the one hand, and a set of certain skills, attitudes and lifestyles, that constitute cosmopolitan subjects (Binnie et al., 2006). Still, there is a lack of empirical and more grounded work on cosmopolitanism, to substantiate the assumptions of urban life's potentiality of creating cosmopolitan attitudes. Defining cosmopolitanism as a social practice rather than the philosophy of world citizenship or a set of certain skills, attitudes and lifestyles, Müller (2011) found that an urban identity can supersede exclusionary national, religious or ethnic identity (p. 15). Still, "cosmopolitanism cannot be envisaged as an unproblematic transcendence of the everyday workings of power and national, ethnic and religious identities" (ibid. 16) but has to be viewed as an ongoing negotiation between existing identities, contact points and class structures. While Müller emphasizes the need for empirical work on urban cosmopolitanism, this paper aims to underline the need to discuss the existing identities, contact points and class structures as given in national, religious or ethnic belonging that have become visible in essentialist notions that seem to be just as prevalent as cosmopolitan attitudes in urban society.

Accounts of "Everyday Cosmopolitanism" (Bayat, 2003), "Everyday Multiculturalism" (Wise and Velayutham, 2009), or "Street-level Cosmopolitanism" (Radice, 2009) deal with citizens everyday practice of living together in multi-ethnic societies. In "Life as Politics" (2013) Asef Bayat formulated a practiced concept of cosmopolitanism: Everyday cosmopolitanism. Instead of ascribing the cosmopolitan idea(l) only to the educated world-citizen, in his research on the Middle East he discovers cosmopolitanism in the everyday life of the citizens who across ethnic or religious differences share a life and certain practices, living in peace. These concepts have aimed to fill the gap of theoretical literature of multiculturalism that a top-down approach has produced and offer a perspective that "explores how cultural diversity is experienced and negotiated on the ground in everyday situations" (Wise and Velayutham, 2009, p. 2).

3 THE COSMOPOLITAN CITY IN CRISIS

Essentialist identification, and with this, essentialist notions of place counter the discourse on cosmopolitanism. These notions are based on the idea that nations represent homogeneous cultures where newcomers, like refugees, are out of place (Brun, 2001, p.17). As Stuart Hall points out, the modern character of nation states is not just a defined territory or political entity but producing meaning as a "system of cultural representation", in which "people are not only legal citizens of a nation; they participate in the idea of the nation as represented in its national culture" (Hall, 1992, p.292). This discourse of national culture has always been imagined in relation and more so as opposed to an other. In recent years, with movements like PEGIDA or the political party Alternative für Deutschland (AfD) in Germany cultural definitions of race have found their way into discourses about nationality and have unveiled that big parts of society reject immigration, and pointing to "a racism which avoids being recognized as such because it is able to line up 'race' with nationhood, patriotism and nationalism. (...) It constructs and defends an image of national culture – homogeneous in its whiteness yet precarious and perpetually vulnerable to attack from enemies within and without. (...) This is a racism that answers the social and political turbulence of crisis and crisis management by the recovery of national greatness in the imagination." (Gilroy cited in Hall, 1992, p.292)

Rightist and nationalist political organisation is still rarely analysed in its relation to public space. As nationalism has generally been depicted negatively in academic accounts, how can we understand the appeal of this construct? John Agnew (2013) deconstructs the critique of nationalism, as 1) nationalism does not simply appeal to an "imagined community", but it has created real and material communities of interest and identity through tying them to a state-organized territory; 2) Nationalism has, as opposed to liberalism and socialism, the mobilizing power through identifying an enemy against which the nation's territory needs to be defended; nationalism developed "in popular appeal alongside industrial capitalism and "modernization" in Europe" and can thus be expected to go in decline in the face of accelerated globalisation and international migration (Agnew, 2013, p.133). Whereas civic nationalism is framed around institutions and political principles, the Ethnic nationalism involves the exclusive identity of the people with the nation whereas civic nationalism involves the inclusive identity of the nation with the people. Thus, if ethnic nationalism is characterized by shared cultural loyalties, civic nationalism is all about shared political principles and institutions (ibid.,p.136). In contrast to the ideal of cosmopolitanism, nationalism relates community and identity to territory and space and therefore serves essentialist notions of space. Though concepts of everyday cosmopolitanism have tried to overcome its normative and elitist

bias, they have not achieved to answer questions of meaning and identity, where nationalism offers handy attachments.

Ebru Bulut (2006) defines populist and popular nationalism as “the exacerbation of nationalist feelings and the increased attachment to the idea of the nation in every-day representations, discourses, and practices which could be observed during the 1990s” (p.102). Based on Turkey’s social and political development she describes how we can understand increased nationalism through the social grammar it develops. This social grammar of popular nationalism is firstly present in pervading national symbols like the national flag or portraits of national leaders at home or in shops. Secondly, this nationalism acts as a form of problematization through which we can understand the world and attach meaning to it, determining categories and rules of discourse through which to think and speak and act (Bulut, 2006, p.129).

The current populist and rightist political backlashes in national politics in Europe and around the world stand in discrepancy to globalised economies and migration and the multicultural realities of cities today. These political backlashes, exposed by the Brexit vote and Trump’s election as President, have unsettled not just the national political classes, but upset members of the liberal middle classes and the metropolitan left. Despite their diverging political aspirations both neoliberal and leftist groups share their support of cosmopolitanism, which is violently rejected by the right. This research aims to help understand what Jeremy Gilbert (2017) has called the “crisis of cosmopolitanism” and its roots in and consequences for the metropolis. The differentiation between civic and ethnic nationalism as described by Agnew, as well as the account of popular nationalism offer valuable perspectives to analyse the celebrations of the national holiday in Austria and its contribution to what I have called everyday nationalism.

4 NORMALIZING NATIONALIST REPRESENTATIONS, DISCOURSES AND PRACTICES IN PUBLIC SPACE

4.1 FROM GEZI PARK TO “DEMOCRACY WATCH”

With the “Genie in a Bottle” Örs (2014) describes how the process of the Gezi protests in Istanbul in 2013 realized a reconceptualization of democracy in Turkey, especially through its spatial occupation (p.491). The public was upset with Erdogan’s project of destroying one of the few green spaces in Istanbul’s centre to rebuild the historical military barracks on Taksim square, a project evaluated as building on “anti-secular, islamist, neo-Ottoman ideologies” (Örs, 2014, p.494).

From a sit-in to hinder the destruction of the park the Gezi park demonstrations grew into a tent city, where LGBTQ and feminist groups gathered next to Kurdish, religious groups and environmental activists and developed a community life where their various opinions and political ideas, that were otherwise not represented in the political parties in Turkey, could be expressed (Benhabib, 2013). The extremely violent clearing of Gezi park using water guns and tear gas ended the “Gezi utopia”, displaying the AKP’s and Erdogan’s government’s stance as being the only democratic body of relevance. The alternative political process of a pluralist democracy sharing values of cosmopolitanism, solidarity and peace represented a threat to the representative democracy in crisis and was thus attacked with full force (Örs, 2014, 497). As a consequence, the government banned all forms of gatherings or protests from Taksim square, paralyzing the once busy square.

The Gezi camp brought about many hopes for Turkish democracy: “Since Taksim Gezi protests erupted in May 2013, a new phase of democracy is starting to be defined in Turkey.” (ibid. 489) The aftermath of the failed military coup in Turkey on 15 July 2016 showed a yet unpredicted phase of turning democracy into autocracy: “Although the identity of the coup plotters remains unclear, President Recep Tayyip Erdogan’s subsequent crackdown on a wide range of his perceived opponents – including the detention of nearly one-third of the high command of the Turkish Armed Forces – could portend a period of sustained turmoil that would seriously strain Turkey’s international relations, exacerbate its already widening democratic deficit and inflict lasting damage on its social fabric.” (Stevenson, 2016) A few months later the fears about the crackdown seem to have come true, with a purge of all critics, throughout political parties, independent media, educational institutions and NGO’s under the state of emergency.

Coming back to the spatial aspects of this political crisis, the revaluation of public squares has been a central strategy of the coup's aftermath. While Erdogan already called for the people to go to the streets to protect their elected government while the military coup was ongoing, thousands of citizens followed the president's call for so called "democracy watches" once the coup had been averted. Over the course of the following nights thousands gathered to show their solidarity with the elected government. These protests were in contrast to the "Gezi Utopia" characterized by their national symbolism, with a blaze of Turkish flags and Erdogan and religious banners (Akyol, 2016). Taksim square was one of the biggest gathering places night after night, where citizens stated their belonging to the state and their support of democracy across party lines and ethnic groups. If "the crisis of democracy strolls in public spaces of the world, seeking an effective redefinition, an update of the concept, a way to bring the public back into the concept of democracy" (Örs, 2014, p. 490-491), Erdogan and his supporters have been successful at bringing the public back into a different concept of democracy. Thus it represents an effective redefinition of not democracy but autocratic state power, seeking legitimation in the streets by calling the people to show their solidarity with the nation and not with pluralistic, bottom-up democracy, as it was lived in the Gezi camp. The democracy watch on Taksim square revaluated the place that once stood for the Gezi protests against the government's radical urban redevelopment and speculation strategy, and then for the disproportionate police violence through which the protest was ended. After the repeated night watches, and images of red flags plastering the square, Taksim stands now for the unity and national identification of the Turkish people (at least those present at the demonstrations) while the purge of all difference is ongoing.

