T16 | URBAN METABOLISM AND TERRITORIAL EFFICIENCY

CO-CHAIRS: MENDEL GIEZEN; SARA CRUZ

Cities have been growing not only in size and density, but have also been evolving towards more complex systems. Dramatic changes in the functioning of urban systems – referring to the physical environment, the patterns of flows, and type of practices – have had a strong impact on the structure and functioning of socio-ecological systems and the services they provide. There is an urgent need for a better understanding of the consequences of these changes on the environmental, spatial and social sustainability. One of the concepts that can help planners towards this better understanding is urban metabolism.

Urban metabolism can be defined as the processing of inflows and outflows of resources and energy within the city. These flows are determined by a combination of (1) the physical needs of a city and its infrastructure, (2) the opportunities and limitations that the natural and geo-physical environment poses to the provision of these needs, and (3) the socio-economic and political processes and power structures within the city. Understanding these conditions determining both supply and demand of resources is crucial to achieve more efficient and sustainable urban systems. Issues, such as uncertainty, diversity and multiplicity are, undoubtedly, aspects that strongly characterize our societies and communities and therefore should be taken into consideration when envisioning territorial efficiency through an urban metabolism perspective.

Despite all the research and debate around issues of climate change, natural resource management and sustainability in general, there is still a knowledge gap on planning responses to the complexity of settings, problems and challenges urban systems face. In addition, different issues reflecting contemporary and future societal challenges, such as, social justice, migration, economic crises and geo-political developments, all pose new shocks to these systems and are topics that need to be addressed. Therefore, some key issues we would like to explore in this track are:

- The potential of the concept of urban metabolism; the advantages and limitations/shortcomings of this approach, as well as ways of overcoming these limitations? Understand how this integrative concept can contribute to a more systemic approach in urban management and planning?
- What are the innovative instruments (tools and methods) developed to study urban metabolism, and how they can be articulated and contribute to spatial and environmental planning? And more general, how can we achieve a more comprehensive and integrative knowledge of the city's functioning in all its dimensions and components?
- How does the objectives of territorial efficiency and environmental justice come together, and what are the policies and strategies needed? How do local people and their knowledge contribute to environmental justice challenges, and what is their role in making spaces of dialog?
- How can we learn from new practices and experiences through bottom-up approaches to increase environmental efficiency?

This track aims to address these issues in accepting theoretically grounded papers of international research and experience, exploring the limits, as well as, the potential of urban metabolism and territorial efficiency in spatial planning.

ID 1525 | URBAN METABOLISM AND WATER-ENERGY-FOOD NEXUS, NEW CHALLENGES FOR SPATIAL PLANNING

Michele Dalla Fontana¹; Francesco Musco¹

¹IUAV University of Venice

mdallafontana@iuav.it ; francesco.musco@iuav.it

1 INTRODUCTION

Resource scarcity has been rising as an increasingly urgent matter in the last decades and particularly in the last years. A combination of factors such as climate change, population growth, rise of the middle class and deterioration of ecosystems contribute to increase the concern on present and future resource availability. Given the situation there is a need for new approaches to resource management in order to change the business as usual model and find sustainable and innovative solutions. To this end, the water-energy-food nexus (hereafter nexus) approach received particular attention in the policy and academic arenas. The rationale behind the nexus is to acknowledge and take in account relationships, synergies and trade-offs between water, energy and food sectors with the aim of finding sustainable and common solutions for the management of these resources (Hoff, 2011). Connections between water, energy and food undoubtedly exist in any circumstances and they occur more or less explicitly. Depending on how these connections are taken into account, they can become opportunities (best-case scenario), or if not considered they can become missed opportunities or develop in unexpected conflicts and problems (worst-case scenario). The nexus approach is still an immature and not well-defined concept (Allouche, 2015), but even so, researches from different academic fields and disciplines increasingly focus on it. Authors discussing on the nexus generally put water at the center of the debate and focusing on agriculture considering water and energy as inputs for the food production. Other researches argue on conflicts that rise for the use of water for agriculture and other purposes. Furthermore, research and analysis on the nexus are typically carried out on global, national, regional or river basin scale. In this panorama, where main focus is on agriculture and large scales, cities and their role on water, energy and food management have been neglected, which is quite bizarre considering the close connection between cities development and resources and the huge amount of energy and materials needed to sustain cities metabolism. Exploring an urban perspective on the nexus is even more important considering that more than a half of the global population is living now in urban areas and this percentage is bound to increase in the coming decades (UNPD, 2011). Developing of cities have been strongly linked to local resource availability for centuries, but this relationship between potential urban settings development and amount of resources available on site has weakened due to a series of events such as industrial revolution, green revolution, technological innovation and globalization (to mention most recent examples). This set of developments have enabled the development of larger urban areas that depend less and less on the local availability of resources such as water, energy and food. In this paper, we propose a path to follow in order to understand where the nexus of water, energy and food lays is in cities and which role it can have in turning cities in more resilient and sustainable systems. In doing so, simplified supply chains of water, energy and food are considered and decomposed in sequential steps to facilitate the identification of connection points between systems. This has the objective of making clearer which are the nexus aspects that more likely fall within urban areas, which is the domain of urban policies and urban planning.

2 FOCUS ON CITIES

Cities are the center of human development and global growth. More than 80% of global GDP is generate in cities (World Bank, 2017) and, despite they occupy around 1% of the Earth's surface, they host more than a half of the world's population. This concentration of activities makes urban areas the greatest consumers of natural resources. The need for linking urban development with sustainable development is well-established and recognized worldwide, although the operationalization is far from ideal. The New Urban Agenda adopted at the Habitat III conference held in Quito in October 2016 set out principles for sustainable urban development, maintaining a close link with what is indicated by the Sustainable Development Goals. The New Urban Agenda often refers to efficiency and reduced consumption of resources in cities and, among other things, there are specific references to water, energy and food. In particular, the New Urban Agenda aims to ensure food security and nutrition strengthening food system

planning, equitable and affordable renewable energy fostering energy efficiency and use of clean resources, access to affordable drinking water and sanitation promoting a sustainable use of water along all the water cycle. More generally the New Urban Agenda commits to reinforce the sustainable management of resources and promotes the local provision of basic goods and services such as water, energy, food and other materials, which usually rely on remote sourcing and thus increasing cities vulnerability to supply disruptions. Furthermore, it promotes “[...] the coordination of food policies with energy, water, health, transport and waste [...] and other policies in urban areas to maximize efficiencies and minimize waste[...]”. The New Urban Agenda asks for an “enabling environment” to be implemented. In the document one can distinguish a set of factors such as economy, laws, national urban policy, institutions and systems of governance, which try to control urbanization forces to achieve equitable growth. On the other hand, there are factors such as urban planning, local fiscal systems and basic services and infrastructures, which are more operational. Despite the New Urban Agenda is not a binding agreement, it is still important that the global vision on the future urban development is linked to sustainability principles and resource management plays a central role in it. Although not always explicitly, sustainable urban planning has been concerned about resource management. Agudelo-Vera et al. (2011) synthetically, but carefully, described this connection between sustainability and urban planning and its evolution in history. Furthermore, they conceptualized the link between resource management and urban planning in a sustainable development framework. The paper revealed that resource management and urban planning evolved separately because they faced different priorities. On one side, resource management deal with the demand for resources, on the other hand urban planning copes with increasing quality of life in cities. Urban planning could play a central role in sustainable development, but to do so, it must go beyond its traditional tasks and engage with different fields and sectoral planning. If resource management is a key connection between urban planning and sustainable development, what is the role of the water-energy-food nexus and urban metabolism approaches in the planning and transformation of our cities? Approaching the nexus from an urban perspective means to reconsider the cities role on the global resource availability. Considering and taking action at the urban-local dimension has the double advantage of improving the internal efficiency of the “city system” as regards resource management and it might reduce cities dependency on external flows and their negative impact on hinterlands and global resource availability. New challenges raised by the nexus approach are necessarily part of a global-local dialectic (Giatti et al., 2016). Water, energy and food security are global challenges, but it is necessary to identify analytical and geographical framework in order to implement actions able to contribute to greater systemic efficiency within the local-global dynamics. Independently from the scale chosen (city, community, river basin, country, etc...), it must be considered as an open and self-organizing system. In this case, one must recognize the system interdependence with other systems. It is therefore impossible to conceive all the elements of the nexus between water, energy and food as part of a single city. In this way, analyzing and taking action in an integrated way at the city scale requires to be able to recognize that sustainability is inherent to connections and dependences to external means. Once the territorial scale has been defined, optimization and efficiency should be sought within the object of analysis. Nevertheless, results must take into account impacts and external dependences. Decision-making on nexus issues is inevitability characterized by multi-level and multi-sectoral governance, which implies the involvement of a wide variety of actors. The nexus approach further complicates the multi-level governance, already very articulated, by adding complexity and indispensable new arrangements between sectors and supply chains concerned with water, energy and food (Giatti et al., 2016). Sustainable urban development can be achieved only through an integrated approach that meets the various dimension of urban life (environmental, economic, social and cultural). In the same way, the nexus can be operationalized at the urban level combining measures on economic development, social inclusion, education and environmental protection with physical urban transformation (urban planning domain). Furthermore, such an approach calls “[...]for strong partnerships between local citizens, civil society, industry and various levels of government...]” (European Commission, 2016). Therefore, urban planning plays a crucial role in the implementation of water-energy-food nexus at the urban level, but a strong cooperation with other urban policies and sectoral measures is necessary. Depending on the current configuration of water, energy and food supply chains and the different objectives for the future development of cities, there are a number of different opportunities to affect the water-energy-food nexus for urban planning and urban policies.

3 GOING ALONG THE SUPPLY CHAIN

In order to identify areas of intervention and understand the flow of resources, it is useful to visualize, albeit simplified, the water, energy and food supply chains and their components (Fig. 1). Every supply chain consists of nodes and connections that may or may not be associated with nodes and connections of other supply chains. The water supply chain, which is embedded in the hydrological cycle, may be different depending on local conditions, but it will normally include collection, treatment, distribution, consumption and wastewater treatment stages. The energy supply chain is composed of energy sources, generation/production, distribution, consumption, emissions stages. Furthermore, the food supply chain may differ greatly from case to case, but it is traditionally composed by production, processing, distribution, consumption, food waste management. Understanding resources supply chains is essential for operationalizing both urban metabolism and nexus approaches. Supply chains changes from context to context and they interest urban areas in different ways and at many levels of the chain. Local urban authorities are therefore able to take action only on certain segments of the supply chain by implementing urban policies and urban planning practices. We here identify some of these fields of action.

3.1 FOOD IN URBAN NEXUS

The food sector is heavily dependent on water and energy inputs along all the phases of the supply chain. The level of consumption of water and energy varies in every phase and depends on factors such as kind of product, technologies and techniques, climate, culture and behaviour, regulations. Despite the differences between countries and cities, the energy consumption in the food sector counts for about 26% of final energy consumption in EU and the energy embedded in food products changes along the supply chain (European Commission, 2015). The energy embedded in the food consumed is distributed as follows: production of food (agriculture and breeding) counts for 33%, 28% processing, 9% logistic, 11% packaging, 13% consumption, 6% waste management and disposal. Dealing with food issues in cities encounters a first major obstacle, food has not been considered an urban issue neither in people's mind nor in urban agenda for a long time. On the other hand, the urban dimension cannot be neglected any longer. Although food has been forgotten by urban planners for a long time on the pretext that it is a subject associated to rural planning rather than urban, it is also true that food is related to many other sectors such as land, transport, social justice, public health, water and energy, which are of main interest for planners (Morgan, 2009). The food system is a quite large matter that comprehends a set of connected actions (Pothukuchi and Kaufman, 2007), and each of these stages has a different level of connection with urban planning and the urban dimension, furthermore they have distinct impacts on water and energy sectors.

3.1.1 URBAN AGRICULTURE AS GREEN INFRASTRUCTURE

Food production is not a function commonly attributed to urbanized areas, cities have indeed become more and more places of consumption rather than production. This has not been always the case, ancient civilizations survived through time also because of the proximity of food systems to urban settlements (Barthel and Isendahl, 2013). Despite the proven importance of local food systems in increasing the resilience of urban settlements, the bond between place of production and place of consumption has been fading. Lately, urban food come back in the political agenda due to events such as the 2007-2008 world food price crisis and an increasing interest by the civil society in initiatives such as urban agriculture and horticulture. Cities such as Belo Horizonte in Brazil, Toronto, London or Amsterdam turned this increasing interest in urban food policies. The city of Belo Horizonte has been a pioneer in the introduction of urban food policy a decade earlier than London did. Main goal of this policy was to tackle hunger and malnutrition, equal access to quality food through several programs such as subsidized food sales, food and nutrition assistance, supply and regulation of food markets, support to urban agriculture, education for food consumption, job and income generation. Although the importance of such programs, it is clear how they are geared to respond to social and economic needs in order to achieve food security whereas, instead, sustainability concerns such as relieving the pressure on water and energy resources are neglected or not expressly addressed. This is also the case of the Toronto Food Policy in which security, hunger and social justice are priority objectives rather than sustainability. That is because sustainability is a much more political issue that may not be welcomed by industry and agriculture representatives (Blay-Palmer, 2009). Urban food strategies have a crucial role in transforming the current food system.

Nonetheless, in activities such as urban and peri-urban agriculture, although ecological benefits are expressed both among motives and objectives, they are rarely considered at the design stage. This can be better understood with two classic examples of climate change effects in urban areas with an inherent potential through the lens of nexus thinking: urban flooding and urban heat island effect. Storm water is a major cause of flooding in urban areas and it is also a threat to human and environment health due to different pollutants transported by storm water (Barbosa et al., 2012). One of the main causes of urban flooding is the combination of extreme storm water events and impervious surfaces. The latter contribute to exacerbate urban heat island effects in some areas. It is thus clear how a different land management, which prefers permeable and green surfaces, may contribute to a better storm water management and to reduce the effects of heat wave in built-up areas. Scholars and practitioners identified green infrastructures as one of the possible (soft) solutions in response to this kind of problems. But following a nexus thinking, which seeks for synergies between water, energy and food, and that prefers solutions that incorporate a greater variety of co benefits, why should not we consider urban agriculture as a green infrastructure? Urban and peri-urban agriculture have the potential to be a challenging socio-economic activity, but at the same time, it can contribute to increase permeable surfaces, reducing runoff and lowering the urban heat island effect. In order to achieve such results more efficiently, the areas intended for food production purposes have to be identified according to a set of criteria. Despite this, re-thinking green infrastructures including food production purposes requires a considerable step forward in terms of research and understanding of the compatibility between different typology of urban agriculture, type of soil, and type of vegetation and ecosystem services that can be provided. In order to do so, urban agriculture initiatives cannot be considered in isolation and implemented randomly, which has been often the case until now, but they have to be part of a more extensive and broader strategy for green infrastructure planning. This can be reached only with regulatory framework and the political commitment of city authorities, which should lead the design process of an urban agriculture system across the municipal territory. Urban agriculture has evident and direct connections with urban planning such as transport sector, land use, economic development, housing, storm water management and other. Including urban agriculture in day-to-day city planning means, for example, to rethink zoning regulations and land use indicators to facilitate urban agriculture development in certain areas. Local authorities might set specific goals including, for example, the preservation of existing urban and peri-urban agriculture areas, conversion of a certain portion of municipal land (e.g. vacant lands) into food production areas, or establishing how much of the food consumed in the city should be produced locally. In this sense, inserting urban agriculture as category in the land use management may facilitate control of such activities, promoting the development of different urban agriculture typologies, each of which is more suitable for specific urban areas. Despite the potential of urban agriculture, it is very unlikely that cities have the capacity, farms, gardens, land or space to even get close to meet their own food demand. A study conducted on the city of Cleveland (Grewal and Grewal, 2012) demonstrated how using 80% of every vacant lot, 9% of every occupied residential lot and 62% of every industrial and commercial rooftop, the city of Cleveland can meet between 46% and 100% of Cleveland's fresh products needed depending on the vegetable production practice, 94% of poultry and eggs and 100% of honey. These kinds of results show how even post-industrial cities have the chance to become more self-reliant in food using proper typologies of urban agriculture. By the way, this can be achieved through massive transformations in cities which are unlikely to happen in the near future. Despite the scepticism in the vision of cities producing entirely their own food, urban agriculture activities can still have their role in bringing back food issues in cities putting them to the attention of city dwellers and encouraging the consumption of healthy and sustainable food, reducing also energy consumption due to long distance transportation. Furthermore, urban agriculture and local food systems more generally shall be considered and designed beyond the food production function, taking maximum benefit from other ecosystem services and to reduce pressure on water and energy resources. Although local food systems are often portrayed as the solution, a local-scale food system is not inherently more sustainable than a global-scale food system (Born and Purcell, 2006), much more important than the scale are the actors and agendas involved and it has to be less dependent on fossil fuel and chemicals fertilizers, occupy less greenfield lands and reduce the "food miles". Characteristics of the site are also very important, it is clear for example that trying to impose a food local system in arid territories could bring ecological benefits for the reduction of fuel in transport that would be outweighed by the need of large water inputs (Born and Purcell, 2006).

3.1.2 FOOD WASTE

Another segment of the food supply chain directly linked to urban areas lies in the food waste management and disposal. Food waste is one of the metabolic outflows of materials after consumption and transformation processes that took place in the city. Nexus thinking, on the other hand, recognizes waste food intrinsic value and the opportunities for more sustainable solutions that involve also the water and energy sectors. Every year around 88 million tons of food are wasted only in the EU (FUSIONS, 2016). This is not just an economic issue, but it implies some serious environmental impacts and it puts under a great deal of pressure limited natural resources. The “waste management hierarchy” proposes a hierarchical order of preference of waste treatment and disposal methods based on sustainability principles and environmental impacts. More specifically, there is the hierarchy for the bio-waste management, in which prevention is still the most desirable solution followed by recycle (preferably composting and anaerobic digestion), energy recovery (incineration), final disposal. Food waste prevention and reduction has a great potential in decreasing water and energy consumption. Encouraging a more efficient consumption of food will result not only in the reduction of waste flows volume produced by cities, but it will also have the effect of reducing food demand and thereby reducing inputs of food flows into cities. This will change the metabolism of cities, reducing also their ecological footprint, water footprint and carbon footprint. In fact, food flows are comprehensive of other virtual elements such as water, energy and nutrients (phosphate, nitrogen, etc.). The reduction of food production should lead to a reduced waste of water and energy with global environmental benefits. But there are also more specific synergies between food waste and energy. Embedded in waste there is a great potential for direct and indirect energy production. Different forms of energy come from a variety of renewable sources such as waste from dwelling, agriculture or industries (Kothari et al., 2010). In cities is more likely that a great portion of waste comes from dwellings (household waste) and a great portion of this waste is composed by food waste. There are of course different models to deal with food waste, and some of them treat food waste in order to preserve the highest value in it. However, even considering that other approaches such as reducing food waste production by changing consumer behaviour, nutrients recovery, compost production for farming purposes, alternative markets for low quality food (e.g. not meet aesthetic standards) or other forms of recycling could reduce significantly the amount of food waste, an unavoidable residual food waste is likely to still remain. According to nexus perspective and a closed loops model, this residual food waste can still become a valuable resource for energy production purposes. Incineration with energy recovery does not seem to be a noble end for food waste, but still it is a practice that provides a certain payback in terms of energy and it is a valid alternative to fossil fuels resources, especially considering decentralized local-based energy production systems. Amsterdam for example, is planning to abandon the domestic use of natural gas by 2050, switching to a centralized system of district heating working on a variety of different resources. Waste, and food waste in it, is already an important alternative source for the waste to energy incinerator that provide heat to 70000 houses of the city through the district heating system (DutchNews, 2016). If incineration still raise doubts and uncertainty regarding efficiency energy transformation, security and air pollution problems, other systems of producing energy from food and organic waste may be considered. The anaerobic digestion of food waste, for example, is a complicated process, which results depends on technology, composition of the waste and others. The composition of the waste is quite important for successful results, it is then fundamental that the organic waste is collected separately from the other materials in order to produce good quality biogas through anaerobic digestion process. Treating organic waste with anaerobic digestion rather than other alternatives, such as composting, has the advantage of producing biogas that has a high percentage of methane that can plays like fuel, composting on the other hand, produce biogas that contains a high percentage of carbon dioxide with no energy value (Curry and Pillay, 2012). More than that, what remains after the digestion process is rich of nutrients that can be used as fertilizer. But, despite potential benefits coming from anaerobic digestion, it is still not a common practice in urban areas. Despite food waste management should have a central role in urban sustainable strategies, urban planning contribution is rather limited compared to other urban policies. Urban planning can contribute to redefined areas intended to food waste management, identifying suitable areas for facilities and respecting criteria of security, self-sufficiency and proximity. At a smaller scale, urban planning can contribute to develop areas in which food management and urban agriculture are combined, but it must be done in strength coordination with other urban policies.

3.2 WATER AND ENERGY IN THE URBAN NEXUS

Water and energy, in addition to being central elements in the nexus approach, are also main flows to consider in urban metabolism assessment. In fact, they are a large proportion of cities inputs and, more than other materials, are essential for almost every activity. In urban metabolism studies, water and energy are considered separately most of the time, failing in highlighting connections between these flows which could otherwise bring out sustainable integrated solutions. The connection between energy and water flows in urbanized areas appears to be a little bit clearer compared to food related issues and it is strongly related to the infrastructure systems related to these resources. Water and energy are generally connected by a two-way kind of relationship, water use along the energy supply chain and, on the other hand, energy use along the water supply chain. Actions to reduce water and energy consumption can be taken along both the supply chains and they include introduction of new techniques and technologies, institutional arrangements, changing in regulations, involvement of actors, policies. Some of these solutions fall within the urban domain both with local and global effects.

3.2.1 WATER

Discussing about water and cities is important to make a first distinction between direct and indirect water issues as explained by Renouf and Kenway (2016). Cities directly rely on local/regional water sources to meet basic needs (drinking, cleaning, etc.) and productive uses (energy production, manufacturing, etc.) and they are usually supported by centralized urban water infrastructures that extend far from cities to exploit water supplies. On the other hand, cities have also a great impact on the indirect consumption of (virtual) water embedded in the products consumed such as food. While acknowledging the importance of both direct and indirect water issues, in this section we focus on direct water, which we consider closer to urban policies and planning domain. The water supply chain is heavily dependent on energy. Around 3 % of the electricity used in the US is, for instance, related to the water sector for pumping, treating and transporting activities and in some cases, it represents the municipality's largest operating expense (OECD and IEA, 2016). To reconfigure the urban water system in order to reduce the pressure on the energy sector is a challenge to be faced at different levels of the supply chain. Water utilities are main actors to be involved in the transformation of urban water systems since they manage different parts of water systems on behalf of national, regional or local authorities. Furthermore, they can play a main role in planning and manage urban water in coordination with urban planners. However, cities have also other opportunities to improve the water supply chain rather than leaving it entirely under the utilities control and this include the support of decentralized systems and grassroot activities. Energy conservation in the water supply chain can come from the combination of different activities at different points of the supply chain. Fields of action can be a compound of the use of alternative water resources with decentralized systems, infrastructure renewal, water conservation and alternative energy use. Since cities are increasingly dependent on imported water from far hinterlands, finding local alternatives such as storm water, rain water and reuse of wastewater can drastically contribute to the reduction of energy consumption and to make urban areas more resilient. Wastewater reuse is less energy-intensive than imported water or desalinization practices (although it must be considered on a case by case basis). The city of Los Angeles is a good example, in which has been proven that recycled water is less energy intensive than imported water from the California Aqueduct. For this reason, the Los Angeles Department of Water plans to increase the share of recycled water in water supply. Recycled water is a clearly viable solution for Los Angeles in which the imported water negatively affect the city energy balance (Younos and Grady, 2011). Other cities might not present the same characteristics and other water supply options should be considered. Besides wastewater, decentralized systems based on the reuse of storm water runoff (both for potable or non-potable uses) is an alternative to overcome energy issues due to water pumping on long distances and difficult topography. Rainwater harvesting systems, as well as reducing urban flood risk, are much more energy efficient than recycled water systems. In this respect, physical readjustments of the urban fabric are necessary and urban planning has a central role both in identifying suitable areas for implement decentralized systems and in the defining the best design criteria. When it is not possible to reduce the energy consumption of the water system, alternative energy use might be considered to reduce GHG emissions. Usually, particular attention has been paid on the wastewater treatment stage because the possibility of energy production from biogas and industrial symbiosis projects (e.g. between energy and water utilities), but energy alternative uses can be implemented along the entire water supply chain by the responsible water utilities. Energy needs of the water system can be met, for instance, through the implementation of renewable energy forms such as wind turbines or use of photovoltaic panels, which are

less water consumptive than fossil fuels. Nevertheless, more appealing and challenging for water utilities and providers is the potential energy embedded in water. Water itself, in fact, contains energy in form of thermal and chemical energy. Examples of water thermal energy is the use of surface water and groundwater temperature for both cooling and heating purposes (van der Hoek, 2011) depending on the period of the year. Other form of thermal energy is embedded in household or industrial wastewater. Part of the drinking water used in household is heated and leaves the house with a temperature that can be still recovered utilizing heat exchangers and heat pumps at different scales (single shower, building, sewage system, etc.). Similar utilization can be applied to heat wastewater streams coming from industries and other productive activities that heat water in their operations. Chemical energy recovery, on the other hand, comes from wastewater and is based on anaerobic sludge digestion and anaerobic treatment of wastewater, which produce biogas usable in both electricity and heat generation. Biogas is also a valuable resource for green gas production, which can be used in houses instead of natural gas or as fuel for vehicles. Chemical energy can also be recovered from drinking water, recovering methane from the drinking water processes. More explicit integration of water and energy (and waste) sectors demands for cooperation between utilities. Waste-to-energy plants and wastewater treatment plants can both benefit from exchange of flows with positive impacts also for the environment. Waste-to-energy plants can, in fact, burn biogas and sewage sludge coming from wastewater plants and produce energy in form of electricity and heat that can be directly used for the plants operation or delivered to the energy network (e.g. district heating) of the city. Utilities can be guided and encouraged to taking such initiatives by the public authorities, but cities have also other options rather than rely only on centralized solutions and they imply a greater involvement of urban planners, civil society and implementation of other urban policies. These kinds of solutions require paying particular attention to the spatial dimension, the link between different city functions, the proximity between potential producers and consumers of resources.

3.2.2 ENERGY

Local initiatives at the city levels on the energy sector are less likely to have direct effects on the local water cycle, mainly because a great part of energy and energy resources that are consumed within the city are instead produced somewhere else. It is here possible to use a similar rationale to that used for food sector. Taking action in the energy sector at the local level is more likely to have effect on water systems at national or global scale rather than locally. Different forms of primary energy production and power generation, such as oil and gas, coal, biofuels, thermal power generation (fossil fuel, nuclear, bioenergy), concentrating solar power, geothermal and hydropower, affect differently water systems both in quantity and quality terms (OECD and IEA, 2016). Other non-thermal renewables, such as wind and solar photovoltaic use very small amounts of water and for this reason they are much more suitable for the future of the energy sector that will have to be less dependent on carbon but also on water. These technologies use less water at the electricity generation stage, but they also have almost no water consumption for the production of fuel inputs and they have a minimal impact on water quality. Biofuels usually need of water for irrigating feedstock crops and for fuel transformation, but on the other hand, biofuels derived from waste products require no water for feedstock, since water is allocated to the activity of primary value such as food production. Wind energy, photovoltaic panels and biofuels from waste are all energy generation systems that help to decrease GHG emissions, but also reduce the pressure on water resources. Furthermore, PV and second generation biofuels from waste are suitable to be implemented at the local-urban level more than other renewable sources. Priority areas for the transition to renewable energy in cities are buildings, transport and smart grids (IRENA, 2016). At the building level is possible to act both with decentralized and centralized renewable energy production. Decentralized measures are focused on the building itself and the implementation of PV panels, thermal collectors and biomass heating systems for each building. On the other hand, centralized systems use renewable resources to produce energy, heat and cold to be supplied to buildings through energy networks (e.g. district heating network, smart grids, etc.). Buildings have the potential to change their status of the largest energy consumers in cities and become the most available urban resource thanks to the large potential of rooftop PV panels installations. Transport sector also counts a great deal of cities energy consumption, although it might change significantly between a city and another with great differences between high, middle and low income cities. It counts, for example, for the 53% of energy consumption in Mexico City, while it counts for 28% in Bologna (Italy) (UN-HABITAT, 2008). Projections show that energy demand for transport will increase further in the future, but fossil fuels cannot be the main source in the transport sector due to their impact on GHG emissions. At the same time, great investments in first generation biofuels will lead to

further stress water resources. Finding alternatives is therefore crucial and cities might have a key role as well. Within cities, transition towards more sustainable systems have to tackle both rail and road transport. Rail transport, trains, metro systems and light rails should be planned in order to rely on electric power. The same applies to road transport that also can count on biofuels and hydrogen technologies. It is important to note that initiatives must be supported by a certain degree of coherence. It is not standing the obvious to say that electricity used for transports must be generate by renewable energy sources. Biofuels are a good alternative, but it is important to distinguish between first and second generation biofuels in order to understand their potential both in nexus and “city” perspective. First generation biofuels (mainly biodiesel, ethanol and biogas) come from agricultural products such as crops and sugarcane and other commodities that are currently used for food (Naik et al., 2010). Although these are prevalent in the global biofuels market, they are source of conflict for the land destination and they put great pressure on water resources. Furthermore, they are not suitable, at least at the production stage, to be considered in urbanized environments. On the other hand, second generation biofuels are made of biomass not from edible feedstock and they largely consist of waste and lignocellulosic material (Naik et al., 2010). Second energy biofuels might be a valiant resource for energy generation in urban and peri-urban areas where there is a large production of municipal organic waste, in which food waste is a substantial part. It is clear that this kind of energy production will not be sufficient by far to meet cities energy demand, even considering only the transport sector, but cities are called to give their contribution in every field of sustainable development. Extending the area in analysis beyond the city’s boundaries, and considering metropolitan areas is more likely to find a larger supply of local renewable resources. For example, The Metropolitan Region of Lille is a good example as it started in the early ‘90s to use half of the city’s organic waste for energy purposes and to produce biomethane for use in public buses (GIZ & ICLEI, 2104).

4 THE ROLE OF URBAN PLANNING

Cities are great consumers of resources, but they also have the potential to reverse this trend and make a huge contribution to the sustainable development process, the only possible on the long term. Moving towards a more sustainable resource management at cities level will have effects at different scales. It is crucial to understand that exists a strong bilateral cause-effect relationship between global dynamics and what happens at the local level. And this is not different when it comes to resource management. Urban metabolism studies try to give a scientific dimension of how cities work and what impacts they have on resources. Indicators such as ecological footprint, water footprint and carbon footprint have also similar purposes, but they all fail at the operationalization stage. Change the metabolism of cities, reducing their impacts on global resources, but maintaining high quality of life and economic development is a major challenge. Water-energy-food nexus approach might help to give a common vision and a set of principles shared by departments, utilities and stakeholders engaged in resource management and that usually work in “silos”. Local authorities are called upon to be leaders in this transition process establishing a clear vision for the future of cities and urban planners have an important role in this. Urban planning is the profession that more than others can coordinate the many factors involved in the transformation of the urban environment and its functions and it can support a fair process of transition towards a more sustainable resource management and city development, bringing together stakeholders and considering the prosperity of the entire population. In addition to this role of coordinator, urban planning in conjunction with other urban policies can act directly on specific fields of the nexus to improve cities resilience and sustainability. Identify the water, energy and food supply chains and their connections allow to distinguish areas of intervention in which urban planners can contribute and it helps to identify main actors that need to be consulted and involved. It is also important to acknowledge cities as open system and be aware of the dependency with other systems and the cause effects relationship between them. Planning departments and urban planners across the world have the skills to give a great contribution to the transition towards more sustainable cities. However, this is not going to happen without a close cooperation with other local stakeholders both from the public or private sector. Planning systems are different, they are subjected to different regulations and they have diverse degree of responsibilities on resource management issues. There are different dimensions in which spatial planning can be integrated and they have different impacts on city metabolism and the nexus. Spatial planning cannot be central in every aspect of the cities transition towards resilient and sustainable systems, there are many other tools that can be predominant in specific aspects (e.g. technology innovation, regulations and financial system among the others). We here focused just on certain areas of interest in which spatial planning is called to

give a significant contribution and we proposed a path to follow, which nevertheless need to be tailored to the specific cases.

1 INTRODUCTION

In the last years, we have been tackling such challenges as rapid population growth, increased materials and energy consumption, growing resource scarcity, climate change, loss of biodiversity, increasing social inequality and poverty (Bina et al., 2016). Cities are the centre of all these challenges, as world population is more and more urban: some 70% of the world's population in 2050 will live in cities (UNDESA, 2015). As a consequence, the combination of urbanization and sustainability results one of the crucial challenges of the coming years (Girardet, 2003; Agudelo-Vera et al., 2011; Musco, 2011). Understanding the relationship between the city planning, urban life style, and the availability of necessary environmental, social and economic resources, is only the first step to build a sustainable and resilient future. City and urban planning become respectively a place and a privileged tool for achieving these two goals (Bulkeley & Betsill, 2003; Pickett et al., 2013).

In recent decades, Urban Sustainability (US) and Urban Resilience (UR) have been two concepts widely studied, both theoretically (WCED, 1987; Jabareen, 2008) and practically (Jabareen, 2006; Jabareen, 2013; James, 2015). However, despite the world scientific community shares a number of issues regarding the achievement and development of sustainable and resilient cities (for example: integrated approach and management, green cities, dense and compact cities, use of renewable energy sources, equity and participation, etc.), it has not yet defined a unique methodological framework. In this regard, in recent years, a series of studies have been developed on the Urban Metabolism (UM), which could represent the nexus able to develop an integrated approach to planning, capable of contributing to the achievement of both US and UR (Kennedy et al., 2011; Thomson & Newman, 2017), also in ecological terms. Nevertheless, these studies remain very generic in connecting UM with spatial planning, and in most cases dealing only with very specific themes like energy and transport (Pincetl et al., 2012).

Within this context, this paper aims to suggest an approach to fill this gap, exploring how the UM can be used as scientific framework, within designing specific plans and policies for cities having as main objective to build US and UR. The theoretical framework presented in this paper stems from researches and studies developed in a Horizon 2020 Project (URBAN_WINS). The URBAN_WINS objective is to develop and test methods for designing and implementing innovative and sustainable Strategic Plans for Waste Prevention and Management as to enhance urban environmental resilience, in 7 different urban areas (Turin, Cremona, Rome, Bucharest, Sabadell, Manresa, Lleira), located in 4 EU country (Italy, Romania, Spain, and Portugal), according to an inter-disciplinary and participatory approach. Specifically, the development of Strategic Urban Plans will be built on the basis of improved knowledge of the factors that influence the UM of the cities.

The work is organized in 4 sections: first, the analysis of relationship between US and UR in urban planning approach; second, introduction to UM; third, analysis between metabolic flows and sustainable and resilient urban planning features. Finally, implication for urban planning and introduction of a new planning paradigm.

2 URBAN SUSTAINABILITY AND URBAN RESILIENCE

'Sustainability' appears as a concept in 50s for the first time, but only in 1987 with the UN World Commission on Environment and Development, it is acknowledged as a development paradigm that minimizes the use of environmental resources and reduces the anthropic impact on the environment, through processes which simultaneously stimulate economy and improve quality of life (Newman, 1999). Since that moment, the link between sustainability and cities became clear, and in 1992, Yanarella and Levine suggested that all sustainability-related initiatives had to be embodied in design, recovery and urban development strategy. Over the years, the concept of US has consolidated as an urban transition process rather than an ultimate and optimal goal: it is a steadily moving target, as knowledge, technologies and capabilities are always improved. Therefore, the US is the concept that crosses and links all plans and measures that insist on a city, creating a flexible support structure and a continuous process of change (van Timmeren, 2014). After a 30-year-debate, US remains unclear in practical and operational terms and recently has been flanked by the concept of UR. Resilience can be defined as the ability of a system, community or society to resist, absorb, tolerate disturbance while retaining its structure and function. Thus, ideal urban resilience can be understood as a city that can easily live and cope with an ever-changing and sometimes risky environment (Fiksel, 2003; Wamsler, 2014). The adaptive capacity, which may lead to new equilibria, is highlighted, and in a resilience perspective, sustainability is not about maintaining a system at its equilibrium state, but rather it should focus on the capacity to create and test opportunities and maintain adaptive capabilities (Holling, 2001). Thus, resilience has become the key to achieve sustainability: there was a shift from a perspective oriented around stability, optimality and predictability to a perspective focusing on inherent uncertainty.

Finally, we may argue that:

- resilience is a prerequisite for sustainability;
- all sustainable systems must be also resilient, but not necessarily always stable;
- in order to achieve US, we should focus on creating and maintaining UR.

As far as implications for urban design and planning are concerned, despite there is no universal design for all cities, as envisioned by Walker and Salt (2006), resilient systems could be characterized by the following features:

1. Diversity: promoting diversity in all its dimensions, from biological to economic, and encouraging multiple components and resource uses to balance and complement homogenizing trends.
2. Ecological variability: Seeking to understand and work with the boundaries of the inherent variability of ecological and socio-ecological systems; attempting to tame such variability is often a recipe for disaster.
3. Modularity: maintaining modularity can help hedge against dangers of low resilience caused by overconnectedness in system structure and function.
4. Acknowledging slow variables: managing for resilience means understanding the slow or controlling variables that underpin the condition of a system, especially in relation to thresholds. By recognizing the importance of these critical variables, we can better avoid shifts to undesirable stable states and possibly enhance the capacity of a desirable regime to deal with disturbances.
5. Tight feedbacks: tightening or maintaining the strength of feedback loops allows us to better detect thresholds. The weakening of feedback loops can result in an asymmetry between our actions and the consequences stemming from them. Salient examples of such dynamics include pollution and overconsumption.
6. Social capital: promoting trust, social networks, and leadership to enhance the adaptive capacity for better dealing with the effects of disturbance.
7. Innovation: embracing change through learning, experimentation, and promoting locally developed rules. Instead of narrowing our range of activities and opportunities, we should be seeking to explore and cultivate new ones.
8. Overlap in governance: developing institutional arrangements that manage for cross-scale influences. Developing redundancy and overlap in governance frameworks enhances response diversity and flexibility.
9. Ecosystem services: recognizing and accounting for ecosystem services while managing and designing for resilience. The benefits society derives from nature are regularly underprized and ignored. Such services are often lost as socio-ecological systems shift into different, less desirable regimes. Considering cities as complex systems, only pursuing a comprehensive and

general UR will be possible achieve US in an uncertain world. Thus, urban planning must be able to consider all these features and turn them into strategy, policy, action and design.

3 URBAN METABOLISM

The concept of metabolism emerged in the 19th century in order to describe the exchange of matter between an organism and its environment. The application of this concept to the city, namely, the concept of Urban Metabolism, is more recent, and it was developed in the industrial ecology field by Abel Wolman (1965) to determine the urban metabolism of a typical American city. UM is used as a metaphor for the resource consumption of cities, and it includes systematic studies of the inputs, outputs and storage of energy, water, nutrients, materials and wastes for a city. UM can be defined as “the total sum of the technical and socioeconomic processes that occur in cities, resulting in growth, production of energy, and elimination of waste” (Kennedy, et al., 2007). In the last decade, following the seminal work of Wolman, many other metabolism studies have been conducted to cities worldwide (Newcombe et al., 1978; Newman, 1999; Barret et al., 2002; Chrysoulakis, 2008). These studies, from the industrial ecology and urban ecology fields, point out particular aspects (such as urban form, material supplies, infrastructure network supplies, or groundwater withdrawals) in the calculation of the overall UM. Within the UM concept, US is considered as a problem of flow (material and energetic) between urban community and its environment. Currently, cities’ UM is mostly linear: for their resources, cities depend on hinterlands and other cities for water, energy, goods import and waste export. The uses of these resources in such linear way is inefficient and unsustainable on long-term, and the external dependency makes cities more vulnerable (Cola et al., 2005) and less resilient. This model is not sustainable and it is associated with two main problems: a) the high rate of resource consumption threatens resource availability; b) massive disposal of waste causes pollutions (Agudelo-Vera et al., 2011). Opposite to linear metabolism, there is the circular one, that is similar to the metabolism of natural ecosystem, has a low consumption rate, and includes reuse and recycling of different urban flows. Circular metabolism has less impact on the environment and contributes to the urban resilience. In the purpose to design more resilient and thus more sustainable cities, UM is also a platform to base a comprehensive urban analysis (Pincetl et al., 2012), and a useful framework for urban planning aimed at UR and US development. As far as our knowledge, all previous studies and researches about UM and urban planning have been vague, or focused only on very specific aspects of planning.

4 FLOW AND URBAN PLANNING

Resource consumption patterns in cities are closely linked with land use and urban functions. But despite it is possible to estimate consumption of different material and energy categories, after establishing ‘the system boundaries’, it is not possible to take for granted the geo-localization of flows in the urban fabric, or establishing the direct links among economic activities, resource final uses, and life cycle impacts. However, material and energy flow analysis (MEFA) is the scientific methodology used to account any kind of flows within a system, and it has already been successfully implemented in several cases with different scales (Browne, et al. 2011). Mapping flows of a city is only the base of the work aimed at reducing consumption and waste production is a resilience and (strong) sustainable-based perspective. After that, the central issue is the capability of assessment environmental impacts of material and energy flows, due to anthropic activities in urban areas, and their qualitative differences among sustainability conditions in different social and economic setting (Fiksel, 2006). This deals with the life cycle approach, and in particular the life cycle impact assessment, that can be used to estimate a large range of impacts, and so, contribute to the environmental strategic assessment, the definition of environmental integrated policies, and monitoring their implementation, even through complex impact indicators. The Life Cycle approach is also useful to define the multi-scalar system boundaries of an urban area, because it permits to include all the other systems and sub-systems connect to the target one. Generally, they are all the systems where input flows originate, and where output flows end. At the same time, not only flows move through a complex of multi-scalar systems and sub-systems, but also the impacts can be effective at different levels at the same time, not only local or global, with different features. In order to understand the behaviour of cities, as complex systems, interactions among flows, urban patterns and ecological and socioeconomic processes operating at differing temporal, spatial, and organizational scales. Cities are driven by a huge

number of processes, facilitated by various institutions, and operating at different levels. Dealing with any single issue separately is not sufficient to address the UR of the city as a whole.

5 CONCLUSION

Even according to an urban metabolism approach to city planning and management, cities are more than a mechanism that processes resources and produces waste. In fact, they are places where opportunities are created (Newman, 1999), and, as a consequence, the US can not only concern the reduction of metabolic flows (input & output) and related impacts, but must also aim at the improvement of living conditions.

Cities, as complex systems that consume energy and material and produce waste, have the possibility and capacity to become resilient and sustainable, producing their own renewable energy, reuse and recycle their waste as internal new resource. To achieve this sustainable future a new urban planning approach must be developed. UM can be used as a useful framework to support and inform urban planners and policy makers. Moreover, we believe that using UM framework is fundamental to construct real and effective strategic planning, able to work at the same time and in a coordinate manner on the several features of UR, in order to improve US.

The challenge for urban planners will be understood in each different case how UM flows are related with city characteristics, such as urban form, infrastructures networks, social and economic situation, in order to build strategic plans, through a combination of new technology, city design and community based innovation, which together will create a resilient city for a more sustainable future.

In this perspective, we have to mention other two other mainstream ideas, both, stemming from the Europe 2020 strategy related to urban systems deal with UM: the Circular Economy and the Smart Community.

Both of them, they require a community-based approach in policy definition and implementation, and a complex vision of sectoral integration, which can be easier achieved at community level, through local institutional cooperation, urban stakeholders' involvement, and citizens' direct participation.

The above mentioned UrbanWINS EU project represents an exceptional example for the definition of strategic urban policies aimed at a more sustainable urban waste management, and reduction in resource consumption. On the one side, these policies are based on the metabolic approach, and are built on the UMAN model, provide by the University of Chalmers (Sweden), aimed at accounting urban material flows, on the other are designed since the idea of circular economy at urban scale, and since the idea of a smarter management of cities, which finally result 'systems', according to such different points of view, as the social, economic, ecologic, territorial, and technological.

The high number of above mentioned fields of work, and research, demonstrates how contemporary city management is complex, and multidisciplinary, and how necessary is the integration of competences in planning, but also in implementing and monitoring 'sustainable' urban development policies.

T17 | BIG DATA, OPEN SOURCES, GENERATIVE TOOLS

CO-CHAIRS: MICHELE CAMPAGNA; ELISABETE A. SILVA; PAULO SILVA

Advances in information technology are rapidly accelerating and the spectrum of digital data resources for spatial planning and design is constantly growing due to the flourishing of real-time open Big Data sources. In the present context of uncertainty and rapid change, the methods and general approaches to information communication and analysis need constant innovation for taking advantage of the potential for putting knowledge into action. Global and local environmental and societal challenges require the ability to generate real-time deeper insights on territorial conditions and dynamics, to generate alternative solutions to guide evolution, to understand the implication and make decisions based on consensus.

To what extent can we take advantage of this Big Data avalanche to address these challenges? To what extent do we need to revise traditional methods and tools to elicit useful knowledge by new data sources? To what extent the use of digital method and tools can help to keep track of planning and design processes for more democratic and responsible decision-making? To what extent those data can contribute to get better insight on the planning and design process itself?

Academic and practitioners are invited to share their findings and discuss the challenges on the use of Big data, open sources, generative tools in territorial representation, dynamics analysis, evaluation, design, impact assessment, and decision-making. Such themes as spatial data infrastructures (SDI), volunteered and social geographic information (VGI and SMGI), big data representation and visualization, spatial analysis and environmental modelling, generative design methods and tools, Planning Support Systems (PSS), and Geodesign.

The emphasis will be therefore broad, covering methodologies, methods, and approaches but fully engaging in the present day challenges and future ways forward.

A selection of papers presented in this track may be invited for publication in a special issue of an international journal.

ID 1393 | WHERE IS THE COMMUTERS? RESEARCH OF SHANGHAI COMMUTING TRAFFIC BASED ON TRANSPORTATION CARDS DATA

Xiaochang Liu^{1,2}; Lingyu Kong³

¹Politecnico di Milano; ²Tongji University, Shanghai, China; ³Shanghai Tongji Urban Planning & Design Institute
xiaochang.liu@mail.polimi.it ; 814396482@qq.com

1 INTRODUCTION

With the rapid urbanization, revolution of housing policy and the development of public transportation technology, the high price of city center drives people to move to the suburbs, the distance between home and workplace shows a sharp rising. Daily commuting becomes an important part of daily life and a crucial issue that cities need to face. On this occasion, commute is becoming a universal phenomenon and a prevalent research issue.

Without exception, commute is becoming a widely common phenomenon in Shanghai which is located in the Yangtze River Delta metropolitan area. In Shanghai, most of commuters select metro as the tool of commuting because of the relevant reliability and punctuality. As shown in the figure 1, hundreds and thousands of commuters crowd onto the metro during the morning and evening rush hours every day in Shanghai. Such curiosity gives rise to this commuting behaviors, emphasizing on spatial distribution of the places that commuters live and work, the commuting transportation tool (diversification or simplification) they choose, some potential suggestions and advice for the decision-making and policy-setting produced based on the commuters' behaviors, with appropriate quantitative evidence and visualization illustrations.

Figure 1 – The metro commuters in Shanghai (Source from: Liu Xiaochang, 2017)

The commuters' behaviors play an important role in studying the structure of jobs-housing spaces. Robert Cervero (1996) proposed that the imbalance between home and workplace contributed to the commuting behaviors [1]. Levinson proposed the accessibility to substitute the balance between employment and residence to analyze the impact of urban commenting. He found that higher accessibility contributed to the less time consumption for commuters. Therefore, Levinson concluded accessibility was more convincing to analyze the commuting behaviors. [2] The commuting behaviors were impacted by the urban spatial structure, major researches focus on the scale of city, the density of residence and employment, as well as mixed land use. Cuertis' research indicated that high-density and inclusive development was beneficial to public transportation. [3] Besides, social elements were also regarded as the important aspects to analyze the commuting traffic. Based on Hanson' research, some social and economic indicators such as age, gender and income can be applied to analyze the commuting behaviors. [4] For many western countries, the official data like the data of population census are open, specific, easy and free to obtain, even some data in individual level are also public, which provide the data base to analyze the groups of commuters and even the individual commuter. Therefore, western researches of commuting traffic are more quantitative and precise.

However, Chinese researches of commuting behaviors are mainly based on fieldworks and social observations. Yanwei Chai (2002) applied the theory of time-geography, and found that the features of time, space, travelling and the methods of travelling were the main elements impacting the commuting traffic. [5] Ke Wang (2010), Yaping Wei (2012), Lin Qiu (2007) found that the percentage of commuters who directly choose the metro as commuting tool would gradually decrease, if the distance from work place or home to metro station increased. Comparatively, the percentage of commuters who took bus firstly and transferred subway would obviously raise. [6] [7] [8] Owing to the limitation of official data about

the relationship between working space and residence place for inhabitants, majority of data are from the survey observation, and sample quantification is significant small. Therefore, a lot of researches only focus on the descriptive analysis of individual commuting behaviors, rather than some particular groups' behaviors.