4.2 THE CELEBRATION OF AUSTRIA'S NATIONAL HOLIDAY IN VIENNA

Since 1965 Austria's National Holiday is celebrated on the 26th of October to commemorate Austria's declaration of unceasing neutrality and independence to foster peace in the world:

"Eingedenk der Tatsache, daß Österreich am 26. Oktober 1955 mit dem Bundesverfassungsgesetz BGBl. Nr. 211/1955 über die Neutralität Österreichs seinen Willen erklärt hat, für alle Zukunft und unter allen Umständen seine Unabhängigkeit zu wahren und sie mit allen zu Gebote stehenden Mitteln zu verteidigen, und in eben demselben Bundesverfassungsgesetz seine immerwährende Neutralität festgelegt hat, und in der Einsicht des damit bekundeten Willens, als dauernd neutraler Staat einen wertvollen Beitrag zum Frieden in der Welt leisten zu können, hat der Nationalrat beschlossen:

1. Der 26. Oktober ist der österreichische Nationalfeiertag.
2. Der österreichische Nationalfeiertag wird im ganzen Bundesgebiet festlich begangen." (Rechtisformationssystem Bundeskanzleramt ris.bka.gv.at)

Both the independence contract and the declaration of neutrality have been denominated at the heart of a positive Austrian national conscience, detached from nostalgic ideas about the former super power or a Pan German empire (Spann, N.D.). Besides a speech by the president, the national holiday is celebrated with an open house day in Vienna where people are invited to visit the central democratic institutions such as the seat of the chancellor or the parliament building, where the different elected parties present themselves. In 2016 the celebrations took place along the Ringstraße boulevard and Heldenplatz, where important historical state buildings, and political and cultural institutions are located, such as the parliament, the City Hall of Vienna, the historic building complex of the Hofburg (the seat of the Federal President), the Chancellor's office, Burgtheater and State Opera, the Museums of Natural and Art History, and the University of Vienna. Two prominent organisations shape the festivities in public space: The Österreichische Bundesheer (BH, the Austrian Armed Forces) and the K-Kreis (Katastrophenschutzorganisation, civil protection organisations), an association of 39 professional and voluntary organisations and divisions of the municipal authorities catering for what they call "security", e.g. wastewater and sewage, electricity and gas, public transportation, police and military police, but also social services. In what they called a "Informations- und Leistungsschau" (informational and performance show) the BH, the institution most prominent in the public spaces of the fair, present military vehicles and innovations, such as tanks, helicopters and trucks, special weapons, gear and even military dogs and the different divisions of the armed forces. Besides displaying the military force of the BH, another stated aim of the show is to recruit new soldiers in the face of illegal migration and the threat of terrorism. The banners of the BH underpin the message of a threat to security and the important role of the Armed Forces to increasingly protect it:

Mit Sicherheit. Auf unser Heer kommt's an. Gerade jetzt. (See fig.1)

Figure 1 - Banners of the BH at the celebrations of the Austrian National Day, October 26, 2017 (© Author)

The square in front of the town hall was used as a fair ground for the “Wiener Sicherheitsfest” (Vienna Festival of Security). As part of the show of the various organizations of the K-Kreis also the police and the military police presented themselves and their special operations vehicles with tear cannons. Again, the security aspect informed the naming of the event and the display of (para-)military machinery and personnel were the main aspects occupying public space. The violent character of these high-tech weapons and soldiers as actual protagonists of war and defense and the paramilitary armament of police seem unfit to be presented in a popular fair. And yet, the people coming to the show apparently enjoyed the day atmosphere, had food and drinks, bought balloons for their kids and took photos together with soldiers in gear holding their pump guns and posing on tanks. The BH and the police presented themselves as approachable and popular while stressing their importance as strong defenders of the country’s and its citizens’ safety in times of crisis. (see fig.2)

In light of the declaration of neutrality and independence that is celebrated on Austria’s national holiday, such a strong presence of the military and the police and their performance show during the festivities seem a bit odd. Opening up the democratic institutions to interested visitors on the other hand celebrate what Agnew (2013) has termed civic nationalism (p.136) as it is dedicated to the democratic institutions (but not yet principles) of Austria. Still, the BH show and the “security festival” in central public spaces in Vienna address principles of populist and popular nationalism. They bring up threats of terrorism and illegal migration as topical issues they tackle and thus affirm the protection of a state-organized territory. Exactly the tying of communities of interest and identity to territory and the protection of that territory against enemy figures are described as appealing to popular nationalism (Agnew, 2013; Bulut, 2006). They, if very subtly, play in the hands of conservative and right-wing discourses on refuge, migration and terrorism, where increased border control and urban securitization are pursued. As Bulut (2006) points out for the case of nationalism in Turkey in the 1990s: “In order to understand the extension of nationalism as the social grammar, one has to consider mobilization not as an ensemble of specific actions but as a continuum which includes actions, sentiments, even silences (non-protestation). It is less a mobilization for action than a mobilization for consensus.” (p. 129)

As internationally military parades are common events during national celebrations, we have not come to question them. The presentation of BH and police armament as a popular fun fair should be recognized though as normalizing discourses of urban warfare and threats of national security as part of rightist federal law as well as urban securitization.

5 REFLECTION – FRAMING A RESEARCH AGENDA

First explorations of nationalist appropriations of public spaces in Istanbul and in Vienna have shown the return of overt and subtle nationalist discourses and practices in cities. They have pointed out that public space is a relevant arena to establish, further and maintain nationalist politics and establish first relationships between national discourses on migration and terrorism and their effects on urban spaces. The democracy watch protests have brought citizens to the streets in national unity and in “defence of democracy” against the enemy identified as the coup plotters. We have furthermore observed the normalizing and trivializing military and para-military presence during the festivities of the national holiday, that has been shaped by the theme of security. The discourses shaping the exhibitions in public space were themed as “security” shows, where a more abstract enemy has been identified with illegal migrants and terrorists.

The urban studies discourse has engaged intensively with progressive movements and their relation to public space, furthering accounts of the cosmopolitan and inclusionary potential of cities. Radically exclusionary movements though still offer research opportunities in their relation to public space and I claim that it is crucial to understand rightist appropriations of space to mobilize people and propagate their agenda as crucial arenas we need to tackle. Though cautious not to promote rightist ideas, urban research needs to analyse rightist movements to raise awareness of the critical factor of space and body politics in establishing, continuing, and furthering ideologies that might threaten the democratic project. This research can also inform urban and spatial planning and its engagement with nationalism, localism and identity of place.

To achieve a broader understanding of the spectrum of rightist appropriations of public space, I want to develop a research project that looks at conservative and right-wing parties, movements and everyday practices in relation to urban space. The aim of such a study then is not to analyse intellectual trends, ideologies and social contexts of those groups in depth but to study their use of and relation to public space in establishing, continuing, and furthering anti-pluralist, xenophobic and nationalist ideologies.

ID 1644 | THE IMPACT OF INTERNATIONALLY URBAN CULTURE IN REDESIGNING AND RECLAIMING LOCAL PUBLIC SPACES VIDEOGAMES AND STREET-ART MOVEMENTS AS DESIGNING PLATFORMS FOR PUBLIC SPACES

Ilir Dalipi¹, Petrit Ahmeti¹

¹University for Business and Technology

ilir.dalipi@ubt-uni.net

ABSTRACT: Public spaces have been seen as common spaces for social gathering and for developing and presenting various art installations. Most of the time public spaces have been designed by city planners from their offices and from their own perspective. This has led to derelict, disconnected from its surroundings, and abandoned spaces. Emerging internet subcultures of video games and underground movements such as street art have progressed beyond entertainment and fun towards a more innovative world. These subcultures have encouraged a different way of thinking, seeing and doing things. The tools that these subcultures have developed can be wisely used to change landscapes and redesign and recreate attractive and usable public spaces. Using these internet platforms to do tactical urban interventions, in a sense of transforming these internet based platforms to useful and practical tools through creative practice, can respond and fill the gaps of cooperation between digital/video games communities and urban/street art, artists and the city planners to addressing the problems with abandoned and disconnected public spaces. This study provides, firstly, an overview of how subcultural theory could contribute to a study of the use of algorithms of video games and urban/street art movements in innovation and creation of public spaces and redesigning of existing ones. The first part will focus on widely used video games such as SimCity and more dynamic GTA to see how these two video games can be used to create innovative public spaces and also to redesign existing ones by engaging the community as well. The second part of the paper will look at the urban/street art global movement and the impact they have in our everyday life and in the public space we together share. Street art movement most of times have sought, through their guerrilla art actions, to reclaim the public space. Due to increased attention, cultural recognition and institutional support graffiti/street art have been gaining in recent times, it is important to analyse the significance that this subculture could have into the creation of the public space. This paper will analyse particular projects that have applied the approach of using video games and urban/street art to reclaim public space and turn it into a creative and attractive public space for all. Although, this approach has been used in different cities around the world in Prishtina this approach has only been used once by the UN Habitat in cooperation with the City of Prishtina to transform an abandoned site into an attractive playground for children and a public space for adults, by using the tools of Minecraft video game. The main objective of this study is to analyse how the combination of the tools we find in video games and street art could transform cities, improve lives and reclaim public space.

KEYWORDS: Public space, urban culture, urban design, videogames, street-art, subculture

1 INTRODUCTION

Public spaces, in its divers contexts, describes as a neutral or shared space of its own urban dynamics. Whether these public spaces are functional or abandoned, used or misused, “free or invaded” they are in close tie with the way how they have been designed. The traditional approach known as “planning from desk or office” led to non-usable space for its first purpose. This kind of “space abuse” or “spatial misuse” (Özkan, 2008) brings to the question of redesigning and reclaiming the value of the public spaces as an alternative. Urban culture as much as complex as it can be, can validate public spaces using subcultures as socially engagement of various communities within.

Videogames and Street-art are internationally renowned subculture movements have impacted our modern society. They also impacted pretty much isolated society’s such as City of Prishtina, capitol city of Republic of Kosovo, through the only platform looking at the world-internet. These two internationally movements that can puzzle-in in locally urban lifestyle as an “imitation game” of these globally urban

movements. It is important to explore other alternatives of approaching in creative and playfulness of planning public spaces. These “tools” gives to our post-conflict society an opportunity to conduct an independent alternative and develop constructive knowledge of modern dynamics of city’s landscapes evolution and its transitions towards more innovative and sustainable public space.

This paper is focused on these two subcultures of urban lifestyle as tool or platforms. First part of the paper (1) describes different aspects of videogames as an indoor activity or how different algorithms of videogame’s virtual space can be used to transform physical local public spaces into lively places for society and its naturally needs. Various perspectives will be discussed, example of Electronic Arts Inc. SimCity, developed more as axonometric, or traditionally known as planner’s perspective. Rockstar’s Grand Theft Auto-GTA conceptually 3D dynamic game, that is more developed from pedestrian perspective. Even conceptually abstract cityscape, put in through Arkham Asylum videogame that storyline comes from DC’s Bat-Man superheroes comic book as part of urban culture steps into reclaiming of public/good from misuse/abuse or evil forces of City of Gotham in a subconscious player’s/planner’s struggle to redesign space that citizens own for their city.

However, in this part (1) the focus of analysis takes an independent videogame as Minecraft by Mojang Ab company, that explores many possibilities to engage different communities in designing public spaces according to their needs. Case of UN Habitat initiative through the program Block by Block in Prishtina, republic of Kosovo can be a good analytical or study case. Starting from the story of game to platform or community tool to discuss community perspective for redesigning or reclaiming public spaces in step of their threshold, this study will give an example how this videogame can work as an alternative tool for redesign these common spaces.

Contrary to videogames “manipulative” aspect of or with virtual space, in second part (2) we analyze globally street art movement as a primary outdoor activity. Although, many definitions of street art, we will try to gather all non-institutional and independent art forms in public spaces that provoke or defines society within. Rather it is graffiti, post-graffiti or street art, guerrilla art or marketing, public art or public interventions, legally or illegally we refer these subgenres under one term of street art movement. Here, we address the impact of several local case studies that uses street art to revalidate and make attractive public spaces.

The notion of space traditionally refers to something anonymous (Sherry 1998; Tuan 1977) and universal, public space are more described as place of meaning of certain activities. Thus, cities are “both physical and imagined” spaces (Brown-Glaude 2008, 114), where “differences are constructed in, and them-selves construct, city life and space” (Bridge and Watson 2000, 507, quoted in Brown-Glaude 2008, 114, quoted in Visconti et al, 2010.). Attempts to change one dimension may prove worthless or even counterproductive in the absence of connectivity to the others. It is, in the end, the symbiosis between the three that matters (Harvey, 2005). So, this paper study refers to public spaces as physical common grounds as a fusion of diverse actions or where life’s drama takes places in its natural order. Referring to it as public space to streets, parks, squares, under or overpasses, etc.

However, the group activities are political, artistic or research group, etc. where virtual environment simulate real world places and activities (Witmer, 1996). In that context need for physical public spaces transgress into processes of socialization online as a virtual public space. This can reveal an important interplay in redesigning physical public space. Virtual space is non-physical spaces created by the development of technology. It could be a music record or Internet social network for example, Facebook and Twitter, where Internet is the first true virtual space (Shields, 1996, quoted Alrayyes, 2012).

Although, “despite seeming like public spaces, these services are really not public. Virtual public spaces try to seem like public spaces, but they are like shopping malls: commercial spaces that encourage only a subset of public behaviours. Virtual public spaces are not public spaces, but as we spend our public time in them, we drain the life from alternative public spaces.” (Smith, 2013). The term of virtual public space known also as cyberspace includes also internet platforms public domains as social media networks, community forums, online videogames, web database sharing content, etc.

Due to different urbanization movements, public spaces as complex structure faded into various impacts and planning methods in a dialectical context. As this topic “surfs” from internet our main method is analytical model of case study. Analytical model is based on qualitative as much as critical analysis of case studies. That includes site location and process analysis based through redesigning those public

spaces. Many of the ideas in this paper study were collected from reading various articles, journals and books or from internet that is main source of our inspiration as videogames and street art and their impact became internationally best known from it. Through the paper, the tendencies are to lean on Henry Lefebvre's "The Production of Space" (1991 (1974)) as theoretical framework of appropriated space or in our case into re-appropriated, redesigned and reclaimed public space, its production from videogames and street art movements.

Accordingly, the community these days are much more active and engage in redesigning their common ground our goal is to present them these new alternative platforms to express ideas in more simple but powerful way of urban design and planning of their/our common ground.

Finally, the aim of the paper is to explore how these platforms as tools can fill the gap of choosing an alternative way to redesign or reclaim public spaces into more attractive appropriating areas of engaging communities to shape and redesign.

2 VIRTUAL PLAYGROUNDS OR PLANNING WITH VIDEOGAMES

Interactions between physical and digital domains that used to be considered as largely different in our concept of perception of time, space and place, social relationships and identity, technologies made it faded or blended in our human imagination. Technologies can be conceptualized as an interface between the digital domain and the city (Ito et al, 2009). These media technologies tie digitally mediated communication and information to physical contexts, and at the same time enable the uploading of "real world" experiences to the digital realm. (de Lange M, 2009). Before trying to explore these tools, the focus is to overview the link between the videogames as urban culture and urb-architectonic aspect of city's landscape.

Shortly, to describe these aspects, Space Time Play: computer games, architecture and urbanism: the next level (Von Borries, et al. 2007: 12-13), is very useful analytical book that shows some 'levels' where games and urbanism meet. First, there is an 'architecture of computer and video games' that is a distinct spatiotemporal design where for architects is important spatial context and quality characteristics from the game. This kind of design is 'democratic' way that player is free to redesign its own game (e.g. Sim City). For videogames creators, on the other hand, it's about finding creative elements that constitute game space and which spatial attributes can give a specific type of interaction. This can lead to videogame players to experience physical space differently and thus use it differently. In this context, videogames in hands of player or communities engaged can provide many creative solutions to reshape public spaces.

Second level of "make believe urbanism" bring coherence of virtually generated spaces and how these 'virtual communities' present their identity between the representation of the city in games and the city as metaphor for the virtual specialization of social relations. Interplay between digital and physical spaces, gives us a city as playground where certain communities besides socio-cultural developments of present they build an imaginative future for public spaces.

Third, "ubiquitous gaming" is actual platform or tool practise that describes real space – public space in redesign process into a videogame virtual space using gaming technologies and creative game concepts or that may modify the social functioning of urban places (de Lange M, 2009). Potential and flexibility of videogaming can produce future redesigning of public spaces. At this level interaction between players and spaces is direct action of social and cultural behaviour of a virtual world as tool.

In the fourth level, "serious fun", or "serious tool" the specific game elements have serious uses in redesigning public spaces. There are some examples where videogames are used in architecture and city planning. UN Habitat settlement program Block by Block is one of them. This program takes place also in not so attractive neighbourhood Sunny Hill which we will discuss later on this part.

In the concluding fifth level of understating virtual spaces through videogames architecture and concepts that defines it, playfulness of videogames critically reflects the future of public spaces. For instance, many maps and mapping apps and their potential whether it can be cultural, social or database of certain activities can be major shift on how we navigate in future. Overall, by understating and using flexibility of virtual space in videogames communities can designed but also reclaim any public space that is invaded

or abandoned into attractive and liveable spaces. These creative platforms can benefit from each other in designed and planning rather than excluding one. Merging virtual and real can be an opportunity and alternative in sustainable planning for cities in general and public spaces in particular.

While videogames are increasingly popular cultural product, it can be a reason that they do inspire our imagination. Even, Situationists said that 'elimination or disappearance of competition is in favour of collective concept of play' which is contrary of videogames concept, 'it's a ludic construction of time and space that must invade the whole life' (Débord, 1958). Later in utopian architectural projects such as "Fun Palace" (Price, 1959) where visions of the public spaces intended to be inventive and playful towards its users as is case in virtually space with videogames. Also, applying of different aspects of virtually playfulness is spotted at "Plug in City" (Cook, 1964), where Archigram's avant-garde ideas was there to provoke debates in which architecture, society and technology can create ludic spaces together. In this context architecture and space within had to be redefined by literally merging with technology.

2.1 GAMEFULLNES - TOOLS OF SIMULATION

"Cities are amazingly complex systems," says Will Wright creator of Sim City in his interview for Guardian... "Millions of autonomous agents – the people – making millions of decisions: where to live, where to work, where to eat lunch. Those millions of decisions are the city." Creators of SimCity acknowledges early foundations of computer simulation model for balancing population, housing and industry within urban space in 1969 "Urban Dynamics" book by Jay Forrester. Than they used his 'simulations proposed predictions to impact urban city and not to solve urban decay by intuition' (Forrester, 1969). Sim City's vividly strong colonial approach is based on abundance of land in early USA cities. However, 'abundance of open space' (Rybczynski, 1995) nowadays this is much more a responsibility than benefit to contemporary urban planners. Sim City, from early beginnings tend not to be just a game. Although, reflects an aspiration towards an "ideal city". Due to GIS rigidity that is based more geographically databased, Sim City is providing data on different socio-cultural issues that can impact city. SimCity demonstrates the fundamental appeal of observing and interacting with systems (Maxis et al, 1989). Therefore, with Sim City communities can play, plan, generate and simulate multiple design options that puts them into city planner's role to recreate public spaces of its own.

In contrary of 'space abundance' (Rybczynski, 1995) in Sim City, Tetris is a narrow but on top endless virtual space of constant falling blocks. While players see a limited space of play – original version is 10x20 square grid – they tend to manipulate blocks by rotating them and shifting them into a puzzle. This gives a player to anticipate in small amount of time and very little space solutions for liberating as much space as they can. Led by this contradiction of space to re-appropriation of space (Lefebvre, 1974) a collective of urban based artist by squatting an abandoned house in Prishtina and transform it to a public gallery or space where anybody can exhibit their works. They also called it Tetris-Manipulative Space (Pic 1.).