Compared with traditional, sampling, partly-quantitative and qualitative analysis methods, the approaching Big Data era provides totally systematic and quantitative methods. Traffic and passengers flow can be precisely described and analyzed based on the whole sample statistic and database. From the macroscopic perspective, the structure of jobs-housing space in Shanghai can be described precisely and analyzed quantitatively in this research. Meanwhile, characteristic rules of special commuters' behaviors from the microscopic perspective. Furthermore, some specific and precise suggestions and advice can be provided for the decision-making and policy-setting of transportation.

2 DATA MINING AND ANALYSIS METHODS

2.1 DATA MINING

The database is based on the metro transportation card data of five continuous weekdays from 30th March, 2015 to 3rd April, 2015. Specifically, database includes the average 9.1 million pieces of data per day from 288 metro stations of Shanghai. There are five important attributes of any certain piece of data: the card number, the name of start metro station where one certain commuter starts his/her commuting travelling, the name of the end metro station where one certain commuter finishes his/her commuting travelling, the time of entering the start metro station for one certain commuter, the time of leaving the end metro station for one certain commuter and the duration from start metro station to end metro station, which are presented in the table 1.

Card number	Name (Start)	Name (End)	Time (Start)	Time (End)	Duration
79796	Road Yan'an	Road Gulin	7:52:05	8:36:42	44
84407	Road Songyuan	Road Siping	9:40:09	10:08:06	28
92416	Beixijiang	Lujiazui	7:44:46	8:14:38	30
.....

Table 1 – The main attributes of metro transportation cards data (Source from: Liu Xiaochang, 2017)

2.2 DATA CLEANING

The subject of research is commuter, therefore data cleaning is necessary. There are three principles of data cleaning. First of all, commuters have nearly same commuting travelling modes every day. If one certain card number only appears once or twice in the database during the five continuous weekdays, the owner of the certain card will not be studied as a commuter in this research. Therefore, this research only focuses on those card numbers that continuously appear three and more than three times. Secondly, this research only focuses on the time of leaving the end metro station is before noon (12:00). In other words, the owner of the certain card who leaves the end metro station after noon will not be regarded as commuter, because the nearly all companies in Shanghai are open before 12:00. Last but not least, the duration of commuting is less than 2 hours (120 minutes). If one certain data simultaneously satisfies the three principals, the data will be defined as the effective one of the database.

2.3 ANALYSIS METHODS

The time of entering and leaving the metro station is random. If this research adopts the method of classification on separated time points, the quantity of data will become significantly huge and the classification will become more difficult. Therefore, classification on comparatively longer period of time is adopted as the analysis method. Precisely, this research defines 30 minutes as one unit period and divides the running time of metro (from 5:00 to 23:00) into 38 periods. In every period, frequencies of entering and leaving metro stations will be accumulatively and independently counted as shown in the table 2 and table 3.

	5:00 -	5:30 -	6:00 -	6:30 -	7:00 -	7:30 -	8:00 -	8:30 -	9:00 -	9:30 -

*****	*****	*****	*****	*****	*****	*****	*****	*****	*****	*****	*****

Table 3 – The statistics of accumulative frequencies for the end metro stations in each period
(Source from: Liu Xiaochang, 2017)

Based on the statistics of accumulative frequencies for the start and end metro stations in each period, the net change of accumulative frequencies in each period can be calculated as shown in the table 4. The value of net change plays a significant role in researching the jobs-housing space structure. For a certain metro station, if the net change is positive value in the morning rush hours and negative value in the evening rush hours, the area in which the station is located is commuters' employment space. Commuters' employment spatial aggregations rise with the value of net change. On the contrary, for a certain metro station, if the net change is negative value in the morning rush hours and positive value in the evening rush hours, the area in which the station is located is commuters' residence space. Commuters' residence spatial aggregations rise with the value of net change.

(Source from: Liu Xiaochang, 2017)

3 GENERAL FEATURES OF METRO COMMUTERS

3.1 DATA INTEGRATION

Through some methods such as data mining, data cleansing, data process and data statistic, this research integrates the average weekdays' data of metro commuters. As shown in the figure, x-axis means the different periods with 30-minutes interval in one day from 5:00 am to 23:00, and y-axis means the net change of frequencies in one certain period. The value of net change includes different five subsections, which are from -10000 to -5000, from -5000 to 0, from 0 to 5000, from 5000 to 10000, and from 10000 to 15000.

Figure 2 – The statistic of metro commuters in different period (Source from: Liu Xiaochang, 2017)

3.2 WHERE ARE THE METRO COMMUTERS FROM?

Where are the metro commuters from? The answer can be concluded from the value of net change in the morning rush hours and the evening rush hours. As mentioned before, for a certain metro station, if the net change is negative value in the morning rush hours (from 7:30 to 9:30) and positive value in the evening rush hours (from 17:00-20:00). Based on the statistic, the metro stations with top 5 extreme values of net change are Xinzhuang (-5509 in the morning rush hours and 3763 in the evening rush hours), Jiuting (-4664 in the morning rush hours and 3323 in the evening rush hours), Lianhua Road (-4195 in the morning rush hours and 3253 in the evening rush hours), South railway station (-4154 in the morning rush hours and 3155 in the evening rush hours), and Tonghe workers' village (-4074 in the morning rush hours and 2316 in the evening rush hours), as shown in the figure 3.

Figure 3 – The statistic of net changes for metro commuters who live near by the stations in different periods (Source from: Liu Xiaochang, 2017)

Meanwhile, the areas in which the stations such as Waihuan Road, Luheng Road, Yangsi, Chengshan Road, Yanggao Road, Jinxiu Road, Fanghua Road, Longyang Road, Century Park, Guanglan Road, Tangzhen, Boxing Road, Shiguang Road, Gongkang Road, Pengpu workers' village, Zhongtan Road, Dahuasan Road, Xingzhi Road, Gucun Park, Taopu workers' village, Nanxiang, Jinyun Road, Beixinjing are located are the significantly typical residence places for the metro commuters, as the blue and green spots shown in the figure 4.

From the distribution of residential spaces, some features can be included: First of all, metro commuters live in between the inner ring and the intermediate ring. Secondly, major metro stations are located within 10km to 15km from the city center, and part metro stations are located within 15km to 20km. In other words, the commuters spend 40 minutes to 60 minutes by metro from their residential spaces to the city center. Last but not least, from the perspective of stations' spatial distribution, the stations are spatially located in the eastern and western sides of Line 2, eastern and western sides of Line 9, the northern and southern sides of Line 1, the northern and southern sides of Line 7, the northern and southern sides of Line 8, the western side of Line 12 and the northern side of Line 5.

Meanwhile, some open-source data such as Baidu Point of Interest (POI) and price of housing from the Fang.com can be used to further demonstrate and analyze the spatial distribution of commuters' residential places as well as the motivation to choose the residential places for the commuters.

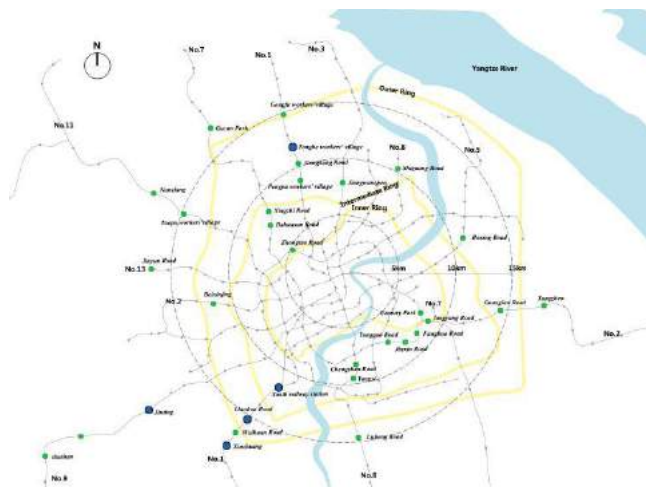

Figure 4 –The resident spatial distribution of metro commuters (Source from: Liu Xiaochang, 2017)

A Baidu POI is a geographic information point with specific coordinators, and it can represent a residential building, a shopping mall, a theater, a metro station, a bus stop, a business building, or a square with its own classification. This part applies the data mining technology based on the Baidu POI with residential attributes. In addition, this part collects the data of average price per square meters of second-hand houses. Although the data of POI and housing price don't have extremely high precision, they are easy to collect with wide coverage. Furthermore, it is an efficient analysis method of spatial structure to do the comparative research based on the same platform including the function, housing price and urban spatial structure.

Therefore, the figure 4 which is the spatial distribution of the areas where the metro stations are located with the typical residence features of residence metro commuters is further analyzed combining the figure 5 which is the spatial distribution of Baidu POI with residential attributes in Shanghai and figure 6 which is the spatial distribution of housing price.

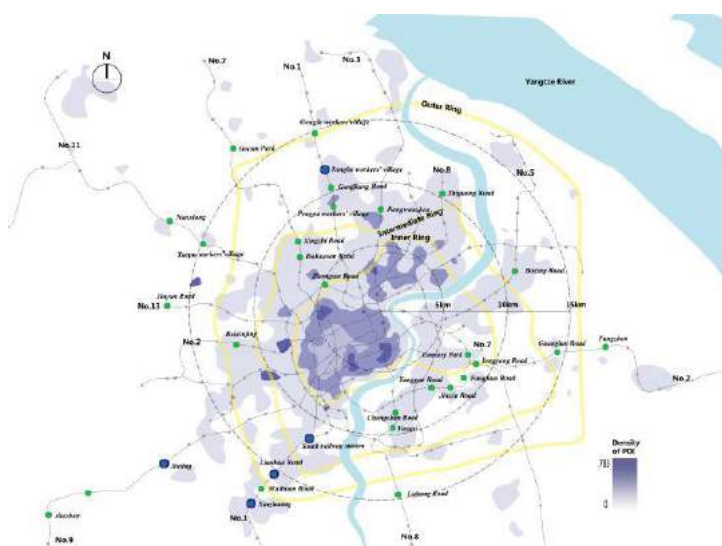

Figure 5 –The analysis of metro commuters' resident style stations overlapping the Baidu POI (Source from: Liu Xiaochang, 2017)

It can be concluded from the overlay analysis: all the metro stations highlighted based on the data transportation cards are nearly located in the areas with significantly high kernel density of residential POI, as shown in the figure 5. It should be noted that, the density of POI is highest in the city center. However,

there are not highlight metro stations in the city center, the reasons can be found in the figure 6. As shown in the figure 6, the housing price per m^2 in the city center is at least 50 thousand yuan/ m^2 (approximately 7 thousand Euro/ m^2), which is not affordable for major commuters. Therefore, residence choice for commuter is a comprehensive process with multi factors such as the time cost and life cost. The commuters are more likely to choose the places with adequate facilities for life (the area with high kernel density in the figure 5), moderate commuting time consumption (40 minutes to 60 minutes by subway, 5km to 15km from commuters' living places to the city center), as well as the affordable and appropriate housing price (from 15 thousand yuan/ m^2 to 35 thousand yuan/ m^2 , from 2 thousand Euro/ m^2 to 5 thousand Euro/ m^2).

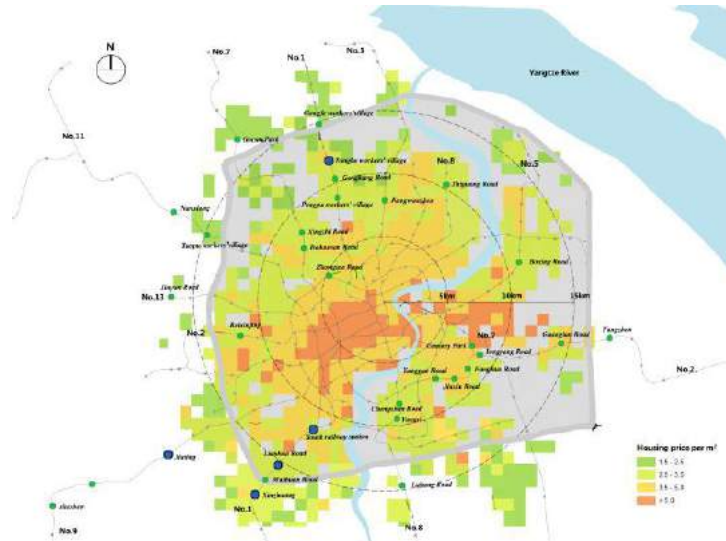

Figure 6 –The analysis of metro commuters' resident style stations overlapping the Housing price
(Source from: Liu Xiaochang, 2017)

In summary, the areas with moderate commuting time consumption, moderate housing prices and sufficient facilities related with residence are along the Line 2 from the city center to the east and west direction, along the Line 1, Line 3, Line 7, Line 8 and Line 11 from the city center to the north and south direction. The residential areas of commuters are mainly concentrated around the metro stations such as Waihuan Road, Luheng Road, Yangsi, Chengshan Road, Yanggao Road, Jinxiu Road, Fanghua Road, Longyang Road, Century Park, Guanglan Road, Tangzhen, Boxing Road, Shiguang Road, Gongkang Road, Pengpu workers' village, Zhongtan Road, Dahuasan Road, Xingzhi Road, Gucun Park, Taopu workers' village, Nanxiang, Jinyun Road, Beixinjing, etc.

3.3 WHERE DO THE METRO COMMUTERS GO?

Where do the metro commuters from? The answer can be concluded from the value of net change in the morning rush hours and the evening rush hours. As mentioned before, for a certain metro station, if the net change is positive value in the morning rush hours (from 7:30 to 9:30) and negative value in the evening rush hours (from 17:00-20:00). Based on the statistic, the metro stations with top 5 extreme values of

net change are people's square (14940 in the morning rush hours and -6550 in the evening rush hours), Lujiazui (12892 in the morning rush hours and -7848 in the evening rush hours), Jingan Temple (10004 in the morning rush hours and -5486 in the evening rush hours), Xujiahui (9193 in the morning rush hours and -3811 in the evening rush hours), and East Nanjing Road (7795 in the morning rush hours and -4148 in the evening rush hours), as shown in the figure 7.

Figure 7 – The statistic of net changes for metro commuters who work near by the stations in different periods
(Source from: Liu Xiaochang, 2017)

It should be noted that there are multiple lagging peaks during the evening rush hours, because commuters will spend their evening activities such as dining, recreation and entertainment in the city center that is full of commercial, entertainment and catering facilities until approximately 21:00 p.m. to 22:00 p.m., then they will take subway to go back home. Therefore, as shown in the figure 7, after the evening rush hours (from 17:00 to 19:00), there is a second peak around from 21:00 to 22:00. Although the value of net change of the second peak is not as significantly giant as that of net change of the first one, the figure of the second peak is one second to two thirds of that of the first peak.

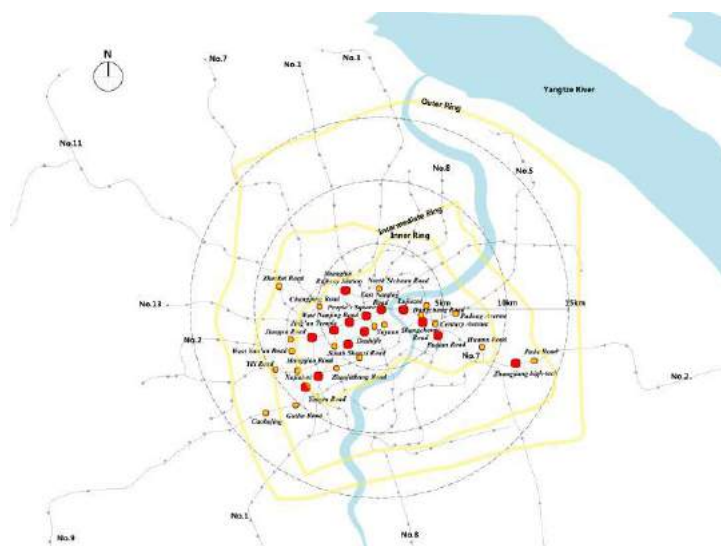

Figure 8 –The working spatial distribution of metro commuters (Source from: Liu Xiaochang, 2017)

Meanwhile, the areas in which the metro stations like North Sichuan Road, Pudong Avenue, Dongchang Road, Shangcheng Road, Century Avenue, Pudian Road, Huamu Road, Jinke Road, Yuyuan, Dashijie, South Huangpi Road, Middle Huaihai Road, South Shanxi Road, Changping Road, Zhenbei Road, Jiangsu Road, West Yan'an Road, Hongqiao Road, Yili Road, Yishan Road, Guilin Road, Caohejing, Zhaojiabang Road, Shanghai Railway Station are located are the typical working places for the metro commuters, as the red and yellow spots shown in the figure 8.

From the distribution of working spaces, some features can be included: First of all, metro commuters work inside the inner ring, and some working places are in between the inner ring and the intermediate ring. Secondly, major metro stations are located within 0km to 10km from the city center, and a part of metro stations are located within 10km to 15km. Similarly, some open-source data such as POI and price of housing from the Fang.com can be used to further demonstrate and analyze the spatial distribution of commuters' working places.

As shown in the figure 9 which is the spatial distribution of POI with office, business, commerce and entertainment attributes, it can be concluded from the overlay analysis: all the metro stations highlighted

based on the data transportation cards are nearly located in the areas with significantly high kernel density of POI with attributes of employment.

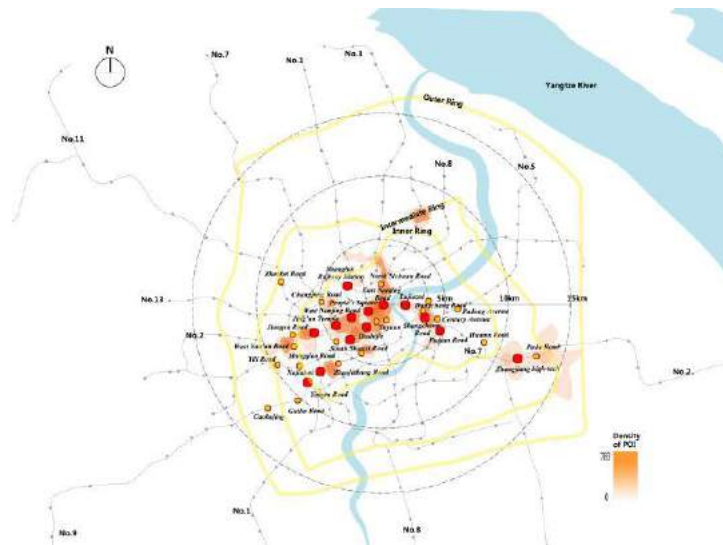

Figure 9 –The analysis of metro commuters' work style stations overlapping the Baidu POI
(Source from: Liu Xiaochang, 2017)

In summary, the working areas for commuters are along the Line 2, Line 9 and Line 10 from the residential areas to city center. The working areas of commuters are mainly concentrated around the metro stations such as North Sichuan Road, Pudong Avenue, Dongchang Road, Shangcheng Road, Century Avenue, Pudian Road, Huamu Road, Jinke Road, Yuyuan, Dashihe, South Huangpi Road, Middle Huaihai Road, South Shanxi Road, Changping Road, Zhenbei Road, Jiangsu Road, West Yan'an Road, Hongqiao Road, Yili Road, Yishan Road, Guilin Road, Caohejing, Zhaojiabang Road, Shanghai Railway Station, etc..

4 TYPICAL FEATURES OF METRO COMMUTERS

4.1 BUS-TRANSFER-METRO COMMUTERS

The Shanghai transportation card is not only available to the subway, but also available to the bus. Therefore, a particular groups who firstly take the bus and transfer metro during the commuting traffic are found in this research. This kind of data account for 20%, which is considerable. In other words, in 100 metro commuter, there are 20 people need to take the bus to transfer subway during the process. It is particularly useful to study the relationship between the bus lines and metro networks, which can provide essential and specific spatial strategies for the development of Shanghai metro systems.

This research classifies the data during the morning rush hours (from 7:30 to 9:30), if one certain transportation card with same ID has a piece of record of bus ride before that of metro one, the owner of this card is 'Bus-Transfer-Metro' commuter, as shown in the table 5 and the figure 10. It is difficult to collect the exact time when the commuters leave the bus, because the commuters will not swipe the card before getting off the bus. However, for all the commuters, they will spend the time in commuting traffic as little as possible, so they will choose the nearest metro station from the bus stop where they get off the bus. Therefore, the time consumption after getting off the bus and before entering the metro station will be ignored. That is to say, the time consumption of commuting traffic by bus is the difference between the time of the time of getting on the bus and entering the metro station.

Card ID	Bus Stop Name (getting on)	Bus Stop Name (getting off)	Time (getting on bus)	Bus commuting time	Metro Station Name (getting on)	Metro Station Name (getting off)	Time (getting on subway)	Time (getting off subway)	Metro commuting time
1000 5287 06	Changyi Road Luoshan Road	Lujiarui	8:17:07	16 mins	Lujiarui	Jiangsu Road	8:33:10	8:53:54	20 mins
1000 5262 00	Jianlian New Town	Lianhua Road	7:36:26	36 mins	Lianhua Road	People's square	8:12:55	8:44:13	32 mins
.....

Table 5 –The record of transferring to subway from bus for metro commuters (Source from: Liu Xiaochang, 2017)

Figure 10 – The diagram of bus-transfer-metro commuters (Source from: Liu Xiaochang, 2017)

This research indicates some typical features of bus-transfer-metro commuters: Firstly, approximately 50% of this kinds of commuters spend about 6 minutes to 18 minutes in commuting traffic of bus, and around 75% of bus-transfer-metro commuters spend less than 30 minutes in commuting traffic of bus. Secondly, as shown in the figure 11, it should be noted that there are 11000 bus-transfer-metro commuters who spend 10 minutes in bus ride before the subway ride in the morning rush hours. Thirdly, with the time consumption of bus commuting increasing from 10 minutes, the amount of bus-transfer-metro commuters sharply decrease, which shows that the commuting mode of selection for the bus-transfer-metro commuters largely depends on the time spent in the bus commuting traffic.

Figure 11 – The relationship between the time spent in bus and the quantity of bus-transfer-metro commuters (Source from: Liu Xiaochang, 2017)

4.2 BUS-TRANSFER-METRO RATE – TAKING THE LUJIAZUI METRO STATION AS AN EXAMPLE

Bus-transfer-metro rate is a ratio to study the situation of bus-transfer-metro commuters in one certain metro station. The bus-transfer-metro rate is the percentage through the quantity of the bus-transfer-metro commuters in a certain metro station dividing by the whole quantity of commuters in the metro station. For example, the bus-transfer-metro rate of metro station A, the rate is: the quantity of bus-transfer-metro commuters in metro station A / the whole quantity of commuters in metro station A. Based on the statistic, there are six metro station with relatively high bus-transfer-metro rate (>50%). They are Lingang Avenue

(86%, 215/250), Xinchang (66%, 1551/2350), Shenshe Road (59%, 6612/11207), Lianhua Road (56%, 9921/17175), Fanghua Road (55%, 4270/7764), and Lujiuzui (55%, 3281/5965), as shown in the figure 12.

In the figure 12, the metro stations with relatively high bus-transfer-metro rate are located in the periphery of city center and the suburban areas, because the level of service of metro system in the periphery of city center and the suburban areas is further lower than that of metro system in city center. As for the commuters who live in the peripheral urban areas, the time consumption on foot from their homes to metro station far go beyond their tolerances. Therefore, they select the commuting mode of bus-transfer-metro.

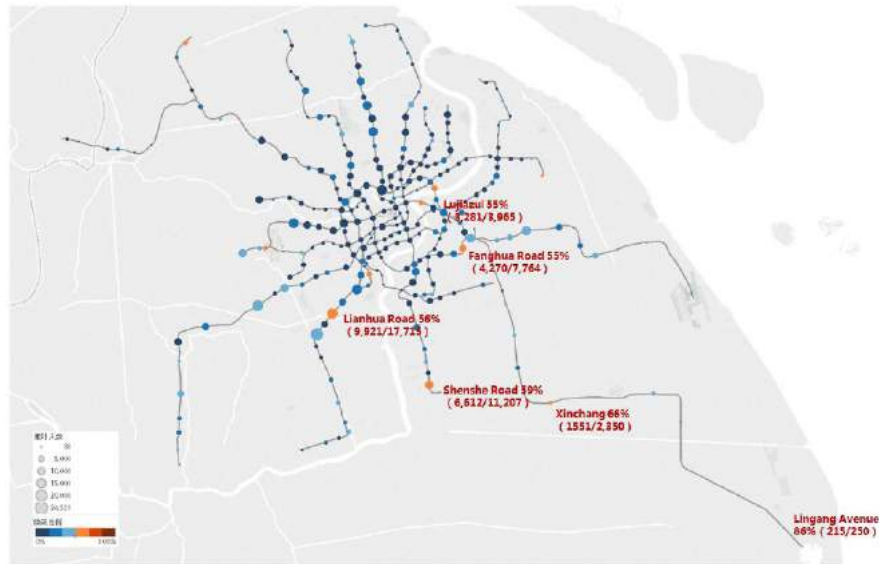

Figure 12 –The spatial distribution of the metro stations with higher bus-transfer-metro rate
(Source from: Liu Xiaochang, 2017)

Beyond expectation, Lujiuzui metro station which is located in the city center has high bus-transfer-metro rate with 55%. This research tracks the 55% commuters through their transportation card ID to find the sources before entering into the Lujiuzui metro station. It can be concluded that: in the morning rush hours, bus-transfer-metro commuters mainly take Bus No.85 (836), Bus No.971 (325), Bus No.799 (305), Bus No.81 (201), and Bus No. 774 (139) to Lujiuzui metro station.

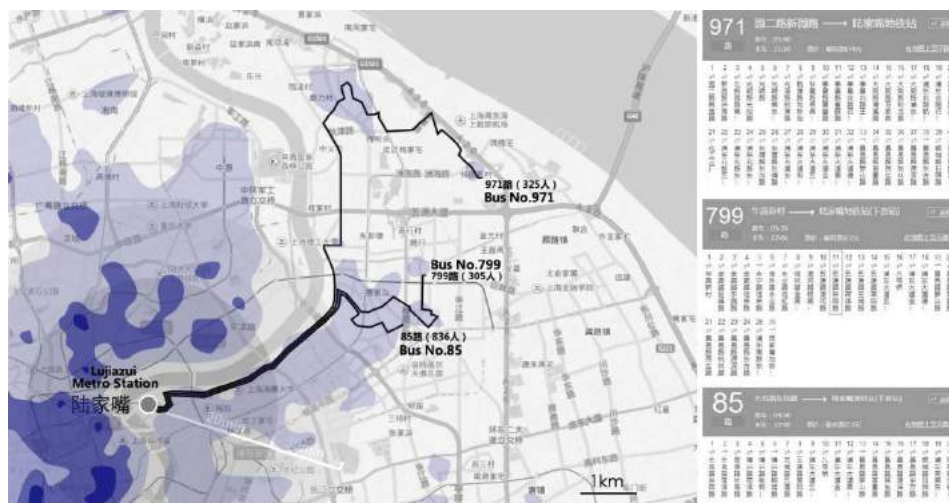

Figure 13 –The spatial distribution of Line Bus No. 85, Bus No. 799 and Bus No. 971
(Source from: Liu Xiaochang, 2017)

From the spatial distribution of the bus lines, some features can be found. Firstly, these buses lines overlap in the Pudong Avenue along the Huangpu River. Secondly, there are massive communities along the

overlapping line such as Jinbang Workers' Village, Longju Huanyuan, Luoshan Workers' Village, Haifang Workers' Village, Linggao Community, Yangjing Garden Town, Huixu-Yayuan, Xishan Community, Haiyuan Community, Meishan Community, Laoshan Workers' Village etc., as shown in the figure 14.

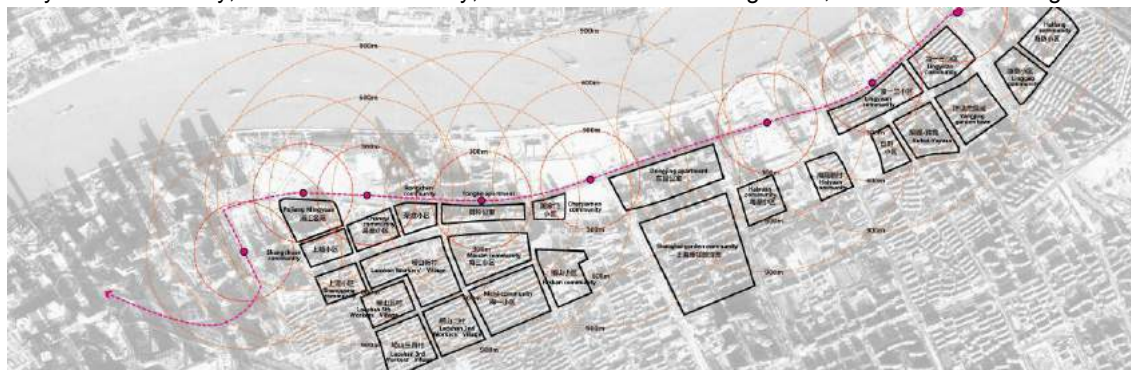

Figure 14 –The residential districts in the buffer of bus stops of Line Bus 85, 799 and 971
(Source from: Liu Xiaochang, 2017)

Meanwhile, based on the interviews of some commuters from these three lines, they gave the similar answers why they chose the bus lines before entering the Lujiazui Metro Station. They said: “We are living the residential areas along the Pudong Avenue. It will take about half an hour, if we walk to the nearest metro station which are about 2 kilometers away from home. You know, 30 minutes are very precious. We want enough time to sleep, especially in the morning. We prefer to spend this 30 minutes in the bed rather than in the way to the metro station. Obviously, we will take bus to metro station. The bus lines are well connected with the Lu jiazui metro station.” According to the contents of the interviews, it is lack of accessibility into the metro system for the commuters who live along the Pudong Avenue that is the main reasons why Lujiazui Metro Station located in the city center has the relatively high bus-transfer-metro rate in the morning rush hours.

Therefore, based on this interesting phenomenon, some suggestions like planning a new metro line under Pudong Avenue can be proposed, which will improve service level of subway along the Huangpu River and increase the accessibility into the metro network for the areas along the Pudong Avenue, especially the residential areas. This proposal is demonstrated in the planning and construction of Shanghai rail transit from 2016 to 2020, a new metro line named No.14 will be constructed.

5 SUMMARY

The approaching Big Data era provides totally systematic and quantitative methods. Traffic and passengers flow can be precisely described and analyzed based on the whole sample statistic and database. Although there are still shortages like the metro stations analyzed are not the exact working places and homes of commuters or the data of POI and housing price don't have extremely high precision and so forth, it is an efficient analysis method of research the commuting behaviors based on the same platform including the function, housing price and urban spatial structure. Furthermore, through studying the commuting behaviors, the features of commuting behaviors can be the reasonable and reliable basis of some specific and precise suggestions for the decision-making and policy-setting of metro development in the future.

For the structure of jobs-housing spaces in Shanghai, the working places for metro commuters are along the Line 2, Line 9 and Line 10 from the residential areas to city center. The areas where the metro stations named People's square, Lujiazui, Jing'an Temple, Xujiahui, East Nanjing Road and Zhangjiang High-tech Park are located are the typical working places for commuters.

Meanwhile, owing to the moderate commuting time consumption, moderate housing prices and sufficient facilities related with residence, the residential places for metro commuters are along the Line 2 from the

city center to the east and west direction, along the Line 1, Line 3, Line 7, Line 8 and Line 11 from the city center to the north and south direction. The areas where the metro stations named Xinzhuang, Jiuting, Lianhua Road, Shanghai South Railway Station and Tonghe Workers' Village are located are the typical living places for commuters.

In all the metro commuters, there are 20% bus-transfer-metro commuters. For the bus-transfer-metro commuting mode, 75% of the time consumption of bus ride is within 30 minutes. The metro stations with relatively high bus-transfer-metro rate are located in the periphery of city center and the suburban areas, because the level of service of metro system in the periphery of city center and the suburban areas is further lower than that of metro system in city center. As for the commuters who live in the peripheral urban areas, the time consumption on foot from their homes to metro station far go beyond their tolerances. Therefore, they select the commuting mode of bus-transfer-metro.

Besides, like some typical cases like Lujiazui metro station located in the city center with similarly high bus-transfer-metro rate, it can be concluded from the precise and quantitative analysis that the areas along the Huangpu River are lack of accessibility to metro system so that the commuters have to take bus to the nearest metro stations and transfer subway to the working places. Therefore, the bus lines along the river play an important role in commuting traffic for solving the "last one kilometer" problems. The features of commuting behaviors can be the reasonable and reliable basis of some specific and precise suggestions for the decision-making and policy-setting of metro development in the future.

1 INTRODUCTION – THE CONTEXT OF THE STUDIES

In Brazil, since the promulgation of federal constitution, in 1988, and the City Statute, in 2001, the interests about “participatory planning” became not only a desire but a law, determining that any decision in territorial planning should be constructed considering collective values. Notwithstanding, we observe lack of methods to support the intention, and in most cases a misunderstood about the sense of participation. The idea of “participation” is understood as to “win the game”, and not to choose alternative futures that are more adequate to social, economic, environmental and cultural context. In this sense, the proposal of Geodesign (Steinitz, 2012), based on a framework that establishes steps to be followed, is a very robust methodology to support opinion making and to arrive to decision making.

We conducted three case studies in Minas Gerais, Brazil, in different scales and challenges, but all of them in areas with conflicts of interests. The case study in regional scale was Quadrilátero Ferrífero, an area of 1.000.000ha characterized by historical cities, environmental resources, axis of urban growth and the most important economic area in the state due to mining activities of gold and iron ore. The case study in district scale was Pampulha, an area of 10000ha in the city of Belo Horizonte, projected by Oscar Niemeyer that had just been nominated as Unesco’s heritage because of its unique modernist architecture and urban landscape. The goal was to discuss risks of not appropriated changings in the landscape, especially urban densification, damaging the harmony in visual axis. The case study in local scale was about a slum, an area of 25ha, with the goal to face complex problems and to give support to legal regularization, considering budget restrictions, fast changing realities and needs in urban and environmental improvements. All case studies demanded studies about systems that represented vulnerabilities and attractiveness in the areas, costs and targets to be respected and achieved, and definitions about groups of interests from different sectors of society.

The Geodesign methodology was proposed as an alternative to plans generally top-down oriented, time consuming and not able to achieve sufficient participation and community consensus on priorities. In parallel with the use of Geodesign Hub, we applied geovisualization tools proposed by Geoproeia (UFMG) to create a collaborative environment and enhance stakeholders’ participation, based on City Engine (ESRI) and Grasshopper+Rhino 3D simulations. We also applied possibilities of interoperability with other platforms, using an App from ViconSaga Web (UFRRJ and UFRJ).

The methodology is based on web platforms and the principals of social media in the sense of sharing information, constructing proposals and arriving to decisions. Geodesign hub is a platform to make people working together. The visualization and interoperability applications amplify the conditions in participatory process, as support to opinion making. The experiences proved to be very effective and robust, as participants started to understand that the objective was not to win the game, even though they played to win, but to construct together the most acceptable alternatives. The main outcome was the capacity to transform data into information and information into knowledge, in a sense that is been called “empowerment”, resulting in more reflexive and critical citizens.

1.1 THE STUDY AREAS

We had the opportunity to develop three case studies applying the framework of Geodesign in Brazil, more specifically in Minas Gerais, a state in the center of the country known by its historical cities, the first network of baroque cities, developed from 1720-1800, recognized as the base of Brazilian culture. The region is also known as the base of modernism in Brazil, since the construction of the first city from republican and positivist value, Belo Horizonte, in 1897. As an evolution from positivism to modernist stile, in Belo Horizonte received the works of Oscar Niemeyer, a very important Brazilian architect. Niemeyer

projected a neighborhood named Pampulha, his very first important project, declared UNESCO cultural heritage in 2016.

Belo Horizonte is inserted on Quadrilátero Ferrífero (Iron Ore Quadrangle), known by the production of mining resources (gold, precious stones and iron), representing the most important economic base of the state, and one of the most significant in Brazil. Among the importance of architecture and urban network, mining activities and all the economic results related to it, the area is also characterized by a notorious landscape, genius loci of the state – a landscape of mountains in which the main rivers of the state are born, with expressive vegetation cover: forests and “campo rupestre”, a native crop field that exists only in that biome, because of iron area.

In this complex territory, characterized by cultural and heritage interests (from baroque to modernism), economic interests (mining activities) and environmental values (mountains, river sources and native vegetation), as most medium and large cities in Brazil, there are also slums (they are generally around area of Belo Horizonte has 5 million inhabitants and the Quadrilátero Ferrífero has 3.5 million inhabitants. The three areas mentioned – Quadrilátero Ferrífero, Pampulha and the slum Maria Tereza were the three case studies in Geodesign. Quadrilátero Ferrífero is a region composed by Belo Horizonte and more 27 cities, in a territory of 12600 km², around 140 x 140 km; Pampulha is a region in Belo Horizonte of 250 thousand inhabitants in an area of 50 km², and Maria Tereza is a slum also in Belo Horizonte, that in 2010 had 400 inhabitants in 0,3 km² (Fig. 1).

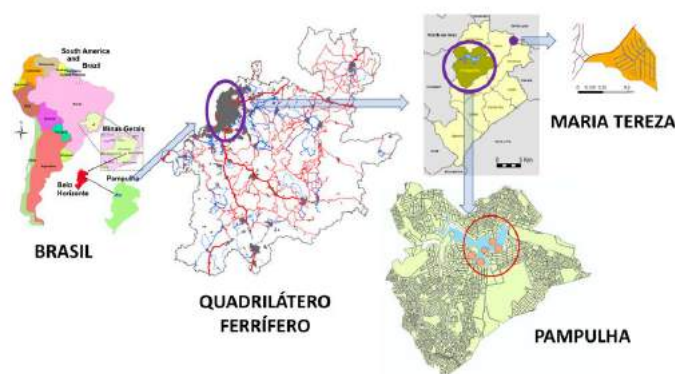

Figure 1 – Location. Source: The authors.

1.1.1. SLUM CASE STUDY – MARIA TEREZA

According to IBGE 2010 Brazilian latest demographic census, around 11.4 million people live in the 6.329 favelas (slums) identified in 323 of the 5.567 municipalities in Brazil. A favela is characterized by an illegal occupation of someone else's vacant land (public or private), lacking at the beginning public essential services such as sewers, waste management, and public facilities, and usually showing an organic morphology and dense built environment with little open space and green areas, usually on improper sites, steep slopes, flood prone areas or even environmental protected areas where the market can't go.

Illegal settlements may have very similar urban infrastructure and housing conditions compared to slums, only they occupy land which has been previously divided into parcels (lots) which have been sold in the informal market, meaning that families who occupy that land paid for it and feel they are owners, even though they don't have legal ownership documents. Being implemented without going through regular planning permit procedures, they do not follow official design criteria (minimum lot area, minimum street width, maximum slope and so on), do not obey environmental constraints (steep slopes, forested areas, springs and water bodies, flood hazard areas, and so on) nor have the basic urban infrastructure that, according to Brazilian urban legislation, is due to real estate developers to implement.

Belo Horizonte has 186 favelas classified as ZEIS – Special Social Interest Zones and 29 illegal settlements classified by AEIS, by the local Master Plan and Zoning, which means they are supposed to stay where they are and be subjected to upgrading programs. Aiming at urban and environmental improvements, as well as legal ownership regularization and socioeconomic community development such as jobs and income generation, these plans, based on a traditional thematic mapping method for both data

collecting/analysis and proposal strategies, have been, however, strongly criticized for being too technical, too time consuming (usually lasting three to five years), expensive and top-down oriented, lacking sufficient participation and the necessary strategic approach to achieve community consensus on priorities under severe budget restrictions to face very complex problems and fast changing realities.

In August 2016, a three-day planning workshop was conducted by then professors from UFMG GIS Lab and technicians from the municipal administration, at Belo Horizonte City Hall, using the Geodesign framework and geovisualization tools to create a collaborative environment and enhance stakeholders' participation for the development of a PRU for the Maria Tereza Neighborhood. (Fig. 2).

Figure 2 – Maria Tereza case study. Source: The authors.

1.1.2. PAMPULHA CASE STUDY

The recognition of the landscape value and the interest on preserving the essence of the place are quite recent in Brazil. Just from the City Statute (Estatuto da Cidade), law passed in 2001 (Brazil) and the approval of the Seal of the Brazilian Cultural Landscapes from 2009 (IPHAN) the landscape protection has been mentioned for the first time. However, there is still no instrument to guide the identification, classification, characterization and to propose sustainable manners to occupy and preserve the landscape. Our studies aim to understand, prospect and develop methodological possibilities, supported by geoprocessing technologies, more specifically the Geographical Information System and Spatial Assessment Models, to start the process of identification, planning and management of the landscape. The visualization and the decisionmaking processes regarding the landscape management are assessed using simulation models and field of view representations and analysis.

We chose case studies of urban area and of remarkable landscape, in different scales of approach. Pampulha was selected for zone scale. It is an area of interest for the study because it has recently received the status of World Heritage Site by UNESCO due to the presence of Oscar Niemeyer's work – a modernist set of buildings and surroundings designed in the 1940s. It faces significant growth and transformation of the area and the risk of loss of remarkable values could be observed. The revision of the Master Plan is required, managing the conflicts of interest. (Fig. 3).

Figure 3 – Pampulha case study. Source: The authors.

1.1.3. IRON ORE QUADRANGLE CASE STUDY

For the regional scale, presenting environmental and anthropized landscapes, the study case is about the Iron Quadrangle, area of remarkable landscape and that translates the genius loci of Minas Gerais state. The first travelers got to Minas Gerais led by the mountain chains of the Iron Quadrangle, where mineral resources were found and the first cities were established, which nowadays composes the Brazilian historical heritage. However, there is a dynamics transformation in the cities network, in the environmental values and in the remarkable landscape, due to the mining activities and the expansion of the urban areas.

The Quadrilátero Ferrífero presents the most important urban network in central area of Brazil, with 95% of population in urban areas, that grow together with mining activities in the landscape. It presents conflicts of interests related to environmental protection (as it's an area of water resources with headwaters and expressive vegetation cover), economic activities (mining exploitation and the spread of urban territories), cultural and scenic values (it's an amazing setting of beautiful mountains and presents historical cities from the XVIII century). (Fig. 4)

Figure 4 – Quadrilátero Ferrífero case study. Source: The authors.

2. GEODESIGN METHODOLOGY

The Geodesign, a spatial analysis methodology proposed by Steinitz (2012), is a framework that aims to establish the forms of participation of different stakeholders in the decision-making process. The methodology derived from Geodesing is based on a representation of the landscape by several variables and on the creation of a georeferenced database, which enables the use of spatial assessment models. It consists of modeling steps aimed at characterization, process analysis, change analysis, calculation of impacts, and adjustments in decision making concerning land use organizations and environmental arrangements. Along the process, it is created the maximization of the common consent, having in mind that there is no absolute consensus, but it is possible to manage a collective decision. The main characteristic of the methodology are iterations, collective revisions and shared decisions (Goodchild, 2010, Campagna, 2012). It is a requirement that the actors involved understand the process, which justifies investments in clear visualization of the information to support the decisions.

2.1. THE STEPS IN GEODESIGN METHODOLOGY

The Geodesign framework (Steinitz, 2012) is based on 6 steps, divided into the goal do construct assessment and to support intervention. Each of these 2 goals are achieved throw the production of data, transformed into information and producing knowledge. The first iteration is organized to understand the area, answering “why” it must be studied; the second is a review of the methods and is planned to answer “how” it should be studied, and finally the third iteration is to perform the study answering “what”, “where” and “when” the proposals can be applied. (Fig. 5).

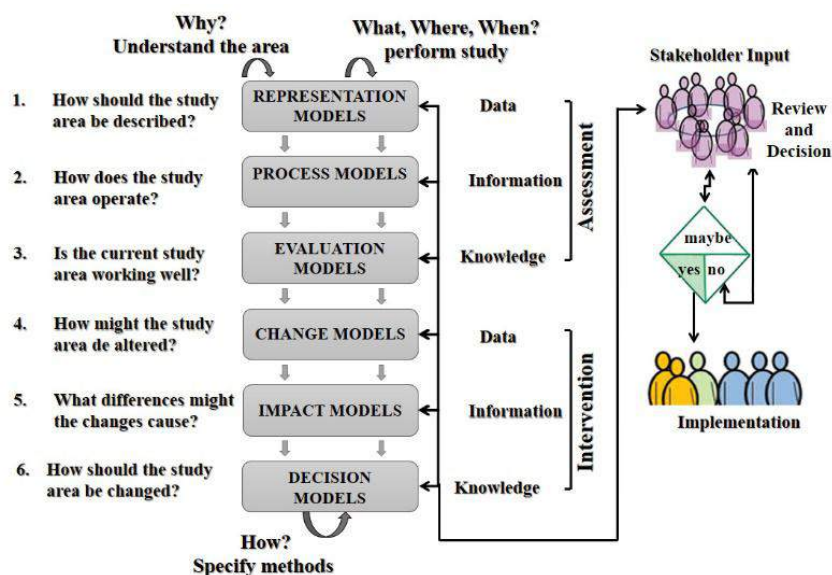

Figure 5 – Geodesign framework. Source: Steinitz, 2012.

2.1.1. STEP 1 - HOW SHOULD THE STUDY AREA BE DESCRIBED IN CONTENT, SPACE AND TIME? THE USE OF REPRESENTATION MODEL.

To propose the Representation Models the user must capture the essence of the place: its main characteristics, considering the vulnerabilities and the attractions to change. In all case studies data were organized and produced to represent the main characteristics of the areas, considering its *genius loci*, its demands, vulnerabilities and attractiveness.

In the case study of Maria Tereza (the slum) the main objective was to plan a better distribution of the many needs to requalify the area, that's why the representation models were organized with data about existing infrastructure, the land use, risks, environmental conditions and the commerce and services in the area. In the case study of Pampulha the main goal was to propose a plan to manage the growth of the area (densification) resulted by the very good existing conditions and to the increasing interests due to the recognition by UNESCO, but also in risk of losing this quality due to the changes. In the case study of Quadrilátero Ferrífero a big effort was done to produce new data, as the area is very complex, what resulted into inedited maps from the territory.

2.1.2. STEP 2 - HOW DOES THE STUDY AREA OPERATE? PROCESS MODEL.

Besides the study of main component variables that favor the space transformation, as catalysts variables, in all case studies it was important to investigate the process between the variables, which results in the characteristics of the spatial composition. The Process Models have the goal to transform data into information. In practical sense, it is the construction of distribution surfaces that tells about the characteristic of each spatial location according to the theme of interest.

In each situation an algorithm of distribution, concentration, combination of variables or neighborhood studies was applied. According to the objectives of the distribution surface we used Kernel Density; Delauney and Triangulated Surface followed by the calculation of slope; Multicriteria Analysis when the goal was to apply weighted sum of variables; Combinatory Analysis when the goal was to establish some compositions in the place; Buffer zone to specify the areas of influence, and so one. (Fig. 6).

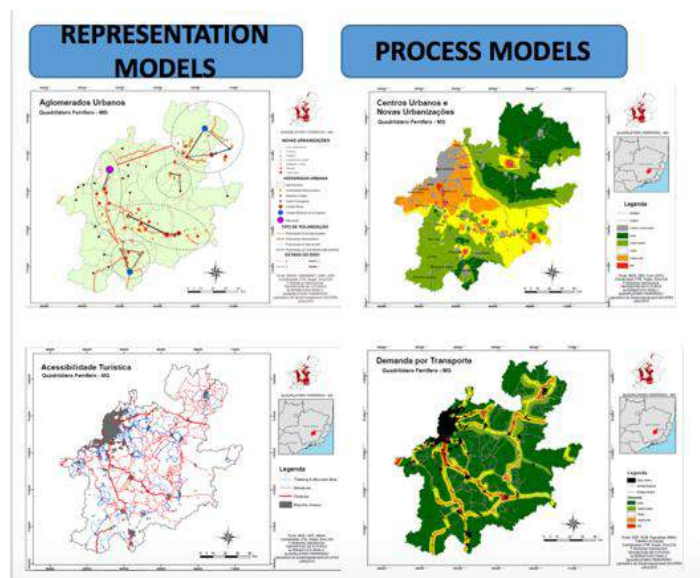

Figure 6 – From Representation to Process Model. Source: The authors.

2.1.3. STEP 3: IS THE CURRENT STUDY AREA WORKING WELL? EVALUATION MODEL.

The Evaluation Model transforms information produced by process model into knowledge. It means that after understanding the main vulnerabilities and attractiveness, it's possible to present a base to support the proposals of the projects and policies to the area. This knowledge of the possibilities and limitations of the place is described as feasible, suitable, capable, inappropriate to receive projects and policies of that theme, but also mapping the area where the resources already exists. These models are the base to construct proposals, and are the systems the participants receive to work with in the workshop meeting. They must represent reality to work as basis to the discussions and the construction of proposals. (Fig. 7).

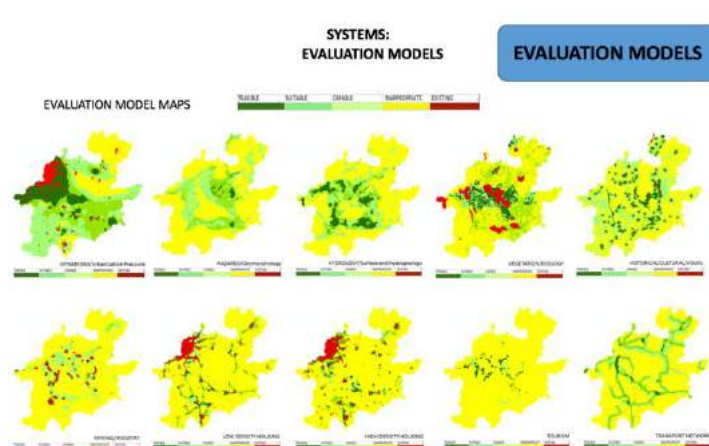

Figure 7 – From Process to Evaluation Models. Source: The authors.

2.1.4. STEP 4: HOW MIGHT THE STUDY AREA BE ALTERED? CHANGE MODEL.

Change models are the production of data in the phase of proposing interventions. They present data about the alternative futures proposed by the participants of the workshop. The participants of the workshop construct proposals of policies and projects to the area, according to each system. The proposals are presented in the format of diagrams. (Fig. 8). We observed difficulties presented by the participants in creating a relation between reality, mental maps and diagram designed. In some cases, people lost the sense of location, proportion and dimension while drawing their diagrams. As a result, we decided to face this issue improving possibilities of visualization as support to better understanding the process. The discussion of this aspect is the main contribution of this paper.

2.1.5. STEP 5: WHAT DIFFERENCES MIGHT THE CHANGES CAUSE? IMPACT MODEL

The coordinators must also prepare studies about targets and costs. Targets can be understood as minimum values to be achieved in area to each system or limits of reference as maximum areas of proposals to each system (Fig. 10). To costs, the coordinator can give a value in hectare to deploy each system or theme. According to the matrix that are constructed, the user can obtain in dynamic cartography the result of each diagram that he proposes, because the impacts are calculated. It's presented in new maps simulating changes, but also in graphics that analysis how much it will cost and if the user achieved the target that was established.

2.1.6. STEP 6: HOW SHOULD THE STUDIED AREA BE CHANGED? DECISION MODEL.

The meeting is organized to have rounds of proposals, going from 6 to 3 groups, and from 3 to just one group. The logic is the maximization of consensus. If it's not possible to arrive to a final proposal in one iteration (remember that the first iteration has the goal to answer "why" we are developing the case study), a second iteration must be done, to review the models and to answer "how", and then a third iteration can

be conducted to answer “where, what and how” the proposals can be implemented. In case study of Pampulha we could do 3 iterations, but Maria Tereza and Quadrilatero case studies we still should propose the reviews and the other iterations. (Fig. 11).

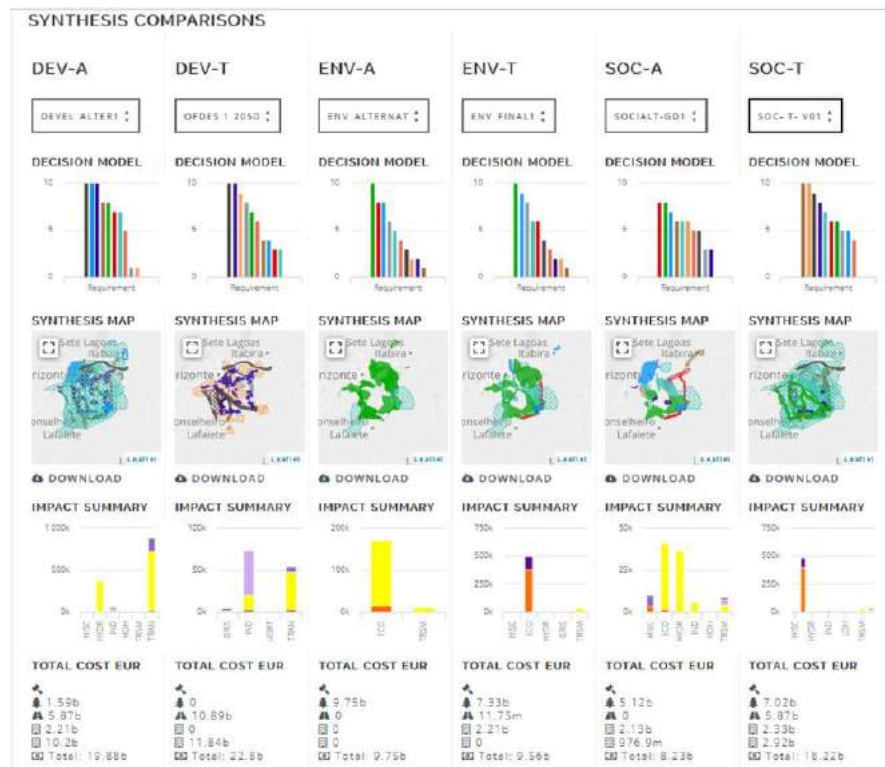

Figure 11 – The designs proposed and their performances. Source: The authors.

3. THE CONTRIBUTION TO SUPPORT OPINION MAKING IN DIFFERENT SCALES

While conducting the workshops we were very interested in analyzing how much Geodesign framework could really support opinion and decision making in very complex situations, characterized by conflicts of interests. Participatory planning in Brazil is still a goal to be achieved, and studies to support the processes must be developed. The Federal Constitution, approved in 1989, declares the obligation to involve citizens in all decisions about territorial planning, considering from land use to urban planning, but it was only in 2001, with the City Statute, that the first political instruments were approved.

We observe that the laws were important but not efficient to promote participation. Master Plans are voted in public meetings, with free access to citizens and their representatives, but the fact that they vote doesn't mean they are really participating and been able to be part of the process. There is a lack in comprehension and visualization of the process (Zyngier and Moura, 2016). In the 3 case studies, we were very interested in controlling if participants were really understanding the steps and were really learning from the experience.

3.1. THE SCALE OF A REGION

In Quadrilatero Ferrifero case study we faced the difficulties in making people understanding the relation between reality and drawings, to understand the dimensions, to visualize alternative proposals and to have a common base to develop a dialog. It was the most difficult case study, because the goal was to promote participation based on defensible information and knowledge, and not only personal opinions or political opinions.

The main aspects were:

- The drawings and proposals were all completely out of scale: the users were constructing diagrams that were bigger than any other existing land use. They arrived at the point of constructing a diagram that covered almost the whole area, that has a media of 140 per 140 km.
- The users had lack of capacity of spatial location. Even using base maps, they had difficulties to understand the territory. The relation between reality, mental maps and digital maps proposed was very generalist. As a result, sometimes they were not accepting diagrams they believed were in conflict, but if they could understand better spatial references and scale they could see they were not in the same position, and the discussion could be: how far can a proposal be from another?

Some participants, as activists, didn't want to accept evaluation models proposed by others, even though the responsibility for each evaluation system was in charge of a professor from the theme. In this case, a process to promote visualization could be very interesting, to make people understand the construction of representation, process and evaluation models, so that they could recognize that the evaluations presented were sufficiently generic but also detailed to contain all their proposals and needs.

The lessons learned in this case study resulted in studies about visualization and interoperability that were tested in other case studies, and that are been in the research interest of the group. From this case study, it was developed a tool to facilitate the download and upload of the diagrams, to be seen in any other software. As a contribution to the Geodesignhub, we created a tool to promote interoperability, that could download the diagrams and designs and upload in any other application or visualization tool, as GoogleEarth or other one. (Moura et al, 2016b). (Fig. 12).

Figure 12 – Interoperability tool. Source: The authors.

3.2. THE SCALE OF A ZONE

The case study of Pampulha was about a very known zone in Belo Horizonte, that was in the central of attention as it was candidate to UNESCO's title. As it was a very known area, people were more able to present opinions and criticism about Representation, Process and Evaluation Models. But we also understood that the scale of work was quite adequate to make people feel comfort about having a mental map of the territory and going directly to discussions.

The main aspects were:

- A scale of "Zone", composed by different land uses and land cover, but connected to a common reference, because the zone has its limits and genius loci quite well defined and recognizable.
- The presence of spatial elements that could give references about dimensions, proportions and locations (as the airport, the zoo, the lake, the university, the boundaries and so one);

As a result, it was easier to the users to construct the link between reality, mental maps and digital representation. With a clear comprehension of the place, they were more able to discuss their ideas. To improve this condition, we developed, after the first iteration, a tool to improve the comprehension about combining variables to construct Evaluation Models. The tool was based in dynamic cartography and tested in in two platforms: City Engine and Grashopper + Rhino 3D. (Moura et al, 2016a).

The idea was to make people understand the role of variables and their combinations, as references to construct Representation, Process and Evaluation Models. Improving their capacity of understanding the logic, they could contribute more with suggestions in those steps, as we had already observed that they

were very interested in that. The applications developed had the goal to make people test Multicriteria Analysis in dynamic visualization, changing variables and their weight in a composition of an Evaluation Map. (Fig. 13)

Figure 13 – Simulation of weights in Multicriteria Analysis – Rhino 3D and Grasshopper visualization facilities.
Source: The authors.

3.3. THE SCALE OF A NEIGHBORHOOD

In the case study of the slum, as we had already observed the importance of providing a mechanism that people could understand the dimension of the diagrams. The need was presented to the programmer of the platform GeodesignHub that added the condition of measuring automatically the dimensions of each line of the polygon while drawing the diagrams. It was really very useful, and the measuring mechanism was added to the hub from that case study. (Fig. 14).

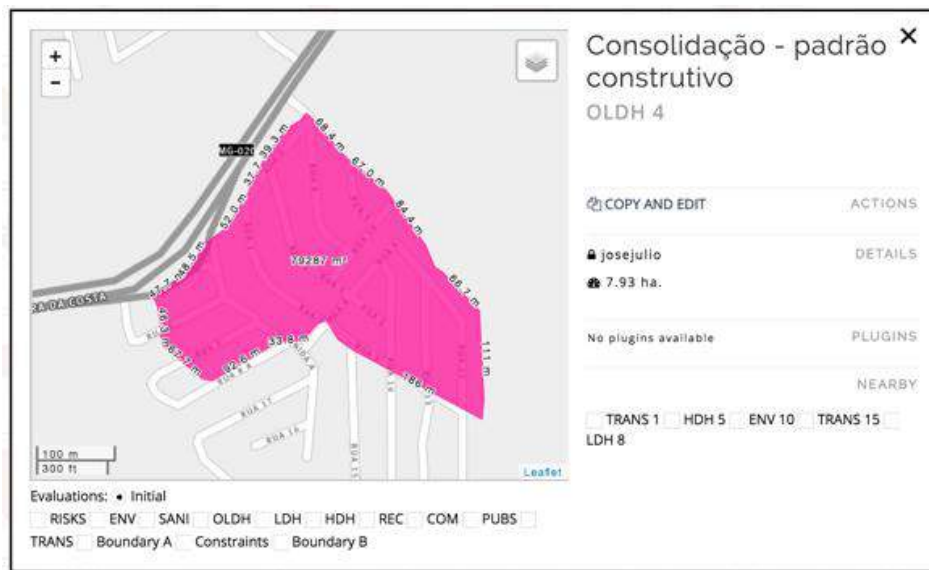

Figure 14 – Diagrams with measures. Source: the authors.

We also observed the importance of providing links from reality to mental maps and to digital designs. To keep the users always in touch with the idea of reality, a 3D Modeling, representing topography and the volumes of buildings was constructed, and during the workshop, while the participants were working in their proposals, a movie with the 3D representation was playing in the main screen of the room. We observed they used a lot the visual contact with 3D representation while they were projecting. (Fig. 15).

Figure 15 – 3D representation. Source: The authors.

To this level of local scale, neighborhood, the main aspects were: - The need to provide possibilities of automatically measure the dimensions, the faces of the polygons, because the lack of comprehension could result in diagrams very far from reality; - The need to improve the link between reality, mental map and digital representation while constructing the proposals;

4. CONCLUSIONS

Facing different scales of conducting a Geodesign workshop to discuss alternative futures to areas in conflicts of interests, we could contribute with tools and methods to improve the relation between data, information and knowledge. In some situations, we developed tools or procedure to contribute in the step of assessment (models of representation, process and evaluation), in others we contributed to the step of intervention (models of change, impact and decision).

This paper was more focused in situations that required improvement on visualization to face difficulties in constructing the between reality, mental map and digital drawings or projections. We also observe that different scales require more support of visualization tools to make that participants feel more secure to construct proposals. We may say that from this few case studies, that were not many but were very analyzed and observed, that the more the users don't connect with reality while taking part of Geodesign meeting, the more difficulties they will have to arrive to a common decision. Because sometimes, in the dynamic of combining diagrams and constructing a common design, they don't realize they are saying "no" to a proposal that is very similar to the one they say "yes".

The game of participation is very tricky because it has the risk to become just a game, in which people behave connected to the act of play and not connected to the act of using a tool to share opinions and decisions, even without realizing it. As much as we promote clear understanding of the steps and of the framework, the more these new digital and web-based tools can be used as a planning support system.

ACKNOWLEDGEMENTS

The Project “Geodesign and Parametric Modeling of Territorial Occupation: new resources of geotechnologies to landscape management of Pampulha Region, Belo Horizonte”, was made possible in part by the support of National Council for the Scientific and Technological Development, Call MCTI/CNPQ/MEC/ CAPES No 22/2014, Process: 471089/2014-1, and “Geodesign e Modelagem Paramétrica da Ocupação Territorial: Geoprocessamento para a proposição de um Plano Diretor da Paisagem para a região do Quadrilátero Ferrífero-MG”, Process 401066/2016-9, Edital Universal 01/2016 and to the Project “Programa Pesquisador Mineiro – PPM IX”, Process TEC – PPM – 00059-15. We kindly thank Carl Steinitz for all his support in Geodesign concepts and methods, and Hrishikesh Ballal for the technological support.

1 INTRODUCTION

The term Geodesign has recently emerged among spatial planners and GIS scholars identifying an approach to planning and design deeply rooted in geographic analysis and able to inform collaborative decision-making. As an integrated and multidisciplinary process, Geodesign includes project conceptualization, knowledge building, analysis, alternative design, impact simulation and assessment, decision-making, collaboration and participation, involving political and social actors and relying on scientific geographic knowledge support. The main innovation in Geodesign compared to previous similar approaches may be found in the extensive use of digital spatial data, processing, and communication resources, such as Information and Communication Technologies (ICTs) and GIS, which in principles may enable a more effective use of scientific and societal knowledge in planning, design and decision-making (ERVIN 2011). As claimed by several scholars, planning professionals and industry experts, the current technology may be considered mature enough to exploit the ICTs support in the planning practices, overcoming many of the barriers which until now have limited de facto the usage of new geographic information technologies. In addition, since the last decade a growing wealth of both authoritative and user generated spatial data resources has started to be freely accessible, slowly shaping into reality the concept of Digital Earth (GORE 1998). The latter can be considered a driver for the creation of a working infrastructure able to facilitate the diffusion of Geodesign methods for it substantially hinder the traditional issues of lack of digital data availability.

Currently, two major categories of spatial data resources may be considered suitable for Geodesign approaches, namely Authoritative Geographic Information (A-GI) from Spatial Data Infrastructures (NEBERT 2004) and spatial User Generated Contents (UGC), commonly referred to as Volunteered Geographic Information (VGI) (GOODCHILD 2007). These two types of spatial information are notably different in nature, but together they might foster advances in planning and design practices exploiting informed decision-making and eventually contributing to more sustainable development processes. Particularly, a subset of VGI, namely Social Media Geographic Information (SMGI), which is the information produced and shared through social media platforms, might enhance the opportunities to collect not only geographic information representing the current conditions of the study area but also the perceptions of users about spatial phenomena.

In the light of these premises, the authors present a critical review of their research findings on the integrated use of A-GI and spatial UGC in Geodesign. The remainder of the paper is organized as follows. In the next section a brief comparative review about the nature of A-GI, VGI and SMGI is given, outlining similarities and differences in production and use of these resources. Then the authors introduce a novel approach to SMGI analytics, proposing its application as support in spatial planning and design with reference to different case studies. The paper ends by a critical discussion on these results arguing for the relevance of SMGI for Geodesign and proposes issues for a research agenda in this field.

2 FROM AUTHORITATIVE TO SOCIAL MEDIA GI

Current advances in the ICTs, the Internet, and more recently, Web 2.0 technologies are affecting diverse domains of interest, increasingly channeling digital Geographic Information (GI) into daily life of a wider public. This phenomenon represents a paradigmatic shift in GI production and dissemination, as well as, in its contents and characteristics (ELWOOD et al. 2012), exploiting a new generation of digital GI. This wealth of public accessible digital GI may foster innovations in the spatial planning domain and most notably in Geodesign methodologies and practices, for the majority of information required to support analysis, design and decision-making is inherently spatial in nature. The major opportunities for innovation and development of methodologies emerge from the avalanche of “big” GI, which Web 2.0 technologies are making available to planners.

First of all, since the late 1990s, advances in Spatial Data Infrastructures (SDI) granted the access to digital geographic data, produced and maintained by public or private organizations for institutional or business purposes. Many countries worldwide started the development of SDIs in order to ease the access and sharing of spatial information between stakeholders involved in spatial governance and planning, in order to support decision-making. Along this stream, the implementation of the Directive 2007/02/CE, establishing a shared Infrastructure for SPatial InfoRmation in Europe (INSPIRE), is leading to the development of SDIs in Member States and Regions, granting the public access and reuse of available A-GI, according to common data, technology, and policy standards. INSPIRE addresses 34 key spatial data themes, such as administrative units, land-use, or buildings to name a few, which are of great value for spatial planning, inasmuch planners may proficiently take advantage of these spatial data resources to analyze and understand territorial system dynamics. Secondly, innumerable initiatives and platforms continue to thrive through the Internet thanks to continuous advances in Web 2.0 technologies, which support the production, collection and diffusion of UGC (KRUMM et al. 2008). Most of these contents may embed a geospatial reference, leading the transformation of the Web in a potential innovative source of spatial data (ELWOOD et al. 2012). This novel type of GI is commonly labeled as VGI, emphasizing the role of users, which act as volunteer sensors to collect and contribute information content related to the geographic world (GOODCHILD 2007). The concept of VGI encompasses a wide range of activities and practices, which in spatial planning processes may provide pluralist sources of both experiential knowledge from local communities and expert knowledge from professionals in a bottom-up approach. In the last decade, the use of VGI has been proven useful in many application domains such as emergency management, crisis management, environmental monitoring and spatial planning (POSER & DRANSCH 2010), as well as, participatory processes and Citizen Science initiatives (KNUDSEN & KAHILA 2012).

Lastly, the huge popularity recently gained by social media platforms and location-based social networks is fostering the diffusion of geo-referenced multimedia (SUI et al. 2012), or SMGI, among millions of users over the global Internet. SMGI may be easily accessed and shared by users, which become seamlessly producers and consumers of personal geo-referenced contents. This kind of information may be considered a special subset of VGI, inasmuch the voluntary production and sharing of GI is not the main purpose of the users. Any multimedia content or information with explicit (i.e. coordinates) or implicit (i.e. place names or toponyms expressed in natural language) geographic reference collected or produced by the users through location based social networks or mobile applications may be considered as SMGI. Moreover, depending on the production modes, SMGI may be actively or passively contributed: applications specifically developed or used to collect SMGI in participatory initiatives originate “Active SMGI”, while the harvesting of information from general purpose social networks (e.g. Twitter, Flickr, Instagram, Facebook) originate “Passive SMGI”. Despite the production differences, the major interest for spatial planning raised by SMGI concerns the opportunity to study not only the geographic facts on the

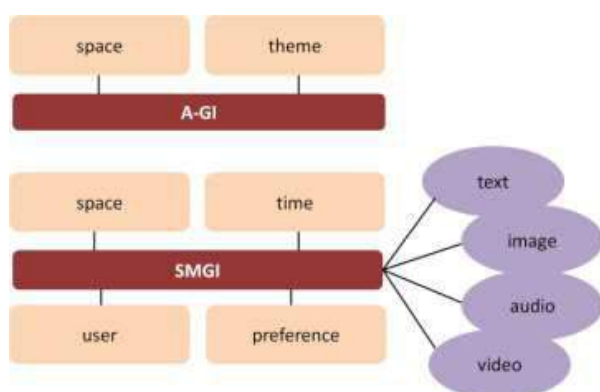

Earth surface but the people themselves, allowing investigations on humans' movements, patterns, behaviors, preferences and needs in social and urban systems.

Nevertheless, SMGI features Big Data nature due to the impetuous and fast cycles of production and consumption and, consequently, traditional spatial analysis methodologies and techniques may be not fully adequate to exploit the enclosed knowledge potential. Hence, new methods for the management of geographic Big Data, the integration with A-GI and for the development of advanced analytics are needed to enable the extraction of relevant knowledge to support Geodesign workflows, which would benefit of a broader and deeper pluralistic real-time understanding of the sense of places.

3 TOWARDS SMGI ANALYTICS

The wealth of georeferenced VGI and SMGI regarding facts, opinions, and concerns of users, freely accessible through the Internet, may strongly affect current Geodesign methods and practices, albeit several major issues may limit this opportunity. The main hurdles limiting a wider use of SMGI may be found both in the lack of user-friendly tools to collect and to manage huge and heterogeneous data volumes, and in the particular data model of this information, which barely may be processed through traditional methods without losing precious information. While the former issue is starting to be addressed by novel approaches offered by Computational Social Science, an emerging field concerned in developing methods to tackle the 'big data' complexity, the latter issue should require the development of advanced analytics methods able to manage the particular SMGI data structure. As a matter of fact, VGI and more notably SMGI are different from traditional vector spatial datasets, such as A-GI from institutional SDIs, with which though it may be integrated for eliciting useful knowledge useful for supporting spatial planning practices. Currently, traditional GI datasets feature a spatial and a thematic component, or dimension; conversely SMGI usually consists of a richer data model that includes both temporal and multimedia components (i.e. image, text, video, audio). In addition, SMGI owns a user dimension, which may include an identifier or other data useful to obtain information about the user's profile. From a semantic perspective this dimension is notably important and enables opportunities for further analyses. Moreover, the appreciation of a SMGI by the social network community, expressed through scores, stars, likes/dislikes, to name few, may increase the analytical dimensions supporting the study of popularity, preferences and opinions of users. The different data models of A-GI and SMGI are shown in Figure 1.

Consequently, any SMGI analytical framework should include not only traditional spatial analysis but also temporal, multimedia, and user behavioral analyses methods. These methods should be tightly integrated in order to fully take advantage of the knowledge potential embedded in data. From a Geodesign

perspective, the integration of these methods within a GIS application would be an enormous advantage, for GIS may be considered the common platform for the planning profession due to the increasing role played by maps and spatial data in expressing the knowledge in this domain.

Fig. 1: Differences between A-GI (up) and SMGI (down) data models.

In the light of these assumptions, the authors developed a framework for SMGI Analytics to exploit this new GI resource in order to enrich the knowledge base about the local context from a pluralist perspective, to be used in spatial planning and governance. To this end, the framework called SMGI Analytics, relies on the particular SMGI data model and includes several analytic methods, which may be applied in different use cases for investigating spatial and temporal patterns, users' movements, opinions and behaviors, as well as, preferences on places and events.

The SMGI Analytics framework developed so far consists of the following methods:

- Spatial analysis of users' interest: SMGI and its comments may enable to investigate the patterns of users' interest in space by density and clustering functions. The overlay with A-GI such as administrative boundaries, transport infrastructure, buildings or land uses, may offer useful hints to public authorities to understand which places are important to the local communities and how those areas are perceived by them. An example of such analysis is shown in Figure 2 (left), wherein popular public spaces for the local community are identified through the clustering of Instagram data.
- Spatial statistics on user preferences: collecting posts by spatial units may enable planners to analyze patterns in users' interest at different scales. An example is given in Figure 2 (right), where the hot-spot analysis of tourist satisfaction in Sardinia (Italy). Booking.com and TripAdvisor data enabled to study the distribution by municipality of positive user' assessments, and to investigate why different tourist typologies prefer certain areas or destinations rather than others.

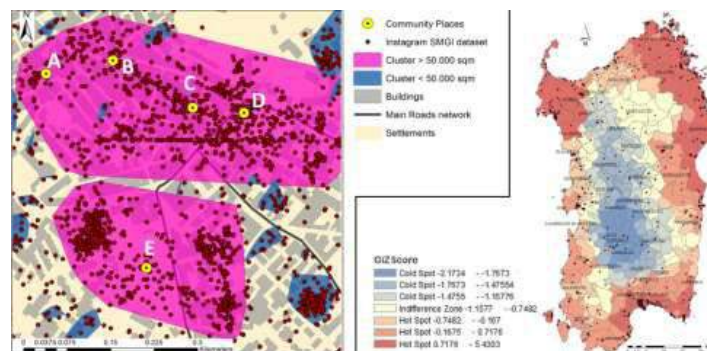

Fig. 2: Most popular public spaces in Iglesias by Instagram users (left). Tourist positive ratings in Sardinia (Italy) (right).

- Multimedia content analysis on texts, images, audios, or videos: this typology of analysis relies on simple or advanced texts analytics to extract useful information from texts (currently it is more difficult to automatically extract useful information from images, video or audio).
- Temporal analysis of users' interests: time reference is usually available for SMGI, enabling to study when specific regional destinations, urban districts, public spaces, or other services are used during different time periods. An example is shown in Figure 3, where the temporal trends of Instagram SMGI contributions are depicted in the Iglesias (Italy) to investigate the municipal temporal patterns.
- User behavioral analysis: querying SMGI by user enables to study users' behavior in space and time. This information can be also used to analyze, for example, if a public space is visited by tourists or by local people. Furthermore, this attribute can be used to apply user profiling techniques.
- Combination of two or more of the previous analyses: such combination may enable to elicit what people discuss in space and time, their behaviors and movements. Tightly coupling different analytics may ease the elicitation of further knowledge that may be proficiently used for spatial planning analysis.

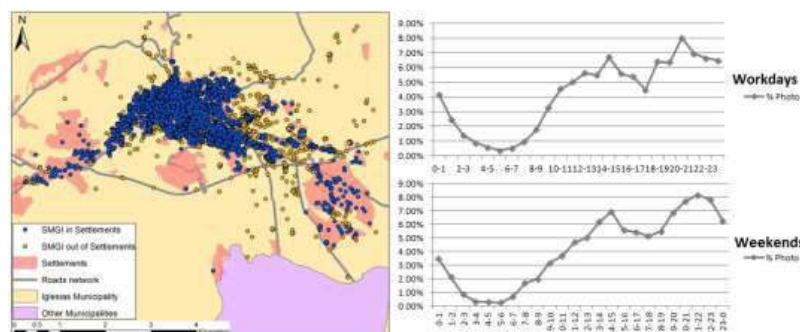

Fig. 3: Temporal patterns in the Iglesias municipality during workdays and weekends.

4 DISCUSSION: SMGI IN GEODESIGN

In the light of the opportunities offered by the SMGI analytics framework, two different categories of spatial data may thus nowadays be used in a complementary way during a planning process. Having as reference the Steinitz framework (Steinitz 2012), which may be used to apply the geodesign approach in spatial planning, in the assessment part (i.e. representation, process and evaluation models) SMGI can be used to complement the knowledge base given by traditional data sources. Unlike A-GI, which is traditionally used in planning, the user generated content may enclose experiential information that is usually missing in the official one, supporting a more pluralist vision of the geographical, social and cultural systems. On the one hand, the A-GI may offer official information about quantitative measurements, while on the other hand, SMGI, as expression of user preferences and behaviors may help in identifying particular social and cultural dynamics affecting the geographic context, as well as the community values and needs.

Operatively, A-GI and spatial UGC might be combined and processed during the process models in order to investigate how spatial phenomena evolve in time. Unlike A-GI which is usually produced and maintained through periodic workflows, SMGI provides updated and (near) real-time information, which may be used to feed predictive models and analyses aimed at identifying trends and phenomena affecting the area in the representation and process model. Moreover, thanks to SMGI analytics A-GI, VGI and SMGI together might disclose notable opportunities to evaluate the current situation of the geographic context, providing further knowledge concerning the preferences and needs of the community which may give valuable information for creation of socially-informed evaluation models. The integration of technical and experiential knowledge may represent a way to gain insights about social and cultural dynamics, which may help decision-makers to promote a constructive dialogue about the future of places, proposing informed alternatives through the help of local community's experience (MARCH 1994). Commonly, the local knowledge of the residents is considered exclusively as opinion in planning processes (FISCHER 2000), but the technical knowledge of the experts, providing only a part of the required knowledge basis, may be not sufficient to properly guide decision-making (LINDBLOM 1990). Hence, the spatial UGC may be fruitfully used to support the assessment of the impacts of the design alternatives, supplying useful knowledge about potential benefits and risks (RANTANEN & KAHILA 2009).

In addition, despite the experiential knowledge is difficult to articulate and convert into useful and explicit information (NONAKA & TAKEUCHI 1995), it can be used to stimulate the interaction among participants (TSOUKAS 2006). In this respect, planning should foster a communicative process, wherein the interlacing between expert and experiential knowledge is crucial in creating collective meanings and consensus (KHAKEE et al. 2000). The integration of A-GI, VGI and SMGI may support this process, providing knowledge about geographic and social context, which may affect the decision-making processes. Hence, the use of Social Media may be not only limited to integrating information about physical or social systems and their assessment, but also by using Social Media applications to support the intervention steps (i.e. change, impact and decision models) of a Geodesign study (STEINITZ 2012), Active social media platforms can be used to involve the local community both in the planning discourse and in the design (ERÄRANTA et al. 2015).

From a slightly different perspective, the novel Geodesign Hub (www.geodesignhub.com), could be considered a social media app for through it participants interact collaborating to the core part of collaborative conceptual design. Also in this case, all the data produced along the collaborative design studies can be saved, retrieved and analyzed – in a similar manner as with more usual social networking app -to understand both participants' preferences and behaviors, in this case not in the real world but in the design space. This way, both technical knowledge and experiential knowledge may be used in order to build a shared and sustainable development process for the territory among the different involved actors.

5 CONCLUSIONS

This paper discusses current innovation potential concerning the use of User Generated Content and more specifically, Social Media Geographic Information in Geodesign. Through selected examples, it is demonstrated how the analysis of social media data is inherently geographic in nature and may complement official GI produced by public authorities and by the private sector in order to represent, analyse, and assess the current state of geographical systems. Moreover, this new type of information represents a unique source of information to understand people preferences and needs which express the

requisites for future territorial transformation. In addition, social media platforms may be used actively to involve citizens in the planning and design discourse. Indeed for a widespread diffusion of SMGI analytics techniques in Geodesign a number of issues should be further investigated and better understood including the issue of privacy, the influence of individuals on the overall discourse both in terms of information, preferences, and contribution to decision-making; the representativeness of the sample; the further test of operative ways and protocols to collect and include this new and peculiar type of information resources in the construction of the Geodesign frameworks models both in the assessment and intervention part of the process. However, early research results may be considered very promising and this research domain is attracting a growing community of scientists, opening alleys for the development of more transparent, pluralist and democratic decision-making in Geodesign.

2 THE GEODESIGN METHODOLOGICAL APPROACH

Geodesign (GD) is a novel methodological approach to design and decision-making in urban and regional planning which is deeply rooted in the geographical sciences. While not strictly essential, Geodesign usually relies on extensive use of (geographic) digital methods and tools. In general, Geodesign can be defined as a process which integrates analysis, evaluation, design and decision support techniques using enabling technologies for planning built and natural environments. Given the complexity of the issues commonly involved in planning processes, Geodesign studies should ideally be carried out by multidisciplinary teams made up of design professionals, experts in the geographical sciences, information communication technology specialists, and, last but not least, members of the local community, who can provide invaluable knowledge and values to inform design and to help create consensus on decisions. From the perspective of methodology, Steinitz (2012) proposed an operational framework for Geodesign (GDF) which starts from detailed representation and analysis of the territorial context aimed at understanding territorial dynamics, in order to understand opportunities and risks of development, so informing the design of possible future states or courses of actions. The framework also includes assessment of potential impacts of change which should inform negotiation during the decision-making process in a collaborative and interactive manner. All the aspects of participation (e.g. knowledge building, collaboration, expressing values and interests, mediation, negotiation, consensus) which inform different participatory planning models (e.g. advocacy planning, transactive planning, communicative) (Khakee, 1998) may potentially be included. However, a Geodesign process is never the same: it should always be tailored to the local context through meta-planning (Campagna, 2016a). Thus, participation may assume many different facets in its application to local processes.

Implementation of Geodesign in spatial planning at various scales and within different contextual settings for decision-making has been tested by Steinitz in many case studies (among them Rivero et al 2015, Nyerges et al. 2016, Campagna et al. 2016), based on his framework. The GDF is structured in six models: the first three models, constitute the assessment phase, describing the current conditions of the territorial context and their possible evolution without new actions, while the last three models, constitute the intervention phase, which aims to identify how the study area should be altered in order to improve the current conditions if needed.

More specifically the Representation Model (RM) describes the study area in its current state, the Process Model (PM) identifies and analyses the possible evolution of the territorial context with no interventions (i.e. the do-nothing alternative), while the Evaluation Model (EM) assesses the identified processes in order to find possible risks and opportunities for future change. Then, in the assessment phase, a Change Model (CM) is built to design possible alternative future states for the study area, which are then assessed in order to find potential environmental, economic or social impacts through the Impact Model (IM). Eventually consensus among the decision-makers and the other stakeholders on a final choice can be achieved through a negotiation process which is supported by a Decision Model (DM). While the process is not necessarily strictly linear, to perform a complete Geodesign, study three iterations should be undertaken, driving the six models from the first to the sixth, or in reverse order. The first iteration aims to identify the case study purpose and this can be considered as a scoping of the study; the second iteration passes through the six steps in reverse order and should clearly define how to carry out the study in terms of methods and tools depending on the needs of the specific planning study. This can be considered as a meta-planning phase. Then, during the third iteration, the study is fully carried out. During a study, the results of the design and the impact analysis can be shared among the stakeholders and visualized in form of maps, charts and graphs (Ervin, 2011) to aid participation. Feedback offers the stakeholders the possibility not only to improve their own designs, but also to collaborate to reach a solution acceptable to all parties.

The application of the Geodesign methodological approach seems to be currently highly relevant because of its strong potential to positively affect the way planning processes should be carried out in Europe according to the Directive 2001/42/EC on Strategic Environmental Assessment. Geodesign can contribute to addressing many of its current pitfalls (Campagna and Di Cesare, 2016), including those relating to the involvement of the public in the decision-making process, which are most relevant to this paper.

3 THE CAGLIARI WORKSHOP

The “Geodesign Workshop on Future Scenarios for the Cagliari Metropolitan Area” took place in May 2016 at the Civil and Environmental Engineering and Architecture Department (DICAAR) of the University of Cagliari (UniCA), Italy, in the form of two intensive planning studio days. The Geodesign Framework was customized to the local decision-making context in order to develop collaborative sustainable future scenarios for the Cagliari Metropolitan City, recently established by Sardinian Regional Law n. 2/2016. The new metro area is located in the southern coastal part of Sardinia (Italy) and is composed of 17 municipalities. Workshop preparation started in January 2016 with close cooperation in the local coordination team, which included a dozen local experts in architecture, planning and environmental engineering, including the authors of this paper.

During the first phases of the study, the coordination team identified the boundaries of the study area and its relevant territorial context, primary goals for its future development, and the main ongoing territorial dynamics: the scoping phase of the study (i.e. the first iteration through the framework). Second, the methods and the tools to be used in the Geodesign models implementation were selected (i.e. second iteration). Next, the representation, process and evaluation models were built (i.e. third iteration). It should be noted that this part of the process was implemented by the Geodesign team of experts, but citizen participation could have been part of these phases if the study had been organized differently. In order to carry out the intervention phase (i.e. CM, IM, DM) of the third iteration of the GDF, an intensive two-day workshop was organised. Thirty-two people, including academics, technical representatives of public authorities, local planning professionals, and students of architecture and civil engineering participated. The group was selected on the basis of the two main objectives of the workshop: to understand and further test the application of the Geodesign methodology, and to rapidly identify central issues, options and choices as a basis for further studies and planning.

In order to simulate local decision makers, the participants were divided in six teams representing major local stakeholder groups. All of them played a primary role in the design and during the intervention part of the GDF third iteration. The coordination team, who had prepared the early phases of the study, limited its role to coordination at this stage.

The collaborative work was supported by a web based application called Geodesign Hub (www.geodesignhub.com). Its architecture combines the concepts of Planning Support Systems (PSS) (Harris 1989) and web 2.0 principles to perform in an integrated and collaborative way the last three models of the GDF. It uses the representation, process and evaluation models, previously prepared with professional GIS desktop application by the coordination team, as input. Geodesign Hub represents a promising way to approach the complexity of the participatory design and decision-making processes. A more detailed review of the capabilities of Geodesign Hub as compared to other similar planning support tools can be found on the “Sketch Planning Tools for Regional Sustainability” report (Avin, 2016). Indeed, it integrates state of the art technologies into the Geodesign workflow, contributing through a user-friendly interface and social networking capabilities the means to facilitate the collaboration of non-expert participants of various backgrounds and skills, to work intuitively and quickly on design and negotiation.

4 THE CAGLIARI METRO AREA

Since Italian Law 7 April 2014 n.56 became effective, some Italian cities and their suburbs formed a new local government level, the so called “metropolitan cities”. Given its special status of Autonomous Region, the Sardinia Regional Government had to transpose the national principles relating to the establishment and management of these new jurisdictions. Accordingly, the Regional Law 4 February 2016 n.2 created the Cagliari Metropolitan City, defining its functions and responsibilities, as well as its boundary, which includes 17 municipalities around the region’s capital. From the spatial government perspective, a metropolitan strategic plan should be adopted as a regulatory and coordination tool for the development of the area. The workshop represented the first design effort to understand central design issues, opportunities and options.

The area, located along the southern coastal edge of Sardinia, Italy (Figure 1), represents an important economic and social attractor for the whole island. In addition, during the last decade the number of tourists visiting the region increased. Thanks to its location on the lower fertile plain of Campidano and

facing the gulf called Golfo degli Angeli, the Cagliari Metropolitan City contains highly diverse natural and cultural landscapes and offers a rich variety of agricultural and fishery activities that characterized the important food tradition of the whole region (Figure 2). The area has the highest population density in Sardinia; however, the landscape is not affected by excessive vertical or volumetric occupation. In 2011, the total population was approximately 420.000 people (Census ISTAT 2011). According to the 25-year demographic projections carried out by the coordination team until 2036 (the established time horizon for the study), there will be a growth of about 25.000 inhabitants (i.e. growth rate +0.055). An additional moderate population growth was considered as a result of policies included in the pro-development scenario of this study, resulting in an estimated total of 50.000 new people in a +25-year target.

Fig. 2: The Cagliari Metropolitan City.

Fig. 3: Cagliari Metropolitan City landscapes.

5 PRE-WORKSHOP PHASE

The workshop organization was carried out by the local coordination team, with the aim of constructing the knowledge base (i.e. RM, PM, EM) in a consistent format with the Geodesign Hub input requirements. The first step was to specify three main objectives for the Cagliari Metro Area development scenario in a twenty-five year time horizon:

- Tourism development: intended as the valorization of existing coastal tourism facilities and their improvement in less equipped areas;
- Agrifood: intended as the valorization of the local agricultural areas, promoting sustainable agriculture, and also the implementation of new tourist itineraries connected to agricultural, scenic and cultural assets, traditional production methods, and gastronomic heritage. This objective aims both to extend the tourist offering and to keep the rural territory alive;
- Cagliariifornia: intended as the creation of an ICT industry pole able to create new job opportunities and to attract new population, given the presence in the area of existing industry in this domain.

In order to describe the main characteristics of the territorial context, ten spatial systems were selected. The choice was based on analysis of the regulatory framework, and adapted to the development scenario. Three vulnerability systems were chosen, namely: cultural heritage (CULTH), ecology (ECO), and hydro-geological hazard (HYDRO). In addition seven attractiveness systems were considered: tourism (TOUR), agrifood (AGRI), transport (TRASP), low density housing (LOW-H), high density housing (HIGH-H), commerce and industry (COMIND), and smart services (SMRT). Each system was analysed starting from the description of its current condition (i.e. RM) and its evolution dynamics (i.e. PM), to the evaluation of the territory in terms of each system (i.e. EM). This gave workshop participants ten evaluation maps (Figure 4) to inform the design. All the EM maps were created by experts through land suitability analyses in a desktop GIS environment, with the aim of identifying the overall resource supply of the territory. The preparatory phase of the workshop (the first part of the geodesign study process) was carried out using a typical rational comprehensive planning approach (as defined in Khakee, 1998). However, while most of the spatial information used to create the knowledge base was retrieved from the Regional Spatial Data Infrastructure (R-SDI), in this phase the coordination team decided to test the use of passive social media geographic information (Campagna, 2014; 2016b). The TOUR evaluation model was informed by the indirect preferences expressed by social media users to different tourism locations. The use of social media to account for public values and preferences can be considered a form of input by the community, though involuntary.

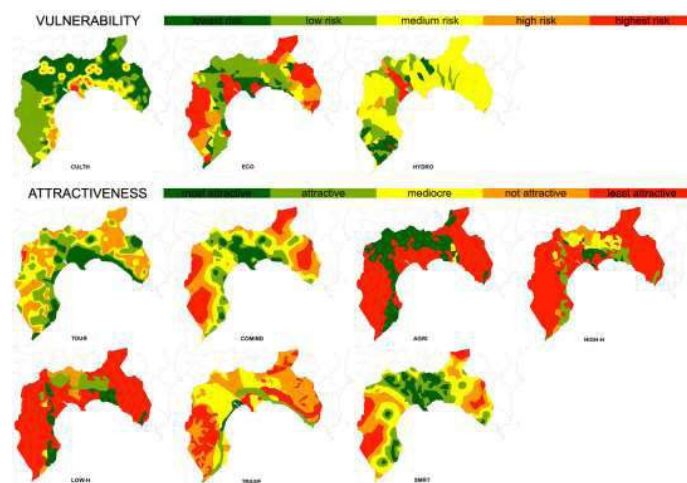

Figure 4. The ten evaluation maps.

The ten EM maps adopted the same color code. The vulnerability maps classified the study area in five vulnerability levels, where red areas indicated those characterised by a very high vulnerability, in which only actions aimed at preserving these sites can be permitted, and the dark green areas are the least vulnerable ones, in which do not present any restriction in use. Likewise, the seven attractiveness maps classified the study area into five levels, but in this case the dark green colour identified very highly attractive areas for developing action in that system, and areas depicted in red identified those of very low attractiveness. The ten EM maps were then uploaded in the GDH platform as a common knowledge base to inform the design. The design then became the responsibility of the workshop participants, initiating the participatory part of the study.

In addition, as part of the assessment phase, a cross-systems impact matrix was compiled by the local coordination team to identify the positive or negative impacts of each single change action on over the ten systems (Figure 5). This matrix was also uploaded in the platform, enabling real-time calculation of the performance of each design proposal during the workshop.

The organizing team established the workshop schedule, which concentrated complex design tasks into an intensive and time-constrained workflow agenda (Figure 6). A collaborative PSS is most useful when applied at the beginning of a study of considerable complexity. Given the scale and complexity of the Cagliari metro area and the number of actors involved, the conductor emphasized that in this phase of the planning process speed is more important than accuracy. In the first phase, the participants were arranged in six groups, each one with a different viewpoint to guide their decision-making, (Table 1 and Figure 7) and with at least one member of the local staff offering technical support and advice throughout the process.

Figure 7. The six teams and their locations in the classroom.

Each member of each team logged-in and got familiar with the online GDH platform. The first task that needed to be carried out was the definition of each group's change priorities according to their specific role and interests in the decision process (Figure 8). They were asked to prioritize -in rank order -the ten systems, through discussion or by using methods for consensus-building (e.g. Delphi Method).

Figure 8. The different Decision Models for the six groups.

Participants in each team were asked to produce a number of geo-referenced diagrams each one representing a conceptual design proposal related specifically to its system. This marked the beginning of the design part of the study, where participants could exploit the innovative potential of the GDH PSS. GDH enables two types of design interventions: projects and policies (Figure 8). Projects are a proposed physical change in the territory shown by a solid block of color, while policies represent decisions and actions that will not have a physical expression, and are shown by areas of color hatching. The GDH platform includes sketching tool for drawing lines and polygons, and visualises changes in the geographic space in real-time, facilitating the assessment of their impacts. Expert and experiential spatial knowledge acquired during the assessment phase of the Geodesign Framework directly influences the change models by giving guidance to the designers. The EM maps were available as base maps in the software design window, providing a color-coded evaluation of the current development opportunities and risks in the area for each of the ten systems. The proposed projects and policies, referred to as diagrams, could be created by an individual stakeholder's initiative or as the result of early negotiations among team members.

Figure 9. Projects (left) and policies (right) examples with the Evaluation Models of the related system as base map.

About 200 diagrams were created in this first stage. They were systematically organized in a matrix by the software, positioned in the column of the related system in chronological order of creation, and shared in real time among all the participants. At the end of the first morning, each group was asked to select a group of projects and policies (a synthesis) in line with their development goals and interests from all 200 diagrams in order to create their first change scenario. The GDH online platform not only supports rapid syntheses, but it also computes real-time impact assessments providing immediate feedback on a scenario's performance, creating the opportunity to rapidly revise the choices (Figure 10). More specifically, a series of maps and histograms shows: i) the direct impact of change in one system both on itself and on the other systems on a three-value scale, from positive (i.e. purple) through neutral (i.e. yellow) to negative (i.e. orange); ii) how the designs perform in light of the target goals; iii) the total cost of implementation. Furthermore, the tool enables dynamic updates to the evaluations maps as the synthesis is assembled, instantly displaying the connections between systems and the changes over the initial conditions.

Figure 10. Real-time impact assessment visualization.

Steinitz (2012) argues that the first design will never be the best one and that the synthesis process should be repeated at list three times to find an improved alternative: the second synthesis is usually better than the first one, and the third is usually the best. Hence, the possibility to rapidly revise and assess the change models represents one of the central advantages of using digital Geodesign technologies to support dynamic workflow. Accordingly, a second and a third design cycle took place, and the six teams could quickly and easily change their syntheses by modifying or creating new diagrams and adding or removing projects and policies until an agreed solution with acceptable impact performance was found.

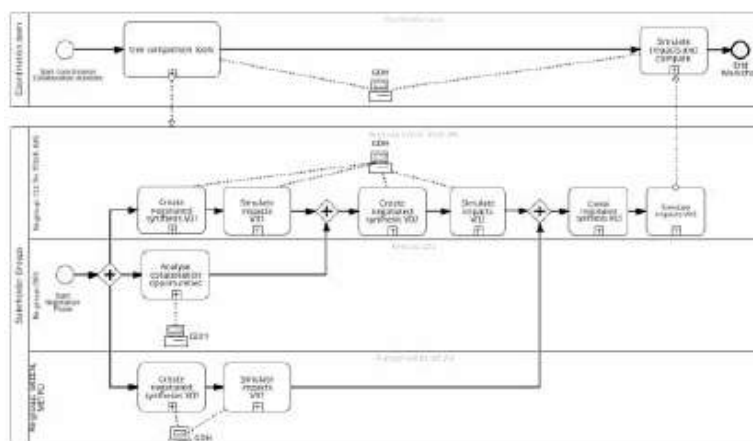

Figure 11. The negotiation phase described with BPMN annotation.

After each round of syntheses was completed, each team leader made a three-minute presentation to explain the main features of her/his group design synthesis. It was possible to notice how in the evolution from the first to the third version, the designs were gradually moving in some cases towards more similarity, in others towards highlighting conflicts. At this stage, the tools in Geodesign Hub for effective visual or quantitative comparison of the alternative scenarios facilitated the early stages of the negotiation process (Figure 11). Eventually, not without some vigorous discussions, the teams reached agreement on a final synthesis.