Pic 1. Public art gallery "Tetris", city of Prishtinas (<https://web.facebook.com/groups/tetrisspace>)

Many say that Rockstar's GTA – Grand Theft Auto takes place in an explicit urban background. Often this kind of influence can tackle our imaginative urban landscape. Here we have a presentation of experiencing a real city. However, it took many artists and designer to replicate scenery of real city. More than 250, 000

photographs and countless hours of video are distilled to put Los Santos, Rockstar's version of Los Angeles to work as their concept was developed. What we have here is vice versa impact of real world that defines the videogame space in virtually world. This pedestrian perspective game allows our imagination to refined other ways of navigation in streets and public spaces. Main character of game is metaphorically Space Fighter, it compares series of selected and possible projective simulations, results and outcomes of urbanistic chain reactions (Maas, 2007). That leads to 'spatial contradictions' (Lefebvre 1974) of powers of social production from its own dynamics

2.1.1 MINECRAFT – AN INTERNATIONAL TO LOCAL EXPERIENCE

For UN Habitat's public space program, urban life is essential for cities to prosper. Specially, cities that can reevaluate notion of 'public' and thereby provide green spaces, parks and other recreation facilities demonstrate a commitment to improved quality of life. Quality public spaces are excellent entry points to improve the standards of urban life for all citizens. The Municipality of Prishtina and UN Habitat-Kosovo office initiated a Minecraft pilot project – among first of its kind in the world – in Sunny Hill neighborhood in Prishtina. Intention was that through application of modern planning methods, enhanced a democratic and transparent way of planning, community participatory process, public spaces policy and strategy formulation that address space cohesion and socio-cultural inclusion.

Minecraft is a 'sandbox' videogame originally launched in 2009 as a beta version by Swedish independent gaming company Mojang AB and was published as a full release version in 2011. To date, the game sold over 50 million copies worldwide, making it one of the world's best-selling computer videogame. Minecraft concept is perhaps best imagined as a complex of digital Lego blocks. Creative concept of Minecraft allows player to build structures out of textured cubes in 3D generating a virtually space. There is multiplayer mode that imitates real world construction site with a lot of workers, carrying out different construction roles simultaneously.

In 2012, UN Habitat and Mojang AB entered in a partnership, named Block by Block that uses Minecraft as a participatory and engagement tool for communities into design and implementing of public spaces projects in Kenya, Nepal, Haiti, Mexico and Kosovo. All the amenities deriving from the final Minecraft solution than where used to define the concept and detailed design to taken forward by the Municipality of Prishtina with UN Habitat's support.

Site selection was selected due to social and cultural interplay. Enhancing community cohesion among variety of social groups. Engaging and empowering youth was one of them. The farmers market place was selected by meeting criteria mentioned above. The broader area is mostly covered by social housing blocks build during 70's and 80's (pic 2.). The area includes some small businesses and facilities. There is a population of ca.4000 inhabitants. The population in neighborhood is divers in terms of income, gender and age (reflecting the national situation of 38% under 20 years old). In regard of connectivity the project site is located along main junction of B segment (Road B). Entire project area is ca. 1836 m² of land under municipal ownership.

Pic 2. Software visualization of the Block by block concept, city of Prishtina (<http://www.unhabitat-kosovo.org>). Issues and problems in current situation with the lack of space treatment, uncleanness, stinking waste smells and is unsafe for passing by. Lack of accessibility leading to lack of frequentation within site,

undefined line between the road and inner spaces and informal trading activities are other problems of abandoned site. On the other hand, by implementing Block by block program, purpose of project is to recreate and reclaim a multifunctional public space that will entwine spaces for socializing, passive and active recreation and enriching small businesses with pedestrian friendly paths and urban furniture.

Considering, that this innovative approach is in pilot phase, expected outputs for this project are respect for public spaces, as well as awareness rising for their importance, maintenance and preservation. Motivation and engagement of all possible stakeholders into planning and implementing that redesign and reclaim their public space. Finally, although Minecraft serves as a solid framework, using Minecraft as tool for planning it refers to Lefebvre distinction of boundaries of re-appropriated common social public space as mode of production or planning. To date, project is under construction (Pic 3.).

Pic 3. Ongoing project implementation of the Block by block concept, city of Prishtina.

3 STREET ART AN ALTERNATIVE FOR PUBLIC SPACES

Street art began as an underground, self-expressed, sometimes anarchic, but more in-your-face appropriation of public visual surfaces. (Lefebvre, 1974). In 1990's street art has recognized itself in urban landscape, projecting its artistic anger potential into facades of cities, giving them an identity. Metropolises like New York, Los Angeles, San Francisco, Paris and London becomes known for its distinctive style of street art. Legends of street art artist started to rise and by late of 90's names like Shepard Fairey, Banksy, Ron English and Swoon become well known for their style and works. During 2000's new generation of artists erupted and along the way leaved their mark in street art genealogy.

A street work can be an intervention, a collaboration, a commentary, a dialogic critique, an individual or collective manifesto, an assertion of existence, aesthetic therapy for the dysaesthetics of urban controlled, commercialized visibility. (Irvine, 2012). This paper study puts focus into logic of re-appropriating public spaces by local initiatives or local art collectives. A good example is the long concrete wall in Road B in Prishtina, where various businesses invaded the wall with very poorly aesthetically advertisements. This caused immense anger among youth generations that started to "bomb" or puts their "throw ups" over them. Lately, a group of young artists have tried to change this situation that led to organized a 'Street art festival' with a help of many international street art artist and graffiti writers through a platform known as "Meeting of Styles".

This was very powerful example of how this subculture impacted the need of ordinary youngsters to change visibility of entire Road B, where these days is friendly pedestrian pavement along with cycling path and an extraordinary city scape or an imitation of bigger metropolises (Pic 4.).

Pic 4. Road B graffiti intervention, city of Prishtina.

Pic 5. District heating company's abandoned building transformed into community space, city of Prishtina

Another, misused space (Ozkan, 2008) is abandon building of city's central heating system in Prishtina, that turned into a community space by collective of fine artists and musicians. They make it the venue space for local 'gigs' and tiny concerts that gathers a community of art lovers. This was achieved firstly by taking action or reclaiming it with street art in buildings facades and then by re-appreciating the space within.

A flagrant example in Prishtina is made by local government when they put an overpass into a very non-appropriating space that derives to unusable overpass even it was needed very much. This structure has been an annoying act for communities and citizens. Instantly, this annoying structure was object of debate among its (non)users whereas this can be torn down. Therefore, a non-formal group named "Free 4 Rent Movement" acted with tactical urban intervention. They put big signs of kind of – renting this overpass with an imaginary phone number. This intervention (dis)led a lot of people who was interested to rent this structure and open probably a café, due to its view to flags roundabout junction. Normally, they were very disappointed when they learned that was city's public property.

After that, a number of artists and other interested communities exhibit their works into overpass spaces. This re-appropriated space is caused by direct action or cities urban dynamics that Lefebvre advocates for many years ago.

Pic 5. Overpass tactical urban intervention, city of Prishtina.

4 CONCLUSION

In this open conclusion, this paper study shows that redesigned and reclaiming public spaces is a very complex process, especially in post-conflict countries like Kosovo. Awareness of respecting common spaces is very important as it is important acting for them. Videogames and street art can be useful tools as direct action of re-appropriating public spaces for common uses of communities. Leaning on Lefebvre framework for 'productive space', these 'tools' can produce very attractive public spaces as listed through examples in this paper study. Impact of various internationally not just artistic movements can be a guide for solutions in urban planning. Although, embracing or coping different global urban movements, postmodern society needs alternative ways as well as tools to exceed problems in urban public spaces.

Furthermore, our aim is to present these urban movement or tools within them in very profound manner to engaged communities into urban planning as the only way towards qualitative life in cities.

ID 1652 | VILLAGE CHARACTER – TO THE ROOTS OF RURAL AESTHETICS

Vít Rýpar¹

¹Faculty of Architecture CTU Prague
ryparvit@fa.cvut.cz

ABSTRACT: Quality of public spaces is one of the crucial themes of contemporary architecture and urban design also because its significance is evident not only to the architects. Even in the era of strong individualism, public spaces pertain to the whole of a community and jointly form its identity. Therefore, it is reasonable to pay attention to their aesthetic nature on a general level. This paper aims to provide an intelligible ground for a creative grasping of the rural character of environment based on two criteria: 1) the relationship of figure and ground, 2) the level of urban character. These criteria apply both to remote territories as well as to fragments of former villages engulfed in metropolitan areas. It is based on the interpretation of selected features of rural environment which are generally considered valuable by architects.

1 INTRODUCTION: APPROACHING THE CHARACTER

An aspect of a village green or a village lane differs from that of an urban square and streets. Or does it? Viewed from distance, many differences between urban and rural environment seem rather obvious; however, the closer we focus on individual features the more difficult it is to determine where the threshold lies or even if there is any at all. Moreover, many features which used to be considered as intrinsic manifestation of ruralness seem to be fading or are being turned into projections of romantic sentiments. Today it is often emphasised that we are living in an urban age or that the concepts of landscape or countryside descend directly from urbanisation. No wonder one has plenty reasons to doubt whether it is legitimate to ponder upon any innate features of rural environment at all.

My argument is that such aim is not only possible but also an important one. In this paper, I shall focus on the space-in-between the houses of rural settlements, or in different words, on the physical facet of public space – the background on which the life of communities happens. My approach will be one of an architect-urbanist, of a profession especially trained in interpretation of material environment in various scales. The countryside will be viewed from a vantage point of central Europe; however the upshots could be applicable in other contexts as well.

2 LIMITS OF CONCEPTUALISATIONS

2.1 THE RURAL IN SOCIAL GEOGRAPHY

From an academic point of view, the topic of the rural is currently most covered by disciplines akin to sociology and geography; their interest in description and mapping of the rural environment dates back to the end of 19th century. Even if it was just because of the vast amount of research which they have introduced since, it is only appropriate that I should start this article by regarding them.

These fields are characteristic by their focus on the space-society relation. Their descriptive approach to it was significantly influenced by a post-structuralist way of thinking especially in the 1980s which replaced the originally more deterministic understanding of the relation. This shift is best apparent in the growth of interest in understanding the rural space as an individual locality or as a product of various social representations (Halfacree 1993).

Especially the later approach is popular as being very efficient for investigating the rural by its attention to situated specificity through (disembodied) cognitive structures. In comparison to investigation of space through descriptive optics, such research of rural representations enables us to better appreciate the dynamism of space and focus on patterns of rural discourses. However, conceptualisation of rural representation – or as Paul Cloke (2006) puts it – the detaching of sign and signification (the rural and its meanings) from their referent (rural geographical space) not only enabled to investigate the blurred boundaries between city and country (not as opposites anymore) but it also led to further split between society–space approaches to the topic. This is well apparent in the proposition of Michael Bell (2007) to distinguish two dominant epistemologies of rural: the first rural as a mater-real category and the second rural as an idea-real category.

To avoid a deepening alienation, in which the rural could be understood in two extreme positions – on one side as an arbitrary analytic distinction (Copp 1972) or as a discursive linguistic interpretation (Murdoch and Pratt 1993) – Keith Halfacree (2006) introduced a three-fold-architecture which bounds the locality and social representation in one model. Since it has been adopted both in English-speaking countries (Woods 2011, p. 9-11) and on the continent (Hruška 2014, p. 50), it seems to be acceptable as a universal framework fitted for the current era of (post-)productivism. The model inspired by Lefebvrian 'conceptual triad' of understanding of spatiality consists of three facets: rural localities, formal representation of rural and everyday lives of rural, all three of them comprise the rural space (Halfacree 2006), however, as its author admits, it "is less about establishing a new understanding than about realizing what we already have" (p. 51).

The concept of space as a product could be approached from a wide scope of different rural discourses. An interesting research which dealt with visual representation of Czech villages in the national competition Village of the Year (Pospěch 2015) was situated in political and expert discourse. Through complex comparison of pictures selected by the local authorities of individual villages, it investigated an image of a good village. A part of the outcome is however very interesting for our topic situated in discourse of urban design. It is the finding that representation of the social facet strikingly dominates the material one – especially when compared to analysis of rural iconography of 1970s – 1990s (p. 81-83).

This outcome is particularly interesting when compared with the outcomes of my own research, in which I closely interviewed over 40 mayors of villages of the year 2013-2015. My presumption was that for most of the representatives of communities that actually placed in the prestigious competition, the question of tangible rural character of a village would be an actual topic. Surprisingly, although my aim was primarily to uncover their views of the physical features, it became clear that it usually wasn't perceived by mayors as a spatial facet but rather as a social one.

A preliminary conclusion which could be outlined from these two examples and some others is that the rural character of material environment is perceived vaguely, rather as a background from which social activities or selected physical representations of their discourses stand out. My task then would be to ascertain whether there is some common ruralness present in the background. The three-fold-architecture model unfortunately doesn't provide much help in this manner. Firstly, it is hardly possible to use it when exploring meanings which possibly lie beyond the common awareness. Secondly, given the bottomless amount of rural discourses, the result wouldn't lead to the rural, but rather to "many rurals" (Murdoch and

Pratt, 1993: 425). If this paper should provide a useful tool, it has to restrict itself to interpretation of one material environment through its relation to other material environments.

2.2 AGRICULTURE AND RURAL CHARACTER

The concepts of rural environment (or simply countryside) and agriculture are so intertwined that it is virtually impossible to regard one without the other. Although the concept of countryside represents a spatial category and agriculture a process category, they have been often and by many discourses understood almost as synonyms. It is no wonder that even today, such understanding is very popular: most of the environment as we see it today is a result of hundreds of years of husbandry, and the current medial image of the countryside still supports this image for its comprehensibility. Yet it's obvious that "traditional" understanding of the countryside (as agriculture) in opposition to the Cities (as markets) – in spite its popularity – doesn't seem to provide a useful guide for current rural character any more. The main reason is the shift in scale, technology and economy of agriculture which led to the situation when the bindings between agriculture and form of rural settlements become rather arbitrary or at least indifferent.

My intention not to ponder on the relation between agriculture and countryside is also given by the situation in Czechia, where the tradition of husbandry practically ended due to the forced centralisation in the 1950s–80s and since the 1990s; although there has been a small-scale revival of family farms, the agriculture employment dropped down to just about 10 % of rural working population, while over 80 % of the rural working population are commuters (Pěluha, 2012, p. 74). The decrease of direct agricultural influence on the life and environment of communities is also obvious from interviews with local mayors. That is why I again argue for an investigation of rural character independent on agriculture and the associated dynamic processes, and for focus on the environmental relations as such.

2.3 RURAL CHARACTER AS HERITAGE

The most efficient way of grasping rural character in planning practice is through the concept of cultural heritage. Such term directly connotes with the preservation of those features of (built) environment which were recognised as being valuable. A form of the protection then varies from common respect to an institutionally forced regime. But even without going deep into the theory of heritage preservation, it is obvious that the core of it lies in the judgement of values – axiology. To put it simply: the stronger a value is perceived, the stronger is the will to its preservation.

The premise behind my research and this paper is that the rural character of a settlement is a positively perceived value which might be worthy of preserving. The basic issue, however, is that we don't know where the substance of this value exactly lies. Therefore, in practice it is hard to decide what should be preserved and what could be left running its own course. (It is important to realise that everything cannot be preserved because preservation is also restriction). That's one reason why in mundane villages I argue for closer focus on public spaces – the pressure on their change is relatively low compared to the buildings.

The fashion in which it is useful to analyse rural environment is given by our objective – to improve design. The relation between heritage preservation and design, however, is a complex one. I dare to outline it in a very simplified diagram as a gradient which has one end labelled as traditional (as it accepts the heritage as a model for the future) and the other as avant-garde (as it doesn't). Most of the design practice lies somewhere in between these two, therefore, any valuable rural features, which might be useful to incorporate into a new development, will be accepted by more designers if it is possible to apply them rather creatively as design principles than mechanically as reproductions.

Understanding the ordinary manifestations of rural environment as a valuable cultural heritage has a long tradition in Czech lands. The beginning of serious research of vernacular architecture and settlements could be dated back to the years 1891-1896 and first complaints on the loss of valuable visual features of its environment are present in journals already before the First World War. For most of the 20th century, the interest in such values on a theoretical level was promoted mainly by enthusiasts. As an academic topic, its form was differing in regard to the varying popularity of many discourses. From the beginning of the 1990s, the interest in rural heritage finally became a part of the governmental programme and since

then it has been mostly promoted on the level of local authorities. Tangible results of their effort are also apparent in the considerable amount of popularizing publications which often follow inspiration from Lower Austria and Bavaria – culturally close regions where similar effort began many years sooner.

The popularizations distributed on regional or national level have without any doubts key significance for planning and design practice by the promotion of good practice examples. Their congenital drawback, however, lies in argumentation why some examples should be considered to be better than others. Many of them openly admit that the reason lies in harmony with local tradition. Such honesty on one hand gives a designer a free hand in decision how such tradition might be creatively interpreted,

but at the same time it presents a weakness. As outlined above, for many people the argument of tradition alone doesn't represent a reason strong enough to establish restrictions on one's own creative freedom.

3 LANDSCAPE URBANISM

For a synthetic approach towards rural character, I would like to adopt three disciplines: landscape architecture, urbanism (which in the continental understanding still represents a synthesis of urban design and urban planning) and environmental aesthetics. In order to regard these kindred disciplines as one, I decided to adopt Charles Waldheim's term landscape urbanism, which is maybe the most illustrative.

To address the current issue of rural character from an urbanistic point of view, I would also like to refer to Thomas Sieverts' concept of Zwischenstadt which derives from blurred notion of space "in which the old contrast between city and country has dissolved into a city-country continuum" (Sieverts, 2003, p. x). Such understanding, which directly results from the ongoing suppression of the importance of physical distance, is very fitting for the densely populated central European countryside.

In Czechia, when viewed from the outside, many villages still resemble the pre-collectivisation state of mid-20th century. The gradual redevelopment and especially the new development, however, create a very different environment. A typical situation is represented by a "vernacular" core of an old village, to which new development with a "suburban" microenvironment is connected. The trend seems to lie either in extensive growth of this suburbia, or in progressive metamorphosis of the village core into it. The latter seems to be more probable, considering the growing emphasis on arable land preservation and often underuse of village core development.

The prognosis is somewhat brighter for settlements and territories which are listed and therefore subject of institutionalised heritage preservation regime, however, such approach is very demanding for institutional capacity, which is a notorious problem of the countryside.

For most of Czech countryside, such regime is unavailable. Thus the new development is (save for minor exceptions) regulated only by vague zoning plans in which detail is given by the scale 1:5000, and by general building codes (identical for big cities and for hamlets). Outcoming rather generic character of it is by many already understood as inevitable (often, the opinion of village mayors in my interviews was that it is how things are done now). A possibility of change is seen in a closer connection of urbanism (planning and design) with practices of landscape architecture. Among advocates of such approach are both Charles Waldheim (Waldheim 2016, p 2-29) and Thomas Sieverts (Sieverts 2003, p. 121).

18 I am aware of works which dispute that such distinction could be stated. For example, very interesting arguments in the field of biosemiotics were pointed out by the Swiss zoologist Adolf Portmann in his seminal book *New Paths in Biology* (1964). However, for the sake of general intelligibility of urban environment, this conceptualisation is good enough.

3.1 URBANISM AS A LANDSCAPE PHENOMENON

The basic dictum of the Zwischenstadt theory lies in the necessity of increasing the legibility and intelligibility of the environment. In the case of the countryside, it could be interpreted for example as a sensual ability to distinguish the character of an urban streetscape from that of a village. Such aim is also

stated in the third thesis of the famous manifesto *Ten Theses on Landscape Architecture* by Dieter Kienast. But are there any such differences innate to either rural or urban environment?

At least one of them is obvious. Cities are places of cultural concentration. It doesn't mean that in the countryside, there is a lack of culture, but that the countryside as a whole stands in relation to other two benchmarks: the wilderness, where the culture is none, and cities, which currently represent the best examples of concentrated cultural effort. As shown by the book of John R. Short *Imagined Country* (Short 1991), such concept of narrative distinction is well comprehensible at least in European tradition. A more uneasy question is how an increased presence of culture is mirrored in the form of landscape.