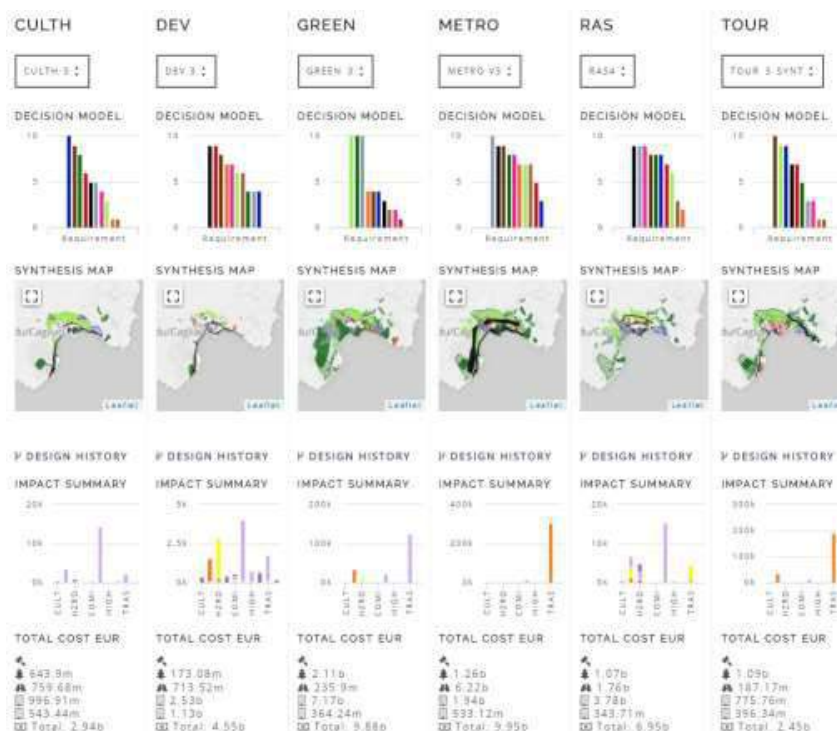

Figure 12. The scenarios comparative tool showing the impacts performance of the six designs at their third version.

7 CONCLUSIONS

Over the last two decades or less, the diffusion of internet and of information communication technologies has opened new possibilities for public participation in many government domains, including spatial planning. Overcoming space and time constraints and digital divides which exist in many countries can pose challenges. Many factors affect the success or failure of digital participation initiatives. Among them, the adoption of suitable methods and tools plays an important enabling role. Geodesign methods and related technologies seem to have broad potential for contributing to collaborative design. The study presented in this paper was developed within an academic research setting, and demonstrate the functioning of a Geodesign process and its enabling technology. Other studies using the same approach and technology proved to be successful in actual practice. Although limited in complexity, this study is useful to demonstrate and describe the functioning of the Geodesign process and its potential. The collaborative method and technology presented in this paper can support participation especially in some specific working situations such as i) when working through a framework in order to understand it, ii) when there is little time and small data, iii) when starting fast to identify central issues, options and choices, iv) when it takes an experimental design to know what the questions really are, and v) when it takes a design to understand what is really wanted. Conditions i), iii) and iv) particularly apply to the Cagliari metro area workshop. In other situations, especially in ii), extending participation into the knowledge building phase of the project, including the creation of the representation, process and evaluation models can be appropriate. The latter part can be the subject of further research, especially from the perspective of using other social media networking platforms and tools to involve the citizens in volunteering data about the physical environment, about ongoing environmental and social processes, and about community values, preferences and need.

ACKNOWLEDGEMENTS

The authors would like to thanks all the participants at the Cagliari Geodesign workshop, which was hosted by the Department of Civil Engineering and Architecture of the University of Cagliari, with the funding of the Autonomous Regional Government of Sardinia under the Visiting Scientists Program 2015, and particularly all the members of the local coordination team, including Xení Kechagioglou, Maddalena Floris, Daniela Ruggeri, Ignazio Cannas, Andrea Matta, Pierangelo Massa, Roberta Floris, Daniele Trogu, and Junia Borges.

ID 1559 | MULTI-CRITERIA DECISION ANALYSIS FOR PROMOTING BIKE-FRIENDLY CITY VISION OF IZMIR USING GIS

Sevim Pelin Özkan¹, Zeynep Özçam², Fatma Şenol¹

¹Izmir Institute of Technology; ²Middle East Technical University,
pelinozkan@iyte.edu.tr ; seplnz@gmail.com ; fatmasenol@iyte.edu.tr

ABSTRACT: Deploying GIS at its analysis of multilayered spatial data about Izmir (the third biggest metropolitan city in Turkey), this paper aims at suggesting ways of providing bicycle routes and roads in the already developed built environment of the densely populated cities. Focusing on multiple characteristics of topography, land use and population, the study deploys overlay analysis and network analysis respectively at city level and district level. Despite of the limited number and characteristics of data available about Turkish cities, this study has been limited to the lack of crime data and travel demand data of related neighborhoods.

1 INTRODUCTION

Bicycle use is widely promoted by many researches and policy initiatives of industrialized countries as the efforts related to sustainable development, carbon-free and non-motorized transportation and “healthy” cities. While some of these policies and researches relate to promoting changes in lifestyles and habits of physical activities (eg., Wendel-Vos, Schuit, De Niet, Boshuizen, Saris, Kromhout, 2004), others focus majorly on planning and design of built environment and of transportation systems (e.g., Huang & Ye, 1995; Rodriguez & Joo, 2004).

A major challenge is how to provide bicycle roads through the developed built environment of the densely populated cities that do not have any prior bicycle routes and infrastructure. This paper aims at answering this question, while deploying geographic information system (GIS) at its analysis of multilayered spatial data about the city of Izmir as being the third biggest metropolitan area in Turkey.

In recent years, making bicycle transportation a part of city life has become one of the main purposes of Izmir Metropolitan Municipality. With this purpose, Izmir aims to promote cycling routes in the following years and the Metropolitan Municipality has been making significant efforts for turning the city into a more bicycle-friendly city. However, availability of physical environment for cycling is an important factor to consider. To promote and upgrade cycling routes in a dense built environment is a challenging process. We claim that Izmir has a potential to offer alternative transportation types and networks prioritizing bicycle, despite its dense urban environment.

This study aims at promoting the bicycle-friendly city development efforts of Izmir. It tries to consider many different spatial factors while promoting bicycle routes within a dense built environment. At its analysis, the study interrelates various data about the characteristics of the natural and built environment and also the spatial distribution of population characteristics at the metropolitan, district and neighborhood scale. This study aims to combine different techniques of spatial analyze at different spatial scales in order to determine potential bicycle routes for areas with different land uses.

This study calls the determinant factors of bicycle facility planning as environmental assets. It mainly aims at taking into action the knowledge of the environmental assets by digitizing and visualizing them. Focusing on the metropolitan scale of Izmir with 30 districts at first step, this study considers environmental assets as parks, recreational areas, topography and analyzes them in the GIS environment. These are the spatial data infrastructure that would able us to reveal potential bicycle route networks. Additionally, some inhibitor factors such as population density and different age range groups are also taken into account. All these spatial data are used to detect the areas that high level of spatial infrastructure are embedded by using overlay analysis. Afterwards, focusing on central districts of Izmir, network analysis is performed between determined stops by taking into account the proximity and continuity at the road network level.

Study findings suggest that overlay analyze technique can be applied to detect neighborhood levels and network analysis can be performed to detect potential routes and to model spatial relations of local nodes. Not only local nodes but also transportation corridors are the basic unit of analysis within network analysis.

2 LITERATURE REVIEW

While promoting the use of bicycle and creation of bicycle networks within a city, it is important to give attention to recent bicycle transportation studies. Studies that relate to the question of how to determine bicycle roads in a city emerge in various fields (majorly urban geography, transportation, urban planning and urban design) and research areas especially about health, healthy living, sustainable transportation and non-motorized transportation (e.g., Huang & Ye, 1995; Wendel-Vos et al., 2004; Segadilha & Sanches, 2014).

Until now, studies related to bicycle network planning have focused primarily on route choice criteria and the factors affecting bicycle use which are giving very useful insights for designing bicycle routes within a city. These studies give emphasis on the factors that can affect bicycle use. These factors are mainly determined as the characteristics of the roadway and bicycle routes, automobile traffic, availability of public transport, and factors related to the built and natural environment (Aultman-Hall, Hall, & Baetz, 1997; Rodriguez & Joo, 2004; Segadilha & Sanches, 2014; Milakis & Athanasopoulos, 2014). Concerning the built environment, bicycle usage is very much related to the location of the areas with higher employment and population density and presence of schools, recreational areas, parks at the origin and the destination (Rodriguez & Joo, 2004; Rybarczyk and Wu, 2010). When it comes to the natural environment, topography and slope become major determinants of bicycle route planning (Rodriguez & Joo, 2004). In addition to all these, safety becomes another determinant of bicycle use (Allen-Munley et al., 2004; Parkin et al., 2007) which is related to characteristics of roadway and automobile traffic. According to Rybarczyk & Wu (2010) these determinants can also be categorized as demand based and supply based criteria for bicycle route planning; the demand-based criteria includes business and land uses such as schools, parks and recreation areas and supply-based criteria includes demographics, safety, public transportation, road characteristics and existing bicycle routes.

Overall, studies underline a set of group of factors that can direct the design and planning of bicycling roads. In particular, bicycle trips tend to increase in the presence of mixed uses of land, slight topography, improved street connectivity, direct routes without interruption and safe separation from motorized traffic

(Aultman-Hall, Hall, & Baetz, 1997; Rodriguez & Joo, 2004). High density areas, schools, parks and public transportation hubs are also anticipated as land uses that support the use of bicycle routes. Therefore, these factors should be taken into account in the planning of bicycle networks in a city.

All these information from prior studies offer the determinants for bicycle network planning however, these studies cannot offer a complete answer to where to develop new bicycle routes within an already developed built environment that lacks a well-connected bicycle network. Only a few studies have applied a comprehensive methodology to determine bicycle routes within a city (Huang & Ye, 1995; Rybarczyk & Wu, 2010; Milakis & Athanasopoulos, 2014). Additionally, as bicycle route planning requires many factors to consider, geographic information system (GIS) technology provides an excellent opportunity to process all available data for bicycle route selection. However, small number of studies have applied GIS in the planning of bicycle routes until this time (Huang & Ye, 1995; Rybarczyk and Wu, 2010). Even more, these studies were dealing with the existing routes in a city. This study, too considers various data about the characteristics of the natural and built environment and also spatial distribution of population characteristics at the city scale and neighborhood scale. While dealing with the data, GIS technology has been used. By this, it is aimed at promoting bicycle routes in the city of Izmir, while making contribution to the GIS based bicycle route planning in an already developed built environment lacking a complete bicycle network.

Relating to these research issues, the design and planning of built environment is discussed and promoted as a tool especially to motivate and assist people's use of non-motorized transportation modes, basically walking and bicycling (Rodriguez & Joo, 2004; Wendel-Vos et al., 2004). In other words, it is expected that if the built environment is designed and planned with adequate and suitable infrastructure, land use, natural assets and allocation of other resources for non-motorized transportation, people will be more willing to use such modes of transportation. Such kind of environments can provide opportunities with healthy living, sustainable living and transportation.

3 STUDY SITE

In recent years, the Metropolitan Municipality of Izmir has the goals of sustainable city development, including environmentally sensitive and sustainable transportation. As a part of these goals, the Municipality aims at promoting cycling routes and has been making significant efforts for turning the city into a more bicycle-friendly city. Accordingly, for providing mobility between districts and city center, the creation of nature-friendly corridors with cycling and walking routes has become a priority in the planning of Izmir (Izmir Metropolitan Municipality, TMP Revision, 2016). However, existing bicycle routes are incapable of providing a complete bicycle network for the city. There are no continuous bicycle routes to serve for the whole city except the coastal road, which is mainly used for recreational purposes. Additional routes are promoted for providing bicycle access to the residential, social and cultural spaces, major transfer stations, university campus areas and other major usages in the city center (See; Figure 1).

Figure 1 – Bicycle Routes

The third biggest metropolitan area of Turkey with a population near 5 million, Izmir is located on the Aegean coast, between the 37°45' and 39°15' north latitude and 26°15' and 28°20' east longitudes and covers an area of 12,012 km² (See; Figure 2) (Izmir Governorship, 2017) with a mild climate during the year. Located on its bay area at the Aegean coasts, the city of Izmir has very high urban densities at central coastal neighborhoods and extends to hilly neighborhoods. With one of Turkey's densest urban population at its central districts at the coast, the city of Izmir has a metro system with its city line and regional line, a newly developing tramline, a limited level of sea transportation and very recently planned bicycle route infrastructure.

Figure 2 – Location of Izmir

In 2015, while the average age of Izmir's metropolitan population is 4.168.415, the average age in its central districts is 35-39 with an education levels higher than Turkey's average (Izmir Governorship, 2017). At a close examination of these 11 central districts, it can be seen that children (age 3—13) ranges are clustered in Karşıyaka, Bayraklı and Gazimur districts, young (age 14—22) ranges are clustered in Karşıyaka, Bayraklı, Konak districts; while seniors (age 55+) are clustered in Karşıyaka, Bayraklı, Balçova and Konak districts (See; Figures 3).

Figure 3 – Maps of age range of 3_13, 14_22, 55+

These age range thematic maps visualize and determine the clusters of different population groups demanding different spatial activity types. We admitted that we should pay attention to the accessibility of the local service areas, especially the neighborhood parks and bicycle routes, within the walking distance. Therefore, we used the "neighborhood ratio" of the age data as seen in the legends. We obtained this ratio by calculating the ratio of the number of each group of people in the neighborhood to the neighborhood population.

4 STUDY METHOD

As bicycle route planning requires many data layers to deal with, GIS can easily integrate these data layers in the form of digital information, thus can reduce the cost of data assembly. Furthermore, GIS can perform spatial operations, such as terrain modeling and network analysis, which are crucial to bicycle route planning; and its network analysis data model and path-finding algorithms make it a straight-forward

way to implement sophisticated cycling models that can incorporate factors such as traffic, topography, built environment attributes and socio-economic data at the same time (Huang & Ye, 1995).

The determining factors for walking and bicycle route planning has been differentiated as demand side and supply side (Wigan, Richardson & Brunton, 1998; Rybarczyk and Wu, 2010). While demand side talks about the spatial distribution of population characteristics such as age, education, gender, and health condition (e.g., Huber, 2003, Wigan et al., 1998), the supply side underlines the physical/environmental characteristics that include natural elements such as topography, slope and land use characteristics such as workplaces, green areas, housing, schools and transportation networks (Martens, 2007; Rodriguez & Joo, 2004). Within the supply side factors, green open spaces have great importance on bicycle route network planning. Recreation areas and parks are desirable destinations within a route (Wendel-Vos et al., 2004) as they generates high level of bicycle use. Lastly, population density provides an estimation of potential demand for and access to bicycle facilities (Huber, 2003; Allen-Munley et al., 2004).

This study calls the determinant factors of bicycle facility planning as environmental assets and takes into action the knowledge of the environmental assets in the GIS environment. Within the context of 11 districts of metropolitan area, this study considers environmental assets as parks, recreational areas, topography and roads that could be determined as supply side. These are the spatial data infrastructure that can reveal potential bicycle route networks. Additionally, some inhibitor factors such as population density, motor vehicle traffic volume and crime statistics are taken into account. All these spatial data are used to detect the hotspot clustering with high level of spatial infrastructure. Afterwards, network analysis is performed between potential clusters based on proximity and continuity. While detecting the clusters focuses on population density, parks, recreational areas, schools, weather and crime statistics, detecting the networks considers motor vehicle traffic volume, topography and main public transportation hubs.

The methodology of the study comprise of two main steps. First one evaluates metropolitan scale big data and determines subscales suitability for route planning. Available data at metropolitan scale are geo-raster data consisting of the population density of each age range, park density, slope and digital elevation. On that aim, overlay analysis has been implemented as using population density of different age ranges, green space density, slope and elevation (srtm-dem of the Izmir province has 90 m of grid size resolution; 45 m of horizontal accuracy; and 15 m of vertical accuracy) data for neighborhood detection. Second one seeks for the bicycle route determination which may be varied based on the different activity within those neighborhoods. For this aim, network analysis has been implemented through road network, stream network and green areas.

5 FINDINGS & DISCUSSION

Within the context of overlay analysis, the population density raster of child and seniors, park density raster, slope and digital elevation data have been reclassified into three defined interval (See; Figure 4). The reclassified digital surface data have been overlapped in the ArcMap environment. The different age range maps have been used to generate different overlay maps. The different age groups have been related with the activity differentiation of bicycle users. Two synthesis maps as a combination of these factors shows the most suitable areas at neighborhood levels for bicycle planning. Within the most suitable areas of two overlay analysis; 'Bostanlı' neighborhood has been selected as the common area for the next step to generate the network analysis (See; Figure 5, 6).

Figure 4 – Reclassified data

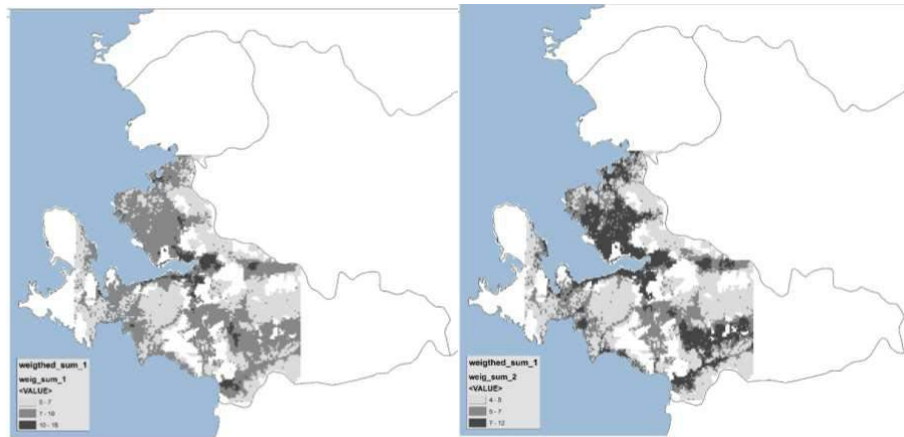

Figure 5 – Synthesis map 1 | Figure 6 – Synthesis map 2

Within the context of network analysis, road networks, work places, transportation hubs, stream networks and the parks have been used respectively for creating network dataset. While work places and road network are associated with the working age group based on transportation activity; the parks and stream networks are associated with the child and old age groups for mostly leisure activity. Therefore, the determinants of the different type bicycle usage have been defined and divided into two categories; the determinants for bicycle use for recreation, the determinants for bicycle use for mobility. Relatedly, analysis has been done according to this categorization.

As an outcome, two potential routes have been determined via network analysis that may serve for two different activity types (See; Figures 7, 8). The Figure 7 shows the route (1) passing through the few numbers of work places and parks starting from the ferry station targeting multi-modal transportation system. The other route (2) shown in the Figure 8 passes through the parks along the stream networks targeting the leisure activities.

This study aims to find out a methodology via GIS environment for detecting potential bicycle routes within the dense spatial contexts. While benefitting from digital visualizations and analyzes, we have used city scale big data to be able to determine the most suitable areas for bicycle route planning. Due to the limited data that is available about Turkish cities, this study has been limited in terms of some social characteristics of the population and the neighborhoods. Thus, crime statistics and travel demand data of the related neighborhoods have been lacked. Determining bicycle routes within the dense spatial context by using the geographical and physical data was another challenge of this study.

Figure 7 – Bicycle route (1) for mobility Figure 8 – Bicycle route (2) for recreation

6 CONCLUSION

The bicycle road infrastructure is gaining ground serving for healthy cities and well-being via non-carbonized, and sustainable mode of transportation. It has been taken as an important option both for physical activity and sustainable mobility. Therefore, the development bicycle road infrastructure becomes an important issue in urban planning agenda, especially in the era in which sustainability is a major goal for future development. As being one of the important metropolitan districts of Turkey, Izmir have also future targets on becoming bicycle-friendly city despite its dense and already-developed built environment with inadequate bicycle road infrastructure. This study aimed to contribute this target, while seeking for a methodology using digital analyzing techniques for new bicycle networks within dense built environments.

While doing this, the study tries to integrate different digital analyzing techniques. The determination of bicycle route has been done by overlapping many different big data at GIS environment. As bicycle route planning requires dealing with many different spatial data at the same time, GIS provided an efficient environment to make this analysis. As a result, two different bicycle routes have been suggested serving for different purposes; namely for mobility (route 1) and recreation (route 2), furthermore we have proposed a comprehensive bicycle route planning method using GIS for promoting the bicycle-friendly city vision of the city of Izmir.

ACKNOWLEDGEMENT

This study is developed in relation to the data of a research project ("Evaluation of Existing Neighborhood Parks based on Need-Based Equity") (Project no: 215K239) supported by the Scientific and Technological Research Council of Turkey.

ID 1569 | SOCIAL TOPOGRAPHY: LEARNING SPATIAL INEQUALITY THROUGH 3D REGIONAL MODEL

Meirav Aharon Gutman¹

¹Faculty of Architecture and Town Planning, Technion
meiravag@technion.ac.il

ABSTRACT: The aim of this research is to develop a digital sand table to facilitate dynamic decision making capable of eradicating spatial inequality. The proposal's innovation lies in the interface it creates between a theory of spatial inequality and a unique laboratory that facilitates 3-D visualization of the mapping of social disparities. This interface, and the unique platform for the formulation of socio-spatial policy it yields, stands to constitute a turning point in the manner in which decision makers 'see' (literally and figuratively) space and subsequently make policy. This proposal's point of departure is the premise that the world 'out there' contains inequality that continues to expand and intensify on different scales in different parts of the world. In recent years, scholars have reported an increase in inequality, as observed, for example, on various scales in the United States and different countries in the European Union (OECD, 2016: 74; Hopkin & Lynch, 2016). Inequality is also intensifying in Israel¹ and its southern periphery².

1 THE PROBLEM: TRENDS AND DEFINITIONS

On a simple level, social inequality can be defined as a situation in which those with the highest incomes earn increasingly more while those with the lowest incomes earn increasingly less. But the situation may also be more complex. For example, some individuals or households may see increases in their income, but increases that are smaller than those experienced by others with higher incomes. This is the essence of inequality: a growing distance between groups (Tasan-Kok, Van Kempen, Raco & Bolt, 2014: 22). This proposal joins a school of scholars who have addressed the phenomenon of spatial inequality (Linda Lobao, Gregory Hooks, Ann Tickamyer, and Jamie Peck).

The study of inequality, these scholars explain, asks "who gets what and why?" (Lobao, Hooks, and Tickamyer, 2007: 1), whereas the study of spatial inequality asks a third question: "where?" In this way, studying inequality from the perspective of spatial inequality means interrogating: "who gets what where?"

This school is based on a first generation of urban and rural sociologists who have sought to advance spatialized sociology (Gans, 2002) based not on a reification of "society" or "space" but rather on an intensification of the link between the two, as well as on the work of geographers who posit that "social relationships are space forming" (Soja, 1989). Scholars of spatial inequality argue the importance of bringing the region back into sociological discussion. Regions includes cities, open areas, and villages; creates territories, such as districts and regions, that help scholars identify networks of divisions and power relations that structure inequality yet remain under the radar. "Some geographers argue for theorizing social relationships in space as a 'power-geometry,' 'a complex web of relations of domination and subordination, of solidarity, and co-operation'." (Lobao, Hooks, & Tickamyer, 2007: 9; citing Massey, 1994: 265).

Sociological and geographical studies interrogating Israeli society have adopted and developed the concepts of center and periphery (Tzfadia, 2012) as a means of conceptualizing the inequality that links ethnicity, class, and geographical distance. These concepts have established a foothold in both Israeli academics and public discourse as an effective means of characterizing inequality in the country. Indeed, the concepts of "center" and "periphery" have constituted a basis for movements of social change, which

¹ The first is the Gini Index, which indicates that as of 2014, Israel was ranked fourth of all OECD countries in terms of inequality, after the United States, Turkey, and Mexico (Keeley, 2015). It also highlights a high incidence of poverty (18%) and an extremely high percentage of employees who earn minimum wage (OECD, 2016: 53-57). At the same time, the share of capital held by the public is on the rise, as are the wages of managers. In Israel, in other words, the strong are getting stronger and the weak are getting weaker.

² The southern Negev region, which reflects sharp social disparities both in comparison to the country's Central region and on a regional scale. For example, 29.9% of all salaried employees in southern Israel earn minimum wage, in comparison to 18.6% in the Central District and Tel Aviv. The gap is more pronounced among women, with 38.8% in the south, 23.6% in the center, and 22.2% in Tel Aviv (Bank of Israel Report, 2014: 120).

have placed questions regarding the division of resources on the public agenda (see, for example, the HCJ land ruling; Hananel, 2009; Meidani, 2005).

The proposed study will make three primary contributions:

- Methodology: The project revolves around the development of a new methodology for the study and eradication of inequality based on the visualization of data with an emphasis on 3-D models.
- Theory: The project contributes to the field of knowledge regarding social inequality by proposing the concept of “social topography” as a new language for capturing socio-spatial relations.
- Policy Making: In conjunction with the concept “Social Topography,” the new methodology will contribute to the formulation of policy aimed at eradicating inequality. To this end, I will develop a digital sandbox to help improve the dynamic process of decision making.

This study is based on a previous study that was also funded by the Ministry of Science¹, which involved building a 3-D model of the Negev. The current project proposes to develop this model into a dynamic platform to assist in the decision making process. By relying on existing technological platforms and theories, we can travel the long road from the research stage to the decision making stage. The proposed study also relies on another significant research effort in which I have been engaged in recent years, along with a number of colleagues: exploration of the labor crisis in the Israeli periphery and analysis of workers’ struggles for their right to work in the periphery (Cohen and Aharon-Gutman, 2016; Cohen and Aharon-Gutman:2014).

This socio-spatial research written in the heart of a technological institute that brings significant added value to the table, both because of the access to unique technological platforms it facilitates and the methodological capacities of neighboring faculties, such as computers, civil engineering, etc.

2 THEORY: SOCIAL TOPOGRAPHY

This study will make a concrete contribution to the work of the abovementioned social inequality school using the concept of “social topography,” which, I posit, enhances our ability to understand society and space as one texture.

To the best of our knowledge, the first person to use the term social topography was French planner, architect, and writer Gaston Bardet (1907-1989). Bardet (1951) contemplated how to give expression to the alchemy that occurs at the meeting point of man and the built environment. Whether in the case of cities or rural regions, Bardet maintained that this meeting point could be structured as the accumulation of people on land: “some men on land, that is to say the urban texture” (Bardet, 1951: 238). This intersection between man and the built environment – this “urban texture” – exists in villages just as it exists in metropolises. In both cases, people and the physical space that surrounds them are interwoven into an integrated social topography (1951:238):

"I came to understand that this urban fabric was made up simply of the interweaving of human activities on the land and on the map I need to represent them. Out of this was born the principle of social topography".

Social topography is not the random expression of human elements on a map; rather, it had to do with their interrelationship. Only an analysis of these elements as one assemblage could succeed in representing the urban texture.

Bardet also developed the concept of “profils sociologiques” (sociological profile), which he regarded as a tool for expressing man’s movement within the maze of large social structures. Most importantly, he believed in the possibility of constructing a sociological profile for different localities. For Bardet, social profile was a visual expression (Image 1). Through the use of his images, he sought to give expression to social rhythm, dynamics, and flow. Considering the means at his disposal in the middle of the twentieth century, Bardet was without a doubt ahead of his time (Bullock, 2010: 355) in his proposal of a dynamic alternative to the inflexible concepts then in use.

¹ "The Challenge of Capital Conversion: How and under what conditions can groups and settlements acquire and trade capital for the enhancement of regional development".

Image 1: A Visualization of social topography according to Bardet (1951).

It is from these models that urban planning, which is always strategic, emerges. The moment the model within which planning occurs is one of social topography, the urban planning that evolves is a direct response to the social element that “dilates with the soul of the social.” The results, he maintains, is “a human geography created by man” (Bardet, 1951: 355).

The concept of social topography did not establish itself with the scholars of its time, and in recent decades scholars have been making minor use of it in various contexts, such as archeology (Little, 2005), psychology (Steger & Kashdan, 2006), sociology (Humphreys, 2005), and anthropology (Hindson, 1983).

In the social sciences, the concept of social topography is associated with the man who developed it in that realm: Pierre Bourdieu. In an article examining Bourdieu’s use of this concept, Helmut, Gerhards & Romo (1995) highlight a fundamental premise of field theory: that social actors are located within the social realm, that is to say, within the topography of social relations that are shaped in accordance with their resources of economic, social, and cultural capital (Ibid., 860). In the same article, Helmut, Gerhards & Romo follow Bourdieu’s lead in arguing that “sociology is a social topography” (Ibid., 893; Bourdieu, 1989: 16).

Bourdieu’s language of fields reflects a structuralist notion, which conceptualizes the dynamics of the individual within cultural and economic structures as movement within space. In this way, social structure is translated into social topography fueled primarily by segmentation and hierarchy (Ibid., 865). Forms of capital undergo segmentation that does not exist on a plane but that rather is hierarchal in nature, meaning that segmentation and hierarchy are linked. We tend to speak of “high culture” and “low culture,” or “mainstream culture” and “marginal culture,” which are all expressions of hierarchal segmentation (Ibid., 865). The same dynamic lies at the core of social topography. It occurs in fields such as culture, education, fashion, and economics, resulting in a social topography within and among all fields.

The proposed study applies this way of thinking – drawn from imagined sociological space and institutional and organizational space – to geographical space. In doing so, it links geographical location to socio-economic hierarchy, which we refer to as inequality. In this way, it seeks to produce a model that gives spatial expression to large social structures (such as unemployment, poverty, and education), not as abstract structures, but rather in an effort to understand the correspondence between socio-economic and spatial structure. The model’s dynamic nature enables us to express and study dynamics and movement, as well as the process through which hierarchal segments are produced in the course of struggles within the fields. This allows us to give expression to the manner in which the outcomes of this social struggle for primacy and control in the field in question change the large structures in which people live their lives.

3 VISUALIZATION: A NEW METHODOLOGY FOR AN OLD PROBLEM

Social research today is based primarily on the written word, which is mediated to people through reading texts and listening to lectures. These two media require readers or listeners to paint a picture in their mind’s eye. That is to say, readers and listeners must engage in a process of translating from the abstract to the concrete, and in fact to transform it into a visual object. This gap is entrenched in our culture and, as

is frequently the case, is mediated by language. We often find ourselves asking a person who has read an article: “Were you able to see the picture that emerges from the text?” It is the picture, then, and not the written word, that is perceived as the thing itself (Sontag, 1979: 91). Realism is a powerful resource for research, and on this basis we highlight the importance of visualization in socio-spatial research. On the level of research and analysis, visualization helps us “see things in ways we had not seen them before” in the sense of the accessibility of knowledge: it makes research insights accessible to increasingly wider audiences, and in this way contributes to the democratization of academic knowledge (Moody and Healy, 2014). It also serves to reduce the distance between science and policy, as policy makers also “now see the picture” and can no longer remain indifferent to it.

VizLab centerpiece is a 3-D immersive theater consisting of a 2.4 x 7.0 m screen with a 75° field of view and three high-definition Projectiondesign projectors. The laboratory provides a 3-D experience in which one participant, followed by tracking cameras, can “move” through the image or manipulate a 3-D object on the screen.

THE FIRST ATTRIBUTE: 3-D TECHNOLOGY THAT IMBUES SOCIOLOGY WITH VOLUME

The starting point was a 3-D model of the Negev. Image 2 is a 3-D representation of train-tracks, roads, industrial areas, nature reserves, etc. The model included a picture of the future of the Negev, based on a spatial representation of plans that have been officially deposited and approved. This model produces integration in a multi-variable environment, the need for which Singer-Villalobos (2014) has effectively articulated by noting that “modeling a city is a big data problem.”

Image 2: A 3-D regional model.

By the end of the study’s first year, we had produced two significant products: a social study based on descriptive statistics and qualitative research, and a 3-D model of most of the Negev, including an image of its future. The most powerful finding of the social study was the immense social disparities it identified in a variety of socio-economic categories, such as employment, unemployment, etc. We are accustomed to consuming the disparities manifested in these categories in 2-D as follows:

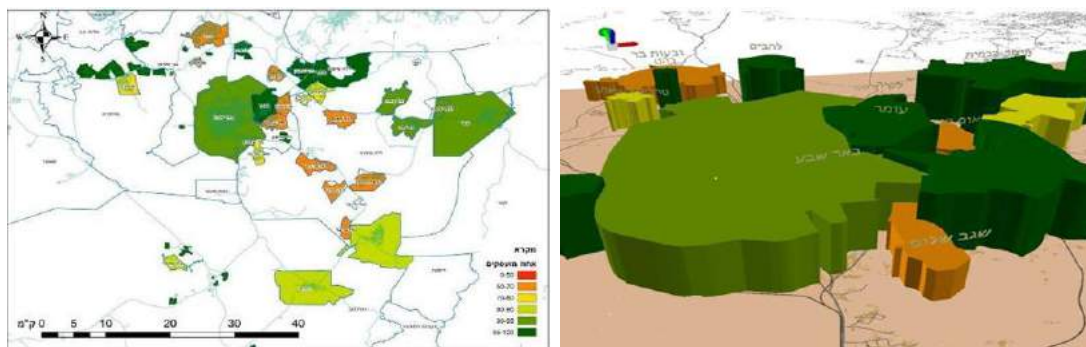

Image 3: A 2-D sociological mapping (employment rate). | Image 4: A 3-D visualization of inequality – first draft.

The 2-D mapping of employees (Image 3) is represented using two elements: geographical location and color. Despite the effectiveness of these maps (Moody and Healy, 2014), we asked ourselves how we could assimilate inequality into our physical model and the research value of doing so.

Image 4 presents our first results: a map that actually consisted of spatially-grounded histograms of sorts. We were not satisfied with this outcome, as we felt it was a “pasting” that advanced neither the research nor the methodology.

We asked ourselves whether we could take the radical step of integrating the social into our model in a way that would leave the social and the spatial inextricably bound to one another, as they are in reality, and as Bardet suggested when he spoke of urban texture as a texture that was at once both physical and social. Our aim was to transform the social into the body of the model and the basic map. In other words, we sought to convert topography into a methodology. Topography here is not only a concept concerned with the height of objects; it is also a method that facilitates the expression of hierarchies and relations of inequality over diverse realms of content.

We also adopted the terminology of geodesic mathematics, which transforms heights into terrain, and applied it to socio-economic measures according to a locality-based index. The results produced can be seen in Image 5.

Image 5: Social Topography | Image 6: Social topography from the perspective of a resident of Beer-Sheva.

The 3-D representation imbued social structures with volume and produced congruence between the life experience in localities that are low on the socio-economic ladder and the modality of data representation, as reflected by the following angles afforded by the model:

Image 7: Social topography from the perspective of a resident of Tel-Sheva, a view from Tel-Sheva toward Omer.

Images 6 and 7 represent the perspective of the residents of Beer-Sheva and Tel-Sheva when they look toward Omer on a sociological level. These images represent grounded visualization, meaning

congruence between the quantitative and qualitative research, and this, to a great extent, is the source of its power (Knigge and Cope, 2006).

THE SECOND ATTRIBUTE: MOVEMENT IN SPACE

Using a navigational device and glasses equipped with sensors, a person in the lab can navigate within the model and engage in rapid movement and transitions between different scales. The user can be inside an apartment in Yeroham one moment and out viewing the region the next. Movement within a 3-D model allows flexible analysis as a result of the quick transitions between different scales it facilitates (Base, 2014).

The movement facilitates the model's animation, allowing movement in dynamic scenarios. Movement in space is experienced as the movement of a person or a body that undergoes a specific spatial experience. Animation allows us to produce "visual narratives," as referred to from a sociological perspective (Harper, 2012), or geo-narratives, as referred to by social geographers (Kwan and Ding, 2008). In other words, we have produced a dynamic model that enables us to generate animation both of people as active agents in space and of the geo-social structures in which they function. This is significant, because it enables us to represent socio-economic structural scenarios of division of wealth and, with the press of a button, to change the social topography presented in the previous section and to analyze the impact of policy x or y on spatial inequality. This methodology lies at the core of the proposed study and is discussed in greater depth below.

THE THIRD ATTRIBUTE: THE LARGE SCREEN AND OUR COGNITIVE PERCEPTION

The third attribute facilitated by the technology employed, which lends added value to the study, is work on a large screen in a dark environment, which disconnects us from everyday life and inserts us into a "different" experience. The large concave screen yields two major attributes that play a fundamental role in fueling the Research Plan: a) the large screen facilitates emotional involvement and assimilation because, on a cognitive level, it affects us differently by producing intensities that have a particularly significant impact on our cognitive perception. b) A second attribute observed in the lab is the fact that in contrast to the augmented reality in which individuals experience intense realism alone, the large screen facilitates audiencing (Fiske, 1992) by creating a situation in which a group of people is party to a shared journey of observation and can have a discussion about it. This is of particular importance in the context of this proposal, as decisions regarding the adoption or rejection of socio-spatial policy are almost always made by integrative teams. This is especially true in the discipline of city planning, which consists of round-tables of experts from different fields, such as economics, the environment, transportation, law, and sociology. The committees in which decisions are made are similarly structured. Stated simply, in conjunction with its movement in space and its dynamic representation of social structures, 3-D realism projected onto a large screen can facilitate discussion among decision makers and yields a spectrum of attributes from which, and within which, a "different" kind of decision making process can emerge.

4 CONCLUSION

לחזון חברתית לטופוגרפיה לחזור The aim of the proposed study is to advance and promote an innovative methodology – the 'Digital Sand Table' as a Visual Means of Shaping Spatialized Social Policy. We believe that this methodology offers three major advantages. First, it gives spatial expression to the existing state of inequality in a manner that incorporates many layers of knowledge into one view, which we name as social topography. Second, it improves our ability to make decisions regarding states of inequality by visualizing the implications and impact of future scenarios. These two advantages have the potential to dramatically impact spatial inequality and social disparities on both the regional and national level. And third, due to the availability of visual technology and its consistent drop in price, the model will be a tool with a high level of applicability. Finally, it is important to note that digital sand tables for decision making do not exist today, making this model a significant step forward in developing decision makers' ability to work with an increased amount of data and, in doing so, to see the full picture.

ID 1570 | AN ECOSYSTEM SERVICES BASED ENVIRONMENTAL SUSTAINABILITY ASSESSMENT TOOL FOR LAND USE PLANS

Emin Yahya Mentese¹; Azime Tezer¹

¹Istanbul Technical University, Department of Urban and Regional Planning
eminmentese@gmail.com ; tezera@itu.edu.tr

1 INTRODUCTION

The mostly used and agreed sustainability definition is maybe the first one made by United Nations World Conference on Environmental Development (1987) in the Brundtland Report stating that sustainability is a development approach that enables progress today without compromising from the abilities of future generations to develop themselves. There is a consensus that human activities must be sustainable and meanwhile there has to be fixed level of disruption of resources based on human activities that reduces the ability of this capital to sustain for the humanity in the future (Arrow et.al, 1995).

In this aspect, land use planning is one of the most critical tool that shapes our living environment by setting the limits of development and urbanization. Hence planning process itself is an important factor in sustainable development. After a detailed literature review including several researches in the fields of landscape planning, landscape ecology, environmental impact assessment, ecosystem management Leitao and Ahern remark that sustainable land use planning is an inevitable conclusion of the evolution of the planning discipline into the 21st century where new social values such as the key concepts of sustainability (solidarity between present and future generations and the need to balance development with nature) are increasingly being seized upon into planning process and regulations (2002). In addition, there are various scientists claiming that sustainability is one of the integral parts of the landscape planning process (Forman, 1995; Grossman and Bellot, 1999). However it has been observed that planning discipline wasn't rapid enough to fit into the principles of ecology and therefore sustainability must be adopted more efficiently in planning process and administrating lands for which new tools are required (Leitao and Ahern, 2002) since its spatial component is strongly related to inter-dependence of land uses and to spatial processes such as fragmentation (van Lier, 1998).

In order to remove this gap, this study adopts environmental sustainability into urban plans, based on Burkhard's ecosystem service mapping approach (2009) that provides an efficient tool for understanding capacity of land use's ecosystem service provision. However, since Burkhard's approach only deals with the service side of the land use, it does not include the impact side of it and hence does not provide insight on environmental sustainability of land use. As the definition of sustainability suggests, by environmental means, the impact of land use must not exceed environmental limits of the planned area. Therefore, in this study, we made an addition to Burkhard's approach, by putting the impact dimension of land use into our analysis and developed a GIS model that calculates a land use plan's performance based on its ES provision capacity and environmental impact. Here our novel assumption is that a land use plan's environmental sustainability is equal to the difference between ecosystem services provided and environmental impacts caused.

With the development of this GIS tool, it will be available for an urban planner to analyze the sustainability difference between current land use and proposed land use plan and hence it will be available to revise the planning decisions for the good of environmental sustainability.

2 AIM & SCOPE

Basic aim of this study is to remove the gap between land use planning discipline and environmental sustainability phenomenon by developing a tool that helps planners to evaluate their decisions. Therefore, our focus is on the assessment of land use plans instead of the planning process because land use plans are the final output of the process and they are actually a combination of different decisions taken throughout the planning course. Moreover plans provide spatial data and they can be related with similar spatial entities such as land covers. In this regard by benefiting ecosystem services (ES) approach and their mapping techniques in current literature, we developed a standalone GIS tool that lets users evaluate

the difference in ES based environmental sustainability level between a proposed land use plan and current land cover. Since our aim is to evaluate the plan's environmental sustainability level, we make the assessment based on regulating ES. Because other ES focus on economic and social benefits provided by ecosystems.

3 METHODOLOGY

In this study we make the assumption that a land use plan's environmental sustainability (EnS) performance is equal to the difference between ES provided and environmental impacts (EI) caused. In order to calculate ES and EI of a land use plan we adopt the methodology provided first by Burkhard et.al. (2009) and then revised by Jacobs et. al. (2014) so called "matrix model". This approach depends on scores for ES provisioning capacity of land covers. These scores are gathered from expert reviews and then enhanced by quantitative data from sources such as actual measurements or simulations where available. In this study we customize this model by using only ES that are directly related with environmental aspects that are known as regulating services in ES literature. On the other hand in scoring process, in order to assess the difference between ES and EI of a land use plan (or a land cover data) we expanded matrix model's scoring scale of "0-5" to "-5 – 5" where negative values correspond to the impacts caused by land use type. In other words we assume that while some of the land cover types (such as forests) increase ES capacity (hence EnS), some of them (such as continuous urban fabric) has negative impact on EnS. For example in a land use plan, while forests provide air quality regulation, industrial land use types (LUTs) not only have zero level ES, but also have negative impact on air quality. Hence, they must be taken into account as sources of EI. In matrix if a value has negative value it is at the impact side of the equation. A fictional sample data is shown in Table 1 where LUT4 has negative impact on ES and EnS as well while LUT1 have positive impact.

	ES ¹	ES ²	ES ³	ES ⁴	ES ⁵
LUT 1	5	3	-5	-3	2
LUT 2	4	4	-3	-3	3
LUT 3	2	2	-3	-1	2

Table 1: Sample ES scoring table

It must also be noted that although the scores provide insight on the potential on provision and/or impact of LUTs; quantity (area) of the LUTs must also be taken into account because their benefit or impact is directly related with their area. The larger the LUT gets, the larger its service or impact level gets. Therefore, after the scores are assigned, they are multiplied with their areal quantity that provide unified unit for all indicators. But for the ease of mapping and viewing purposes, in calculation areas are converted in "km²" unit.

As a result, this GIS tool calculates EnS level for each land use type by summing ES and EI level it produces based on function below:

$$EnS\ level = LUT\ Score \times LUT\ Area$$

(Formula-1)

3.1 EMBEDDING THE METHODOLOGY INTO SOFTWARE

In order to embed the methodology into software, we preferred to use pre-defined classes for assessment. Since the methodology basically depends on ES and Land Cover relation (as in matrix model), we defined the variables for these two themes beforehand.

Incorporation of land use plans into system is the integral phase of the methodology but it is hard to find a standardized land use planning taxonomy by means of establishing a solid relation with ecosystems. Therefore standardizing these classes is a critical task for increasing the ease of use. Hence we needed to use a common and widely used taxonomy for this study. In this regard, instead of trying to create a new classification, we chose Corine Land Cover dataset since it is one of the most widely acknowledged dataset that can also be used almost in every planning stage as a basemap.

Meanwhile, other important task has been the selection of ES indicators related with environmental sustainability. As defined before, these are basically regulatory services as described in many ES frames, which are composed of environmental benefits provided by ecosystems. For determining the relevant indicators ES indexes of Millennium Ecosystem Assessment (MA) (2005), The Economics of Ecosystem and Biodiversity (TEEB) (2011) and Common International Classification of Ecosystem Services (CICES) (2013) (Table 2) are reviewed. In this study, we preferred CICES categorization since it is the latest version for ES classification and embraces its predecessors.

ES Frame	ES INDICATORS									
MEA	Water purification and waste treatment	Erosion regulation	Water regulation		Air quality regulation	Pollination	Pest regulation	Disease regulation	Soil formation (supporting service)	Climate Regulation
TEEB	Water purification and waste treatment	Erosion prevention	Regulation of water flows	Moderation of extreme events	Air quality regulation	Pollination	Biological control		Maintenance of soil fertility	Climate Regulation
CICES	Mediation by biota	Mediation by ecosystems	Mediation of mass flows	Mediation of liquid flows	Mediation of gaseous / air flows	Lifecycle maintenance, habitat and gene pool protection	Pest and disease control		Soil formation and composition	Atmospheric composition and climate regulation

Table 2: Ecosystem services categories (derived from The Biodiversity Information System for Europe (BISE) webpage

As a result we pre-defined two themes in the software: Land Cover Classes and Ecosystem Services. When the user uploads the data into system software enables to match uploaded data with predefined classes and reads areal values of the shapefiles to compute EnS scores. The main scoring values (varying between -5 and +5) are also kept in the system and can be updated within a new window including the matrix as described in Table 1.

4 SOFTWARE PROCESS

The software is designed with the aim of reducing software knowledge requirements of a user. Therefore it has a simple and yet comprehensible interface (Figure 1).

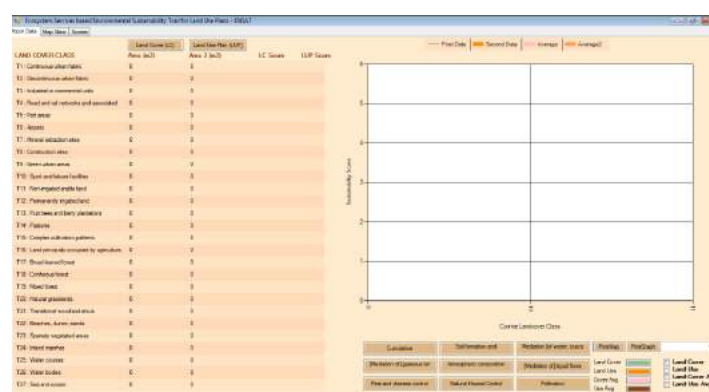

Figure 1 - Main Interface

The left column of the interface includes predefined land cover types gathered from Corine Land Cover (CLC). The right bottom corner includes ES buttons also defined beforehand based on CICES approach. The chart area is used for drawing EnS graphs of input datasets.

“Land cover” and “Land Use Plan” buttons open new dialog windows that let users upload a shapefile format including current land cover data and land use plan. When the land cover and land use plan data is uploaded the first thing system does is to prompt a window to read the land cover/land use classes and areal values (Figure 2).

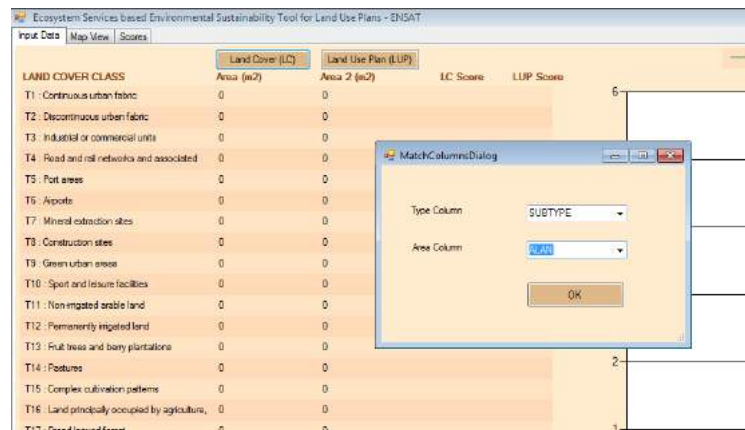

Figure 2: Class Matching Interface-1

But it is highly possible that land cover class names and class names in the uploaded data would not match exactly. So we designed another interface phase (Figure 3) for matching where user can match the classes with the defined ones in the system. For example in Figure 3 there are two incompatible types in uploaded land cover data and by selecting the suitable predefined CLC classes, matching process is completed.