A fruitful hint is though provided by the ancient polarity of natural and anthropogenic order.¹⁸ The application of such relation to the physical environment enables to distinguish different manifestations in urban and rural environment. Although this optic could seem self-evident (everybody knows that a quality of the rural is its closeness to nature), I would like to emphasise that the decisive factor isn't just the presence of nature, but in particular it is the way how it is present.

Countryside – also called by pleonasm cultural landscape – isn't the same as the so-called natural landscape. As it was outlined in the chapter dedicated to agriculture, such environment is to a great extent created by man – or in better words – it was won from the nature. Christophe Girot distinguishes two archetypes of such winning: the *hortus conclusus* and the forest clearing (Girot, 2016, p. 13-25).

Even though a particular situation is usually a combination of the two, it is possible to derive the general nature of two different countrysides; the southern, which is by its nature an artificial environment constructed on barren lands and kept alive by complex irrigation systems, and the northern, which is won by continuous cultivation of living wilderness. Not surprisingly, the development of geometry, chronometry and mathematics is closely connected to the landscape of the southern archetype – through the Mesopotamian irrigation system management (Hodgkin, 2005, p. 14-17). Analogously, the less the landscape of the northern archetype is an apparent embodiment of abstract thinking, the more the cities stands out of it – by being closer to the first archetype. Even though such concept taken literally may seem far-fetched, it is illustrative for comprehension of the “empty space” as architecture. But how does it perform?

A high level of human control formally imprinted upon an environment has a fitting expression in a term civilised which is a derivate of city (similarly to an urbane form). A process of civilisation (we may also say urbanisation) is in physical environment expressed through the structuring role of architecture (Vesely 2004, p. 106), shaped by abstract concepts, geometry and ideas (p. 92). Since the purpose of architectonic structures lies in communication, it is clear that the requirement of legibility and intelligibility has a strong impact on the form. Considering the character of contemporary communication, we can see the urban as a (relatively) unified aesthetics tending towards universal, or more precisely, global identity of environment. This intelligibility is characteristic by the growth of anthropogenic order expressed formally, both in the artificial and natural matter. This is what I mean by an urban form of landscape.

3.2 LANDSCAPE AS AN URBAN PHENOMENON

“Ultimately I claim that landscape has always been urban, it is fundamentally urban by definition” (Waldheim 2016b). This quotation from a lecture of Charles Waldheim is directly connected with one of two basic conceptions of landscape – landscape as a scene. Such concept derives from the tradition of landscape painting and is therefore connected with a view from outside (from the comfort of a city). The other concept of landscape is very close to the term environment. This is a view of an insider and it is adopted by the European Landscape Convention. Different understanding of the concept has significant impact on understanding of rural character. The issue is, however, well covered by the relatively young field of environmental aesthetics.

Environmental aesthetics presents a vast field of diverse approaches which relates to the environment in a broad sense of the word. In this paper, I adopt the narrow definition of aesthetics as a matter of how things appear to sense or mind (Sparshott 1972, p. 19). Being aware of the fact that the things are both of narrative and ambient nature, I will focus on the latter as it better suits the objective of this paper and in

that respect, I will also avoid the controversial decision on the ethical content of aesthetics as well as whether to accept the traditional precondition of disinterestedness.

If we look closely at both concepts of landscape from the point of aesthetical judgement on rural character, the limits of both are apparent at the first glance. The concept of scene, which is accepted by many in planning practice as well as in research, is problematic because as in the case of paintings, the assessed object is in fact the picture and not the environment and even if assessed on-site, the concept is still bounded just to selected vistas – which might be useful in special cases, but it could hardly replace the whole. The environmental concept is on the other hand too closely bounded to the narrative dimension, that it is often not clear whether one assesses what he truly senses or what he knows he should be sensing. As Cheryl Foster puts it: “Ambient dimension of aesthetic value emerges as an accompaniment to, rather than a replacement of, the narrative dimension.” (Foster 1998, p. 132).

I would like to adopt an alternative concept which derives from the view of landscape as a scene, but which is extended both in space (time) and scale. Most of the visual assessments I found tend to evaluate a specific setting as if it was an object – that is from an “optimal” direction and distance. An environment, however, must be evaluated in multiple scales (depths of detail) as well as from multiple views.²⁶ Among environmental aesthetics, at least Allen Carlson took this into account when he proposed three such “concepts”: territory, terrain and place (Carlson 80-83). A human being most often experiences an environment on the level of a place. But a place’s character derives from a spatial coherence with higher-scale levels – there is a certain link between preformation across them. For example, if a relation derived from distant view inappropriately changes when coming closer, then the coherence was broken and the character of the place suffers accordingly.

For non-architects a question of scale (depth of details) may seem of little consequence. But it is essential – from the process of perception and conceptualisation to the process of creative projection. The importance of a scale is also decisive for the concept of wholeness which is also a key feature of the living structures’ theory which currently embodies a structural model as close to comprehensible reality of built environment as possible (Alexander 2002). The theory has been further elaborated by Nikos Salingaros, who derived precise scaling hierarchy and other mathematical principles (Salingaros 2008).

4 THESES ON RURAL CHARACTER

4.1 FIGURE-GROUND RELATION

The intensity of rural character of a public space is directly related to the ease with which it can be seen seamlessly as a natural background from which only figures of buildings stand out.

When we consider the already outlined relation of natural and urban as proportional, the most evident feature of the rural environment is the predominance of non-built-up landscape over the built-up. Adopting Alexander’s concept of wholeness, it is easy to identify a set of buildings and their clusters (settlements) as figures on a prevalently natural background of the landscape.

Since forms of suburban building today hardly differ from the rural (typically a single-unit housing detached in the middle of a plot), the most available feature that creates the rural identity may be not the appearance of the house itself, but rather the semantic horizons of the background in which it is placed (Merlau-Ponty, 2013, p. 95). Thus a problem could emerge inside a dense village, where close contact with the external landscape is often broken. The settlement itself then becomes the background, which means that its rural character is given just by semantics of its vernacular identity. Therefore even a small change of the building type could completely alter the resulting character. That is why it is necessary to pay increased attention to the space in-between the houses.

Even small details could be significant: grass growing through the edge of a blacktop surface creates a much more obvious component of the natural background than the otherwise identical grass-plot with edges emphasised by the sharp edge of a curb framing. Unfortunately, the common practice rather emphasises the spatial division of the public space, which makes it difficult for our subconscious to perceive it as a fluent continuation of the natural background. For the background appears to continue beneath the figure (Merlau-Ponty, 2013, p. 52), it means that if we strip away the houses and gardens, the

resulting public space should give the impression that it is a natural continuation of the landscape surrounding the village settlement. Another hint on how to achieve such an impression is provided by the background's quality of seeming blurred in comparison to the figures (p. 98).

4.2 LEVEL OF URBAN CHARACTER

Urban and rural character aren't complementary terms, but the first contains the latter. Ruralness is a low level of landscape urbanness.

The figure-ground relation is a good tool. But it can only be useful if we understand the nature of the background – the rural landscape. In the space in-between the buildings as well as in open landscape, the growth of anthropogenic order is subconsciously connected to the rise of civilised or urban character. If a city centre is an example of urban character at its maximum level, and wilderness is its absence, then the countryside – a transition between the city and the wilderness – gains various degrees in the whole spectre of this transition.

It is important to realise that the rural environment is not culturally equalized. It contains a hierarchy of differentiated places and localities. The task of a planner or designer is to consider each of them in relation to its surroundings and to decide whether the particular level of urbanness should be kept, increased or decreased so that the result is be harmonious and coherent.

Rural landscape contains many places which create appropriate islands of high-level urban character. Those are e.g. small towns, palaces and villas, pilgrimage places, surroundings of outstanding buildings, surroundings of highways, resorts, campuses and other compounds, etc. Apart of them the environment consists mostly of open landscape and settlements (villages, hamlets, dispersed homesteads). It is my conviction that a harmonious whole could be achieved by maintaining a lower level of urbanness within the settlements and a higher level of it in the surrounding landscape.

1 INTRODUCTION

1.1 SOUNDSCAPE AS A NEW APPROACH TO URBAN NOISE

This paper discusses urban sound and is based on the work of the Sounds in the City2 team, operating out of McGill University in Montreal, Canada. The team's focus is an approach called soundscape, which is a departure from a more traditional approach to urban sound. Urban planning education and practice have traditionally been focused on noise mitigation, concentrating almost exclusively on reducing urban noise levels. However, this method has its limitations because a quiet city is not necessarily an interesting or better one. The soundscape approach, on the other hand, encourages positive sounds in urban environments while mitigating only unwanted sounds and it also necessitates planning the environment far in advance rather than waiting for noise problems to occur. This approach is attracting the attention of many as an innovative and positive shift in the way we create, manage and control sound in our cities. It also presents the opportunity for more collaboration between planners, designers³ and sound experts to improve our urban spaces.

Soundscape has been defined by a diverse International Organization for Standards (ISO) working group of soundscape researchers and professionals as “the acoustic environment as perceived and experienced by people or society, in context” (ISO 12913-1, 2014). The soundscape approach captures the idea that

sounds 'appropriate' to the context can be used to positive effect, whereas the traditional urban noise mitigation approach aims to make the city less negative but not necessarily more positive. These positive sounds can be ones that we rely on to navigate, give us a sense of place and connect us with our activities. Certain sounds may be very welcome in a bustling pedestrian zone filled with outdoor cafés and restaurants, but these same sounds may be unwelcome in a park where people go to escape the busy streets, relax or read a book. Therefore, this component of context from the soundscape definition is key in how we define what is desired and undesired.

Indeed, not all sounds have negative effects on us, and some sounds even improve our lives and moods, help orient us, and shape our understanding of a space. The most obvious example of this positive type of sound is music, but several others are common, such as bird sounds in parks and neighbourhoods, water sounds from fountains in public environments, and the sounds of lively conversations at marketplaces and outdoor cafés and terraces. As a precursor to the Sounds in the City project, a McGill research team added music to the gazebo of a busy Montreal pocket park. Through interviews and questionnaires, the team discovered that park users found the space more pleasant and vibrant with the music. Furthermore, the presence of music did not have a detrimental effect on perceptions of the space's calmness and soundscape appropriateness (Steele et al, 2016). As stated in the soundscape definition, it's important to consider the context in which the sounds take place and how these sounds may be interpreted differently by individuals. For example, the bustling sounds of Times Square in New York City can represent, for some, a world of commerce and opportunity, but these same sounds would generally be less welcome by those trying to sleep in such an environment. The sound of an approaching metro train is welcome if someone is on the platform waiting for it, but the sound may be interpreted differently if a person is further away and running to make the train. Recognizing, understanding and mastering these various sound sources in the context of their appropriateness has immense implications for our cities. It is clear that good urban soundscapes require an understanding of the needs of residents and space users, and that the users should also somehow be involved in these emerging collaborations between soundscape experts and planners. This is in line with some major contemporary trends in urban planning advocating public participation (e.g. Healey, 1997).

Soundscape can be a framework that helps achieve global planning goals. By imagining a space through its sound, we can achieve many of the following: minimize wasted space by identifying incompatible urban activities in proposed programs; better match the visual environment with the auditory one; and improve quality of life. It's important to note that the soundscape approach does not totally do away with advances in acoustics. It's also important to have a fundamental knowledge of acoustic principles, such as an understanding of sound propagation, in order to understand what activities may be compatible within the same environment. This need for both some expertise in urban planning practice and traditional acoustics presents interesting challenges to those working in soundscapes, discussed in detail in Steele et al. (2012). These challenges can be the result of different expectations of knowledge and styles across disciplines, or the way people access and deal with new information, such as from research.

1.2 GAPS FROM RESEARCH TO PRACTICE

A number of factors have slowed the evident transition from a noise mitigation to a soundscape approach in urban planning. Recent research (Pijpers van Esch, 2015) has probed the information sources of urban planners to uncover that while planners consult subject-matter experts on a regular basis, they rarely visit the scientific literature on their own. While these subject-matter experts may themselves access scientific literature, planners may not necessarily encounter new trends arising from academia that challenge traditional notions cemented by their training. Another key factor is that the most pressing urban problems get solved first. Weber et al. (2011) demonstrate how catastrophic failures can quickly advance public policy, such as a factory explosion compelling new public safety laws. In the domain of noise, while there are problems, they have not been catastrophic, allowing the status quo to persist. While poor outcomes for noise are serious and can have deadly consequences for humans and animals, their effects on the public can take time to manifest themselves. According to a review by Passchier-Vermeer and Passchier (2000), it has been known since at least the 1960s that noise exposure poses a public health risk for its ability to cause hearing impairment, hypertension, heart disease, annoyance, sleep disturbance, and decreased school performance. To counter these negative effects, cities have responded largely with punitive bylaws for noise-makers, as opposed to adapting urban strategy and planning decisions.

In the realm of education for planners, sound (or “noise”) continues to receive limited attention. The American Planning Institute, which offers work certifications in the US and Canada, provides outlines on its website for the topics covered in its examinations. For the general planning examination, 64 topics are listed in the exam outline, none of which include noise or sound. Two specialized examinations are also offered: one for environmental planning where the topics list enumerates dozens of factors under examination - noise is mentioned only as a sub-topic of “public-health indicators”; and one for urban design where a list of hundreds of topics exist, yet noise or sound are not mentioned. Additionally, the second edition of Kevin Lynch’s seminal book *Site Planning* (1984), which is still widely used, has a chapter called “Light, Noise, and Air”. This chapter includes only two pages of information on decibels, attenuation, barriers, and sources.

Challenges also remain in determining tools for education. Raimbault and Dubois (2005), in an interview study, found that even experts in acoustics can fail to agree on basic technical vocabulary to describe sound events. This vocabulary is even less precise outside of acoustics, as they found when interviewing planners and other practitioners that intervene in the city. For example, there is no clear terminology to describe the sound made by a car door closing, whereas a wall pattern could easily be described visually as “polka dot” or “red and white”. We are often lacking consistent and easily understandable terminology to describe everyday sounds.

1.3 BRIDGING THE GAP TO SOUNDSCAPE

Soundscape, having partially emerged from the noise mitigation approach, continues to have issues with the research-practice gap. Soundscape calls for an interdisciplinary approach often using mixed-methods (i.e. integrating qualitative and quantitative approaches) with a focus on users that offers the potential to better bridge the gap between the planning community and sound experts. A transition has begun, but it is not fully realized. While there are established conferences in noise mitigation (e.g. InterNOISE, and IC BEN Congress on Noise as a Public Health Problem), soundscape only plays a small role with a handful of sessions during these larger conferences. A soundscape approach presents an opportunity for multiple disciplines to collaborate and take a more proactive approach to planning our urban sound environments.

Another aspect of soundscape, which is helping to reduce the research-practice gap is the focus on the user and their perceptions. However, in addition to a focus on the 'city user', there is a need to consider the role and contributions of the 'city makers.' The way planners deal with the information they have on sound has a profound impact on the way the city is shaped and used. The Sounds in the City project has been formed to respond to this need.

2 SOUNDS IN THE CITY – AN INTRODUCTION

A new collaboration between university researchers, acoustic consultants and the City of Montreal addresses this gap between soundscape research and urban planning and design practices. Through outreach and knowledge co-creation activities with practitioners of the built environment, city officials, and the general public, the Sounds in the City team is aiming to improve the quality of urban sound environments.

The team's research agenda aims to position Montreal as a leader in urban noise management and soundscape by connecting research and practice. With expertise in soundscape, urban planning, design, and noise regulation, and a collaborative track record, the research team is uniquely positioned to address this established research-practice gap, and be among the firsts to do so.

The project is supported by an Insight Development Grant with Canada’s SSHRC (Social Sciences and Humanities Research Council), a major funding agency. The Insight Development Grant was initiated to promote “knowledge and understanding from cross-sector perspectives”, to “support new approaches on complex topics that transcend the capacity of any one scholar, institution or discipline”, and to “mobilize research knowledge” .

3 PEDESTRIANIZATION WORKSHOP AND KNOWLEDGE CO-CREATION – “ANIMATING PEDESTRIAN ZONES IN THE SONIC DIMENSION”

As the project necessitates strategic outreach, knowledge co-creation, and collaboration, the Sounds in the City team chose to run a 2-day workshop at McGill University in November of 2016, which united members of the soundscape research community with practitioners of the built environment, students and professionals from a variety of disciplines, city officials, and members of the general public. The workshop included presentations but also focused on case studies and collaborative exercises for animating the soundscape. More specifically, the event was organized using three separate educational formats: instructional (with presentations by researchers and practitioners), co-design exercises (with a focus on three new pedestrian zones in Montreal, which are scheduled to open in 2017 and 2018), and audio demonstrations (with demos to recreate different soundscapes, explain the current noise regulations, and relay the experience of low-vision users who rely on sound to navigate through public spaces). The workshop was titled, Animating Pedestrian Zones in the Sonic Dimension.

Today, there is no established and authoritative world expertise on the problem of sound in pedestrianized areas (commercial or otherwise). With a focus on knowledge co-creation from different domains, the event included the participation of soundscape and design professionals from Montréal, Germany, the Netherlands, and the UK. Planners, designers and other participants were challenged to incorporate sound considerations while designing a pedestrian zone, and sound researchers were challenged to appreciate the complexity of planning real urban spaces, which have a host of practical considerations and challenges (e.g. transport, budget, emergency services, etc.)

3.1 MOTIVATION: WHY PEDESTRIANIZATION

The creation of pedestrianized zones is on the rise in cities around the world. Typically, streets or sections of streets are closed to automobile traffic and the entire space is given over to pedestrians. These spaces can become landmarks for a city when they work well - Think of NYC's Times Square since its renovation - or they can become heavily politicized scapegoats when they don't. For example, cars were reintroduced to Sacramento's K Street Pedestrian Mall in 2011 to “increase vibrancy and accessibility” after a long period of stagnation. One aspect of these places that is crucial yet rarely discussed is the role that sound plays in the function of these spaces and the impact that these sounds have on the public.

Each project begins when we remove the largest source of sound - the traffic. Reducing “noise” is beneficial for health and quality of life, but the traffic noise may also have been serving a purpose. If we imagine ourselves in a large city park, the traffic-free silence is potentially calming, but in a commercial environment, traffic noise can offer steady sound masking and, thus, a form of privacy among all of the users. Without this masking, we could be subject to “awkward silence” where there is nothing left “underneath” the traffic noise. Such a soundscape could contribute to a negative cycle that compromises the space's ability to function as a productive public space. But this then begs the question, what is the appropriate sonic ambiance?

A vibrant pedestrian zone needs sounds that reflect the culture and activities of the local area at all hours of the day. Furthermore, the visual environment and the sound environment need to work together. Is the sound of a water fountain or music appropriate to add to an environment? Could sonic artworks encourage lingering and commerce or affect the behaviours of the people and animals in the environment? Well-designed pedestrian zones necessitate the collaboration of planners, designers, city officials, sound experts, and citizens. Planners and designers need to articulate their goals and concepts for an environment and soundscape experts can then collaborate with the team to develop a site-specific soundscape strategy. It is also crucial that citizens be included in the entire process, as they will be the ones who are primarily using the environments.

Figure 1 – Left: Montreal site visits led by planner; Right: Presentations from soundscape experts

3.2 SITE VISITS

The November 2016 event began on the first day with site tours (see Figure 1) led by the city employees responsible for each of the selected pedestrianization projects. These site tours lasted approximately 2 hours and spanned the entirety of 2 of the 3 projects underway, and most the third project. There was ample time for discussion at the end of the walks, so participants had the opportunity to ask questions about specific details.