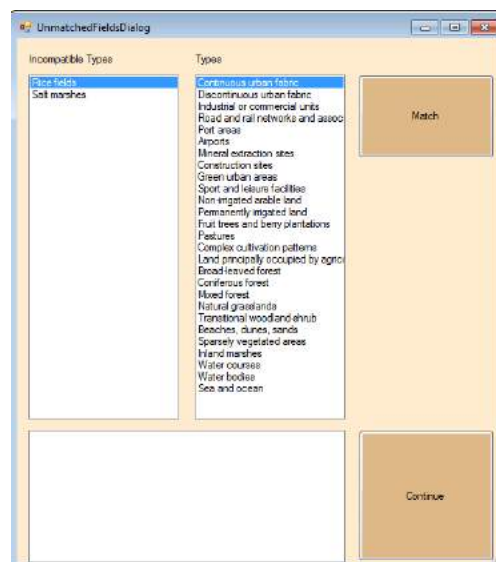

Figure 3: Class Matching Interface-2

After the data is uploaded into system software calculates the EnS scores based on areal values and ES scoring gathered from expert review and/or actual computations/measurements that are kept in "scores tab". Then system applies "Formula 1" for both datasets and plots their graphic on the system (Figure 4).

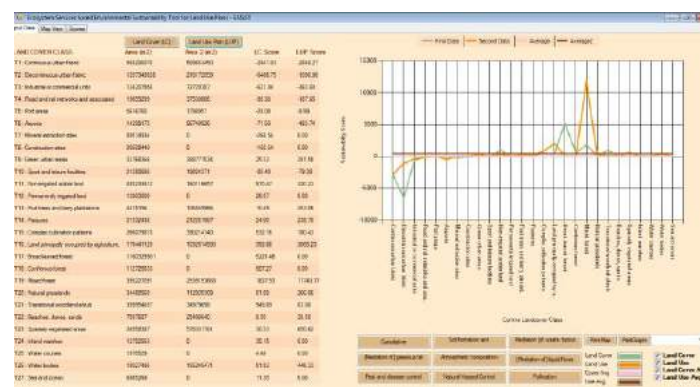

Figure 4: Comparison of Land Cover and Land Use Plan Data

The graphic is plotted as cumulative scores for each land use type which means it is the summation of all ES and EI for each LUT. Nevertheless in cases of special focus or needs, some specific ES can also be looked at. In this case buttons at the right bottom side are used for changing the graphic view for a specific ES title. In this same area of the screen, colours can also be manipulated. In Figure 5 “Natural Hazard Control” ES is looked at. The average values are the arithmetic average of scores for each datasets and they are the main output that enables to understand the change in EnS level.

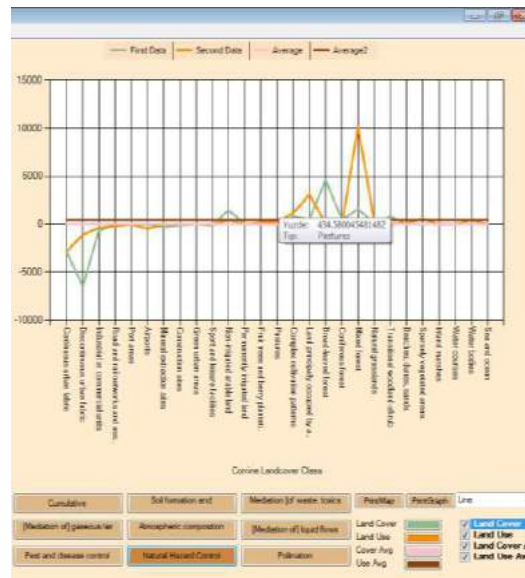

Figure 5: Natural Hazard Control Graphic Plot

In grey taskbar above, “map” tab opens the uploaded shapefiles’ location on Google Maps provided from Google Online Map services (Figure 6). In this panel the map is symbolized between green and red where green corresponds to the scores of the land use types. Green colours correspond to higher scores where reds correspond to lower scores of EnS. There are also tools that helps user to navigate in the map (zoom in, zoom out and pan) and an “info” tool to gather information about the data. The info button reads the dataset’s attribute table and prompts an info screen (Figure 7). The selected polygon is highlighted in light blue. These attributes are implemented via dot spatial framework libraries.

Figure 6: Map View of the Datasets

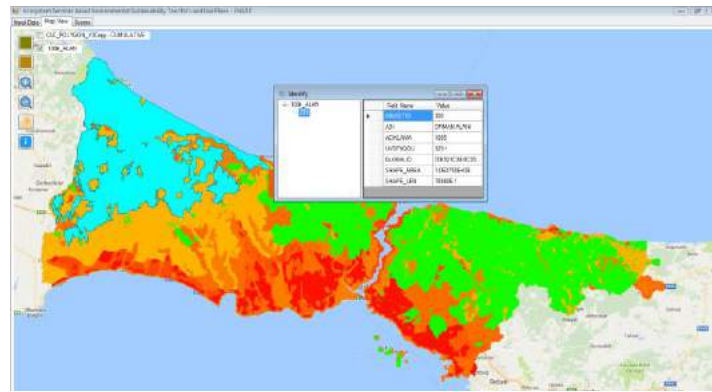

Figure 7: Info Tool in Map View

Next to the map tab there is “scores” tab that opens the tabular matrix where users can manipulate the scoring (acquired from table for their area of planning and generate a unique scoring table for their studies (Figure 8). This table is where ES and EI potential of land covers are scored. These scores are used for EnS calculation in “input data” view. Here the rows are land covers as predefined from CLC and columns are ES that are gathered from CICES frame. The values in the table can be updated by clicking on the scores and hence EnS can be renewed as well. These values are kept in a separate .mdb (Microsoft Database) file and once the table is updated, the .mdb file is updated too.

5 CONCLUSIONS

As a result, with the development of this tool, by using GIS capabilities and ES approach, it is easily available to assess a land use plan's EnS performance compared to its land cover. Hence an urban planner or a decision maker can efficiently understand the level of impact or contribution made by planning process on the planning area by means of environmental aspects. As a part of an ongoing project, there will be updates to this tool to be more inclusive and comprehensive but even in this level, it helps planners to evaluate their planning decisions in the light of regulating ecosystem services and analyse whether these decisions lead to an ecological surplus in the planning area or not. Therefore it serves as an integral system to enhance land use planning decisions that are eventually one of the main pillars of sustainable human development.

6 ACKNOWLEDGMENT

The authors of this paper would like to thank Marmara Municipalities Union for their PhD scholarship support and Mr. Mehmet DEMIR for his invaluable contributions in developing the software.

ID 1624 | MEASURING BUILDING DENSITIES (FSI/GSI) FOR THE NETHERLANDS

Arjan Harbers¹

¹PBL (Netherlands Environmental Assessment Agency)

arjan.harbers@pbl.nl

1 INTRODUCTION

Densities are a key feature in urban planning and design. Density influences amongst others energy consumption, mobility, livability, food production and economy.

Building densities (that is Floor Space Index (FSI) or Floor Area Ratio(FAR)) relate the gross floor area to the surface of the accompanying base land area. The surface of the base land area can be defined on

many scales, from plot to municipality. By now floor areas, parcels shapes and building footprints etc are available as open data for the whole of the Netherlands, so we can script the calculation of building densities for the whole of the Netherlands. We did this according to the recent Dutch standard: NEN 9300:2013 nl, Areas and densities in urban planning - Terms, definitions and methods of determination. The first results have been tested in a mobility study. The results can be applied as well for morphology studies and as reference projects for future urban design.

Along with FSI we can easily calculate the Ground Space Index (GSI) which relates the footprint of a building to the surface of the accompanying base land area and an index for the mixed use of functions (MXI). This paper describes the datasets used in the script and the main steps that were scripted to calculate the building densities on several scales.

2 THE SCOPE OF DENSITIES

Densities play a key role in urban planning and urban design. High densities are supposed to have positive qualities: less mobility (Kenworthy and Newman 1999, 2015), less energy use (UNEP 2017, Bettencourt 2013, Rode et al 2014, Salat 2009), higher productivity (Bettencourt et al 2007, Raspe et al 2015),

more fine grained businesses (Hausleitner 2012) and less material use (so fewer costs) for infrastructure (Coppola et al 2014). In the social field high densities are supposed to work out in a positive way for example a higher modal share for walking (Moudon and Lee 2009), less criminality (Hillier and Sahbaz 2008), better conditions for circular economy (Rood and Hanemaaijer 2016) and higher vitality (Jacobs 1961).

Many international organisations therefore recommend to build in high densities and to densify existing cities (IEA 2009, UNEP 2011, European Commission 2014, OECD 2012, UN-HABITAT 2012, Worldbank 2014). However, higher densities may lead to a decrease of open spaces in the existing urban tissue and to an accumulation of traffic congestion, noise nuisance and air pollution (Coppola et al 2014, Breheny 1992), an increase of real estate prices and social disclusion (Coppola et al 2014), social problems (Leidelsemeijer et al 2014), urban heat islands (Heusinkveld et al 2014) and health issues (Peen et al 2010).

The density effects mentioned above occur depending on the context. Effects can be tempered or intensified through flanking social, spatial, economic or mobility policies. Same goes for the design of the buildings and the public spaces that can either make or break liveability. A certain density alone is no recipe for a “good” spatial planning. It actually is a condition for “good” planning.

Knowledge about densities and being able to compare urban tissues can help finding spatial solutions for a specific intended density in a specific context. This is important in considering inner city or suburban urban growth (Van Duinen et al 2016). In the case of city extensions not only the landscape quality is under pressure, but the food supply as well (Swilling 2016).

3 INDICATORS

3.1 FLOOR SPACE INDEX

In Dutch spatial planning densities are usually measured in dwellings per hectare. This unit counts the number of dwellings (or households) on a certain land area. This unit is interesting for the residential project developers market, but doesn't give full insight in the spatial density, since schools, offices and ware houses and the like are not included here. Utility buildings can be included in the Surrounding Address Density, that counts the number of addresses within a specific radius. This method, however, doesn't take into account the wide range of square meters that buildings can have. A building can for instance be a 5 m2 pavilion or a 200.000 m2 office building. So address density is not the perfect indicator either. Besides, address densities are not available on the scale of the building block.

By using Floor Space Index (FSI, or its synonym Floor Area Ratio (FAR)) as a unit for density, the restrictions mentioned above are being overcome. On top of that the FSI is a more accurate indicator for an area's physical morphology, especially in combination with GSI and MXI (see next chapter).

FSI calculates the ratio of one or more buildings' total floor space to the accompanying base land area. In case an area is covered all over with one storey, the FSI is 1. In case half of the base land area is covered with a 2 storey building, the FSI is 1 as well.

3.2 GROUND SPACE INDEX AND MIXED USE INDEX

Parallel to the FSI calculation, we can calculate the Ground Space index (GSI), indicating the share of a base area that is covered with buildings. GSI is a worldwide used indicator in urban design and urban planning.

Additionally the Mixed Use Index (MXI) being the ratio between residential floor areas to the total floor area can be calculated for a specific area (Van den Hoek 2008). A mixture of residential and working related uses contributes to a reduction of mobility, a sharing (over time) of infrastructure and parking lots (van den Hoek 2008), more vitality (Jacobs 1961, Gehl et al. 2006), a higher safety perception (Gehl et al. 2006), and, in relation to density, less criminality (Jacobs 1961, Hillier and Sabbaz 2008, Traunmüller et al 2016). On top of that a mixed use areas allow for higher densities, since locations that are unequipped for housing, for instance because of lack of daylight, can often be used for non-residential uses.

Pols et al. (2009) observe that existing mixed use urban areas do not interfere with a high liveability. PBL (2010), however, observes that an increase of mixed uses not necessarily leads to a better liveability. There seems to be a relationship between mixed use urbanism and liveability, but this is depending on the type of jobs, the grain size of the mixture and the type of neighbourhood.

4 DATASETS

So far, FSI, GSI and MXI have been hardly used in the Netherlands. Data on floor space has not been available on a large scale and had to be determined manually. That is why FSI is only being used in small scale urban design studies, such as Urhahn and Bobic (1994), dRO (2001), Nabielek et al (2012) and Faro architecten et al. (2012).

Since the availability of new datasets for the whole of the Netherlands we are able to automatically generate FSI, GSI and MXI for the whole of the Netherlands. We mainly use the following datasets: BAG (Basisregistraties Adressen en Gebouwen) which contains the floor space and use for every address in the Netherlands; National Land Registry data, containing every single parcel shapes, the digital zoning schemes and the BGT (Basisregistratie Grootchalige Topografie) containing detailed topographical information on a map (scaled 1:5000).

5 SCALE AND STANDARD

Densities differ depending on the aggregation level on which they are being calculated. The building density of a municipality is generally lower than the building density on district level, since areas for nature and agriculture are included on a municipality level. In a similar way, district parks lower densities on district level compare to the neighbourhood level. The smallest scale that we will publish is the building block, being the space between surrounding streets, in which one or more buildings are located.

Since 2013 there is a Dutch standard: (NEN 9300) on areas and densities in urban planning (NEN 2013). In this standard is laid down which elements (such as streets, railways, parks, water) to count in for a certain level of aggregation: Parcel, building block, neighbourhood, district and municipality. The standard distinguishes in nett and gross areas on all aggregation levels. For the building block, for instance, the adjacent built-upon parcels make up the nett building block. To the gross building block half of the street profiles as well as small unbuilt parcels are being added.

This standard has never been intended to generate areas and densities automatically. Often the standard's interpretation depends on the spatial context and the user's expertise. So the results that are being generated automatically may differ from manual, analogue results. Nevertheless we have tried to

remain as close as possible to the standard and we describe the steps that we have not been able to script.

6 DESCRIPTION OF THE SCRIPTED PROCESSES

When calculating the FSI the gross floor area is the numerator and the base land area is the denominator in the fraction.

6.1 GROSS FLOOR AREA

The gross floor area is a building's floor space according to the NEN standard 2580 (NEN 2005). The gross floor area includes construction and circulation areas, as well as underground and cantilevered building parts. The gross floor area is based on the floor areas provided by address in the BAG dataset. As BAG provides usable floor area and leasable floor area, the values are multiplied by index numbers for different uses (based on IGG Bointon de Groot (2014)) in order to estimate the gross floor areas.

In case a building does not have an address (for example glass houses, barns) the footprint of the building is taken as the gross floor area. The assumption here is that these building types have only one storey. Buildings smaller than 4 m² with no address will be excluded, in accordance with NEN9300. The buildings' footprints are being retrieved from the BGT dataset.

The gross floor area remains unchanged on every level of aggregation, but the base land areas usually increase with every step of aggregation.

6.2 BASE LAND AREA

The base land areas will be determined on four aggregation levels: building block, neighbourhood, district and municipality according to NEN9300. Below we describe the scripted process for the selection in brief.

6.2.1 DETERMINING THE NETT BUILDING BLOCK

In accordance tot NEN9300, the nett building block is determined by "land registry or other borders". In general this means adjacent built-upon parcels form a nett building block. For this scripted method we use 4 types of borders. The buildings' footprint on ground level is the connecting thread here.

1. Each built-upon parcel (from the land registry dataset) belongs to the nett building block. Since buildings sometimes exceed the parcel's perimeter minimally, we use a 2 meter buffer: Only if a building footprint takes more than 2 meter of a parcel, the parcel is added to the nett building block. Buildings that have no address and that are smaller than 4 m² are excluded here as well.
2. Some (municipal) parcels consist of large parts of public space. Schools, children's farms or council housing for instance are located on municipal parcels that contain besides the yard, the surrounding street networks. In order to exclude the street networks here, we use the zoning schemes and select the built-upon zoning perimeters that are schemed as residential, catering, social, park, mixed or business, including adjacent garden zones.
3. From buildings situated on zones schemed for infrastructure and green, such as railway stations, road houses or bridge control buildings, we only select the footprint as nett building block, because the accompanying parcels can stretch out for kilometres long.
4. Underground buildings, such as parking garages or subway stations, contribute to the gross floor area. In case these buildings do not have a footprint, they will be excluded from the 3 steps described above. By taking the building contours from the BAG dataset - that contains (besides the footprints) projections of cantilevers and underground building parts – we can select underground buildings. For these cases we construct a symbolic square meter place holder as a nett building block.

From these surfaces, we deduct all infrastructure (roads, foot paths, cycle lanes), even if they are on private property. This infrastructure is taken from the BGT and digital zoning schemes datasets. Besides parking lots larger than 500 m² and areas that are not schemed for building purposes will be subtracted from the nett building blocks. These non-building areas are selected from the BGT dataset categories: sand, agriculture, meadows, forest, heather, dune and the like.

Large parks and ponds are also excluded from the building blocks. They are selected from the CBS dataset on Ground Use (BBG) and will be added, depending on their size, to the neighbourhood, district or municipal aggregation levels.

6.2.2 DETERMINING THE GROSS BUILDING BLOCK

The gross building block consists of the nett building block and the tare building block. Tare is the difference between gross and nett. The tare consists on the one hand on public space smaller than 4000 m² (such as public green and playgrounds) and on the other hand the infrastructure that is needed to disclose the nett building block. The surface of the total street profile is split and assigned to the two adjacent building blocks. If there is no nett building block available the street profile will locally not be assigned to the gross building block.

6.2.3 DETERMINING THE NETT NEIGHBOURHOOD

The nett neighbourhood is the aggregated gross building blocks within the neighbourhood contours derived from Statistic Netherlands (CBS)

6.2.4 DETERMINING THE GROSS NEIGHBOURHOOD

The gross neighbourhood is the nett neighbourhood combined with the neighbourhood's tare. The tare contains the roads that are higher in hierarchy. These are (parts of) roads that do not disclose addresses and only disclose other roads. The tare is also composed of exclusive tram - and bus lanes. All of them are selected from the BGT dataset (proxy: regional roads, tram rails, public transport lane). Parks and ponds between 4,000 and 60,000 m² are also added to the gross neighbourhood.

6.2.5 DETERMINING THE NETT DISTRICT

The nett district is the aggregated gross neighbourhoods within the district contours derived from Statistic Netherlands (CBS)

6.2.6 DETERMINING THE GROSS DISTRICT

The gross district is the nett district combined with the district's tare. The tare contains the motorways (from TOP10) and railways (from BGT). Parks and ponds between 60,000 and 400,000 m² are also added to the gross neighbourhood.

6.2.7 DETERMINING THE NETT MUNICIPALITY

The nett municipality is the aggregated gross districts within the municipality borders.

6.2.8 DETERMINING THE GROSS MUNICIPALITY

The gross municipality is the whole municipality. The surfaces for agriculture, nature and public spaces larger than 400,000 m² are added to the nett municipality.

6.2.9 ALTERNATIVE BASE LAND AREAS

Perhaps the base land areas above do not suit specific purposes. Alternative land areas can be composed from for instance handpicked (nett or gross) adjacent building blocks.

In a similar way densities can also be calculated per neighbourhood as aggregated building blocks.

Another possibility is to project the gross floor areas in a grid and select the surface of a grid cell as a base land area.

6.3 FLOOR SPACE INDEX (FSI)

The floor space index is calculated by dividing the gross floor areas by the base land areas.

6.4 GROUND SPACE INDEX (GSI)

For calculating the GSI, we use the buildings' footprints from the BGT dataset. This one is without projections of cantilevered building parts and underground buildings.

6.5 MIXED USE INDEX (MXI)

The Mixed Use Index is calculated by dividing the gross floor area for residential uses by the total gross floor area for a specific land area. There is no difference here in nett and gross land areas. The BAG dataset differentiates in 11 uses, for instance residential, sports, industry, office, retail etc.

7 DISCLAIMERS

Spatial densities can be determined much more accurate if done manually instead of scripted. However, it would be a sheer drudgery to manually calculate densities for a single municipality let alone for the whole country. Scripting the calculation process has some drawbacks:

- Human interpretation is missing: Manual determination of base land areas can be more accurate. For instance tram lanes are added to a district's tare, but sometimes tram lanes are to be found in fun parks as well, where a human would classify the tram lane to the tare of a building block.
- The quality of the results depends partly on the quality of the datasets. Some datasets contain (obvious) mistakes. We expect them to be adjusted in future updates.
- Not all datasets are available for the whole of the Netherlands. The BGT datasets and the digital zoning plans are not yet complete by now. This influences the results. We expect these datasets to be fully covered soon.
- The various datasets are not internally synchronized. In the case of new constructions or demolition some datasets might not be up to date while others are.
- The gross floor area is based on the floor areas provided by address in the BAG dataset. As BAG provides usable floor area and leasable floor area, the values are multiplied by index numbers for different uses in order to estimate the gross floor areas. This estimation might be way off for individual cases.

8 RELATION TO NEN9300

In scripting the FSI and GSI we tried to follow the NEN9300 standards. In some cases we were, for the time being, not able to script this standard, because of complexity reasons.

- Whether public spaces are classified to a certain scale depends on their surface. According to the standard this also depends on the average width. We did not consider the width in our script.

- The tare of a building block is, in general, half of the street profile. According to the standard the whole street profile is assigned to a building block in case the parcel across the street is not zoned for buildings. For the time being, we did not script this exception.
- The neighbourhood's tare contains the roads that are higher in hierarchy. These are (parts of) roads that do not disclose addresses and only disclose other roads. As a proxy we selected regional roads from the BGT dataset. This proxy is quite weak.
- All water bodies have been excluded from the nett building blocks even if it is a part of private property, such as small ponds in gardens. We have not yet scripted this differentiation.

9 TENTATIVE RESULTS

We are able now to calculate all FSI, GSI and MXI for the whole of the Netherlands. We will run the script in late summer 2017. Figure 1 shows an earlier test, the FSI in nett building blocks in Leiden.

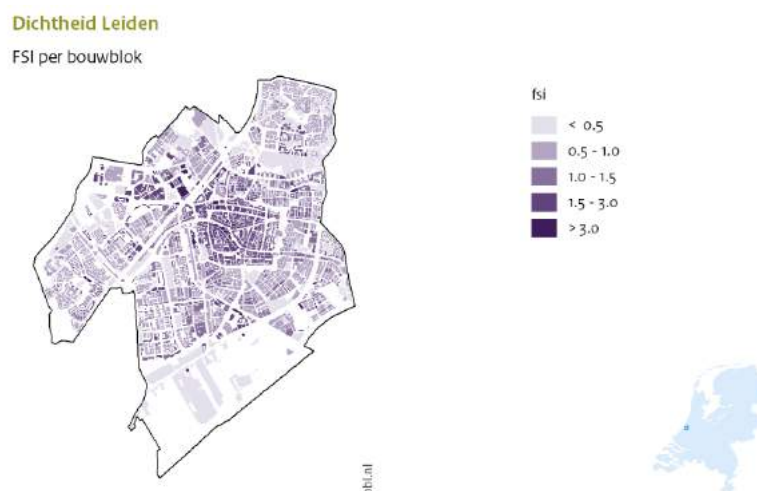

Figure 1 – FSI on nett building blocks for the Leiden municipality (draft)

The results have also been tested in a pilot study on mobility for province Noord Holland, carried out by Vereniging Deltametropool. See figure 2.

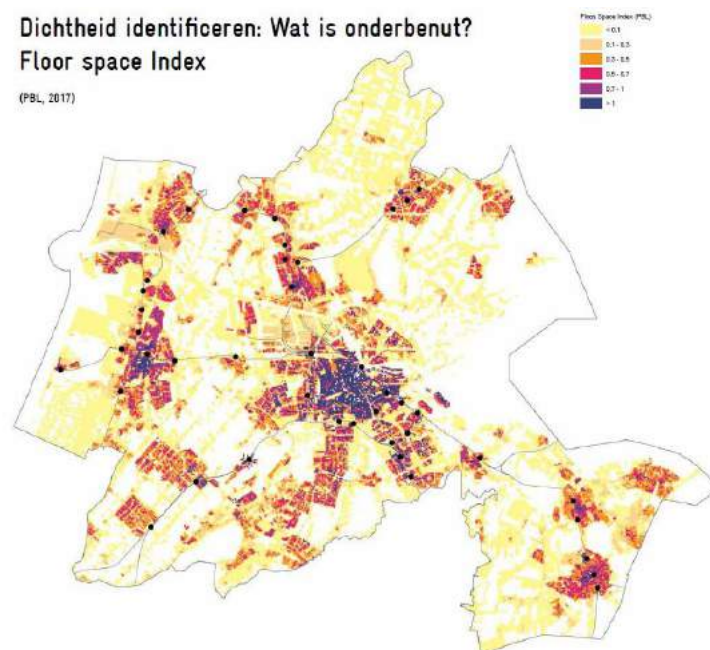

Figure 2 – FSI in the Amsterdam region

10 FUTURE APPLICATIONS

The produced FSI, GSI and MXI on several scales provide material for a wide range of research (for instance on real estate prices, liveability mobility, building capacities) and morphological comparisons.

Further ideas for the near future include:

- a website that links FSI, GSI and MXI to Google Streetview and Bing Maps (bird's eye views)
- developments over time. We can rerun the script in let's say every 3 years and monitor the changes.
- International comparisons: Berlin, Vienna, Zürich and Paris have similar datasets available

1 INTRODUCTION

The generation of forecasts regarding the further physical development of urbanised areas is a key part of spatial planning, and indeed integrated planning as conceived more broadly. A key role in the process is played by land capacity analysis, which permits both an assessment of the current state of utilisation and management of an area and the possibilities for development – by transformation or augmentation or else

the de novo designation of land for building; along with indications as to how that land may be used. Further upgrading of methods by which to analyse land capacity can thus be seen as a priority where the improvement of planning methodology is concerned.

According to Kotarbiński [1973], a method is a planner's way of pursuing a complex task that entails a defined selection and juxtaposition or configuration of component activities that seek to bring about a single, identified objective, while at the same time being suitable for multiple (repeat) use.

However, the methodological issues actually representing such a key aspect in effective urban planning (here conceived of as an inherent feature of the process by which development is managed) are only taken up very rarely in Poland, and if they are – this is mostly as some kind of side issue. It is now ever-more typical to see authors [like Markowski 2010] espousing the idea that post-1990 Poland has experienced regress ("gone backwards") when it comes to urban-planning methodology. In this, it is also worth recalling how the output from Polish urban-planning thought is seen to include many examples of applied methods that have now passed into history. To be included among these is the threshold analysis method after Stanisław Malisz¹, as well as the "Warsaw Optimisation" method² after Kolipiński [2016].

Among many other things, Poland's first steps along the path to socio-political and economic reform entailed work to change the planning system. In the event, the changes were so far-reaching that they went hand in hand with a severing of continuity in virtually every aspect of urban planning, up to and including the methodological [Jędraszko 2005]. A conviction becoming widespread at that point was that physical development plans needed to minimise limits and curbs on possible development of given areas of land. In practice, that translated into local authorities (at the level of the Polish gmina) earmarking as potential building land as many sites as possible, effectively almost wherever natural conditions and the rigours of the law allow for it.

Thus, among the land that gmina-level Studies and Local Plans indicate as suitable – and even designate – for building, only a part is land in which the planning designation reflects any real or distinct market need, e.g. as reflected in rapid commencement of real-life construction work. Many other areas have gained designations as "for building" more or less "at the request" of owners of land, who see here a kind of future financial security, or else gain a regular income in the here and now by selling off parts of their estates piece by piece. This in turn denotes the appearance of exceptionally diffuse built-up areas, often coming into existence site-by-site, and in essence at chance (rather than thought-out) locations. In essence, this very specific view of "social justice" espoused at gmina level is allowing as many owners of land as possible to engage in construction work if they so wish, under conditions that are more or less similar, averaged out and so – in some conventional and oversimplified understanding of the term – "just" [Solarek 2013].

The further consequence of this approach is the disappearance from each plan of what should be – and once was – its most fundamental premise, objectively-defined need as regards development, translating into the goal or objective of the plan itself, as a whole. What this has denoted is activity to negate the sense behind the application (as in the past) of what are now defined, or dismissed as "traditional" methods of drawing up plans (i.e. with a clearly pejorative flavour now being attached to the word "traditional"). This thus represented an almost total severing of previously-existing ties between theory and practice [Zuziak 2005].

Against such a background, it becomes hugely important for local authorities to define the actual needs of given settlement units as regards development, taking real demographic processes and economic potential into account. The aforesaid huge surplus of land designated for building in gmina-level Studies and Local Plans is giving rise to irrational use and management of land, while also having hugely negative financial consequences for local authorities. And the scale of the phenomenon indicates the lack of methodological rationality characterising today's urban planning in Poland – a problem that professionals began to take note of some years ago now [e.g. Izdebski et al. 2007, Solarek 2005, Kowalewski 2013],

¹ A tool for selected strategic directions to a city's development in relations to defined time sequences. This entails the identification of limitations and thresholds relating to development which can only be overcome if disproportionately high costs – as set against the number of new inhabitants – are incurred.

² This is set to select what would be socioeconomically the most favourable variant for the distribution of an anticipated programme of new development across space. It entails analysis of costs of implementation of the said development, with these arising out of natural features of the land concerned, as well as locations in respect of source elements of technical infrastructure.

and one now finding its reflection in domestic law, with 2015 amendments to Poland's Planning and Physical Development Act finally generating a requirement that a series of spatial analyses be carried out for both urban and rural areas [Ustawa o planowaniu... 2003].

In accordance with the regulations now in force, the so-called "Study on Physical Development Conditions and Directions" *inter alia* takes account of conditioning arising out of the balance of land designated for building. Also laid down is the required scope of research necessary as such sites are demarcated. Among other things, there is a requirement that capacity be assessed as regards: "areas located on the territory of a given gmina supporting a fully-developed and contiguous functional and spatial structure within the boundaries of a settlement unit (...)", with this therefore being considered utilisable area within buildings and/or already-utilised built-up land, in which there is also an assignment of functions. Further: "estimates shall be made of the capacity of land within a given gmina designated for building in Local Plans (...), as expressed in terms of the area of utilisable building land, with a division into functions".

The results of the analyses of this kind, as combined with demographic forecasts, are compared with and set against a given gmina's financial and organisational capabilities. The effect of this is then an identification of land on which new construction work is actually to take place, along with indicator values for that work [Ustawa o planowaniu... 2003]. It is an obligation for local authorities to pursue such studies, but thus far methods by which they can discharge this duty efficiently and reliably have not been developed.

2 RESEARCH AIMS AND A CHARACTERISATION OF THE LAND SELECTED FOR STUDY

The aim of the research work detailed here has been to attempt to automate land capacity analysis using the GIS tools whose utilisation in planning has been increasing steadily in recent years. This is happening in line with increased quantity, quality and accessibility of spatial data that can serve as a basis for analyses suitable in assessing and forecasting development in urbanised areas, *inter alia* those discussed in this article. Use of the Model Builder application, which offers models for how to proceed compiled from tools available in its programming, can streamline the processes by which necessary spatial analyses are carried out, all the more so if the same procedures can then be implemented in respect of many other towns and cities. An activity pathway once put in place would then be suitable for multiple and repeat use.

The use of GIS tools is a matter already taken up by many researchers, albeit with some publications confining themselves to a very broad conceptualisation of the tool(s) [Foresman 1998, Gaździcki 1990, Eastman 2001, Litwin and Myrda 2005]. Others focus in on the use in planning [O'Looney 2000, Urbański 1997, Malczewski 1999, Piwowarski 2009, Malczewski and Rinner 2015, Geertman and Stillwell 2003, Joerin et al. 2001], or devote themselves to matters of urban-planning design [Hanzl et al. 2011]. Making an occasional appearance in foreign literature are articles on capacity-limits in the environment when it comes to needs as regards the locating of new construction work and built-up areas [Senes and Toccolini 1998]. In Poland, there are just a few papers dealing with the use of GIS tools in forecasting spatial development [Parteka and Czochoński 2003, Fogel 2007, 2013]. Only rather recently has it started to be seen as essential for new methods applicable to development planning to be devised [Biegański 2016].

Work detailed here has thus sought to fill a research gap as regards spatial-planning methods, with a view to a tool suitable for practical use by local authorities being proposed. An equally important objective has been the study and presentation of the current spatial structure characterising Warsaw as a city and as capital of Poland, with this not being confined to analysis of the spatial breakdown of functions set against each other, but also including an analysis of the percentage shares accounted for by different functions in delineated accounting units.

The work described here thus analysed the situation of land within the city limits of Warsaw, as the most functionally and spatially diverse urban area in Poland. The capital city is at present divided into 18 Districts characterised by varying degrees of urbanisation of their land. By reference to observations made, the areas of these Districts were further divided into accounting units, differing from one another in terms of their physical development – with, for example, one including areas in which the multi-family

housing function prevails, and another being characterised by a clear prevalence of more-extensive built-up areas featuring single-family housing.

3 DESCRIPTION OF THE LAN CAPACITY RESEARCH CARRIED OUT IN WARSAW

3.1 OBTAINING DATA

The first stage to the research work described here entailed the collection of the necessary spatial data concerning the city of Warsaw. Such data were obtained from the so-called EGIB¹ base (where the abbreviation for Ewidencja Gruntów i Budynków denotes registration of plots of land and buildings). These are vectoral spatial data that include, not only the geometry of buildings, but also other attributes relating to each premises. For the purposes of displaying and analysing the data obtained, use is made of the ArcMAP program, forming part of the ArcGIS package. Data on buildings and plots are displayed as layers, along with tables of attributes. Initially, the layer with buildings contained attributes as follows, i.e. a unique code for the given building, X-Y coordinates for buildings, and area data simultaneously equivalent to the area that is built-up, but also information on numbers of floors and functions (though not in every case). The layer relating to plots in turn encompassed a unique code for the object, as well as coordinates, and information on size of the area – which is at the same time equivalent to plot area.

The existence of all of these attributes make it possible to calculate basic indices like the share of building plots that is actually built on, as well as the overall floor space accounted for by built premises², obtained by multiplying the area a building covers by its number of floors. In fact, these attributes do not suffice to calculate the utilisable area on premises³, even if they do represent key data for further analyses and the obtainment of relevant results. Rather, the data actually required are obtained once relevant conversion factors have been determined and applied.

Following sub-chapters detail the process by which the necessary indices are established, along with information on their use to calculate utilisable area, with a subordination of the overall figure to different identified functions.

3.2 DATA ANALYSIS TO DETERMINE THE UTILISABLE AREA WITHIN LAND UNITS

In making an appropriate selection of conversion factors applicable to buildings, it is necessary to analyse functions and means of utilisation in detail, as well as to determine the time at which buildings came into existence. This all reflects the way in which the above features impact upon coefficient values. Residential buildings arising at different times in history differ in the form and manner of construction, ensuring that conversion factors are also different. Buildings meeting service-related, industrial or commercial functions will also be characterised by various different values for the conversion factor. To streamline the process by which functions and ages are assigned to buildings, and to take account of the marked spatial differentiation present within the Warsaw city limits, it was decided to assign the accounting units identified to different zones from the point of view of the different ways in which land is utilised. The functional zones distinguished are as detailed in the table below.

¹ EGIB – Ewidencja Gruntów i Budynków or Register of Land and Buildings – this is a land-survey-related public register featuring quantitative and descriptive data on land, buildings and premises, as well as property ownership.

² The overall area is the sum of all floor space on all floors of a building, obtained straightforwardly by multiplying a building's area by the number of floors.

³ The utilisable area measures the floor space on all floors within premises that serves to meet demands associated with the assigned designation, as measured here by multiplying the overall area by an appropriate conversion factor.

Symbol	Category	Additional information
EW	Hard media services	Power supply, media and fuel, e.g. heat and power plants, areas with water pipelines, etc.
MN_0	Built-up residential areas of low-rise single-family housing	Free-standing houses, semi-detached or terraced, together with other building sometimes present on plots
MN/U	Built-up residential areas of multi-family housing plus services	Built-up residential areas where housing and premises rendering services are mixed together, as where certain old villas have been adapted to serve as Embassies or the seats of firms, also buildings in which there are service premises on the ground floor with housing functions on higher floors
MW_0	Built-up residential areas of multi-family housing	Built-up residential areas of multi-family housing either lacking services or with services hardly present – as mainly on gated housing estates
MW/U	Built-up residential areas of multi-family housing with service premises (mainly ground-floor)	Premises rendering services primarily located in the ground-floor areas of buildings and mainly on the edges of residential quarters
MW_U	Built-up residential areas of multi-family housing with services	Premises rendering services not confined to the ground floors of buildings, though mainly in buildings immediately adjacent to the unit's main streets. Present primarily in the city's Śródmieście, Wola, Ochota and Praga Południe Districts.
PR	Industry	Industrial premises
US	Depots and warehouses	Premises designated for storage, including warehouses designated for commercial functions, and not merely those serving industry's needs
FUS	Abandoned	Abandoned premises in a poor state or in ruins, uninhabitable
TR	Transport	Stations and airport terminals, Metro stations, bus and tram depots, multi-storey car parks, large concentrations of single-place garages adjacent to multi-family housing
TK	Rail transport	Buildings on railway land and/or servicing rail transport (excluding the station premises included under the TR function)
UA	Administration and public security	Premises used in public administration, e.g. courts, Ministries, Embassies, District Offices, police stations and headquarters, buildings used by the Armed Forces, etc.
UB	Office buildings	Commercial premises, buildings within business or office parks
UF	Non-material services	Premises used by the financial and insurance services, finance centres, banks and exchanges
UH+UM	Commercial and material services	Service premises found mainly on housing estates
UI	Other services	Services not assignable to other categories referred to above
UK	Cultural and recreational services, the hotel industry and tourism	Local culture and community centres, theatres, cinemas, museums, stadia and sports halls, buildings associated with gyms and sporting premises, hotels and related premises and those associated with tourism
UO	Educational and scientific services	Creches and kindergartens, primary schools, junior high schools, high schools, establishments in higher education and scientific institutes
UU	Various services	Areas in which a variety of services are concentrated – e.g. shopping centres and malls
UZ	Health services	Hospitals, health centres, clinics, offices of specialist practitioners, first-aid rooms and other medical premises

Table 1 – Division of land into functional zones. Source: author's own elaborations

This differentiation between the functions areas serve makes possible the automatic ascribing of features to the buildings present at given sites, bearing in mind the spatial relations pertaining between areas and their buildings. The use of the spatial tools is further preceded by relevant assignment of time intervals, given the likelihood that particular points in time will be associated with a prevalence of one construction technology or another, with this in particular influencing energy-consumption features of the given buildings. Information on such features can prove valuable in various different kinds of analyses of urban areas, i.a. related to their energy needs.

Category	Justification
Pre-1981	Up to the 1982 time of introduction of the FN-82/E-02020 thermal protection standards
1982-1991	Up to the 1991 time of introduction of the FN-91/E-02020 thermal protection standards
1992-2001	Up to the time of introduction of the E0 value describing energy consumption
Post-2002	Binding limit values for energy consumption, wide application of layered walls and development of insulation technologies
BD	No data – applied to buildings for which no data on age can be found
ND	Not applicable (n/a) – applied in circumstances where excessive diversity made an age determination impossible, e.g. where there are aggregations of single-family housing in built-up areas, but also where the information in question is not critical, as with warehouses and stores, as well as construction of a temporary nature

Table 2 – Categorisation of buildings in line with time of construction, given the influence on energy-consumption attributes. Source: authors' own elaboration

Supplemented in this way, the tables of attributes were used in statistical compilations concerning land utilisation within the Warsaw city limits, with a division into Districts, and beyond that into the designated accounting units. As the databases arising in this way included large numbers of these, the decision was taken to return to calculations based around Districts. This was associated with a repetition of successive steps in the case of each District. Through ArcGIS programming a model by which different tasks could be carried out in a defined order with the aid of simple tools was developed. This could then be applied successively to Warsaw's 18 different Districts, the use of the action model allowing the necessary activities to be proceeded with much more rapidly than would be the case were separate operations to be carried out.

Conversion factors allowing for the shift from overall area to utilisable area were brought together in a table later combined by relationships with the layer containing buildings. Merging was achieved using appropriate Standard Query Language queries. Utilised conversion factors are as presented below.

Type of building/premises	Time of origin	PU coefficient
MW	Old Town built-up area	0.69
	19th-century tenement buildings	0.75
	so-called "large-panel" construction	0.79
	1992-2001	0.83
	Post-2002	0.85
MN	n/a	0.7
P – halls and production-related	n/a	0.97
U – service premises	Pre-1992	0.8
U – offices, services and high-rise buildings	Post-1992	0.9
Farm or utility buildings	n/a	0.8

Table 3 – Indices used in calculating PU in relation to building ages and technologies.

Presented below is a schematic representation of the action model created for the needs of the research using the Model Builder application, which is used to create, edit and manage models for data flow between geoprocessing tools. A further aspect here is that results may serve as input data to be used by other tools.

Fig. 1. The action model meeting the needs of the research conducted, under the Model Builder application.
Source: elaboration by A. M. Jachimowicz

The use of this procedural model for layers, with its spatial data relating to different Districts, allowed values for utilisable area in these Districts to be obtained more rapidly. The statistical tool developed facilitates the compiling and aggregation of data, including values for such basic indicators as overall areas, lowest and highest values, mean values and standard deviations.

GIS programming not only allows for the collection, compilation and analysis of data, but also for their presentation in a user-friendly manner, in the form of maps and graphics of which examples are provided below.

Fig. 2. Distribution of built-up areas of differing functions and ages.
 Source: elaboration by A. M. Jachimowicz

To achieve a transparent presentation of the obtained totals for utilisable area related to the different functions in accounting units, appropriate values need to be assigned to the latter within units. Totals for the different units are then obtained using the Intersection tool, which can designate the geometrical common part, via a kind of multiplication of the layers by themselves. The layer containing the buildings, their functions and utilised area with a division by functions is multiplied by the layer containing the accounting units. A layer with buildings is obtained in this way, along with different attributes, with the operation resulting in a location in the appropriate accounting unit. It is then necessary to carry out an aggregation of values for the utilisable areas in respect of different functions. This aggregation is made possible by the Dissolve tool allowing for the merging of objects on the basis of defined attributes – in this case in relation to function, as well as allowing for the calculation of statistics relating to the aggregated objects that arise – with further analysis making use of the function of a total. The consequence was the obtainment for each unit of a vector layer containing a number of objects that corresponds with the number of different functions present in the given accounting unit. For results obtained to be used, not only in the form of a table, but also by way of appropriate geovisualisations, use also needed to be made of Join table, which assigns totals obtained previously to relevant units.

Fig. 3. Procedural diagram. Source: elaboration by A. M. Jachimowicz

Thanks to the above actions taken it inter alia became possible: (1) to use cartograms in visualising the results obtained and (2) to engage in the comparative analysis of data. An example of the use of cartograms to visualise the roles of the different functions in a given unit is given in the following figure.

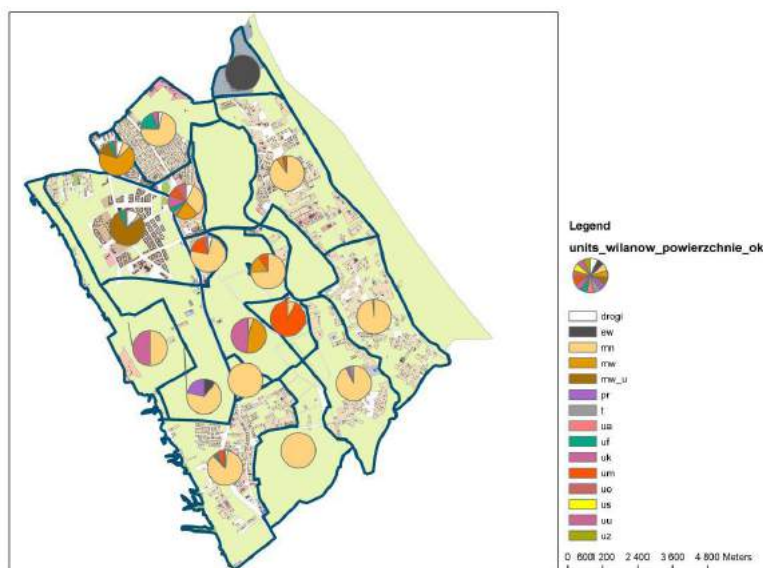

Fig. 4. Sample diagram of a District with a division into accounting units.
Source: elaboration by A. M. Jachimowicz

3.3 DATA ANALYSIS TO COMPARE THE CURRENT INTENSITY OF DEVELOPMENT OF A BUILT-UP AREA WITH THAT PERMITTED IN THE SUICKZP¹

The analysis involved here resembles the previous one in being carried out by reference to the spatial extents of Districts. This was again achieved by harnessing the creative possibilities of the action model, which streamlines the process by which the same kinds of analysis are pursued for consecutive Districts.

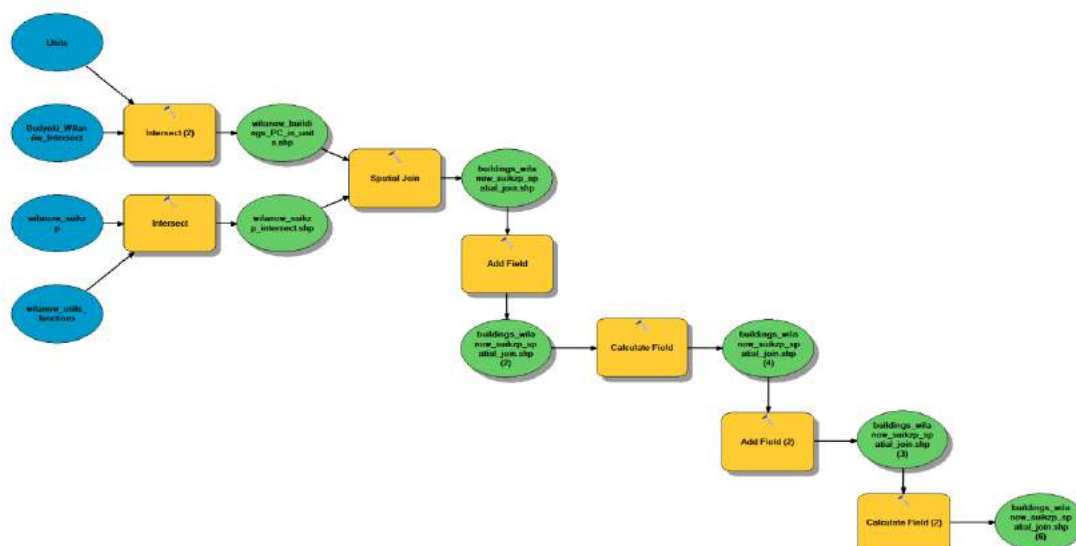

Fig. 5. Procedural diagram. Source: elaboration by A. M. Jachimowicz

The model referred to, presented above in graphic form, is described in detail in what follows. The first stage of this analytical part entails repeat application of the Intersection tool, this time in multiplying the layers with zones of management determined in the first analytical part with a layer containing a division into areas designated in the SUIKZP. This activity allows for the assignment to management zones of

¹ The SUiKZP or Studium Uwarunkowań i Kierunków Zagospodarowania Przestrzennego is the ("Study on Physical Development Conditions and Directions") document providing mean values for the coefficient of the intensity of development into built-up areas, for land as designated in diagram form.

permitted gross values for the intensity of development in built-up areas, as designated in a Study. Subsequently, with the aid of the Spatial Join tool, it is possible to calculate the total area of all buildings located within each different zone. Following the application of this tool to the table of attributes of the layer arising, a column is added that is designed to retain values for the intensity of development indices. Calculated at this point in the management zones is the gross value of the index for the present intensity of development of the built-up area, on the basis of the formula:

$$Int. = GBA/Area(of\ plot)$$

where:

*GBA is the overall area with buildings = BA * NF*

BA – building area

NF – number of floors

Area (of plot) – is the area of land for which the coefficient for the intensity of development of the built-up area is being calculated

In this way, each of the management zones designated previously has a table of attributes featuring two values that relate to the intensity of development as it is at present or could be in line with what is permitted. The comparison of these values makes use of a quotient of the value for the coefficient as it is at present set against the permitted value. An extra column is thus added to store values for the quotients anticipated.

The results obtained from this activity are values across a [0; 2] interval. Values obtained for the quotient are classified in line with: present value being lower than that permitted, present value being equal or nearly equal to that permitted and present value exceeding that permitted.

3.4 RESULTS

Objectives described at the outset did prove achievable through the analysis detailed above. The methodology adopted to automate analyses and calculations showed that the application of Spatial Information System tools is particular effective as land-capacity analyses for towns and cities, or parts thereof, are carried out. Resort to Model Builder, which allows users to develop their own complex tools, facilitates the calculation process, most especially where particular operations need to be conducted in sequence for different objects. In such a case, use can be made of the iteration¹ of successive lines in the table for the layer containing the Districts making up the City of Warsaw.

The application of the aforesaid complex tools, as tailor-made using Model Builder, provides for the at-least partial automation of the analyses detailed. In consequence, a model generated one off can subsequently serve many times in calculations, as only the values for input data will change. The generation of a tool of this kind facilitates and abbreviates analyses where the necessity is to engage simultaneously with a greater number of entities, such as towns or cities or the Districts thereof.

The results of the analyses in question can be presented in various ways. The first entails the export of tables of attributes to xls files, but also to databases. The basic statistical compilations for particular layers can also be presented as a generated report containing a plot for selected data and values thereof like totals, means, minima or maxima.

Obtained results can also be visualised as maps or schematic representations. Examples of these were included in earlier chapters – a schematic representation of the distribution of a function (Fig. ...), of the ages of buildings within a unit (Fig. ...) or one with percentage shares of utilisable area as assigned to different identified functions.

The second analysis carried out for example provided for the identification of areas in which the quotient for current against permitted intensities of development assumes lowest values or fall within given intervals [0; 0,3]. Such low values for the quotient indicate a zone in which the current level of development is not very intensive, with land in this area capable of being designated for supplementary construction work, of course if there is no other counter-indication for that.

¹ iteration is the act of repeating (most often many times) the same instruction(s) forming part of a loop. The term is also applied to operations conducted within a loop of this kind.

4 DISCUSSION AND CONCLUSIONS

The analyses conducted allowed for determinations of percentage shares of utilisable land within given units, as broken down in relation to a variety of identified functions, and this in regard to both existing and planned physical development of the city of Warsaw.

Studies on Physical Development Conditions and Directions (SUiKZPs) designate general directions for cities' spatial development. In the case of Warsaw, the relevant document relates to the period up to 2035. This is to say that it has been drawn up in line with indicators the Study gives as permissible in the cases of the different zones. The value for overall area was to have been achieved in a period lasting approximately up to the year 2035. The largest share in this overall area is taken by built-up land serving a residential function, be this with single-family housing (in free-standing, semi-detached or terraced houses) or multi-family. By multiplying the relevant area by an appropriate proportion reflecting the way in which these two types of built-up area co-occur, and then by the conversion coefficient, it is possible to obtain the predicted 2035 figure for the area in use for single-family or multi-family housing. In turn, by comparing the anticipated area for residential use with the area currently utilised residentially, the size of the increase can also be noted. In line with the availability of land in Warsaw, the SUiKZP yields a capacity equal to around 3.5 million people. Setting the results obtained against demographic forecasts for Warsaw whose most probable scenarios assume 1.5 million inhabitants in 2050 [Śleszyński 2016], the building-land figures are markedly too high.

The analysis carried out allowed for the additional designation within Warsaw of zones that are undeveloped – as presented in Fig. 6. Consideration of the lowest figures for the quotient suggest that such units are mainly in the urban zone, or in the suburbs¹. In the city-centre zone as such, there are only now single plots in different places that remain free of construction, with the coefficient of intensity of development for the latter now assuming values close to 0. Thanks to the results elaborated, it is also possible to offer a ratio of built-up to unutilised areas in a given District of Warsaw, or within one or other of the accounting units.

Fig. 6. Areas possible to build on them. Source: elaboration by A. M. Jachimowicz

The results obtained may serve as input data for further spatial analyses. One such analysis might involve the designation of the non-built-up areas that should be the first to commence with development. Together with the layers referred to already, layers dealing with public roads can for example be used in designating the above zones. Roads are of relevance given the way in which it is possible to determine commute times to particular parts of the city. Environmental matters are also obviously of relevance.

¹ The urban and suburban zones are two of the three that the SUiKZP identifies. The third zone is that of the inner-city sensu stricto.

While GIS instrumentation is still rarely used in the planning process in Poland, the trend for analyses of this kind is an upward one, and understandably so, given that the use of GIS can provide for the at least part-automation of the process by which land capacity is determined.

The results obtained will inform the decisionmaking process, and that shaping policy in Warsaw's further development, while also representing input data for further spatial analyses concerning the Polish capital. The means of conducting analyses of capacity presented here can be used in practice, also of course in other cities, towns and local-authority areas.

ID 1666 | OPERATIONAL RESEARCH IN SPATIAL PLANNING

Magdalena Wagner¹

¹Wrocław University of Technology

magdalena.wagner@pwr.edu.pl

1 INTRODUCTION

The need to develop new methods supporting spatial planning is nowadays one of major challenges of modern urban planning. Discourse on new ways of urban management gains new meaning and is in fact a discussion about the contemporary urban planners skills and tools. The paper presents new solutions which could provide a support for coordinated, rational, and transparent decision making under conditions of risk and uncertainty. MCDA is a sub-discipline of operational research and was developed in 1960s in the business sector. MCDA is used in the situation of having multiple, usually conflicting, criteria and therefore has a potential for implementation in spatial planning. Some examples of using the MCDA methods for the purpose of urban management are offered. General evaluation of the proposed approach is conducted in order to identify strengths and weaknesses that could be addressed in further research. So far, it seems that bringing together economics, operational research, ICT, and applying them in the field of urban studies, could improve city policy making and urban management. It seems fair to say that urban planners might have no other choice but to look far outside their own academic discipline in search of new tools; therefore, the paper encourages a discussion on whether methods derived from operational research could be incorporated into spatial decision making process.

2 DECISION MAKING AND PLANNING PROCEDURE

In the process of urban policy making several steps can be distinguished: complex analyses are followed by formulation of a vision, mission, and main objectives, then operational tasks are identified, and finally projects/activities pursuing these goals are recognized. This procedure is connected with making up the balance of resources and time schedule of urban projects (Ossowicz 2003). Between these elements several complex interrelationships, feedbacks, and correlations could be identified. An attention should be paid to a relatively large number of bodies, institutions, and groups involved in the decision making process and the fact that the interests of these parties may sometimes be in conflict. Therefore, following issues should be taken into consideration:

- the essence of city governance: definitions (city management, city governance, spatial policy, urban policy, etc.), features of governing, city governance in the light of organization and management theory, uncertainty and risk in spatial planning;
- local government: its role and tasks, structure, features, and management instruments;

- urban planning: actors, features and attributes of the local level spatial planning, models of integrated planning in cities, models of strategic planning (including models taking into account the specificities of public organizations management);
- city finances;
- controlling and monitoring.

The decision making process both within regional and municipal planning addresses a broad spectrum of issues such as, among others: transportation, environmental protection, research and development, competitiveness and innovativeness, economic activity, or social inclusion. The interrelations between these fields are described to some extent, however, no numerical (quantitative) analysis has been conducted.

3 METHODS

Literature review and own observations of planning practices indicate lack of comprehensive and advanced tools which could support decision making at local or regional level. The procedure of prioritizing spatial projects in a big city was described by Ossowicz (2003) who also paid attention to the use of mathematical analysis in the urban policy making. However, it seems fair to say that this matter has not been thoroughly investigated and resolved yet. The need to develop new solutions providing support for coordinated, rational, and transparent decision making is an important prerequisite to undertake a research on the topic of spatial decision making. In the next chapters of this paper, numerical solutions derived from operational research are offered and discussed. MCDA (multi-criteria decision analysis) is a sub-discipline of operational research and was developed in 1960s in the business sector and is helpful in the situation of having multiple, usually conflicting, criteria. In general, it is used to improve a decision making process by making it more rational and transparent (Figueira, Ehrgott, Greco 2005). There are several methods which help with: choosing the best option, building a ranking, or sorting alternatives – in general, these methods advocate rational choices. There is also a group of methods which do not support the decision making process directly, however, they are useful for problem structuring. Two of multi-criteria decision making methods, namely DEMATEL and PROMETHEE, are the focus of this paper.

3.1 DEMATEL

Decision Making Trial and Evaluation Laboratory (DEMATEL) is a robust analysis tool used for identification of cause-effect relationships (Fontela, Gabus 1974). It can be used for both tangible and intangible factors. The method has been applied to illustrate the interrelations among criteria and to find the central criteria to represent the effectiveness of factors/aspects. It has also been applied in many situations, such as marketing strategies, control systems, safety problems, development of the competencies of global managers, and group decision making (Lee et al. 2013). The end product of the DEMATEL process, namely the impact-relations map, is a visual representation of importance and causative nature of each analysed factor. To evaluate the relations, a pairwise comparison is conducted. The measurement criteria of 0, 1, 2, 3, and 4 are used to illustrate no influence, low influence, medium influence, high influence, and extremely high influence, respectively. Despite the interesting features, no application of DEMATEL method in spatial planning (neither regional nor urban) has been identified. The steps of the DEMATEL method (Lee et al. 2011) are described as follows:

Step 1: Find the average matrix

Step 2: Calculate the normalized initial direct-relation matrix.

We then create a matrix D by using a simple matrix operation on A. Suppose we create matrix D and $D = s \cdot A$ where

$$s = \min \left[\frac{1}{\max_{1 \leq i \leq n} \sum_{j=1}^n |a_{ij}|}, \frac{1}{\max_{1 \leq j \leq n} \sum_{i=1}^n |a_{ij}|} \right].$$

Matrix D is called the normalized initial direct-relation matrix. The (i, j) element d_{ij} denotes the direct-influence from factor x_i to factor x_j . Matrix D shows the initial influence which a factor exerts and receives from another. Each element of matrix D portrays a contextual relationship among the elements of the system and can be converted into a visible structural model—an impact-relations map—of the system with respect to that relationship.

Step 3: Derive the total-influence matrix T

A continuous decrease of the indirect effects of problems along the powers of matrix D , e.g. $D^2, D^3, \dots, D^\infty$, guarantees convergent solutions to the matrix inversion, similar to an absorbing Markov chain matrix. The total relation matrix T is an $n \times n$ matrix and is defined as follows:

$$\begin{aligned} \sum_{k=1}^{\infty} D^k &= D + D^2 + D^3 + \dots + D^n \\ &= D(I + D + D^2 + D^3 + \dots + D^{n-1}) \\ &= D(I - D)^{-1}(I - D^n) \\ &= D(I - D)^{-1}(I - D^n) \\ &= D(I - D)^{-1}, \end{aligned}$$

where I is the identity matrix and T is called the total relation matrix. The (i, j) element of the matrix T , t_{ij} , denotes the full direct- and indirect-influence exerted from factor x_i to factor x_j .

Step 4: Obtain the prominence and relation.

Once $T = [t_{ij}]_{n \times n}$ is obtained, we can define r and c as $n \times 1$ vectors representing the sum of rows and the sum of columns of the total relation matrix T as follows:

$$\begin{aligned} r &= [r_i]_{n \times 1} = \left(\sum_{j=1}^n t_{ij} \right)_{n \times 1}, \\ c &= [c_j]_{1 \times n} = \left(\sum_{i=1}^n t_{ij} \right)_{1 \times n}^t, \end{aligned}$$

where the superscript $'$ denotes transpose.

Let r_i be the sum of the i -th row of the matrix T . Then r_i shows the total effect, both direct and indirect, given by the factor i to other factors. Let c_j denotes the sum of the j -th column of the matrix T . Then c_j shows the total effect, both direct and indirect, received by the factor j from other factors. Thus when $j = i$, the sum $(r_i + c_i)$ gives us an index representing the total effect both given and received by the factor i . In other words, $(r_i + c_i)$ shows the degree of the importance (total sum of the effects given and received) that the factor i plays in the system. In addition, the difference $(r_i - c_i)$ shows the net effect that the factor i contributes to the system. When $(r_i - c_i)$ is positive, the factor i is a net causer, and when $(r_i - c_i)$ is negative, the factor i is a net receiver (Tzeng et al. 2007).

Step 5: Set a threshold value and obtain the network relationship map

In order to explain the structural relationship among the factors while keeping the complexity of the system to a manageable level, it is necessary to set a threshold value p to filter out the negligible effects in matrix T .

3.2 PROMETHEE

Another promising method is PROMETHEE (and its descriptive complement geometrical analysis for interactive aid which is better known as GAIA). The main advantage of the PROMETHEE method is the clear reasoning which helps decision makers build well-structured framework for the decision problem. It is useful for solving complex problems with several criteria that need to be evaluated. The method could be

applied to: choosing the best location for an investment, ranking action projects or investment plans, allocating resources. The information requested by PROMETHEE and GAIA is particularly clear and easy to define for both decision makers and analysts. It is based on a preference function associated to each criterion as well as weights describing their relative importance. Usually there is no alternative optimising all the criteria at the same time, therefore a compromise solution should be selected. (Brans, Mareschal, 2005). The algorithm of the method is as follows:

Step 1: Using the data contained in the evaluation matrix, the alternatives are compared pairwise with respect to every single criterion. The results are then calculated and expressed by the preference functions, which are calculated for each pair of options and can range from 0 to 1, where 0 means that there is no difference between the pair of options (indifference), 1 indicates a strong preference, and value between 0 and 1 indicates weak preference:

$$P_j(a, b) = F_j [dj(a, b)] \quad \forall a, b \in A$$

where:

$$dj(a, b) = gj(a) - gj(b)$$

For criteria to be minimised, the preference function should be reversed or alternatively given by:

$$P_j(a, b) = F_j [-dj(a, b)]$$

In order to facilitate the identification of preferences six types of particular preference functions have been proposed (Brans and Mareschal, 2005). Additionally, such parameters as threshold of indifference or threshold of strict preference can be used.

Step 2: Aggregated (global) preference degree for each pair of alternatives on each criteria is calculated:

$$\pi(a, b) = \sum_{k=1}^q P_k(a, b) \cdot w_k$$

Step 3: Positive and negative flow scores are calculated:

$$\begin{aligned} \phi^+(a) &= \frac{1}{n-1} \sum_{x \in A} \pi(a, x) \\ \phi^-(a) &= \frac{1}{n-1} \sum_{x \in A} \pi(x, a) \end{aligned}$$

Step 4: Net flow score is calculated in order to obtain a complete ranking of alternatives:

$$\phi(a) = \phi^+(a) - \phi^-(a)$$

4 RESULTS

In this chapter two example uses of the aforementioned methods are presented. The research is checking whether selected method, namely DEMATEL, derived from operational research could be incorporated into decision making process at regional level. The focus is on the 2020 Development Strategy for Lower Silesia Voivodeship which is one of the most important development documents prepared in and for the region. However, the methodology presented in this paper could be adapted and used while creating development strategies for modern and smart cities (Lorens, Martyniuk-Pęczek 2010). The method can be used for analysing linkages between urban policy goals or for evaluating planning process at local level (Ogrodnik 2015). The Development Strategy for a Voivodeship is the most important document drawn up by the self-governments of the Voivodeships (which are equal to NUTS-2). The document identifies strengths and weaknesses of the region and indicates objectives and priorities of the regional development. The strategy is a tool to design and stimulate the development: it serves as a guideline for the authorities and indicates fields requiring regulations and financing. The purpose of this document is to indicate the directions for economic and infrastructural development. It also serves as a tool for improving the life conditions of the inhabitants of Lower Silesia. The structure of the strategy is rather typical (compare: Dymon 2013, Kożuch 2011): initial analyses and diagnosis are followed by identification of

development goals; then, territorial dimension of the policy is described; next, financial aspects and implementation system are discussed; in the next step, the so-called development macro-spheres are identified; the document's last part is the monitoring section where development indicators are described. The most novel feature of the document is identification of macro-spheres which are groups of projects pursuing eight development goals. These goals cover eight key groups, so-called macro-spheres. Each macro-sphere is related to at least one strategy goal and they are aimed at strengthening the economic development of the Lower Silesia region. The relations between abovementioned macro-spheres and strategy development objectives are presented in the Table 1 below.

	Development of a knowledge-based economy	Development of sustainable transport and improvement of accessibility	Strengthening the competitiveness, especially of small and middle enterprises	Environmental protection, efficient use of resources, adaptation to climate change	Increasing the accessibility of information and communications technologies	Increase in employment and labour mobility	Social inclusion and improvement of life quality	Increasing the level of education and lifelong learning
Infrastructure		X		X		X		
Development of urban and rural areas	X	X	X	X	X	X	X	X
Resources				X				
Tourism		X	X	X		X	X	
Health and safety		X		X	X		X	X
Education, science, culture, sport and information	X				X	X		X
Society and partnership	X		X		X	X	X	X
Entrepreneurship and innovation	X		X		X	X	X	X

Table 1. Relations between adopted strategy goals and macro-spheres.
Source: own compilation; based on: The 2020 Development Strategy..., 2013.

The strategy offers also proposal of financial distribution of assets, however it is "an initial, qualitative", not quantitative, division (Strategia... 2013). This share was determined in an experts panel discussion, but no numerical methods have been used to support the process. This research offers an analysis of cause-effect relationship between the macro-spheres which could be useful for better structuring the problem. For the purpose of this study, the relations between macro-spheres have been analysed and named by the (former) Director of the Department of Regional Development in the Marshal's Office, who was co-responsible for preparing and issuing the 2020 Development Strategy for the Lower Silesia Voivodeship. The relations provided by the specialist are presented in the table below (Table 2), which is a direct-relation matrix

	Infrastructure	Development of urban and rural areas	Resources	Tourism	Health and safety	Education, science, culture, sport and information	Society and partnership	Entrepreneurship and innovation
Infrastructure	0	4	1	3	4	2	2	3
Development of urban and rural areas	3	0	1	3	4	4	4	3
Resources	1	3	0	3	3	1	1	2
Tourism	2	4	1	0	3	2	3	1
Health and safety	1	3	1	3	0	2	4	2
Education, science, culture, sport and information	2	3	3	2	2	0	4	4
Society and partnership	2	2	2	3	3	3	0	4
Entrepreneurship and innovation	3	4	3	1	2	3	3	0
Scale	0 – no direct impact (one medium to another); 1 – low impact; 2 – average impact; 3 – high impact; 4 – very high impact							
Example	Macro-sphere “Education, science, culture, sport and information” has a very high impact (4) on the sphere “Entrepreneurship and innovation”, while “Entrepreneurship and innovation” has a high impact (3) on “Education, science, culture, sport and information”.							

Table 2. Direct relations between macro-sphere. Expert's evaluation.

The findings indicate that “Development of urban and rural areas” is the most important macro-sphere with the value 11.98, while “Resources” is the least important component with the value 7.25. The ranking of macro-spheres based on their prominence is as follows: “Development of urban and rural areas”, “Society and partnership”, “Entrepreneurship and innovation”, “Education, science, culture, sport and information”, “Health and safety”, “Tourism”, “Infrastructure”, “Resources”. “Infrastructure”, “Resources”, “Education, science, culture, sport and information”, and “Entrepreneurship and innovation” are net causes, whereas “Development of urban and rural areas”, “Tourism”, “Health and safety”, and “Society and partnership” are net receivers (based on $r-c$ values). The cause and effect diagram is shown in Figure 1. The most “causative” (i.e. the most influential) macro-sphere is “Infrastructure”, followed by “Education, science, culture, sport and information” and “Resources”. Two macro-spheres: “Entrepreneurship and innovation” and “Development of urban and rural areas” are very close to the cause-effect borderline. The most “effectual” macro-sphere is “Health and safety”, then “Society and partnership”, then “Tourism”.

Figure 1. The relationship map.

Another method that seems to be promising for use by urban planners is PROMETHEE, which (as all outranking methods) can simultaneously deal with qualitative and quantitative criteria. Criteria scores can be expressed in their own units. The method can be used for example for solving a locational problem. If we consider buying a building plot, we take into account several attributes. For instance, we may consider following criteria:

- f1 – utilities/services (water, electricity, etc.) – if yes, then value 1; if not, then value 0;
- f2 – price of a plot (thousands, PLN – Polish Zloty)
- f3 – ground surface (square metres)
- f4 – number of shops within d = 300 metres
- f5 – distance from city centre (kilometres)

We assume that price of a plot and distance from city centre should be minimized and ground surface and number shops should be maximized. In this example we consider four alternatives a_i , $i=\{1,2,3,4\}$. The starting point is an evaluation matrix, which presents the performance of each alternative in relation to each criterion. Weights giving the relative importance of the criteria are given in the last row of the table (Table 3). Decision makers are required to weigh criteria and to choose a preference function. PROMETHEE does not provide specific guidelines for determining weights to criteria, but assumes that the decision maker is able to weigh the criteria appropriately, at least when the number of criteria is not too large (Macharis et al. 2004).

Alternatives:	Criteria				
	f_1	f_2	f_3	f_4	f_5
a^1	0	249	850	1	21,5
a^2	1	386	923	8	7,25
a^3	1	366	873	11	12
a^4	0	324	640	4	8
w_k	0,2	0,3	0,25	0,1	0,15

Table 3. Evaluation table

Next steps of PROMETHEE method, i.e. calculating global preference degree for every pair of alternatives and calculating net outranking flows are presented in the tables below (Table 4 and Table 5).

$\pi(a^i, a^j)$	a^1	a^2	a^3	a^4
a^1	0	0,300	0,300	0,55
a^2	0,625	0	0,261111	0,525
a^3	0,486111	0,125	0	0,55
a^4	0,175	0,300	0,397	0

Table 4. Global preference degree for every pair of alternatives

	ψ^+	ψ^-	ψ
a^1	0,383	0,429	-0,045
a^2	0,470	0,242	0,229
a^3	0,387	0,319	0,068
a^4	0,291	0,542	-0,251

Table 5. Net outranking flows

In the example discussed above, the best solution, according to the given criteria and their weights, is alternative a_2 , followed by a_3 , then a_1 , and last one is a_4 . In other words, plot number 2 seems to be the best choice for the decision maker – according to the criteria and weights he provided.

5 CONCLUSIONS

The paper presents possible application of two methods derived from operational research. Selected application case of the DEMATEL technique in spatial planning deals with the development strategy for a Voivodeship (region equivalent to NUTS-2). The calculations presented in this paper allow to determine the prominence and cause-effect relationships between important regional development strategy components. The analysis of the macro-spheres, which are directly linked with strategy goals, help with better structuring and understanding the problem. The reflections presented in the paper may serve as

guidelines for division of financial assets between macro-spheres, i.e. between groups of projects pursuing strategy objectives. The DEMATEL technique was exercised on a regional level; however, merits of the method make it suitable for solving other decision making problems, for instance in urban planning while preparing a city policy or city development strategy. It seems fair to say that such methods may be a promising tool while designing a “smart” development strategy.

The PROMETHEE methods (or outranking methods in general) could be used in various multi-criteria problems, such as ranking of investment plots (for various activities) or ranking of city development objectives/goals in the process of strategy making. By providing a ranking of alternatives, the PROMETHEE method allows for evaluation of alternatives and therefore for supporting the decision making process. Thanks to this, the process of choosing the optimal solution gains transparency and objectivity. Methods presented in this paper may be useful for solving locational problems or for formulating development policy at local or regional level.

ID 1697 | MULTI-CRITERIA DECISION ANALYSIS FOR PROMOTING BIKE-FRIENDLY CITY VISION OF IZMIR USING GIS

Sevim Pelin Özkan¹; Zeynep Özçam²; Fatma Şenol³

¹Izmir Institute of Technology; ²Middle East Technical University; ³Izmir Institute of Technology
pelinozkan@iyte.edu.tr ; zeynepozcam@gmail.com ; fatmasenol@iyte.edu.tr

ABSTRACT: Deploying GIS at its analysis of multilayered spatial data about Izmir (the third biggest metropolitan city in Turkey), this paper aims at suggesting ways of providing bicycle routes and roads in the already developed built environment of the densely populated cities. Focusing on multiple characteristics of topography, land use and population, the study deploys overlay analysis and network analysis respectively at city level and district level. Despite of the limited number and characteristics of data available about Turkish cities, this study has been limited to the lack of crime data and travel demand data of related neighborhoods.

1 INTRODUCTION

Bicycle use is widely promoted by many researches and policy initiatives of industrialized countries as the efforts related to sustainable development, carbon-free and non-motorized transportation and “healthy” cities. While some of these policies and researches relate to promoting changes in lifestyles and habits of physical activities (eg., Wendel-Vos, Schuit, De Niet, Boshuizen, Saris, Kromhout, 2004), others focus majorly on planning and design of built environment and of transportation systems (e.g., Huang & Ye, 1995; Rodriguez & Joo, 2004).

A major challenge is how to provide bicycle roads through the developed built environment of the densely populated cities that do not have any prior bicycle routes and infrastructure. This paper aims at answering this question, while deploying geographic information system (GIS) at its analysis of multilayered spatial data about the city of Izmir as being the third biggest metropolitan area in Turkey.

In recent years, making bicycle transportation a part of city life has become one of the main purposes of Izmir Metropolitan Municipality. With this purpose, Izmir aims to promote cycling routes in the following years and the Metropolitan Municipality has been making significant efforts for turning the city into a more bicycle-friendly city. However, availability of physical environment for cycling is an important factor to consider. To promote and upgrade cycling routes in a dense built environment is a challenging process. We claim that Izmir has a potential to offer alternative transportation types and networks prioritizing bicycle, despite its dense urban environment.

This study aims at promoting the bicycle-friendly city development efforts of Izmir. It tries to consider many different spatial factors while promoting bicycle routes within a dense built environment. At its analysis, the study interrelates various data about the characteristics of the natural and built environment and also the spatial distribution of population characteristics at the metropolitan, district and neighborhood scale. This study aims to combine different techniques of spatial analyze at different spatial scales in order to determine potential bicycle routes for areas with different land uses.

This study calls the determinant factors of bicycle facility planning as environmental assets. It mainly aims at taking into action the knowledge of the environmental assets by digitizing and visualizing them. Focusing on the metropolitan scale of Izmir with 30 districts at first step, this study considers environmental assets as parks, recreational areas, topography and analyzes them in the GIS environment. These are the spatial data infrastructure that would able us to reveal potential bicycle route networks. Additionally, some inhibitor factors such as population density and different age range groups are also taken into account. All these spatial data are used to detect the areas that high level of spatial infrastructure are embedded by using overlay analysis.

Afterwards, focusing on central districts of Izmir, network analysis is performed between determined stops by taking into account the proximity and continuity at the road network level.

Study findings suggest that overlay analyze technique can be applied to detect neighborhood levels and network analysis can be performed to detect potential routes and to model spatial relations of local nodes. Not only local nodes but also transportation corridors are the basic unit of analysis within network analysis.

2 LITERATURE REVIEW

While promoting the use of bicycle and creation of bicycle networks within a city, it is important to give attention to recent bicycle transportation studies. Studies that relate to the question of how to determine bicycle roads in a city emerge in various fields (majorly urban geography, transportation, urban planning and urban design) and research areas especially about health, healthy living, sustainable transportation and non-motorized transportation (e.g., Huang & Ye, 1995; Wendel-Vos et al., 2004; Segadilha & Sanches, 2014).

Until now, studies related to bicycle network planning have focused primarily on route choice criteria and the factors affecting bicycle use which are giving very useful insights for designing bicycle routes within a city. These studies give emphasis on the factors that can affect bicycle use. These factors are mainly determined as the characteristics of the roadway and bicycle routes, automobile traffic, availability of public transport, and factors related to the built and natural environment (Aultman-Hall, Hall, & Baetz, 1997; Rodriguez & Joo, 2004; Segadilha & Sanches, 2014; Milakis & Athanasopoulos, 2014). Concerning the built environment, bicycle usage is very much related to the location of the areas with higher employment and population density and presence of schools, recreational areas, parks at the origin and the destination (Rodriguez & Joo, 2004; Rybarczyk and Wu, 2010). When it comes to the natural environment, topography and slope become major determinants of bicycle route planning (Rodriguez & Joo, 2004). In addition to all these, safety becomes another determinant of bicycle use (Allen-Munley et al., 2004; Parkin et al., 2007) which is related to characteristics of roadway and automobile traffic. According to Rybarczyk & Wu (2010) these determinants can also be categorized as demand based and supply based criteria for bicycle route planning; the demand-based criteria includes business and land uses such as schools, parks and recreation areas and supply-based criteria includes demographics, safety, public transportation, road characteristics and existing bicycle routes.

Overall, studies underline a set of group of factors that can direct the design and planning of bicycling roads. In particular, bicycle trips tend to increase in the presence of mixed uses of land, slight topography, improved street connectivity, direct routes without interruption and safe separation from motorized traffic (Aultman-Hall, Hall, & Baetz, 1997; Rodriguez & Joo, 2004). High density areas, schools, parks and public transportation hubs are also anticipated as land uses that support the use of bicycle routes. Therefore, these factors should be taken into account in the planning of bicycle networks in a city.

All these information from prior studies offer the determinants for bicycle network planning however, these studies cannot offer a complete answer to where to develop new bicycle routes within an already developed built environment that lacks a well-connected bicycle network. Only a few studies have applied a comprehensive methodology to determine bicycle routes within a city (Huang & Ye, 1995; Rybarczyk & Wu, 2010; Milakis & Athanasopoulos, 2014). Additionally, as bicycle route planning requires many factors to consider, geographic information system (GIS) technology provides an excellent opportunity to process all available data for bicycle route selection. However, small number of studies have applied GIS in the planning of bicycle routes until this time (Huang & Ye, 1995; Rybarczyk and Wu, 2010). Even more, these studies were dealing with the existing routes in a city. This study, too considers various data about the characteristics of the natural and built environment and also spatial distribution of population characteristics at the city scale and neighborhood scale. While dealing with the data, GIS technology has been used. By this, it is aimed at promoting bicycle routes in the city of Izmir, while making contribution to the GIS based bicycle route planning in an already developed built environment lacking a complete bicycle network.

Relating to these research issues, the design and planning of built environment is discussed and promoted as a tool especially to motivate and assist people's use of non-motorized transportation modes, basically walking and bicycling (Rodriguez & Joo, 2004; Wendel-Vos et al., 2004). In other words, it is expected that if the built environment is designed and planned with adequate and suitable infrastructure, land use, natural assets and allocation of other resources for non-motorized transportation, people will be more

willing to use such modes of transportation. Such kind of environments can provide opportunities with healthy living, sustainable living and transportation.

3 STUDY SITE

In recent years, the Metropolitan Municipality of Izmir has the goals of sustainable city development, including environmentally sensitive and sustainable transportation. As a part of these goals, the Municipality aims at promoting cycling routes and has been making significant efforts for turning the city into a more bicycle-friendly city. Accordingly, for providing mobility between districts and city center, the creation of nature-friendly corridors with cycling and walking routes has become a priority in the planning of Izmir (Izmir Metropolitan Municipality, TMP Revision, 2016).

However, existing bicycle routes are incapable of providing a complete bicycle network for the city. There are no continuous bicycle routes to serve for the whole city except the coastal road, which is mainly used for recreational purposes. Additional routes are promoted for providing bicycle access to the residential, social and cultural spaces, major transfer stations, university campus areas and other major usages in the city center (See; Figure 1).

Figure 1 – Bicycle Routes

The third biggest metropolitan area of Turkey with a population near 5 million, Izmir is located on the Aegean coast, between the 37°45' and 39°15' north latitude and 26°15' and 28°20' east longitudes and covers an area of 12,012 km² (See; Figure 2) (Izmir Governorship, 2017) with a mild climate during the year. Located on its bay area at the Aegean coasts, the city of Izmir has very high urban densities at central coastal neighborhoods and extends to hilly neighborhoods. With one of Turkey's densest urban population at its central districts at the coast, the city of Izmir has a metro system with its city line and regional line, a newly developing tramline, a limited level of sea transportation and very recently planned bicycle route infrastructure.

Figure 2 – Location of Izmir

In 2015, while the average age of Izmir's metropolitan population is 4.168.415, the average age in its central districts is 35-39 with an education levels higher than Turkey's average (Izmir Governorship, 2017). At a close examination of these 11 central districts, it can be seen that children (age 3—13) ranges are clustered in Karşıyaka, Bayraklı and Gaziemir districts, young (age 14—22) ranges are clustered in Karşıyaka, Bayraklı, Konak districts; while seniors (age 55+) are clustered in Karşıyaka, Bayraklı, Balçova and Konak districts (See; Figures 3).

Figure 3 – Maps of age range of 3_13, 14_22, 55+

These age range thematic maps visualize and determine the clusters of different population groups demanding different spatial activity types. We admitted that we should pay attention to the accessibility of the local service areas, especially the neighborhood parks and bicycle routes, within the walking distance. Therefore, we used the "neighborhood ratio" of the age data as seen in the legends. We obtained this ratio by calculating the ratio of the number of each group of people in the neighborhood to the neighborhood population.

4 STUDY METHOD

As bicycle route planning requires many data layers to deal with, GIS can easily integrate these data layers in the form of digital information, thus can reduce the cost of data assembly. Furthermore, GIS can perform spatial operations, such as terrain modeling and network analysis, which are crucial to bicycle route planning; and its network analysis data model and path-finding algorithms make it a straight-forward way to implement sophisticated cycling models that can incorporate factors such as traffic, topography, built environment attributes and socio-economic data at the same time (Huang & Ye, 1995).

The determining factors for walking and bicycle route planning has been differentiated as demand side and supply side (Wigan, Richardson & Brunton, 1998; Rybarczyk and Wu, 2010). While demand side talks about the spatial distribution of population characteristics such as age, education, gender, and health condition (e.g., Huber, 2003, Wigan et al., 1998), the supply side underlines the physical/environmental

characteristics that include natural elements such as topography, slope and land use characteristics such as workplaces, green areas, housing, schools and transportation networks (Martens, 2007; Rodriguez & Joo, 2004). Within the supply side factors, green open spaces have great importance on bicycle route network planning. Recreation areas and parks are desirable destinations within a route (Wendel-Vos et al., 2004) as they generates high level of bicycle use. Lastly, population density provides an estimation of potential demand for and access to bicycle facilities (Huber, 2003; Allen-Munley et al., 2004).

This study calls the determinant factors of bicycle facility planning as environmental assets and takes into action the knowledge of the environmental assets in the GIS environment. Within the context of 11 districts of metropolitan area, this study considers environmental assets as parks, recreational areas, topography and roads that could be determined as supply side. These are the spatial data infrastructure that can reveal potential bicycle route networks. Additionally, some inhibitor factors such as population density, motor vehicle traffic volume and crime statistics are taken into account. All these spatial data are used to detect the hotspot clustering with high level of spatial infrastructure. Afterwards, network analysis is performed between potential clusters based on proximity and continuity. While detecting the clusters focuses on population density, parks, recreational areas, schools, weather and crime statistics, detecting the networks considers motor vehicle traffic volume, topography and main public transportation hubs.

The methodology of the study comprise of two main steps. First one evaluates metropolitan scale big data and determines subscales suitability for route planning. Available data at metropolitan scale are geo-raster data consisting of the population density of each age range, park density, slope and digital elevation. On that aim, overlay analysis has been implemented as using population density of different age ranges, green space density, slope and elevation (srtm-dem of the Izmir province has 90 m of grid size resolution; 45 m of horizontal accuracy; and 15 m of vertical accuracy) data for neighborhood detection. Second one seeks for the bicycle route determination which may be varied based on the different activity within those neighborhoods. For this aim, network analysis has been implemented through road network, stream network and green areas.

5 FINDINGS & DISCUSSION

Within the context of overlay analysis, the population density raster of child and seniors, park density raster, slope and digital elevation data have been reclassified into three defined interval (See; Figure 4). The reclassified digital surface data have been overlapped in the ArcMap environment. The different age range maps have been used to generate different overlay maps. The different age groups have been related with the activity differentiation of bicycle users. Two synthesis maps as a combination of these factors shows the most suitable areas at neighborhood levels for bicycle planning. Within the most suitable areas of two overlay analysis; 'Bostanlı' neighborhood has been selected as the common area for the next step to generate the network analysis (See; Figure 5, 6).

Figure 4 – Reclassified data

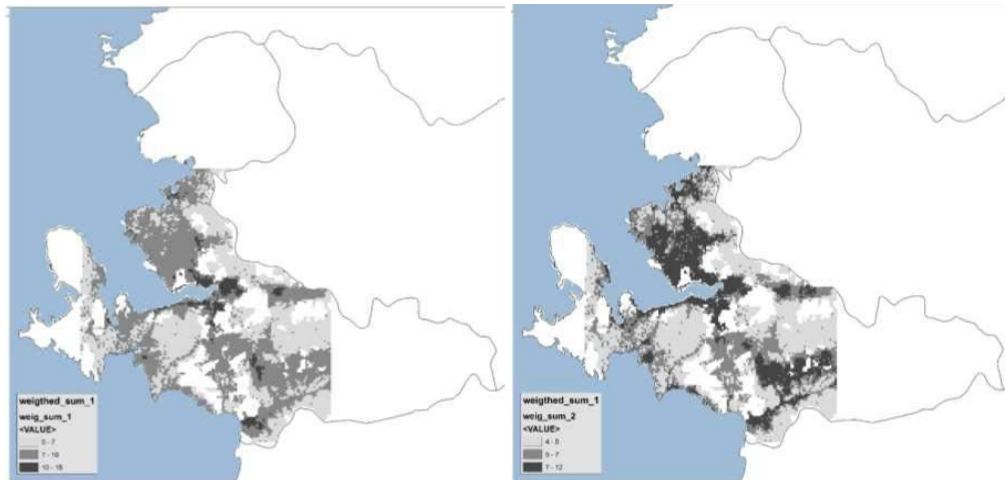

Figure 5 – Synthesis map 1 | Figure 6 – Synthesis map 2

Within the context of network analysis, road networks, work places, transportation hubs, stream networks and the parks have been used respectively for creating network dataset. While work places and road network are associated with the working age group based on transportation activity; the parks and stream networks are associated with the child and old age groups for mostly leisure activity. Therefore, the determinants of the different type bicycle usage have been defined and divided into two categories; the determinants for bicycle use for recreation, the determinants for bicycle use for mobility. Relatedly, analysis has been done according to this categorization.

As an outcome, two potential routes have been determined via network analysis that may serve for two different activity types (See; Figures 7, 8). The Figure 7 shows the route (1) passing through the few

numbers of work places and parks starting from the ferry station targeting multi-modal transportation system. The other route (2) shown in the Figure 8 passes through the parks along the stream networks targeting the leisure activities.

This study aims to find out a methodology via GIS environment for detecting potential bicycle routes within the dense spatial contexts. While benefitting from digital visualizations and analyzes, we have used city scale big data to be able to determine the most suitable areas for bicycle route planning. Due to the limited data that is available about Turkish cities, this study has been limited in terms of some social characteristics of the population and the neighborhoods. Thus, crime statistics and travel demand data of the related neighborhoods have been lacked. Determining bicycle routes within the dense spatial context by using the geographical and physical data was another challenge of this study.

Figure 7 – Bicycle route (1) for mobility Figure 8 – Bicycle route (2) for recreation

6 CONCLUSION

The bicycle road infrastructure is gaining ground serving for healthy cities and well-being via non-carbonized, and sustainable mode of transportation. It has been taken as an important option both for physical activity and sustainable mobility. Therefore, the development bicycle road infrastructure becomes an important issue in urban planning agenda, especially in the era in which sustainability is a major goal for future development. As being one of the important metropolitan districts of Turkey, Izmir have also future targets on becoming bicycle-friendly city despite its dense and already-developed built environment with inadequate bicycle road infrastructure. This study aimed to contribute this target, while seeking for a methodology using digital analyzing techniques for new bicycle networks within dense built environments. While doing this, the study tries to integrate different digital analyzing techniques. The determination of bicycle route has been done by overlapping many different big data at GIS environment. As bicycle route planning requires dealing with many different spatial data at the same time, GIS provided an efficient environment to make this analysis. As a result, two different bicycle routes have been suggested serving for different purposes; namely for mobility (route 1) and recreation (route 2), furthermore we have proposed a comprehensive bicycle route planning method using GIS for promoting the bicycle-friendly city vision of the city of Izmir.

ACKNOWLEDGEMENT

This study is developed in relation to the data of a research project ("Evaluation of Existing Neighborhood Parks based on Need-Based Equity") (Project no: 215K239) supported by the Scientific and Technological Research Council of Turkey.

1 INTRODUCTION

Some categories of citizens are excluded by most decisions about how to manage, transform and use urban space. Among these weak categories of citizens there are teenagers, who are the object of many specific urban policies, even if they are rarely involved as active subjects of the policy making process.

The understanding of the real urban geographies, through bottom-up perspectives, and the engagement of citizens, with participatory policy-making, are central in the smart cities narratives, often associated to the use of ICT technologies.

There is often a gap between the city for teenagers – formally planned and ruled by adults – and the city of teenagers, which is actually lived, transformed, occupied and represented by young people. Can the use of ICT fill this gap of knowledge to support participatory policymaking?

This contribution presents the methodologies and the results of an action-research project called Teencarto, carried out by the University of Turin and the City Council. The project involved more than 600 teenagers from 16 schools, in a massive process of community mapping aiming at producing a representation of their urban geography.

The mapping process has been based on First Life, a map-based social network, which aims at reconnecting digital and real spaces, using cartographic representations and crowdsourcing. The specific relational perspective allowed by the social networking functionalities of the application, specifically redesigned for this project on user-centered principles, favors a real shared representation of urban space.

2 TEENAGERS AND URBAN SPACES

Does something like a “teen geography” exist?

As it is known, the existence of adolescence or teenage, as the transition between childhood and adulthood, is a cultural construction, characterized historically and geographically (Aries, 1968; Levi, Schmitt 1994; Savage, 2009; Lesko, Talburt, 2011; Furlong, 2013; Cieslik, Simpson 2013; Kamp, Kelly 2014).

In this context, teenagers are acknowledged as a specific social group, characterized by psychological and behavioural specificities and playing a specific role in society (Avanzini, 2012).

Among the reasons for the “invention of adolescence” in Western society (Savage, 2009), we can identify historical factors, such as the abolishment of child labor and the extension of compulsory education; cultural factors, with the social acceptance of the increased length of the period of dependence of

teenagers by their parents (Berrini and Cambiaso, 1995); economic and market factors, in particular through the identification of teenagers as a consumer group particularly sensitive to marketing (Brooks, 2003).

Of course, despite some common traits, hardly teenagers can be treated as a unitary world, even within the cultures of the most economically advanced countries. The multiplicity of microcultures among teenagers is indeed one of the central themes of the sociological and cultural hub of studies on youth (Skelton and Valentine, 1998; Bennett, Kahn Harris 2004; Hodkinson, Deicke 2007; Istituto Giuseppe Toniolo 2014, 2016; The Subcultures Network 2014; Genova 2015; Blackman, Kempson 2016).

Adolescence is also associated with a specific spatial behavior, partly related to the affirmation of power relations, which define what are the acceptable spatial behaviors of different age groups (Massey 1998; Holloway, Valentine 2000; Holt 2011). The literature suggests though that the sociocultural and psychological characteristics of teenagers are actually translated into specific modes of attendance, use and perception of urban spaces, which form the basis of teen geography, distinct from the general youth geography (Weller, 2006).

Matthews et al (1997) have proposed a useful systematization of some characteristics of the micro-geographies of adolescents, according to which the spatiality of teenagers would be characterized by elements such as the need to create physical spaces of independence and exercise their recently gained and still limited autonomy; spaces in which each juvenile microculture can perform its peculiarities and is recognized through the creation of exclusive territoriality; ordinary and apparently marginal spaces, which are given value as part of everyday geographies.

Lieberg (1995) identified two main typologies of places in the teenager geography: a) "places of retreat" (e.g. backyards, basements, parking lots, etc.), where they can stay away from the adult gaze, which is always present at home and in "institutional" places and b) "places of interaction", where they can perform their public character, seeing their peers and being seen by them (e.g. main streets, shopping malls, etc.).

The places of the individual and collective geographies of teenagers in the city, though, are planned and managed by adults, which perform their power of parents, educators, city planners, private players. The public space is an adult space (Collins and Kearns 2001), in which adults reproduce its authority in a hegemonic way and in which adolescents perform some sort of negotiation, or even resistance (Hil and Besant, 1999), eventually bringing to a separation between the city for teenagers - which is planned and thought for them - and the city of teenagers, which is actually used, performed and represented by adolescents.

A typical trait of the teenage relationship with space is the limited capacity that they have to formally intervene in transformations, since they are seldom involved in decision-making processes and lack the legal power to own and manage private property, thus becoming frequenters and producers of "landscapes of powerlessness" (ibid.), which can change without them having the power to intervene, following the action of adults or other groups of peers who can exercise more power.

If streets and outdoor public spaces were the typical space of action and interaction of teenagers in urban areas (Cahill, 2000), the progressive privatization of the public space in the contemporary neoliberal city and the emergence of public uses of private spaces (Mitchell, 1995; Ewins, 2002; Bottini, 2010; Nemeth and Schmidt, 2011) contributed to a growth of control of behaviors in urban spaces and to a "moral panic" toward some groups of people, among which teenagers (notably if non-white and male) (Evans, 2008). As a consequence of the progressively bigger control on behaviors in public spaces, of families' increased perception of unsafety in urban streets and of commercial strategies of private actors, teenagers lost the habit to hangout and spend time in squares, parking lots and streets and more and more often moved to clearly stated private spaces that they use as public ones, typically shopping malls (Anthony, 1985; Matthews et al, 2000), not only in North American, British or Australian cities, where this trend firstly emerged, but also in Italy (Lazzari e Quarantino, 2010).

Even if some researches, showed the still existing importance of material meeting places in the daily geography of adolescents (Martino et al, 2015), the pervasive diffusion of personal digital technologies contribute to change the approach of youth with urban space.

The ability to decide in real time where to meet, with a phone call or message, has changed the way the meeting places traditional had for teenagers. Moreover, chat and social networks represent virtual meeting places unknown to those who were only teenagers a decade ago and that partly took the place of the "hanging around" places that characterize teen geographies (Vanderstede, 2011).

The research presented in this contribution aimed to explore teenagers' geography in physical space starting from the creation of a virtual space, through a process of community participatory mapping, based on the idea of Volunteered Geographical Information (VGI), presented in the next paragraph.

3 PARTICIPATORY PRODUCTION OF GEOGRAPHIC KNOWLEDGE

In 2007, Michael Goodchild introduced the term Volunteered Geographic Information (VGI), categorizing those geographic information systems through which information is collected directly by users (considered as human sensors) on a voluntary basis.

Since then, the term VGI has become representative of a phenomenon that is spreading more and more in the world of geoICT, particularly on the web, fully responding to the web 2.0 paradigm where interactivity plays a key role in the development choices of computer platforms. The willingness and the ability to enter geographic information by users entails different challenges and raises new research questions that require an increasingly interdisciplinary approach (Capineri, 2016)

The spread of systems for crowd mapping led to the emergence of a new figure, the neo-geographer (Haklay, 2013). The collection and dissemination of geographic information through contemporary cartography changes to the extent that the cartographer, in the age of geoWeb 2.0, no longer has to be "expert" in the construction of a digital card, but to be engaged in interacting with more and more user friendly platforms .

This passage, considered by Critical Cartography (Crampton et al 2005, Casti 2013), takes on the connotations of a substantial transformation of the very meaning of the maps, which become the result of a collective gathering of information.

The awareness of the added value that the involvement of citizens, who do not necessarily have mapping skills, can guarantee the processes of analysis and representation of territories and geo-referencing processes dates back to well before the advent of the contemporary digital mapping revolution, which is based on concepts like neogeography, crowdmapping and volunteered geographic information.

Although some methodologies have already been experimented with experiences such as the mental maps proposed by Kevin Lynch (2006; 1960) or the English Parish Maps, the first participatory mapping definitions, in the field of the analysis of the territorial processes, were produced by the FAO around the mid-1990s (Burini, 2004).

The field of application of the first structured participatory mapping experiences is the evaluation and management of local resources by rural communities, particularly in developing countries (Chambers, 2006). In this context, the co-production of cartographic knowledge, often carried out under international cooperation projects, allows the emergence of territorial values that are invisible in the eyes of external experts, increasing the degree of legitimacy and acceptance of development projects by local communities (Burini, 2004).

In Italy, participatory mapping is used in some of the most interesting participatory planning cases, for example in Piano Paesaggistico Regionale (landscape regional plans) of Apulia and Tuscany, using methodologies such as community maps, aimed "to foster the role of inhabitants in the construction of maps able to represent in a communicable and meaningful manner, through weak formalization techniques, their living space (territory of daily life), expressing the environmental, territorial, landscape and productive values recognized by the local community "(Magnaghi, 2010).

The diffusion of digital technologies and automatic geolocation and geo-referencing systems has radically altered the concept of participatory mapping directly involving maps users in the production of geographic knowledge. The most used concept to describe this new perspective, of almost total disappearance of the rigid boundary between those who produce cartographic knowledge and those who use it (Rana and

Joliveau, 2009) is the one of “crowdmapping” (Aitamurto, 2012), which transfers to the field of mapping the idea of information crowdsourcing, giving a role in the production of knowledge to large and diversified groups of people, not necessarily previously formed (Heipke, 2010). More and more each of us is subject to passive crowdmapping, and understanding how to become aware subjects of active crowdmapping essentially appears to be a project of political geography. The relationship between unintentional (data that users provide unintentionally) and voluntary (in a planned crowdmapping process) geographic information is a matter of great importance (Capineri, Rondinone, 2011).

The possibility to easily produce cartographic representations of the territorial complexity led the participatory digital cartography to gain a central role both in institutional participatory planning (through the so-called Public Participation GIS, PPGIS: Brown, 2013), and in many bottom-up and grassroots practices of active citizenship and community participation, as a tool of the so called “counter-cartography”, opposed to official cartography produced by experts and by the most influential actors (Parker, 2006, Schofield, 2014).

On the one hand, it seems undeniable the potential of participatory mapping in terms of information democratization, particularly with regard to the inclusion of the weaker actors, the transparency of information and the empowerment of population involved processes of self-reflection about themselves and their relationship with places, resources and other actors (Parker, 2006).