3.3 WORKSHOP ORGANIZATION AROUND THREE STYLES

Day 2 of the event was structured into three distinct types of activities: presentations; sound demos; and co-design exercises. Within this format, participants were first introduced to soundscape concepts and case studies, and then given the opportunity to practice their learnings during co-design exercises and discussions later in the day.

3.3.1 ACADEMIC PRESENTATIONS WITH “BUILDING BLOCKS”

The organizers began the morning session with presentations introducing the soundscape approach and the Sounds in the City project. Four invited speakers then gave 30-minute presentations on their sound research (see Figure 1). As many of the workshop participants were not from sound disciplines, soundscape presenters had been encouraged to clearly explain their core concepts, important key terms, and definitions. Many participants were not from research disciplines, so presenters were encouraged to focus on their findings and the implications of their research more than on their research methods.

Each organizer was asked to end their individual presentation with an extra 5- to 10-minute summary of their thoughts on a particular topic that would help participants make more informed decisions about the sounds of pedestrianized areas. These summaries were called “building blocks” as the intention was to use them again later in the following two sessions. These building blocks were made up of suggested best practices and potential pitfalls based on the presenters' years of research experience and were designed to be easier to understand than the academic portion of the presentation. The six building blocks are listed in Table 1.

	“Building Block” Title	Presenter
1	Soundscapes and activities	Daniel Steele
2	Visualizing soundscapes for planning	Martijn Lugten
3	Soundscape and public art	Lisa Lavin
4	Interactive sound installations (Using audio islands)	Andre Fiebig
5	Using water features	Jochen Steffens
6	Music for public space	Romain Dumoulin

Table 1 – “Building block” presentations from soundscape experts for sharing practical soundscape tools to be used later in the co-design workshop

3.3.2 LABORATORY DEMONSTRATIONS

In the next session, participants were split into small groups and rotated through two separate audio demos (see Figure 2) of about 15 minutes each.

One of the two audio demos, led by Romain Dumoulin, was an immersive interactive audio installation allowing the reproduction of existing and virtual soundscapes using ambisonic8 technology with both ambisonic recordings and a large multi-channel sound system. With custom software, virtual sound sources could be added anywhere at varying sound levels and at various positions of the listeners' surroundings. In the context of a training on noise regulations, a number of real-life noise complaint scenarios were demonstrated including a short example where an annoying, but legal (from a regulatory perspective) sound source was added; then a non-disturbing but technically illegal sound source was added. The installation aimed to educate participants on the complex relationship between regulatory noise levels and annoyance and raise awareness on inherent limitations of noise regulations. Finally, the potential of the installation as a soundscape design and planning tool was highlighted with several demonstrations where additional sound sources such as cars, crowds, fountains and AC-units were virtually added to existing sound environments. These demonstrations highlighted the idea that sound sources should be evaluated on a case-by-case basis such that they are appropriate for a particular context and highlighting the weakness of the approach that only aims to satisfy the regulatory conditions in both noise and urban planning by-laws.

Figure 2 – Left: demo of blind city walk; Right: ambisonic virtual demo

The other audio demo was a self-narrated tour of the city of Montreal. A blind individual took a walk with researcher, Florian Grond, while wearing a helmet camera fitted with microphones. The individual then sat down with the researcher to re-listen to the walk while retrospectively narrating his experiences on the walk. Participants reported being surprised at the complexity of the cues the narrator relied on to navigate his environment. The purpose of this demonstration was not only to heighten participants' awareness and sensitivity to how a blind person or individuals with specific visual disabilities may use sound to navigate his or her environment, but also to demonstrate how sound plays a crucial role in how we interpret our sense of space and orientation.

3.3.3 CO-DESIGN WORKSHOP

The third and final session was a co-design session where all participants, presenters, and organizers collaborated in smaller teams to complete a structured exercise based on the three Montreal pedestrian zones and the six soundscape building blocks.

All of these co-design sessions took place in the same large window-filled room on the 8th floor of the CIRMMT tower, and took place within a three-and-a-half-hour period from 14h-17h30. We'd intentionally set up half of the room to resemble a sort of "working design studio space." Tables were grouped together to represent each of the three pedestrian zones and red street signs, depicting each of the three pedestrian zones, sat atop the three working spaces (see Figure 3). Each working space had several different style street maps in colour and black and white, in addition to lots of coloured pens, pencils, post-its and blank paper. Audio recordings were also taken with participants' permission, so the Sounds in the City team would be able to refer to the workshops for later analysis.

Knowledgeable city planners and architects responsible for each of the pedestrian zones kicked off the session by providing brief overviews of each of their projects. Participants were then instructed to physically move into the design studio space and choose the pedestrian zone that interested them most. Each team was then tasked with applying their learnings and insights from earlier in the conference in order to plan the soundscape for their designated pedestrian zone. We had divided the exercise into three phases: Strategy/Planning, Design and Production and had given “suggested times” for each group to spend on each section. In each team, a sound expert played the role of team leader and guided the group through the exercises. Participants had roughly an hour to work through the exercise and then each team presented their proposed ideas to the larger group.

In the Strategy/Planning section, we wanted participants to consider and discuss the usage of the space throughout different times of the day, week and year. In order to facilitate fruitful discussions, we had provided a series of prompter questions. In the design section, we challenged the participants to create a soundscape that supports the envisaged activities, maximizes pleasant features and minimizes unpleasant ones, and matches the visual environment. Like the previous section, we provided prompter questions to generate ideas and discussion and also made suggestions on the types of sound interventions which could be considered such as water features, sound art, music, or natural or human-generated interventions, derived directly from the earlier “building blocks” presented by the soundscape researchers. Lastly, for the production section, the participants were challenged to consider how they would put their soundscape plan into action. Again, prompter questions were provided.

Figure 3 – Left and Right: Small groups discussing soundscapes of pedestrianized areas in a co-design workshop

Production prompter questions: How could you prototype and test your ideas before moving into a production phase? Would you need any infrastructure changes to implement your plan? Who would maintain the sound features you propose? Do any of your proposed interventions require curation (e.g. updating content, selecting performers, etc.)? Which aspects of this intervention are high and low priority? Are there any laws or regulations that may pose challenges for implementing your proposed ideas?

Groups next presented their ideas and designs to the whole room. We had originally created guidelines for the structure of these presentations, but then spontaneously decided to leave the style and structure up to the discretion of each group. All groups worked very diligently on their task at hand, and we had a very lively and fruitful discussion following the presentations. However, it was very noticeable that the group dynamics and outcomes varied quite dramatically from one table to the next. We will elaborate on this more in detail when we discuss some of the key take-aways related to the structure of the workshop and the group dynamics.

Before taking a 15-minute coffee break, participants were asked to take a few minutes to write down something on an index card that came up for them related to soundscapes during the exercises (e.g. a burning question, a clarification needed, a challenge they face, something that they’ve learned during the conference that they’re excited to share and implement, etc.). Based on the proximity of the tables and the active participation of many participants in the previous discussion, we decided to conduct the discussion as a larger group as opposed to breaking out again into smaller groups.

4 WORKSHOP SUMMARY AND QUESTIONNAIRES

The workshop officially had 64 registered participants; however, between no-shows and participants who could not stay for the whole day, there were generally between 30 and 40 people at all times. Based on the survey responses, it appears there was a good balance between the sectors (of 20 respondents who answered a prompt about their sector, 7 identified as public sector, 7 identified as private sector, and 6 identified as academic sector).

4.1 BREAKOUT SUMMARY AND ANALYSIS

Each of the three group facilitators detailed their impressions and observations of their team's experience in collaborating on the exercise. At each table, three very different working styles and types of discussions were observed, based on many factors: the specifics of the actual pedestrian zone (stage of completion of the project, goals, time-frame, challenges, etc.); the expertise and backgrounds of the people at the table and the group dynamics; the openness of the Montreal city employee to discuss new ideas; the ability of the facilitator to keep the participants focused on the task at hand; and the team's receptiveness to exploring new concepts.

The organizers felt that, in general, the projects that were the most developed were the least receptive to new soundscape ideas. In other words, the more planning, design and production that had been done on a project, the less receptive planners were to considering integrating soundscape interventions into their process. Also, some projects elicited more general sound intervention strategies where soundscape was used to enhance project goals whereas some other project teams had focused on specific acoustics problems. For example, on the Promenade Fleuve-Montagne, a multi-kilometre walking path connecting Montreal's river to its mountain, the discussion centred on whether or not there should be a musical venue and where it might go. However, on the St. Catherine project, located in Montreal's most central shopping corridor, the discussion was centred on whether specific features of a proposed inflatable installation, which the City will be installing, would serve any acoustic advantage on the site.

Practical solutions were also raised. In an effort to make a comfortable acoustic environment on the aforementioned Promenade Fleuve-Montagne, the site planners were very receptive to an idea involving traffic. On a particularly steep part of the promenade, adjacent traffic was traveling in two directions, but at the suggestion of the soundscape experts, the possibility was raised that the traffic traveling uphill be relocated to a different street, rendering the street a one-way, to help remove the sound of the accelerating motors from the site. This idea was deemed feasible and may be incorporated into the actual plan.

4.2 FOLLOW-UP QUESTIONNAIRES

24 of the 64 registered participants completed an online exit survey about their experience at the soundscape workshop. In general, responses indicated strong levels of interest for all aspects of the workshop. Participants were invited to take the questionnaire and give their feedback in French or English. They were asked questions about their own practice and whether they found each aspect of the workshop to be both useful and interesting.

Unless otherwise reported, all questions are on a 5-point Likert scale. The scores for interesting were always slightly higher than the scores for useful. The lowest mean (3.92) was a question on whether participants considered sound in their work practice. Given the relatively low mean for this response, we believe that, to some extent, we had reached our target audience. All other means exceeded 4.0 and are presented in Table 2.