On the other hand, though, there are many critical voices on participatory mapping, which go far beyond doubts about the accuracy, quality and cleanliness of the data collected through the involvement of unskilled users without the application of appropriate filters (Flanagin And Metzger, 2008).

The main doubt raised in the field of the so-called critical GIS (Sheppard, 2005) is the actual increase in the involvement of the weaker population groups through participatory processes using GIS tools, whose technological character, especially in the early years of their dissemination, it is more likely to marginalize them less digitally literate citizens (Elwood, 2002).

The weakest groups of population continue to be excluded from certain processes: it is therefore essential to observe the relationships between digital participatory mapping and democratization processes with a sufficiently critical analytical gaze (Haklay, 2013).

A study of Tabusi and Dumont (2012) on the relationship between societies and virtual spaces shows that the articulation of society and power in cyberspace passes for many actors and for many positions, not always immediately evident and never only virtual. It is unhelpful and unrealistic then to talk about virtual space as other than traditional space. The two authors propose to use the concept of “increased space”. Recalling this inspiration we can therefore speak of increased spatiality and territoriality, resuming the definition of territoriality proposed by Raffestin (2012), and highlighting how the whole of relationships with externality and alterity can be expanded through the use of ICTs (biometric sensors, satellite navigators, personal digital maps, etc.).

As a result of the incredible spread of geoICTs and the growing interest surrounding them, the new challenge is to exploit the multiple nature of the information, to reach a representation of space as a social product, focusing on those social phenomena that, even articulating in space, do not have with it an immediately apparent relationship. We can investigate the meaning that space assumes in a relational dimension between different social actors, thus focusing not so much on the “representation of space” but on the “space of representation”. According to Lefebvre (1991), we can define the latter as the living space of sensations, imagination, emotions, and meaning that is part of our daily life practices.

The research described by this paper is based on a conceptual framework linked to the world of VGIs that is constantly evolving. Cases of use and technological development are increasingly characterized by mutual dependence. Taking this perspective into account, it is necessary to emphasize the function of off-line accompaniment of users. In particular, the digital engagement given by the usability of proposed technology and the definition of maps’ legends and categories should be the results of participated debate and discussion.

The ability to process large amounts of geolocalized information is only possible through the use of new technologies. As a result, the challenges we face today seem to relate to balancing off-line methodologies of participation with digital activities. On the other hand, the increase in the quantity and quality of

computable information opens new perspectives in relation to the potential for processing and the creation of new information.

4 METHODOLOGY

The work in schools was structured in three two-hour classroom meetings for each of the 36 involved classes (for totally 620 teenagers involved).

The first meeting aimed to engage students and share with them the aims and the spirit of the project. The main goal of this phase was to convey to teenagers the idea not to be just objects of research, but rather actors in a wider process of participation and co-production of knowledge, aimed at dialogue with institutions. On the same day, students were introduced to concepts of co-production of knowledge, participatory mapping, crowdmapping and web narrative. The theoretical part of the lesson was followed by two practical activities aimed at increasing the confidence of pupils with the production of maps and with the role of knowledge producers that the project intended to attribute to them. The first activity consisted in the drawing of mental maps of their neighborhoods or towns, with the purpose of introducing them to the production of maps and to the self-reflection about spatial behaviors.

The second activity focused on a sort of digital “treasure hunt”, during which students, divided into groups, had to find the locations of some murals painted on the walls of Turin, of which only one photograph was provided.

In the second day of activity students were involved in the actual production of a map of the most significant locations in their daily geography.

Participatory mapping work has developed around three main themes.

At first, boys and girls were asked to reflect on the places in the city that they mostly frequented (the “frequented city”), putting them on the map and attributing to them names, formal or informal ones, thus creating an interesting teenagers’ toponymy map), a detailed description and keywords.

The same activity was carried out to map the “inaccessible city” asking them to indicate which places they avoid or which ones they can not attend for various reasons (economic, perceived insecurity, prohibitions).

Thirdly, particular attention was given to the city that the boys and girls imagine for the future, asking them to imagine a transformation project for the city (“the imagined city”). These imaginative projects could involve the creation of new places or the transformation of existing and perceived places as degraded or unsuitable to the needs of adolescents.

The third meeting was devoted to this, during which a discussion was held in each class about the interest and feasibility of the proposed projects.

5 RESULTS – YOUTH GEOGRAPHIES IN TORINO

5.1 SPATIAL DISTRIBUTION ANALYSIS

Activities which have been carried on during the project have led to the collection of 2465 points of interests (POI), whose 2069 are within Torino’s administrative boundaries. Figure 1 shows the neighborhood where the schools involved are located. It can be seen that we have covered both the center and the peripheries of the city.

Data has been mapped using First Life (Antonini et al., 2016) and they are described by the following metadata:

- Name: a text field where adding the formal or informal name of the spatial object;
- Category: a set of mutually excludable categories describing spatial objects (Art, Food, Education, Work, Nightlife, Meeting Spots, Shops, Sport, Services, I imagine);

5.3 POPULAR NEIGHBORHOODS AND THEIR FUNCTIONS

Teenagers have been explicitly asked to use the tag “frequent” to pinpoint, among the places they have added, which of them are the ones where they generally go to. Places tagged as such are of particular interest for our analysis. We have analysed them considering how they distribute in the 23 neighborhoods of the city.

Particularly, we wanted to identify which are the most popular neighborhoods, how they are used and if there is a relation between the diversity of an area and its appeal for the young population.

The map in Figure 5 shows the most frequented neighborhoods. The city centre contains about 40% on the total, while the percentage of points within the other neighborhoods reaches a maximum of 10%. It appears clearly that the city centre is considered the most attractive neighborhood to young people; however, there are some peripheral areas, which are quite frequented as Santa Rita and Pozzo Strada.

To identify the specific character of each neighborhood the relative frequency of points by categories has been calculated (see Figure 6). The relative distribution of the POI classified as Sport and Meeting spots, which are the most used categories, is shown in Figures 7 and 8.

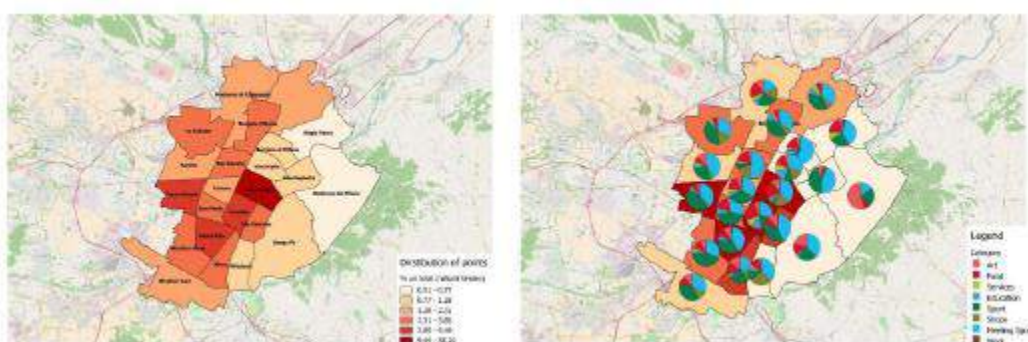

Figure 5 | Figure 6

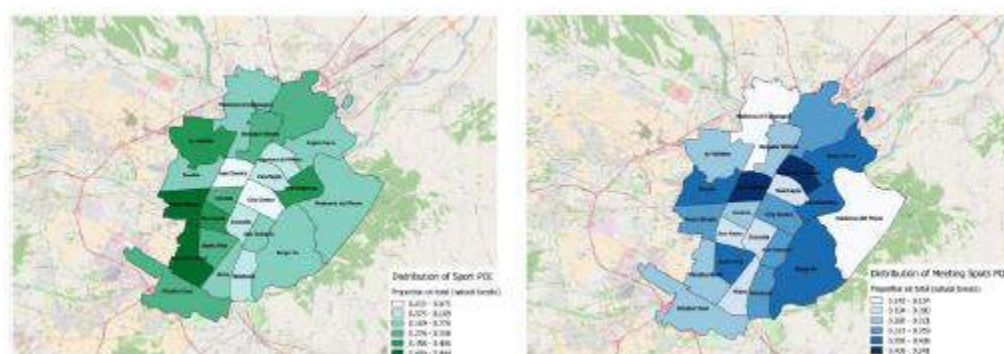

Figure 7 | Figure 8

Mirafiori Nord and Pozzo Strada have the highest proportion of Sport POI driven by a park and the Stadio Primo Nebiolo in the first case and the Juventus Stadium in the second; only about the 3% of the POIs are classified as sport places in the city center. Regarding the distribution of the most used category, we can see neighborhoods where the proportion of meeting places is particularly significant and it is interesting that they are not in the city center, such as Barriera di Milano, San Donato, Parella and Santa Rita.

Finally, we calculated an index to estimate the uncertainty in the identification of functions by neighborhood in order to take into consideration the diversity of uses by neighborhood.

Indexes of diversity are generally used to measure biodiversity in natural ecosystems; applying the same method to urban ecosystem we calculated the Shannon Index. The idea behind the index is that the more different categories there are, and the more equal their proportional abundances in the neighborhood, the

more difficult it is to correctly predict which category can be attributed to that neighborhood. It has been calculated as follows:

$$H = -\sum (p_i \log p_i) = 0$$

where p_i is the proportion of characters belonging to the i th category in the neighborhood and C is the total of categories. Figure 9 shows the index value by neighborhood. As it can be seen, we can distinguish highly specialized neighborhood such as Barriera di Milano, Pozzo Strada, Mirafiori Nord and San Donato (respectively as being characterized by places where doing sports and places where meet, see Figures 7 and 8), from more diverse neighborhood such as the city centre and Vanchiglia. It is important to underline that the index has resulted independent from the distribution of POI by neighborhood ($R=0,27$). Therefore, we cannot say that highly specialized neighborhood are also the most frequented nor the contrary.

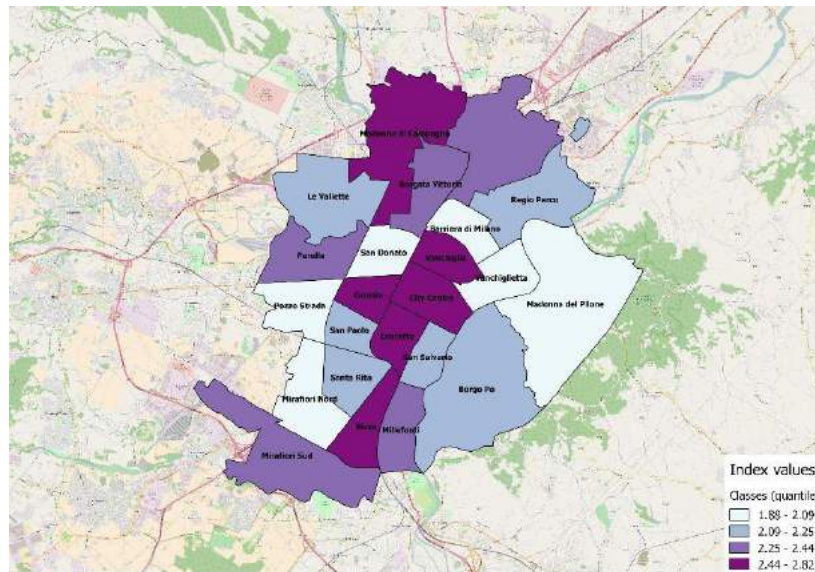

Figure 9

6 CONCLUSIONS

Youth geographies have shown the city as an archipelago of places where young people live following their own rules and needs. It has resulted the importance of open spaces for young people and their need to have places where gathering and playing. Institutional places (i.e. youth centers), planned to be for teenagers, have not been mapped by them. Therefore, the gap between the city for teenagers and the city of teenagers has emerged clearly.

Looking at their geographies we have seen that on the one hand, except for the city centre only which has almost the 40% on the POI total, POIs are rather evenly distributed over the city. They appear to be much more related to the presence of noteworthy places such as stadium, squares or park rather than on the centre-periphery relation. On the other hand we have classified neighborhood that have more diverse or highly specialized uses in the perspective of teenagers daily life in the city.

In conclusion, we strongly believe in the potential of using VGI in order to give voice to teenagers, enabling them to play an active role in supporting youth policies decision making.

ID 1720 | DEMOCRATIC PLATAFORMS: FROM MUNICIPALIST APPROACH TO DEMO-CRATIC SPATIAL AGENCIES

Frederico Canuto¹

¹Federal University of Minas Gerais

fredcanuto@gmail.com

1 INTRODUCTION

Since 2008 financial and economical melt down that became a democratic and political crisis with repercussions all over the world due liberal management attempt to profit in a general crisis landscape, a new political context has reemerged. In Spain, for example, the reappearance of the Municipalist Movement due the 15M experience in Madrid's occupied square remembered the municipalist Spanish heritage of the XIXth century, for example (Cf. OBSERVATORIO METROPOLITANO, 2014, CAVA, BELTRAN, 2015). In this 2008 context, new forms of experience politics and this return to the political emerged and are emerging in a world where virtual platforms are a media that is central to this insurreccional and social movements. The use of twitter and other social media platforms gained centrality to the democratic debate because real time is a possibility that was never envision in democratic processes. New forms of cartography processes with the help of internet allowed new visibilities to emerge, new people to appear and new forms of struggle to be (re)invented.

The use of a social media network (from twitter to crowdmaps) to organize the movement was the first step. Since the protests have a local and temporary effect, the next challenge was how to take such energy and knowledge and transfer it to a possibility of domination of politics, i.e., the state. The question appear as how to use the social media apparatus to mobilize a take over of the state, of political representations in order to exercise direct democracy in everyday life space.

Since 2015 cities elections in Spain and victories in Barcelona, Madrid and other cities, these municipalist movements are beginning to aim the potentiality of these media through the creation of their own virtual platforms. Creating sites that amplifies the voices of groups and people and mapping the city regarding the impacts of public policies, such platforms are experiments of make visible public policies, the people's power and help them to consider the state as a partner as well.

This presentation intends to discuss these virtual democratic plataforms build by the spanish cities administrations, in special Barcelona. Having as a critic parameter the idea of democracy and its paradox as portrayed by political scientist Chantal Mouffe, and Jacques Ranciere critique of Democracy as well, opposing it to the term demo-cracy (power to the demo, i.e., the people), the present text aims to point out the spatial limits of the plataforms in order to achieve power to intervene in planning operations in the city with or without the state.

2 POLITICS, POLITICAL AND 2008

The political scientist Chantal Mouffe in her book *The Democratic Paradox* analyses the main problem regarding modern democracies that is related to its lack (intentional or not) of understanding of what it means democracy, its modes of expression and exercise on the territory and its relation to politics.

To her, politics "(...) would be characterized by a set of practices and discourses that seek, on an institutional level, to establish a certain order and organize human coexistence"(MOUFFE 2005). So, politics is directly related to the idea of hegemony, a key concept created by Italian philosopher Antonio Gramsci and brought back to the center of discussion by her and Ernesto Laclau. Politics is the intense dispute over the hegemony of a certain political, social, economical and cultural status quo. Politics is related to preserve or change the state of things using the institutions of the State itself like schools, universities, cultural centers, media and others organizations that produce a unitary image of the nation, of people.

On the other hand, when Mouffe discusses the political, the subject is no longer how to maintain a certain design of relations and a certain organization, but how to disrupt them and create new forms of democracy, redimensioning even the central role of State. The political is a disruptive force that can be a creative one when used to think how to achieve another state of things.

In the financial and political crisis that emerged in 2008, politics and the political emerged and make extremely visible in bodies and streets such democratic paradox, turning it into a contradiction. Representation and direct action became two forces that collided on streets and institutions. Representatives became symbols of a decaying form of politics, the place of the State as the only public or collective oriented institution was put in check due the emergence of social movements and associations that represented more than the state itself.

The protests that erupt in that financial crisis context are the emergence of the political and its objective is simply to destroy the usual manners of how politics are made through negotiations that are invisible to the majority of people and by representatives that represents no one, having as objective the profit of some despite the poor conditions of the many. Putting in the edge the idea of representation that modern and western democracy took for granted in a very specific manner during Modernity, associating it to freedom, was the first step to the political.

After the protests that begun 2008, what became more necessary was to rethink how this deconstitutional power of the streets could be turned to a constitutional one, in streets or in representatives spaces. But it does not mean to stop to occupy streets and representatives spaces as public squares and public buildings as Spanish social movements did. It means that from that moment on, it was necessary to dispute politics by inserting the political in it. And in Spain, among many others countries in Europe like Greece, it happened.

3 THE SPANISH CONTEXT

During XIXth century, when Spain was not a nation but a project of a unified nation, there were various attempts to transform a set of cities and municipalities into a country, a state nation. Against the municipalism, a project of nation. What is interesting to point out is that such nationalist project found political and local barriers to come to existence: every time that such unity was proposed, autonomous cities defy such objective in order to maintain its autonomous and decentralized mode of operate and live. Insurrections happened in the cities against attempts to build a nation; federalists pacts were made in order to give an alternative to the nation project. The communist spectrum in 1848 had as consequences in Spain the formation of revolutionary groups; independence uprisings were made due a class struggle in the 1870's (OBSERVATORIO METROPOLITANO, 2015). Such history regarding autonomy, class struggle and decentralized organization is a memory lived in cities, in neighborhoods, in autonomous and local movements, it is a municipalist spectrum. Before the attempt to erase such past of struggles against the nation ideology known as Spanish civil war, the country nowadays known as Spain tried to invent other forms of political and economical organizations and that is a memory that arise in 2008: more autonomy regarding the planning and management of the city and the country.

their own site and they base their understanding of democracy resumed to vote. The sites produced all try to think democracy as a question of deliberation.

The vote problem is a central problem because the site gives to people the possibility to choose, but to choose between options already given. In a political science context, it is very easy to comprehend why the deliberation option is celebrated. If others town hall sites and its relations with the politics and political are analysed, it is going to be perceived how a city that gives a possibility to choose is a novelty in terms of democratic approach. But it is limited because people cannot build their own option. And even if they have the desire to do it, the site itself does not give to the citizens tools to build it, specially if it is considered the complexity of create public policies. As Marques (2017) states, the site with options approach creates dissent and helps to build autonomous citizens because debate is fomented but, at the same time, it create a destructive and not a constructive critic.

The participatory budget (orçamento participativo), an participatory initiative demanded by people from a city in south of Brazil at the beginning of the 80's and that was transformed in public policy, has the same questioning in its history (SOUZA, 2006). In a first moment, it was celebrated as a new form of make politics with the help of citizens and it was replicated in a various numbers of Brazilian cities and even in other countries as an example of democratic approach to urban planning. Through assemblies and public encounters with common people, representatives of associations and Non-governmental groups, it was given to people the possibility to chose where to apply the city budget. The central point is that the options of use of the city budget were previously given. Such assemblies and encounters were not moments of discussion and creation because the State already proposed solutions based in technical studies with the popular participation as an optional approach. Since 2000, in Belo Horizonte city for example, such public policy became virtual too at the same time that the town hall decreased the percentage of the city budget to be discussed and deliberated in the participatory budget.

The option issue is a problem because this platform should permit and potentialize the possibility of invent new forms of manage the city as happened in 2011, in Puerta el Sol in Madrid and in many others cities. The platform informs a lot, but it lacks the possibility of people create its own possibilities, ones that are not already designed by the State. So, the point here is that the site should be more permissible to the possibility of invent options that are not stated. The site should create interfaces to people discuss among themselves and create. Instead of a site that informs, a site that promotes games between citizens, government officials and others could be a interesting manner to make the site a platform and not just a window-shop. Doing so, the site is not just a representative space of policys created outside her, but being a creational tool, it would be a device to create political inventions.

Using here the concept of black box of philosopher Villem Flusser (2002) regarding the limited relationship among photographer, photography and the photographic machine due the fact that the last is impenetrable to the conscious use of its internal mechanisms by the first, the site could be more than a black box if it were designed to be opened and played like a game – another Flusser's concept (ASSIS, 2015). It is not just a matter of the right design of a certain type of pre-structured organization, but the idea of pre-structured that bases the whole site scheme.

The manners that people interact to the site are not specific, but generally the same as with another sites. What is different is the content of the information that the citizen will look for or give to the platform. What they get from the site is either a space to vote in some subject that affects the city or news informing new manners to work to the city or a possibility to insert themselves into the initiatives that are taking place in Barcelona sectors sponsored by Barcelona en Comú. New possibilities of not just work with the municipality, but to create with it through the virtual platform could be very interesting and considered if it the demo-cratic question is raised. That could take information and make it not just visible and public, but specially designed, articulating people that could work together, or that share the same interests in places very near from each other.

If the platform were to be more demo-cratic, a large variety and diverse possibility of situations should be possible to be invented. The demo-cratic site should be a virtual space where the people invent new forms of associations in order to dislocate themselves from the pre-structured paths of the State. More democracy means more possibility, even the ones that were not thought before the site was ready.

4.2 DEMOCRACY AND DEMOCRACIES

The Democratic paradox stated by Mouffe proposes an understanding of democracy as a continuous movement between the political and politics, between direct action and representation. But it does not mean that the only democracy is one or another. Between occupy streets and votes inside representative spaces, there are a myriad of possibilities. If it is taken the municipalist heritage in consideration, the great urban planning advanced concept of such memory is that the planning activity is not an exclusivity of the State or of the nation.

In an urban planning sphere, such citizenship movements and neighborhoods associations are autonomous cells that produce and discuss their own strategies and tactics regarding urban planning. As SOUZA (2006) states, urban planning is not an exclusive activity of any power, specially the State. Organized groups and social movements that occupy streets or empty buildings, for example, make their own urban planning. Urban planning is not an exclusive activity of the State, although the State has the power to make it in a more complex and broader scope. This means that these other social-spatial actors act as urban planners, but they are not interested in constitute a central power. They battle for spaces, for representation, for inches in streets but they are not interested in replace the state, they are supplementary to the State. They add to the State possibilities of participation and planning that the State itself would never foresee.

The municipalist site should be more than just a space to present public policies created by the government, but a platform to launch initiatives with the aid of the State. If the site could be more a game than a reflex of a structure, like a platform it could be more decisive and more productive. State could help to invent and not to forbid the invention as it is seen all over the cities. New forms of exercise democracy and not only democracy could reinsert in the State a new way of urban planning.

If the municipalist history is related to more autonomous forms of planning and manage the cities, using neighbourhoods as local cells of such decentralized organization, the site should be decentralized itself, giving to local people and collective associations possibilities to administrate the site, creating their own version for example. If the site can be used by associations and the people just as a place to get information, schedule, facebook addresses and pin local initiatives, it is limited.

5 CONCLUSION

A democratic platform is not enough to a municipalist approach to urban planning. If democracy is not a back and forth between direct action and representation, but between them invent new forms of act and plan the use and production of space; and if popular participation is not just a slogan or put all the information transparent to all but a program and objective to the municipalist project; any virtual platform have to be more than a representation of a space and an apparatus to act in space. Such platform should be either an agency of desires, actions and representations, which means that it should have as a central objective a democratic project, making possible alliances between groups and citizens in order to produce new identities, new groups, new people. This democratic approach should be aimed to the invention of new multiplicities.

The municipalists initiatives in Spanish cities are beginning to understand what means municipalism in XXIst century. Even if it is a preoccupation on how technologies and social media can help to build a more democratic virtual environment, it seems that they do not realized yet that this democratic project should be more open to the participation of everybody (including an every that does not exist), what means that the site is not only a reflex of a political project, but a tool to make it happen.

T18 | UNRAVELLING COMPLEXITY FOR PLANNING

CO-CHAIRS: GERT DE ROO; WARD RAUWS; JORGE BATISTA E SILVA

This track explores how interactions between the complexity sciences and the planning discipline can result in better understandings of and productive strategies for urban planning in a world of change.

Cities and urban regions across the globe face a series of pressures and challenges. One can think of global warming, processes of globalization, migration flows, technological innovations, geopolitical shifts, etc. A key question for spatial planners and governance experts is how to support cities and regions in remaining vital places under these conditions. In other words, how to boost quality of life, reduce social inequalities, support urban developments and transformations, and balance environmental sustainability and economic development in a fuzzy, dynamic world that includes both foreseen and unforeseen changes.

Introducing concepts such as self-organization, coevolution and bifurcation, the complexity sciences can help to clarify the interdependent, recursive and adaptive nature of processes underlying spatial transformations. Therefore, this track is about exploring ways to unwrap / disentangle / decode the 'complexity' of spatial systems and networks. Not with the aim of simplifying complexity, but with the ambition to identify the opportunities and limitations of a complexity perspective for the discipline of urban planning. This can include:

- Alternative conceptualization of neighbourhoods, cities and regions that allow planners to grasp the dynamic patterns of change.
- Advanced models that strengthen our understanding of, for instance, spontaneous pattern formations, processes of path-dependency and transition trajectories.
- New institutional designs which are time-sensitive and allow actor-coalitions to deal with a plurality of perspectives and non-linear routes of development.

Hence, the track 'Unravelling complexity for planning' explores the conditions under which 'spaces of dialogue' and decision making emerge, alter and disperse. It invites academics and professionals to rethink their tools and strategies in order to promote better places, respecting the dignity of life, in a context of change, interdependency and uncertainty.

ID 1334 | PLANNING IN POST-COMMUNIST CITY: BY FLEXIBLE PLANNING TO NATURAL GROWTH AND DEVELOPMENT

Tomáš Hudeček¹; Ondřej Boháč²; Lenka Švecová¹

¹MIAS Czech Technical University in Prague; ²Institute of Planning and Development of Prague
tomas.hudecek@cvut.cz ; bohac@ipr.praha.eu ; lenka.svecova@cvut.cz

1 AGE AND STABILITY OF STRUCTURES

A city which has been through a long historical development and continuity in its planning resembles a naturally growing primeval forest in which it is possible to find and well distinguish old, solid and stable structures from those young ones which are still looking for their place in the world (Hrůza 2014).

The basic genetic code of all cities without distinction, much the same as the double-helix of DNA made up of combinations of 4 elements is typical of all that lives on the Earth, is a concentration process. Gravity, all the attractive forces, attractiveness, catchment and commuting, but also human desire and human interest are just different names for the same fundamental process inscribed in the innermost nature of our world (Clegg 2012, Hudeček 2010, Hudeček et al. 2011). And, on the other hand, the opposite of concentration - "thinning" in the sphere of the universe of expansion and cooling, in the places of prevailing gravity and curvature of space-time, as a result of the course of time the common duration in hours, days, years or even millennia. Two opposites, but at the same time eternal companions are the cause of all diversity as well as, on the other hand, the cause of the interesting similarity in the reality of the existing structures Chardin 2003, Veverka 2013).

From the mutual and never-ending tug of war between the two basic directions of development – concentration, thus from chaos to order by means of self-organization in the presence of coincidence (in social systems then through the expression of free will) and thinning, i.e. development from order to chaos and growing entropy – operating at the same time on various scale levels in our reality emerge all the structures that we are, after all, even as people able to perceive (Prigogin 1997, Wolfram 2002). Those, in the direction of development all the way to us, in our corner of the developmental fractal, gain on simplicity that also we are able to understand and pass on – straight streets, clean lines of houses, refrigerators or cars. The existence of fundamental physical constants, energy and matter, of carbonaceous living matter on the planet Earth, subsequently of man and his consciousness, these all are structures on whose existence cities stand as well, and without which no city would exist.

The key feature of from the eternal conflict of order and chaos emerging structures is their durability and stability. Each new structure is unstabilized and very unstable. Each old structure which on the day of observation still exists is, on the contrary, stable and stabilized. Structures become stable only by their subsequent existence, by their linking with existing structures and mainly by means of new, younger structures standing on their shoulders. Exposed topsoil is easy to slide, while soil covered with grass will survive even great natural disasters. Each new structure takes its roots in old structures, slightly upsets them but, at the same time, strengthens them.

These days, chaologists and especially catastrophologists swell with pride over their "predictions" of approaching revolutions and more or less great ends of our days (e.g. Tainter 1988). Partly justifiably because even each system of mutually interconnected structures built one upon the other will once sketch in its developmental fractal, economies of scale will find their limit and will meet with losses of scale. In these moments self-organization will reach its critical gradient (Bac et al. 1987) and, subsequently, the entire cascade of structures built one upon the other will collapse like a house of cards. Visions like that humankind also needs a bit (Harari 2011) because only our awareness of black swans (Taleb 2007) can prepare us for these events at least a little bit. And that their number will grow is not, as a result of human existence these days really all over the Earth, anything else but a proof of such a depicting of the developmental fractal. On the other hand, even though in the history of the development of e.g. animal species on the Earth, such great changes – the mass extinction of species – have already happened at least six times and in the history of the development of the concentration of population in settlements as well, we do not have, as people living on average about 80 or 85 years, many other options than to keep trying to solve the emerging problems and to create new structures. Not to allow the direction of

development from order to chaos, ubiquitous due to the ordinary flow of time measured by our clocks, is an eternal motivation for humankind.

2 STRUCTURES IN THE CITY – THE ASPECT OF SPACE

If we want to devote our attention to cities, their planning, management, and decision-making regarding their further development, we must be able to orient ourselves in the tangle in the history constructed and, above all, in up to now surviving structures (e.g. Hampl 2000, Jacobs 1970, or Hayek 1986). A certain selection of the basic direction of examination is needed – for example, the level of spatial localization of cities. From this point of view, the physical-geographical, i.e. terrain conditions are the oldest structure. Those precede or can be even one of the causes of the idea of the original inhabitants to settle down, again as a result of a conflict between concentration and thinning, an effort of people, in a larger number, to defend themselves against the outside environment over time (= thinning, cooling). However, that does not mean that there is only one single recipe, the only most suitable old structure that would guarantee to the city thousand years of existence and its harmonious development. Fertile soil, coast, good conditions for defense, suitable climate bound to the angle of slopes and many other factors are, from the viewpoint of currently existing cities, ancient structures, which could have played different roles at different times. In the years full of conflicts, fertility of the place, and therefore an easy way to earn one's living of local inhabitants, as a primary structure, did not have to be sufficient for the city to stand the competitive struggle with other cities. History is written only by survivors, and although we know much more about the past than decades ago, archaeologists are still able to find cities even larger and earlier than ancient Rome and by their inner structure cities even more primitive and in a way even stranger than we could even imagine a century ago.

The sixth layer of the more than 9000 year-old Turkish city Çatal Hüyük uncovered by archaeologists has no streets (Melaart 1967). Habitations composed of a system of dwellings dug into the ground lacked a good separation of the private from the public (Figure 1). The delimitation of the moments of shared time and private time, fundamental attribute of human life, an old biopsychological structure, had to be reflected also in the nature of the city. Therefore apart from this so far rare historical exception, we have only to do with cities made up of streets, squares and houses and therefore it is possible to compare cities in accordance with their ground plans, shapes of streets and public spaces.

Figure 1 – Çatal Hüyük
Source: Hrůza 2014

The organically grown nuclei of historical cities and their intertwined and crooked network of streets and public spaces had been gaining their contours precisely according to the needs of the time, the demand for other crafts and activities that were missing in a small town at that time (Figure 2). By exceeding a certain level of wealth, each such city paid planners, and that is how a street grid came into existence, in fact the basic structure of the city. Sometimes simpler and altogether regular, sometimes more complex. Later founded cities, like virtually almost all cities in the New World, often start with this grid. Too great wealth of some of the most important centers of world empires led to the fact that these cities decided to rebuild their own nuclei in the historical Renaissance and Enlightenment eras. The industrial revolution provoked a similar pressure on the existing spatial structure of cities, which then resulted in the formation of the movement of preservationists.

Save for exceptions, in the existing cities their original structure has remained in existence even for thousands of years. Even major disasters like citywide fires, droughts, floods, or epidemics of diseases, which were always followed with an instruction in the form of new building regulations, better and more resistant infrastructure equipment and hygiene standards, rarely led to the reconstruction of the city grid. And even in situations more than appropriate for the overall transformation – for example, in the by the war

heavily damaged London or totally destroyed Dresden – restoration of the original ground plan of the city eventually took place in quite a satisfactory degree. These cities, even despite the historic opportunity, chose the resuscitation of their former appearance. Nowadays, due to the large thinning in time (settling and consolidation of structures) neither city planners nor the majority of decision-makers have the strength and energy to rebuild cities. It is like when cooling (thinning) creates little crystals of solid matter in the fluid binding to themselves more and more substance until, gradually, all of the liquid solidifies.

Figure 2 – Toledo
Source: Hrůza 2014

From the thousand years of existence, save for exceptions of the enormous stability of the city grid, we can proceed to the interior of the individual parts of this grid – to the blocks of houses filling the space between the public spaces of streets and squares. From the photographs of the historical center of, for example, Prague from the end of the 18th and 19th centuries, it is possible to make out that houses in the historical center grew a little taller, at the average by two floors (Bárta et al. 2006). However, not every city at that time led such a discussion on the preservation of its historical values, and immediately beyond the border of the historical core there was a similar situation as in other centers of the then world events. Factories and workers' quarters were growing and with the invention of the elevator also high-rise administrative and other buildings. The key to unraveling the durability of an already constructed building or block is to know the speeds and frequencies of changes at that time, especially the frequency of technological inventions, the development of quality of building materials and other factors. The character of the built-up area, the height of buildings, the appearance and exterior facade, the shape of the roof and other characteristics do not survive, save for exceptions, for thousands of years. In a sufficiently stabilized area, blocks of houses remain if not absolutely identical, then at least very similar even after many decades. Therefore, an appropriate time measure of the stability of this structure seems to be hundreds of years.

The interior of houses and apartments, the functional use of the floor area are subject to ever faster changes. The idea to establish a company and to start a business on some type of a digital device is now possible in one's apartment overnight. The times when industry or administration by their negative externalities drove people out far from factories and work for long periods of time, and thus fixed the internal functions of apartments and houses in the three categories set by the Athens Charter – housing, work, recreation – are already gone (e.g. Koolhaas 2014). A city of short distances, mixed types of functional use disrupting the typical transport scheme – in the morning, everybody in one direction and in the afternoon in the opposite direction, livable or, even more modernly, lovable projects of new neighborhoods that contain both real living – housing and preferably even recreation and work, these all are, among other things, consequences of the ever-accelerating and more unstable time into which our human society has entered. Change is becoming a common part of our life and consequences of each such change are, much the same as new structures, looking for their space in older structures. They grow through them with their roots, disrupt them, transform them partially according to their own need, and thus strengthen and confirm their existence in the future.

3 PLANNING, MANAGEMENT AND DECISION-MAKING REGARDING FURTHER DEVELOPMENT OF THE CITY

A plan is nothing else but regulation, control over the future. If I plan a meeting for the evening, I have refused, regulated, all other possibilities of spending the evening time. And including those possibly good and better than the arranged meeting could be. If in the meantime I thoroughly connect the meeting with other meetings or, for instance, with a place, changing it will become very difficult for me. I have exchanged flexibility and a possibility of a different choice for the expected benefit from the meeting.

I can "provide" planning – to create a plan – for a short period of time, or longer. In short-term planning – for example, if I intend to abstain from eating meat tomorrow – it is easy for my inner energy to overpower my long-standing habit of eating meat. However, in a long-term planning, after a certain period of time, our effort to achieve a slim figure, which we have resolved, for instance, on New Year's Day, slacks off, namely due to the effect and influence of strong, older and more stable structures (for example, "when I see food, I lose my self-control and I eat it"). In a medium-term planning, both the influences are then mixed in an extreme and impenetrable complexity.

However, is getting on long-standing, stable structures that like railway lines lead around us from a distant past to the far future, still planning? And what about that above-mentioned short-term effort to surpass oneself? Thus, is not the right planning rather the identification of those old structures worth caring for, which have been proven and have been carrying their fruit for years? Preserve them and thoroughly consider possible minor changes to each of them? Therefore, is not that, when managing the city in its entire complexity, rather about the management or, even better, about the decision-making on the basis of these old structures, and that based on a certain change of state in the surrounding, usually the local environment?

In our head, the above-mentioned planning is happening subconsciously and automatically when planning our own time. Our subconscious mind chooses, based on our experience, which is nothing else but old stabilized structures, what is good for us and known to us. In the form of emotions, "I want – I do not want", it subsequently informs our consciousness about the intention to, for example, reach out for pears or apricots on the table (e.g. Kahneman 2011, Lehrer 2009). Our neurons, but also all the cells in our body, by means of mutual arguments, interconnections and power alliances by a complicated yet for us a subconscious way, make their way to the suggestion of a solution which naturally comes to our mind.

In planning evolutionary higher and further complexes, such as cities, the same process takes place among all people and more intensely among the involved participants in the city development – interested persons, companies, nonprofit organizations, etc. Thus, planning, as the initiation part of the whole process, in which the citywide emotion "I want" shows itself, does not make sense without a final goal. However, this final goal, if possible, should never be achieved. To plan without a plan at its end, on the other hand, does not quite make sense. The substitutes found so far and the solution to this "planning paradox" of the type of a continuous updating of the plan seems quite artificial in this respect.

Planning without a final creation of a plan people call a mistake but this is probably the only option we have and we have to reconcile with that for the future. Thus, it is much more about the process of planning itself than about the resulting plan, even though, as apparent from the above-written, it is at least appropriate to plot certain space-based structures on the map. That such a map is subsequently called a plan is just a matter of a perhaps a bit unfortunate agreement.

This all is a bit related to the partialization of planning as a type of activity. If, for example, in a city a few of its oldest structures are history (culture), associated with the thinking of in the city living and in the city concentrated people, then, as we have said, undoubtedly also natural conditions, but also the, on a long-term basis stabilized, structure of the street development, then the separation of city planning from other types of planning does not make any sense at all. From the spatial arrangement, the history and culture of the city unfolds, and vice versa. Even the common terms themselves – land-use and strategic planning – make the situation and its understanding quite difficult in this respect. Is not the word strategy a synonym for a plan, and is not then strategic planning just an empty collocation saying "planning planning"? Would not it be better to think of city planning rather from the viewpoint of more logical words of planning – pertaining to space and time? Or perhaps even better to space-time. Is not one planning face to face with

the above-said more than enough, and is not, after all, a land-use / spatial plan, enriched with long-term framework priorities, what should the current strategic plan be?

4 INTERRUPTED CONTINUITY AND CURRENT SITUATION IN A POSTCOMMUNIST CITY IN THE CZECH REPUBLIC

In Eastern European and Central European countries, with the socialist past, the issues described above are very clear. Due to the long-term influence of the totalitarian regime, in the Czech Republic, for example, 40 years of communist central directive planning, we cannot even speak of any continuum of old structures. Moreover, looking further into the past, the Czech Republic and other states before World War I were incorporated into the Austro-Hungarian Empire where they played a non-dominant role. Thus, unlike the centers of the monarchy – Vienna and Budapest – in Prague, save for exceptions, reconstruction of the central part of the city essentially did not take place. When we are looking for continuity from the present perspective, this can also play a positive role, which is completely in compliance with the developmental theory of systems and the role of a gauge in relation to order or chaos.

Therefore, if we stay, for the reason of both topicality and especially simplicity, only in the second half of the 20th century, it was the absence of private property and private business which played the title role in the development of cities and their planning. Thus, any form or even only a hint of "bottom-up" planning has become virtually unthinkable, and it is not surprising that through the Velvet Revolution the Czech Republic has entered a period when planning and a plan (those notions were not differentiated too much and are not differentiated up to now) are in essence considered to be dirty words.

It did not take long for the results to show because the rapid and unrestrained development of investment activity on the one hand, and, at the same time, the more and more awakening civil society on the other hand, could not exist parallelly, side by side, for a long period of time. The ambivalence of society, rapid oscillations of the social pendulum, the alternation of the "from one extreme to the other" critical states had to be subsequently reflected also in city planning in the form of the re-emergence of a certain analogy of the extreme centralization of decision-making. Land-use plans of villages and towns in the Czech Republic have been, roughly since the turn of the millennium, again formed in the directive way with an extreme emphasis on the strong, in particular functional regulation. Thus, land-use plans of Czech municipalities, instead of the initiating role in the development of the territory, determine what in each small piece of the given territory must be – instead of what in the given territory can be. Instead of limits of utilization of the territory from the viewpoint of the capacity of the environment, infrastructure, population density and movements throughout the day, a certain parallel to the communist-style decision-making on the territory was agreed upon, which was based on the obligatory use of the territory determined by the planner, and which was from the viewpoint of the then social development logical, yet very inappropriate for the whole society and especially for the cities.

Figure 3 – A part of the present land-use plan of the City of Prague
Source: Koucký et al. 2014

In the present land-use plan of the Capital City of Prague (Figure 3) , there are more than 50 such types of the use of the territory and it is totally understandable that, in the long run, such a plan cannot succeed face to face with the ever-accelerating time generating new and new demands. During the first ten years of its existence (2000- 2010), this plan has been changed by the institute of the so-called changes of the land-use plan more than 3,000 times, which means roughly at a rate of 1 change per day. The city administration can carry out such a change to the land-use plan based on a request from owners or developers. These days, this process in the complicated legislation in the Czech Republic takes usually 2-4 years. In extreme cases, it can take even 7 or 10 years. Therefore, in the course of time, investments and development projects have completely stopped and these days, the capital of the Czech Republic, which has more than a million of inhabitants, is struggling with a lack of apartments and houses, a rocket rise in the prices of properties as well as rents, extreme suburbanization and urban sprawl in the wide surroundings, overloaded transportation, technical and social infrastructure. All this due to rigid and inflexible planning and an obvious lack of respect for older, stable and stabilized structures.

5 A LESSON FROM DEVELOPMENT AND OVERCOMING OF DISCONTINUITIES

As natural both in nature and in society, we perceive that which is sufficiently stabilized. By our biological nature, we are not and we don't want to be reconciled to the fact that change is natural. But not equality, but hierarchy; not uniformity, but difference or self-resemblance are the fundamental characteristics of the world around us. Thus, to find the natural features in the development of the city, that which we could pick up the threads of by our further decisions, it is necessary to thoroughly focus on inequality and irregularities. To look for regularities in irregularities. While in a city that has been developing naturally over a long period of time, such as London, Vienna and many others, hierarchies and inequalities are long-established, and hence obvious, cities affected by the central directive planning are far from that.

The communist panel housing estates as a solution designed to solve the lack of apartments for the growing population and implemented by the national planning authority in the period between 1960 and 1990, then after the Velvet Revolution massive suburban construction of the so-called Business Baroque as a result of demand of people for their own houses dampened by communism for a long period of time, later, around the turn of the millennium, the rising fear of the continuation of uncontrollable growth without rules and, finally, the cessation of virtually any kind of construction nowadays – these all are only consequences and sediments of unstable structures on the surface of development. These are not deep, developmental and stable structures. These are essentially erroneous decisions and dead ends of development, which have to be partly inscribed into the overall development as historical epochs, too. However, with regard to the above-written, it is possible and also necessary to overcome them in the further decision-making about the development of the city. To incorporate their existence sensitively into the overall shape of the city.

In the city of Prague in 2012 development hierarchies were sought first. An unprecedentedly extensive and detailed field survey was conducted which focused on every detail of both public spaces and all urban buildings. All address locations, houses and buildings, numbers of floors, roof shapes, dimensions of roads, parks, technical networks and all other buildings in the city were mapped.

Therefore, it was possible to proceed to the mapping and consistent division of all urban structures according to their hierarchy. Fractal distribution of communications according to their importance, capacity and width, hierarchy of parks and recreational, residential and administrative sites were defined. The city was divided into about 800 historical sites, inside of which there are natural hierarchies again. On the map of the city, white and brown spots were identified – the so-called urban jungles – as priority areas for further construction and investment. Those were hierarchized and prioritized based on the multifactor analysis. The cultural history of the city, tourism, inspirational environment were identified in the hierarchy of importance of structures as key for the city, and possibilities for their further development or partial transformation were determined.

Apart from the spatial aspect of the city development, more than 1,500 experts, urban planners, geographers, architects, economists, as well as philosophers, theologians, lawyers, doctors, teachers, and many other representatives of professional chambers, as well as representatives of civic associations and major business corporations participated in more than 200 round table discussions and conferences with the aim to aggregate additional – even soft – data.

Subsequently, new building regulations, a new strategic plan, a new public spaces manual, a new document dealing with the development of the banks and the littoral areas of the Vltava River were created

(Figure 4). And, of course, a creation of new city land-use plan was started (Hudeček et al. 2016, Koucký et al. 2014). The Institute of Planning and Development was established with an annual budget of over 15 million Euros and about 200 employees – as an organization able to face the complexity of the city and the creation of a new flexible land-use plan was initiated.

Figure 4 – Strategic and concept documents of the Institute of Planning and Development of Prague
Source: Institute of planning and Development

Thanks to this data collection, their aggregation and analysis, it was possible to approach all that happened in Prague in the past, even though the tendencies of these events were often contradictory, from the viewpoint – as I have suggested above – of a deeper perspective of long-term development structures. With its certain small part all that is past and has already been realized participates and will participate in the whole in the future. Duration in time (= thinning) gradually abrades the sharp edges of from the present view often illogical decisions and it was necessary to proceed on the basis of the deeper nature of the development of the city. The key characteristics of this process of ours were, and in the future also have to be, two fundamental courses: flexibility (of plans) and resilience (of newly built structures).

5.1 FLEXIBILITY OF THE PLAN AS A SOLUTION FOR OVERCOMING DISCONTINUITIES OF DEVELOPMENT

First of all, on flexibility as an essential feature of urban planning. The historical experience of a country which has been through extreme changes in the directions of development in the past and, unfortunately, still in the present is, in the case of the Czech Republic, obvious: Impossibility and blockage of change (due to, for example, totalitarian directive planning) sooner or later will necessitate a change of the whole system. The possibility of a change is a fundamental, the most substantial and a very deep structure, arising directly from the fundamental conflict of order and chaos in our reality.

From the viewpoint of flexibility of planning and of the plan (for example, a land-use plan), there must be a reasonable amount of order and chaos, i.e. the degree of regulation corresponding to the given place at a given time in the city (Figure 5). Thus, the new prepared city land-use plan of Prague divides the territory, among other things, also in accordance with their stabilization into 4 basic types:

- Protected preservation area
- Stabilized areas of existing buildings
- Transformation areas within the boundaries of the city and existing buildings
- Development areas outside the city boundaries and existing developments.

Figure 5 – Flexibility and stability – four degrees of regulation
Source: Koucký et al. 2014

The preservation area, in Prague moreover under the patronage of UNESCO, certainly does not allow much flexibility. Neither do stabilized areas with utilized high-quality buildings. Transformation territories, the above-mentioned city jungles – in the plan these need flexibility for dealing with investors very much. And, finally, the development areas, i.e. new premises for construction, apart from the areas built-up nowadays, except for general needs of the city, should be open to various other variants of development as much as possible. In practice, this different regulation means that these particular types of areas are in the city plan subject to a variety of directions or, in other words, to regulation of various intensity and limits of utilization and transformation of the territory.

Flexibility in the case of urban spatial planning means, for example, limits of utilization of the territory from the viewpoint of transportation, instead of a directive functional delimitation of what the territory must contain. In the case of the long-term intentions of the city, thus a kind of contemporary analogy to the strategic plan, flexibility then means the possibility of a slight stepping aside of development trends and a possible rapid adaptation to new trends.

Or, flexibility can also mean the greatest possible individualization and localization of the solutions of intentions of the development, with the existence of only a few important citywide framework rules. Hygienic limits, noise, limits of infrastructure, hierarchized street network, maximum height of buildings, or, for example, the need for social housing, these all are frameworks on whose foundation the current existence of the city stands. When negotiating individual projects among investors, cities and other participants, these can be discussed directly, over a common map, and there is no need to supplement them further with any other directives such as the aforementioned future functional uses.

It seems, that we are probably in a situation where, any minute now, only a common map and a few rules will be called a land-use plan – see the frames outlined above – which will be written down on a few pages of a supplementary handbook for city negotiators and approvers of projects. And perhaps the time is not far when even the words "limit" and "directive" will not be the right ones and the notion of information and informative, in the interlinked society, will be playing the same role in ensuring a rational development of cities in society built on the basis of democratic mechanisms. Especially at a time when we do not have the slightest idea of many future professions that will occupy a significant percentage of the population already in the following 10 or 15 years.

5.2 RESILIENCE OF NEW STRUCTURES

And now on the resilience of structures. Already from the introduction we know that an old and still existing structure is stable and a new structure is always unstable. But how can a city planner, hand in hand with a decision-maker, know that the new structures promoted by them will become stable in the future? That they will survive and endure the subsequent thinning over time and that they will succeed in competition with other structures? That, in consideration of the main purpose of work for the public sector – continuity of development – they will last longer than one electoral term or work period?

Resilience of structures needs to be estimated from structures from the past and trends in other, similar cities. For example, if a city center is filled with cars, we already know that walking is an older structure than driving a car, a given part of the city was built still at the time when there were no cars, only narrow roads for pedestrians, then preventing car access will undoubtedly be a stable structure in the future. Or, if in the vicinity of some brownfield there is a stabilized built-up area, which contains a complete hierarchy of public spaces, streets, parks and other, for example, social amenities, then it is possible, in this neighboring brownfield, to plan a distinct neighborhood only with respect to, for instance, the capacity of the surrounding transport infrastructure. However, if in the surrounding hierarchies there is some other significant deficit (Figure 6), the development of a new nearby area should primarily fill in these "holes". If this approach is violated, it will be subsequently necessary to bend and change the result of the bad decisions again and the instability of these and all the following structures will be immense.

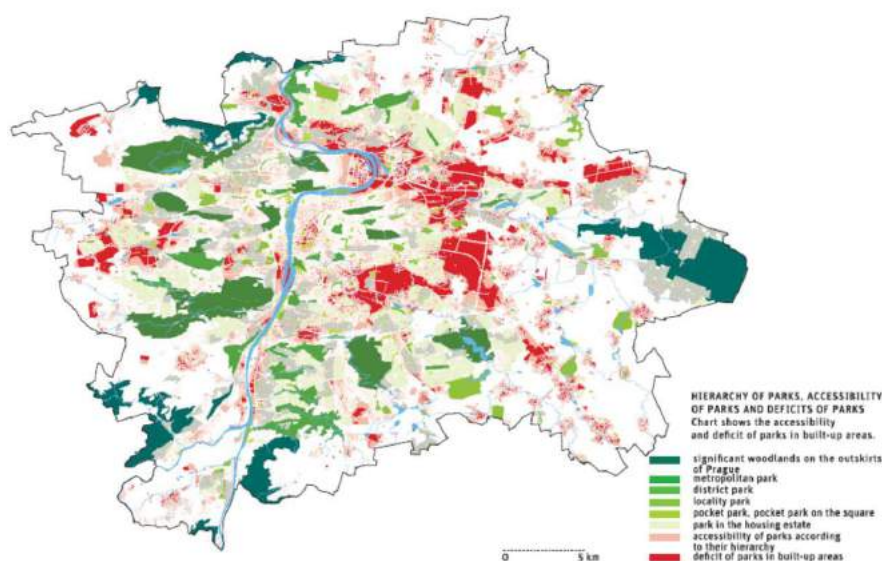

Figure 6 – Deficits of parks in the City of Prague
Source: Hudeček et al. 2016

What is also essential for the creation of stable structures is the fact that the oldest process in reality – concentration – will unstopably continue until we reach a situation in which either we all end up in driving distance of one hour or we will be similarly close to each other, yet within walking distance. Humankind will seek and favor rather the other way of realizing concentration because we do not want to destroy the environment with extreme transportation. Extreme regulation, which is currently being implemented in the Czech Republic – and as a consequence of which even the number of new apartments required by a normal reproduction of population in the city (Prague) will not, after all, be built – does not seem to be a too resilient structure for the future.

Of course, it is possible to perceive resilience also as the resilience of the entire city system and ensuring its functioning and existence. Fires and deficiencies of infrastructure, blackouts or epidemics, these all are real threats in which the aforementioned catastrophologists see the truth and which we must also bear in mind when deciding, managing and planning the city.

5.3 SUMMARY AND CONCLUSION

Experience from a country which in the past 150 years has been through a development via many different political systems – a multinational monarchy, inter-war democracy, totalitarian regime, wild capitalism, anchorage in Western European supranational structures – is extraordinary when looking for answers to questions posed in the introduction.

Natural development built on long-term development trajectories was specific even in contemporary post-communist cities. However, despite this, if we look inside the urban structures thoroughly, especially at their inequalities and hierarchies, it is possible to overcome even the highly contradictory developmental tendencies and to find the naturalness for further urban development planning once again.

Rather than planning, it is a sequence of decisions, let's say merged into a certain succession – thus, management. Planning, especially strategic planning, in the mirror of the experience of post-communist countries seems to be at least a confusion of notions, but rather an activity of "planning for planning itself".

The solution for overcoming the developmental discrepancies of the post-communist city is the understanding of the deepest developmental processes – concentration and thinning – and subsequently the identification of their influence on the developmental structures existing in the city and further operating. By setting an appropriate degree of flexibility for different areas of the city, and by priority effort in resilience of newly built structures, it is possible to establish, after the era of a too much swinging pendulum of the social development, the much needed stability of further development and to avoid the developmental excesses that get repeated.

The example of Prague, a city well appreciated by tourists, but not so well perceived from the viewpoint of its own inhabitants in the current situation of a large increase of living costs, seems to be more than suitable in this respect.

ID 1341 | THE USE OF BOUNDARY SPANNING IN SPATIAL PLANNING AND COMMUNITY PLANNING TO PROMOTE WELLBEING

Jordan Benson¹
¹Ulster University
benson-j3@email.ulster.ac.uk

1 INTRODUCTION

This paper will discuss how the activity of boundary spanning in the context of spatial and community planning can be harnessed to promote wellbeing via advancing a networked approach to governance using six defined types of cross-boundary activity (buffering, reflecting, connecting, mobilising, weaving & transforming) in order to ameliorate against “wicked issues” (Rittel and Webber, 1973) through the realisation of ‘The Nexus Effect’ and the building of social capital through engagement and participatory mechanisms.

The Nexus Effect primarily relates to collaborative gain and according to Ernst and Chrobot-Mason (2011:18) it occurs through understanding that, “organisational leadership is more than the sum of its parts; it is more than groups working in independent isolation, within their own boundaries – it is the nexus of groups working collaboratively across boundaries that produces direction, alignment and commitment”.

Figure 1.0 – Boundary Spanning
Schematic Leading to the Nexus Effect
Source: Ernst and Chrobot-Mason, 2011

Relatedly, social issues that cannot be resolved by one actor alone but require the collaborative action of multiple actors have been cited by Sorensen and Torfing (2009) as providing the rationale for boundary spanning e.g. tackling poverty and social exclusion. The author takes this normative agenda as a starting point for conducting this multidisciplinary investigation as it has been said that such connective capacity is highly significant in order to realise mutually supported and qualitatively good outcomes in networks surrounding complex governance issues (Koppenjan and Klijn, 2004; Healey, 2006; Edelenbos, Bressers and Scholten, 2013).

1.1 PLANNING FOR WELLBEING

Furthermore, the research is both relevant and timely as since the Stiglitz Report (2009) was released, there have been marked shifts in the metrics of social progress used by governments. Doran et al (2014) take this conversation forward by highlighting how the introduction of wellbeing as a policy goal in Northern Ireland could serve as a theory of change by offering alternative visions of the future via asking questions to develop a meta-narrative such as, “what price do we pay (in terms of wellbeing) for continuing divisions and segregation?”. Further rationale in favour of a more outcomes focused policy direction has been presented by Easterlin (1974) and Matthews (2006), who respectively elucidate the shortcomings of GDP as a determinant of social progress in light of the Easterlin Paradox – findings that GDP and life satisfaction are not correlated in a linear way - and the less quantifiable social and environmental trade-offs that GDP inherently obscures. Figure 2.0 displays updated findings where the inverse relationship between increases in gross domestic product (GDP) per capita and decreases in the annual rate of change in life satisfaction (used as a measure of wellbeing) have been gleaned.

Figure 2.0 – Average Annual Rate of Change in Life Satisfaction and in GDP
Source: Easterlin, 2010

It is important to recognise that the increasing discourse on wellbeing is a growing global phenomenon and that its origins as an organising principle can be traced to the Kingdom of Bhutan and to indigenous cultures within Latin America (Frey and Stutzer, 2010). Planning practitioners as the democratic custodians of the public interest and the resulting conduits of social change (Forester, 1980) have a duty to seek the enhancement of the general populace's wellbeing equally as much as they strategise in shaping emergent futures. On the subject of collaborative planning Healey (1997a) goes on to remark that,

"We make structural forces as we are shaped by them. So we 'have power' and...can work to make changes by changing the rules, changing the flow of resources and, most significantly, by changing the way we think about things". (p.49)

1.3 LINKAGES BETWEEN BOUNDARY SPANNING, SOCIAL CAPITAL AND WELLBEING

In connection, boundary spanners are actors involved in activity of the same name and there are two key types of boundary spanning agents. Firstly, there are those whose role is principally defined and determined by new cross-sectoral governance arrangements and secondly there are individuals who perform this role as part of a wider portfolio of activities (Williams, 2010). These individuals form a distinctive and valuable class of leader which can operate across the five dimensions of boundary as identified by Campbell et al (2009). These dimensions have been denoted in the literature as: vertical, horizontal, stakeholder, demographic and geographic. Although for this particular investigation, the author will focus on examining the stakeholder dimension in greater detail as it best enables for the exploration of related concepts e.g. collaboration, social capital and participation. All of which are prerequisites for the boundary spanning, spatial and community planning processes.

The stakeholder dimension refers to the collaboration and leadership necessary beyond an entity's boundaries, or conversely within its internal departments in order to successfully fulfil its exigencies and duties e.g. avoiding back-to-back planning issues and information sharing between the planning and environmental health departments. It predominately concerns the management of an entity's relationships with external partners (i.e. members of the public, polity & enterprise) where issues relating to current affairs, community, commerce and the environment may often arise. Boundary Spanners are innovators who utilise their competencies in diplomacy, mediation and negotiation together with their characteristic feature of a collaborative mindset to overcome aforementioned boundaries by preventing them from becoming borders. A border stifles human potential and restricts innovation plus creativity but by the same token, boundaries can also be converted into frontiers: "the location where the most advanced thinking and breakthrough possibilities reside" (2011:219).

Trust has been conceptualised as social capital within the literature and has been articulated by Putnam (2000:19) as pertaining to, "connections among individuals – social networks and the norms of reciprocity

and trustworthiness which arise from them". By harnessing the resource colloquially known as civic virtue, it is possible to socially engineer win-win scenarios rather than win-lose situations and incrementally recast society by, "developing the I" into "We" (Rohe, 2004). Consequently, this approach is facilitative in engendering the collective wellbeing of the many – "eudaimonia, often translated as individuals reaching their daimon or human flourishing" (Newton, 2007).

In Putnam's seminal text, "Making Democracy Work" (1993) his findings explain how the creation (and scrupulous use) of social capital can ameliorate against a miasma of intractable social issues. They have been non-exhaustively listed as; 'defection, distrust, shirking, exploitation, isolation and disorder' which work in pernicious circles to intensify one another. Social capital is believed to remedy these conditions by restoring social equilibrium through instilling individuals, communities and wider society with high levels of 'civic-ness'. Civic-ness is formed on the predicators of cooperation, trust and compromise, all of which are facets of the nebulous phenomenon of reciprocity which akin to dysfunction, occurs in mutually reinforcing and self-perpetuating ways (Ibid).

Social capital which is an intangible asset and has been described as 'critical resource for community wellbeing and resilience' (Assist Social Capital, 2017). Whereas participation mechanisms have been said to lead to empowerment as genuine engagement redistributes power, therefore changing the status quo (Arnstein, 1969).

The above observations are noteworthy contributions to dialogical debates in spatial planning as improving outcomes and narrowing inequalities cannot be achieved without multi-actor and multi-scalar responses to form integrative solutions adapted for the 21st century (Peel, 2013). The ensuing conversation uses the field of spatial and community planning to unpack the themes associated with promoting wellbeing via boundary spanning responses. It embraces the coterminous nature of these different themes and reconfigures them in a novel way by advocating that planners assume the mantle of reticulists and by so doing, emphasise the importance and value of boundary spanning agents and activities to address the shift brought about by changes in state-market-civil relations (decentralisation) together with its associated impacts on the local governance landscape.

The influence of boundary spanning actors has been said to be less well examined in the literature surrounding network governance in terms of the functioning and performance of networks, especially those existent around complex urban projects (van Meerkerk and Edelenbos, 2014). However, a strong correlation between the presence of boundary spanners and improved network performance, understood to consist of policy formulation, decision-taking and policy delivery, exists (2014:2). An identified challenge in terms of bridging between both the conventional land-use planning practitioner and the more contemporary community planning officer is that there's a dearth of boundary spanning actors operating from within the public sphere and instead are to be predominantly situated within private and voluntary sector environments.

Mediation, trust building and managing multiple accountabilities are core competencies and attributes of boundary spanners as successful collaborators who enable improvements in stakeholder network performance. This is brought about by the enhancement of social capital stocks to tackle crosscutting, pan-institutional and inter-jurisdictional issues e.g. designated communities experiencing persistent deprivation levels (Wagenaar, 2007; Williams, 2011). Interdependencies between various actors require reciprocity and common understandings as interactions must be sustained durably over time amongst diverse sets of stakeholders with often heterozygous or competing interests. In order to secure greater network and economic efficiencies, it's vital for boundary spanners to navigate the dilemmas associated with partnership working in the midst of multiple accountabilities, participants with higher autonomy and lower incentivisation towards network level goals (Provan and Kenis, 2008).

Likewise, each actor may harbour a different perception of policy problem definitions and the most appropriate responses and interventions depending on their chosen frame of reference (Teisman, 2000). However, in the words of Kooiman (2000:142), "no single actor, public or private, has the knowledge and information required to solve complex, dynamic and diversified problems...no single actor has sufficient action potential to dominate unilaterally". This reality represents the proverbial 'carrot' for collaboration towards the formation of a constructive interface between societal quandaries such as improving wellbeing, reducing health inequalities and the ensuing approach to governance employed (Grint, 2005).

The aforesaid approaches comprise issue-specific networks, which 'emerge around concrete complex urban problems dealing with specific urban development' (2014:6) where networks established are temporally sensitive and goals desired finite and readily quantified e.g. the reclamation of a vacant brownfield site to be used as an open recreational space for leisure purposes. The realisation of optimal network performance in the context of closed-loop problem definitions has been said to necessitate a sizeable connective capacity resource (Edelenbos et al, 2013). To assuage silo mentalities and mindsets formal (first order) and informal (second order) boundary spanners must play active roles in governance processes occurring in the fresh spaces between public, private and societal organisation although empirical research relating to this contemporary phenomenon is rather scarce (Van Hulst et al, 2012).

The determiner of an agent's boundary status has been said by Levina and Vaast (2005) to be their ability to, "gather and transfer information from outside of their sub-units". A sub-unit is understood to be either their home institution, organisation or primary contractor and thus is internal; or it can refer to foreign institutions, organisations and stakeholders and hence be external. It's the combination of these different linkages which form the effectiveness and competencies of boundary spanners by enabling them to achieve 'The Nexus Effect' and improve multidimensional wellbeing outcomes. These outcomes across a remit of health, education, economy, safety and environment are vitally important because it's at this part of the results-chain at which positive change has been said to occur for the citizen (Friedman, 2005).

2 SPATIAL AND COMMUNITY PLANNING INNOVATIONS

The author has chosen to investigate how the innovation of boundary spanning leadership can be utilised within a planning context as the art of reticulism has been shown to remain integral to both the person and community-centred enterprises of spatial and community planning (Peel, 2013; Farnan, 2016).

Furthermore, such reticulism in urban planning is not a new phenomenon as it can be traced back to early 20th century Geddesian principles as embodied by the planning visionary's triad of "Folk – Work – Place" which served as a precursor to modern understandings of sustainability as illustrated by Figure 3.0 below.

Figure 3.0 – Geddes' Triad of Place-Work-Folk
Source: Welter, 2002

Along these lines, research conducted by Kent and Thompson (2014) highlights the capability of planning to better connect the built and natural environments in order to improve the quality of life of individuals and also to strengthen communities. Public participation and the effective engagement of citizens surrounding land-use decisions and the delivery of public services which affect them engender community empowerment via ascribing them with the power to decide and control. Such initiatives foster a sense of community and belonging within places where people, live, work, learn and travel. Consequently, a supportive context of community connection has to be an influential determinant of positive mental and physical health (Ibid).

3 THE USE OF BOUNDARY SPANNING IN PLANNING TO PROMOTE WELLBEING

At the crux of this think-piece is what the application of boundary spanning to improve wellbeing across the "stakeholder dimension" of boundary might look like from a spatial and community planning perspective. From an island of Ireland context, both planning enterprises share an obligation to conduct public engagement exercises and have built this necessary phase into the formulation of their respective plans

(Department of Environment NI, 2015; Department of Environment NI, 2014; Government of Ireland, 2007; Department of the Environment, Community and Local Government, 2015).

The engagement method of 'Focus Groups' has been selected to outwork the practice-oriented example as they are utilised widely but, "can be specifically geared towards prioritisation...concentrate on a single issue or a programme of topics to obtain ideas and innovative thinking" (Chambers, 2002) thereby clearly accommodating the notion of wellbeing.

The tabulation below is a summary outlining the six different practices of boundary spanning leadership as itemised previously via Figure 1.0. Each column represents one of the five different types of boundary, however in this instance we will be focusing on the stakeholder dimension in particular. It's important to acknowledge that the various phases of boundary spanning are non-linear and iterative e.g. if one element of the model has already taken place such as, 'Transforming' it doesn't necessarily mean that this won't have to be re-worked or updated later on in the collaborative process or engagement initiative (Center for Creative Leadership, 2013). Before going into further detail, I will provide clarification of the three key strategic goals of boundary spanning practice.

Firstly, "Managing Boundaries" as shown below in Table 1.0 relates to the first step of spanning boundaries which is ironically to create or strengthen them e.g. defining roles and areas of specialisation. And in so doing, taps into the power of differentiation in order to build safety and respect across boundaries (Yip et al, 2009).

Secondly, "Forging Common Ground" seeks to identify what is universal and shared. This strategy is about finding common ground and bringing individuals and groups together to achieve shared goals. Fundamentally it is about integration through adoption of a collaborative mindset in order to build trust, engagement and shared ownership across boundaries (Ibid).

Penultimately, "Discovering New Frontiers" as figured below relates to the discovery of new possibilities and potential within the intersections and fresh spaces existent between boundaries. These intermediate zones characterise frontiers which involve the harmonisation of differentiation and integration by way of simultaneously unifying novel groupings of difference and specialisation. In such scenarios, the whole is demonstrably greater than the sum of its parts due to the amalgamation of expertise, experience and resources in a complex system driven by a shared vision. In essence, the synergies reaped through the realisation of The Nexus Effect (collaborative gain) support breakthrough innovation, transformation and reinvention.

Managing Boundaries					
	Vertical Boundaries (Hierarchical Levels and Ranks)	Horizontal Boundaries (Functions, Units, and Disciplines)	Stakeholder Boundaries (Partners, Suppliers, Customers, Communities)	Demographic Boundaries (Gender, Religion, Age, Culture, Ethnicity, Education, Ideology)	Geographic Boundaries (Locations, Regions, Languages, and Markets)
Buffering — monitor and protect the flow of information and resources across groups to define boundaries and build intergroup safety.	During times of organizational crisis, remind people of proper communication channels to ensure critical information flows across levels effectively and accurately.	Prepare a team "charter" of roles and responsibilities. Share it with others in the organization so they understand the amount of work your group can effectively manage.	Specify "nonnegotiables" or "rules of engagement" that specify how your team and an external team will interact during a joint venture.	Sponsor affinity groups within your organization (women, Hispanics, etc.) so that nondominant groups have an opportunity to network and share experiences with their own group members.	Build a "buffer" between your team and headquarters if agendas are competing. Create a document that summarizes your team deliverables and get written buy-in and agreement from HQ.
Reflecting — represent distinct perspectives and encourage knowledge- exchange across groups to understand boundaries and foster intergroup respect.	Initiate a meeting with senior management so that you can advocate upward the innovative ideas generated by your employees.	Invite leaders from other units to your team meetings so they can discuss how each unit can help the other to solve pressing organizational problems.	Arrange "field trips" for your team to visit client sites or customer markets. Ask them to take photos and document what they observe as it relates to an organizational initiative or strategy.	When an issue comes up that involves race, gender or religion, consider making it a "teachable moment." Let everyone have a chance to share and learn about their differences and unique perspectives.	Encourage international business travelers to add an extra day to their trip to hit the streets, experience the culture, and learn about the local market. Ask them to share their observations at a team meeting upon return.

Table 1.0 Part (a) – Boundary Spanning Leadership Summary

Forging Common Ground					
Connecting —link people and bridge divided groups to suspend boundaries and build intergroup trust.	Host an outdoor lunch picnic to bring people together from different levels of the organization. Ask everyone to “share a blanket” with people they don’t get to spend time with regularly.	Set up some comfortable chairs and a whiteboard in the connector wing between two departments to encourage informal, collaborative conversations across functions.	Rotate meetings with a key vendor between your site and theirs. When visiting their site, request time for “putting names with faces” by having your team walk around and meet people in their organization.	Mix it up outside the office. Get people of different generations, races, or nationalities together for a sporting event.	Reserve the first 15 minutes of your bimonthly global videoconference for relationship building. Spend time sharing personal milestones, news, or updates of interest.
Mobilizing —craft common purpose and shared identity across groups to reframe boundaries and develop intergroup community.	Establish “skip level” meetings for your staff to have conversations with your manager about higher organizational goals and strategy.	Following an organizational merger, get people from the same functions in the two organizations together—have them craft a compelling mission about a new business opportunity that everyone can rally behind.	Articulate a goal that your organization and another organization can partner around in order to beat a common competitor in the marketplace.	Identify a core set of organizational values that are inclusive and motivating for all demographic groups.	Install common organizational symbols, wall hangings, and icons in all your offices that build community and represent “your organization at its best” anywhere in the world.

Table 1.0 Part (b) – Boundary Spanning Leadership Summary

Discovering New Frontiers					
	Vertical Boundaries	Horizontal Boundaries	Stakeholder Boundaries	Demographic Boundaries	Geographic Boundaries
Weaving —draw out and integrate group differences within a larger whole to interface boundaries and advance intergroup interdependence.	Debrief a successful organizational accomplishment by bringing groups together across levels to discuss what factors created the “win” from their unique vantage points.	When divisions are in conflict over an issue, help them articulate the source of their differences and then explore ways to creatively reconcile them for the overall good of the organization.	Integrate the unique strengths of your organization and an organization in a different sector (e.g., nonprofit, government agency) to solve a shared problem in your community.	Bring different demographic groups together to talk about market needs and trends within their respective groups, and how the organization could create new products to serve them.	Develop “glocal” solutions—draw and integrate global best practices within your company and local market knowledge to envision new products, services, or internal processes.
Transforming —bring multiple groups together in emergent, new directions to cross-cut boundaries and enable intergroup reinvention.	Bring members of your network together who represent vastly different levels from top to bottom. Facilitate a dialogue about “how they see things in the business” and explore an unconventional idea that arises from the conversation.	Host “alternative future conversations.” Invite anyone in the organization to attend; provide no agenda other than to imagine the ideal, transformed organization five years from now.	Strike a small-scale partnership with your no. 1 competitor. Explore new, collaborative frontiers that could be discovered together.	Create action learning teams with “maximum diversity” (e.g., age, gender, race, culture, education, personality differences) to develop business plans of entirely new markets or services than your organization currently offers.	Get the whole system in the room. Bring together a large cross-section of key leaders from around the world once a year to envision “game-changing” opportunities.

Table 1.0 Part (c) – Boundary Spanning Leadership Summary
Source: Ernst and Chrobot-Mason, 2011

Additionally, as a precursory note before providing more detailed explanations of each of the six boundary spanning steps. The framework above has been co-opted from the corporate world for management consulting. It has been repurposed in the context of innovations in planning in order to principally derive more social benefit from it:

- i. **Buffering** All sets of stakeholders (spatial/ community planning professionals and members of the public) must initially agree upon the timing of the engagement process e.g. frontloaded, and for how many and how long each focus group session on improving health and wellbeing outcomes ought to last. Moreover, what the desired level of participation is e.g. to inform, consult, involve, collaborate or empower must also be decided (IAP2 International Federation, 2014). Being open and transparent about the level of resources available at the outset of the engagement exercise is vitally important in order to manage expectations alongside acknowledging related limitations. Moving forward participants need to be made aware of how their input will be used and where appropriate, feedback on contributions received should be given and made publicly available. Likewise, the provision of information on proposals, plans or services is part of any communication plan to support engagement but does not in itself constitute community engagement. One of the first collective endeavours at this stage will be to develop a

- shared understanding of wellbeing encompassing its hedonic, eudaemonic and quality of life dimensions to provide a reference point to work from.
- ii. **Reflecting** This boundary spanning practice is about fostering respect of difference and this is a vital factor for forming consensus in participatory planning processes. Through immersion, or having experience in an alternate environment on the other side of a boundary divide it is possible for individuals and groups to enhance mutual respect and understanding. A focus group made up of spatial/ community planners in concert with members of the public is likely to consist of a wide demographic range of individuals with different needs, values, beliefs and wellbeing preferences. In addition to “field trips” to different neighbourhoods to appraise which the most appropriate spatial and service delivery interventions would be in order to promote health and wellbeing e.g. provision of more active transport routes and the establishment of healthy food producing community gardens; the social learning that takes place as part of formal engagement activity enables groups to build social capital, learn about one another and develop respect for differences as well as commonalities. Furthermore, shared engagement processes create an opportunity for spatial planners and community planners to gain a better understanding of one another’s roles, professional cultures and jargon to facilitate the integration of services and generate new innovative ideas. With both explicit, tacit and procedural knowledge exchange taking place in such instances, the probability of planning practitioners to make sense of the complexity inherent within ‘planning for wellbeing’ is increased. What’s more, as leaders of the Reflecting process charged with building respect amongst various actors by moving beyond an “us versus them” outlook e.g. not dedicating all resources solely on addressing a single wellbeing matter such as the creation of mixed income, mixed tenure housing developments. But instead looking at the non-material aspects of societal prosperity as well (Aller and Seligman, 2016).
 - iii. **Connecting** The Connecting boundary spanning tactic is about building trust within and between multiple stakeholder groups and builds upon the previous step of Reflecting which garnered respect between assortments of individuals. As mentioned earlier in the paper, trust and social capital enhance the effectiveness of collaborative projects which rely upon networked nodes of governance – thus, having a greater capacity to bring about positive social change (2014:4). Striving to find where mutual interests and win-win scenarios lie to bridge divergences between individuals and groups is a key tenet of successful boundary spanning Connecting practice. Often the answers to moving beyond the labels of “Planner” and “Local Resident” lie in the construction of strong personal relationships by allowing focus group participants time to get to know one another on an individual basis. To instigate this process, focus group meetings could be held at community centres located across a local government authority’s administrative area on a rotational basis. These act as introductions to the identities of respective members of the public involved in the participation exercise and provide credence for their unique perspectives and a broader level of trust to overcome any disagreements or difficulties in decision-making, nullifying them as creative tensions. More than merely bringing groups together, the leadership activity of Connecting over time leads to the development of mutual confidence and integrity in stakeholders’ words and actions (2011:134). From a professional angle, it means breaking down silos between planning functions and in this instance engagement processes and timelines. Subsequent data, feedback and observations received through engagement should also be pooled and shared in the same vain the appropriate institutional arrangements and trust being sustained on a long-term basis. With this step secured, a shared direction is established toward the Nexus Effect as individuals’ personal interests have been divested in favour of commitment to the interests and wellbeing of others.
 - iv. **Mobilising** Boundary spannings ‘Mobilising’ phase refers to the act of developing community and when looked through the stakeholder dimension perspex, an entirely new set of power relations and deliberative approaches to planning for societal betterment are spawned. The mobilisation transcends the former status-quo and is embodied for instance by spatial/ service delivery initiatives like the “Community Right to Buy” and/ or the “Community Right to Control” which empower communities to take over buildings, land or the running of services if they have the resources or can prove they’ve the ability to run it better. Forging common ground by bringing together spatial and community planning is symbolised by the proliferation of intergroup community. The mobilisation of people to envision a more inspiring future where the value of health and wellbeing serves to improve peoples’ daily lives can be enshrined by becoming a dedicated topic in the public participation in planning process. A key challenge for mobilising around the wellbeing agenda is to ensure that it is inclusive and meets the needs of a diverse

range of groups. Moreover, mobilising creates a new common shared identity across all individuals by encouraging groups to move outside their smaller group identity and move inside a wider collective identity which caters for all and simultaneously provides a new frame for finding productive solutions to problem definitions. To elaborate further on the rather ambiguous term of identity, it can be conceived either as a vision i.e. a place without childhood obesity, a goal i.e. to reduce greenhouse gas emissions by 50% by 2020 or a task i.e. decide upon how wellbeing outcomes are to be measured and monitored. The resultant state is “intergroup community” and is described by Ernst and Chrobot-Mason (2011) as, “a state of mutual belonging and ownership that develops when boundaries are reframed and collective action is taken”.

- v. Weaving - The “weaving” tactic in spanning boundaries relates to advancing the interdependence of individuals and/ or groups. It involves integration of the two aforementioned strategies of “managing boundaries” and “forging common ground” illustrated in Figure 1. In combination, these form two fundamental human needs – differentiation and integration which when explored unleash synergies yielding transformative results. Weaving is a paradoxical action where differences are drawn out among the group or organisation mobilised previously during step 4 and then creatively brought together or reconciled to advance intergroup interdependence. For example, a stakeholder engagement technique predominantly designed for land-use planning would be the use of charrettes whereas a more archetypal community planning technique would be to conduct community surveys. Post data collection, if these two bodies of knowledge could be overlaid or shared, then new insights can be produced as explicit and tacit knowledge are required to understand the concept of wellbeing holistically for the development of more targeted approaches to achieving outcomes. Translating weaving from barriers to frontiers is the key to tapping into the transformative potential of differences to uncover the most pioneering and innovative opportunities. Accurately encapsulated as a “journey of change” (2011:173) weaving occurs over a series of time and can involve interjurisdictional, cross-regional and cross-boundary activities and dialogues which are often related to wider strategic change initiatives. Some of the wellbeing barriers boundary spanners would grapple with to effect positive change are along the thematic spectrum of health, education, economy, environment and society. By situating them in place e.g. the London neighbourhood of Tottenham, then citizens and planners can work in partnership to look at the scripts that people have written for them and how these can actually change. The link between the engagement mechanism and the conduits of spatial and community planning to generate responses for wellbeing remains place and context dependent as there are no generic answers to issues with multiple path dependencies and in fact, within such a dynamic environment of antagonism, this observation is likely one of the few things to remain static. Hence, it’s essential to take a variegated approach to decision-taking on highly similar data gleaned during focus groups regarding health and wellbeing in unison with the public. This is due to demographic, geographic, cultural and class-based differences in communities who may present with a common problem e.g. fear of crime but taking steps to remedy this could be vastly different for instance, high-level police-led CCTV surveillance interventions or the simple installation of some more street lighting and Neighbourhood Watch signage in less hostile and challenging environments.
- vi. Transforming The final step of the boundary spanning process is “Transforming” and is about enabling reinvention and realising the states of renewal, alternative futures and emergent possibilities once the preceding “Weaving” phase has made the ground febrile for advancing intergroup interdependence on conceptual, procedural and operational levels. When this occurs, groups form a new identity and the author proposes that such a paradigm shift has already taken place in the field of health via integration of both the medical and social models of health into jointly delivered, “health and social care” by public health authorities. This denotes the cross-cutting approach necessary for spatial planning and community planning to model in order to maximise the value of the symbiotic relationship inherent between both planning enterprises with a key aspect of that being public participation and stakeholder engagement. Redefining the conventional structure and agency relationship between the planning systems, planning professionals and the communities and people they serve is a hallmark of the transformative change sought for by boundary spanning initiatives, which ultimately forge alternative futures which are as exciting as they are necessary. What we are witnessing above is the powerful strike up effect of intergroup reinvention which is the last requirement before entering the Nexus Effect – “in it groups are empowered to co-create emergent direction, align collaborative action and renew, re-envision and reimagine themselves and their environment in ways that enable them to

thrive in a dynamic world” (2011:202). Significantly, all five practices described previously can also be used during the transforming process and as such it represents the boundary spanning approach in its totality (synthesising ideas from the fields of organisational development and social psychology).

4 CLOSING REMARKS

In summary, the vision of spatial and community planning responses conducive to promoting health and wellbeing, like reinvention is an unfolding process without a definitive start or end as there's no single agreement, intervention or incidence to unravel the intractable issues that Rittel and Webber (1973) spoke about as cited at the beginning of the paper.

1 INTRODUCTION; COMPLEXITY THEORY AND LANDSCAPE RESEARCH

"I would not give a fig for the simplicity on this side of complexity; I would give my right arm for the simplicity on the far side of complexity" Oliver Wendell-Holmes Jr.

At every stage in a research project an academic is faced with the problem of acknowledging complexity, attempting to process its implications and reaching for the elusive simplicity that we hope exists on the far side. For a researcher in the field of landscape architecture this is a particularly pressing problem, due to the nature of the landscape itself as a complex emergent system. My PhD is a participatory research project, which aspires to acknowledge the role of all participants in this system as "researchers, as agents of change, and as co-constructors of landscape knowledge" (Deming and Swaffield, 2011: 202). So, in studying the implications of complexity theory for public engagement with a transport megaproject, what glimpses might there be of simple solutions?

Complexity theory can help us to comprehend the nature of landscape, its problems and their possible solutions, because it offers a way of understanding how landscape works. It gives us the perspective of 'emergence', from which we can aspire to conceptualise the landscape in a pragmatic way. The term 'emergence', in the technical sense used by complexity theorists, was coined by English philosopher G.H.

Lewes (Goldstein, 1999: 53). Lewes' definition is pithy: "The emergent is unlike its components insofar as these are incommensurable, and it cannot be reduced to their sum or their difference" (1875). Steven Johnson's illustration of the concept expands upon this. He describes a number of different emergent systems in animals, humans and computing. He uses the example of studies of slime mould (*Dictyostelium discoideum*), beginning with the work of microbiologist Evelyn Keller from 1968 onwards (Johnson, 2001). He describes the apparent simplicity of slime moulds, which are, during the winter, independent single-celled amoeba-like organisms. However, under the conditions of a temperate summer the individuals "coalesce in to a single, larger organism which begins its leisurely crawl across the garden floor, consuming rotting wood and leaves as it moves about" (Johnson, 2001:13). For thirty years this phenomenon was not understood, as scientists believed the behaviour must be instigated and controlled by 'pacemaker' cells, but such cells could not be found. Only in recent years has there been an agreement that "slime mould aggregation is now recognized as a classic study in bottom-up behaviour"(Johnson, 2001:16). In other words, it is self-organizing, a complex adaptive system that illustrates the nature of emergence: "the movement from low-level rules to higher-level sophistication is what we call emergence."(Johnson, 2001:18).

In the slime mould therefore, its aggregated manifestation is far more than the sum of its individual cells and as such its form and behaviour could not be predicted from knowledge of the initial circumstances, the constituent cells and the basic known laws, for example of physics and chemistry, that apply to them. Substitute the word 'components' for 'cells' and you have a description of how landscape works. Goldstein's definition of emergence supports this understanding, as he says that it is: "the arising of novel and coherent structures, patterns, and properties during the process of self-organization in complex systems. Emergent phenomena are conceptualized as occurring on the macro level, in contrast to the micro-level components and processes out of which they arise."(Goldstein, 1999 :40).

This is arguably an accurate description of any landscape, rural or urban, in any part of the world. Some, such as a river delta, may be more apparently emergent, from the point of view of the human observer. The basic components of the delta are known and understood in that scientific knowledge informs us as to the nature and behaviour of water molecules, as well as about the nature and processes of the soils of the delta. However, it is not possible to accurately predict the branching of the river and overall form of the delta landscape from this knowledge.

For Goldstein, then, emergent phenomena are 'coherent'. This view is one shared by British landscape architect and author Simon Bell. In his influential book 'Landscape, Pattern, Perception and Process' Bell states he is influenced by chaos theory and emergence but states that "the changing world is neither chaotic nor unpredictable"(Bell, 1999: 5). He wishes to see "the fundamental natural order in the world"(Bell, 1999: 8) and claims that "irregular effects on process and pattern can be mistaken for randomness, but belie a deep order" (Bell, 1999: 35). Emergence is not a theory of randomness, and it operates in an essentially coherent manner, in that emergent phenomena arise out of the normal operation of known rules or scientific 'laws'. An acceptance of the unpredictability of the resulting landscape forms and processes is, however, central. Many examples could be cited of unpredictable landscape events, such as erupting volcanoes, landslides, floods, forest fires or sudden rapid growth of shanty towns, which arise from the nature of the component systems of those landscapes.

In recent years landscape architecture has arguably begun to draw on emergence theory through its links with the field of ecology. Ecologist William Holland Drury Jr. wrote of the problems associated with "clinging to romantic notions of nature's grand design" (Drury, 1998: 1-2) and the misguided rhetoric of "nature's balance" (Drury, 1998: 5). In contrast to Bell, he emphasises that the "first principle is that chance and change are the rule" (Drury, 1998: 6). Drury traces back some of the influences over our tendency to look for 'balance' and equilibrium in ecosystems to Linnaeus' essay of 1749; "The Economy of Nature". Linnaeus' system of classifying living things and allocating to them a standard globally applicable scientific name using 'genus' and 'species' is common to many specialisms today, and pertinent in this case as landscape architects will have gained their understanding of plant and animal species from ecologists and horticulturalists who depend on the Linnaean taxonomy of Kingdom, Phylum, Class, Order, Family, Genus and Species. For Drury, "Linnaeus's system carries a profound subliminal message: that each species was created as it is." (Drury, 1998: 16). Drury's lifetime of experience and observation, however, suggest that species cannot be so easily distinguished; "I remember my botany professor searching over a hillside covered with individual plants of a particular species until he found a "perfect" representative of the variety he had in mind. His comment when he finally found the right specimen was that this individual was

“typical”.” (Drury, 1998: 17). This anecdote reminds us of exactly the problem/opportunity of emergence; that as we can never truly state what the precise characteristics of any species are, it is untenable to subscribe to an essentially fixed view of nature. This observation directly addresses a key proposition of emergence theory, summarised as follows by leading thinker in the landscape field, landscape architect Rod Barnett: “the real processes, objects and relations that comprise the world and which landscape architecture undertakes to design, organize and manage, are continually unfolding, producing further relations and making new connections.” (Barnett, 2013: 4-5). Thus, as a species of wildflower evolves so do its pollinators, these changes in turn influence the wider ecological systems of insect predation, soil and vegetation patterns. All of these systems are open to each other and ultimately to every other system in the landscape, be it climate, hydrology or human society.

In 2008 ecologist and landscape architect Frederick Steiner offered this definition of landscape: “A landscape is more than a picturesque view; it is the sum of the parts that can be seen, the layers and intersections of time and culture that comprise a place – a natural and cultural palimpsest.” (Steiner, 2008: 4).

This description of the structural qualities of landscape and acknowledgement of the interplay of layers of physical objects, human systems, natural processes and the passing of time, is true to the landscape architect’s view of landscape that persists for the most part to the present moment, but the publication in 2013 of Barnett’s ‘Emergence in Landscape Architecture’ marks a significant move by the academic establishment away from Steiner’s definition and towards a qualitatively different understanding, which has real and potentially revolutionary implications for practice. Barnett repeatedly reminds us that “Open systems are complex...their components are connected by networks of feedback loops operating at different levels, different scales and different rhythms. Landscapes work like this.” (Barnett, 2013:49-50). In accordance with Barnett, this paper takes landscape to be an emergent, non-linear and open system. In order to illustrate this position, emergence theory will be applied to a brief description of the rural parish of Ashley, near Manchester, England, which is due to be the site of construction of high speed rail infrastructure in approximately 2030.

2 UNDERSTANDING THE PROBLEM

HS2 is the UK’s proposed high speed rail network. Due to begin on site in the south of England in 2017, it has much in common with transport megaprojects the world over. It has a long linear site, the boundaries of which are subjective and indefinite. It poses questions about how the identity of the infrastructure at a local scale nests within the national scale. There are problems of compulsory purchase, very substantial land take and large numbers of residents affected by proposals. Running the project are hundreds of people from different disciplines, including designers, planners, engineers, ecologists, archaeologists, politicians and public engagement professionals, who are led by changing governments (for HS2, four prime ministers within five different governments to date). Multiple cascading effects begin before work starts on site, within a landscape that is already complex and emergent, with its own flood events, road building programmes, imminent housing developments and so on. A new railway line, therefore, has impacts apart from its physical presence, as it traverses the countryside between major cities it has significant effects on human psychology, social networks and economies as well as on views, road networks, hydrology and all other ecological systems. There is, arguably, nothing along the proposed alignment of such projects that remains unaffected during the phases of anticipation, construction and post-completion.

For local landscapes, the risk is that the result will be “universal low-density mess.” (Nairn,1955: 363). Nairn was writing in a special edition of the Architectural Review, in which he describes a journey from Southampton to Carlisle. His concern is the sameness that he encounters at different locations on the journey, and the likelihood that, by the end of the twentieth century “there will be no real distinction between town and country” (Nairn, 1955: 365). Such erosion of distinctive local character is at least as pressing an issue now as it was in 1955, and it is not clear that HS2 will make any positive impact on the problem.

The above considerations suggest why complexity theory is relevant here. This body of thought leads us to begin to understand landscape at every scale as an emergent entity, in that the continuously evolving whole is greater than the sum of its parts and comprised of a limitless number of interacting open systems.

It is “a continuum of multiplicities continually self-differentiating” (Barnett, 2013:44). Compare the fluidity of this landscape condition with the operation of many public engagement exercises, which attempt to operate within a complex emergent field and yet themselves are inflexible, top-down ‘snapshots’ of public opinion. Such processes tend to start too late, finish too early and be determined by adherence to statutory requirements rather than motivated by a desire to access the expertise held by citizens about their local landscapes. HS2 Ltd plan to “engage with communities over the life of the project” (HS2 Ltd, 2015: 9), such that “national pride in the system is matched by a sense of local ownership” (HS2 Ltd, 2015: 11), yet an examination of HS2 Ltd’s public engagement processes as enacted on the ground in rural English parishes illustrates some of the inherent problems.

2.1 ASHLEY, COMPLEXITY AND HS2

Ashley is a small parish in rural Cheshire, with Ashley village at its centre. It lies immediately south of Greater Manchester, and the border with the city is formed by the river Bollin. It covers an area of approximately 8.5 square kilometres and has around 325 residents, living in a predominantly agricultural landscape with scattered farmhouses and other dwellings. It has a railway station, The Greyhound pub, St Elizabeth’s church (built 1880) and a cricket club (1888). In the past there have been a village shop, post office, primary school and filling station. These facilities used to contribute to a stronger sense of a village centre, but their continued operation has not been sustainable.

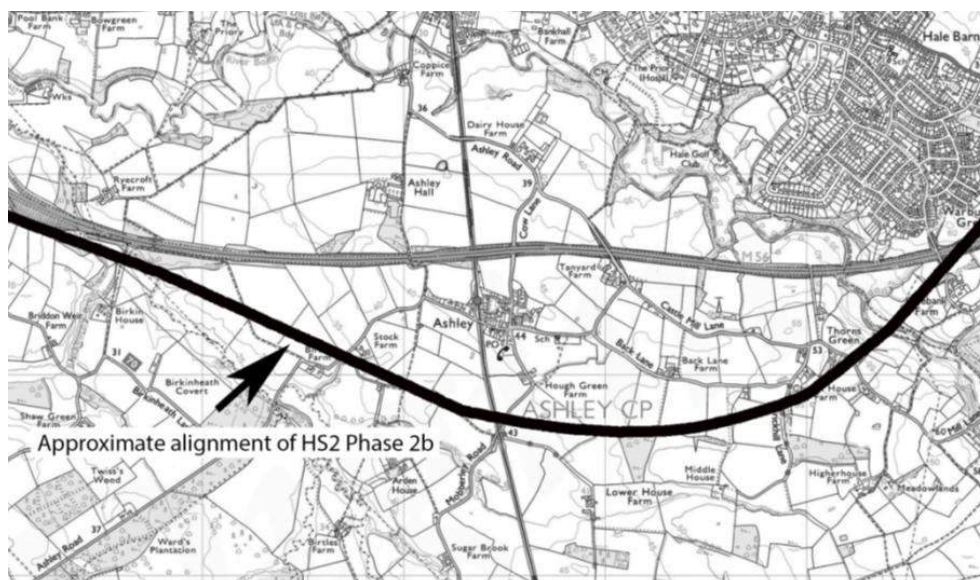

Figure 1. Ashley, Cheshire (author’s own image, base map from digimap.edina.ac.uk)

Ashley was chosen for study because it is already the site of significant linear transport infrastructure projects (see Error! Reference source not found.). The railway line of 1863 bisects the village, running on a north-south alignment. The M56 motorway divides the parish west to east. Runway two of Manchester Airport is a significant presence in the landscape, lying very close to the Parish’s southeastern boundary, and the proposed HS2 alignment isolates Ashley village between the new line and the M56. This research is concerned with the potential cumulative effects of these infrastructures. The motorway is a significant presence in Ashley, through noise and air pollution from vehicles, visual impact of the structure and associated gantries, and traffic flow to and from junctions. In winter, motorway traffic is clearly visible and audible from places in the village, for example the churchyard. The Victorian railway line has less impact both visually and in terms of noise, but still presents a physical landscape barrier. Large-scale transport infrastructures therefore contribute to an erosion of the clarity of Ashley’s rural character, whilst research data shows that residents still feel strongly that theirs is a rural place that is rich in wildlife and natural beauty.

Central to conceiving of the landscape of Ashley is recognition that, like all landscapes, it is undergoing a constant process of change and development, and will continue to do so. There are obvious changes marked on the landscape itself, visible to the eye and in later years recorded by cartographers; the building

of roads, the demolition of houses and enclosures of agricultural land, for example. Less visible but still identifiable are changes in occupation patterns by plant species, demographic changes and climatic shifts. Impossible to comprehensively observe and quantify, further changes continually occur; rhizomatic fungal growth in the topsoil at Stock Farm, fluvial deposition from the River Bollin, changes in the emotional states of drinkers at the bar of The Greyhound. Thus, the place has never 'become', it is simply always 'becoming'. This way of seeing stands in contrast to careless perceptions of timeless, unchanging rural landscapes. In the case of Ashley, we are alerted to the fact that conditions at any given moment are never fixed so must not be idealised; likewise its future is not mappable in the sense of factual prediction, but only as an imaginative projection of the future.

Essential to accepting that landscape is emergent is the concomitant notion that it is an open system. The loops and branches of its constituent processes are not separable and always open to being affected by other systems. Within the boundaries (real only to people) of the Civil Parish of Ashley it is possible to make measurements of air quality, but it is not meaningful to study this in isolation from the air quality of Manchester, or the northwest region. Likewise one could study aquatic species in the Bollin, but never in isolation from the effects of conditions upstream, in the wider catchment and in the entirety of the hydrological cycle. Barnett explains the effects of this view on our thinking as landscape architects; "A landscape has no outside, for its connectivity to other multiplicities is always complete." (Barnett, 2013: 52). This is an essential acknowledgement that site boundaries, or in this case the entirely arbitrary parish boundary, absolutely cannot be considered to be the true 'edge' of a site; "A landscape is only and always an ecotone, an edge, a continuous immanent spatiality." (Barnett, 2013: 52).

In Ashley, then, landscape architects (and, for that matter, planners or civil engineers) can in no way consider themselves to be external to the site or in control of its future. Each person is indivisible from the site; "In my capacity as an effect, an event, a component of the assemblage that is arranging around me, I am inseparable from the hour, the season, the air, the street, the 'weeds' in the cracks of the paving. I am always in composition with the landscape I am connecting to." (Barnett, 2013: 52).

Such concepts of landscape are not new. In his poem of 1731, 'Epistle IV, To Richard Boyle' Alexander Pope gives his advice to a landscape designer about the role of the 'genius of place', which we would also call 'spirit of place' or 'Genius Loci';

*"Consult the Genius of the place in all;
 That tells the waters or to rise, or fall;
 Or helps th'ambitious hill the heav'ns to scale,
 Or scoops in circling theatres the vale...
 Now breaks, or now directs, th'intending lines;
 Paints as you plant, and, as you work, designs."*

Here, Pope casts the 'Genius' as the power of the landscape itself, which exerts its agency through controlling rising and falling waters, the making of mountains and valleys. In this verse, it very much has intentionality, as it directs visual elements or 'lines' in the landscape, and as 'you' toil away in your humble role of planting, it paints the wider scene and designs the world around you. In this particular poem, the designer is incidental to the wider system or network of the landscape, which never ceases to design itself.

2.2 PHASE TRANSITION AND CASCADING LAND DEVELOPMENT

To inhabitants of Ashley, a landscape meshed in the protections of green belt policy, the constant change inherent in the landscape may seem incremental, continuous and not especially momentous. Things do develop, but the scene is much the same and the various actors broadly similar. However, complexity theory illustrates the nature of change such that we can understand how, in apparently stable and constant conditions, revolutionary developments can occur. Roger Lewin calls such an event a 'phase transition' and uses the example of the point at which life on Earth changed from being contained entirely in single-celled organisms, to the advent of multi-cellular organisms. He says that for 3 billion years on this planet, "the highest form of life was the single cell...it was aeon upon aeon of mind-numbing sameness. Then suddenly, and with spectacular effect, the trick of cellular differentiation and aggregation in to multi-cellular organisms evolved. An explosion of new forms occurred" (Lewin, 1993: 17-18).

Other writers use different terminology to describe the phase transition in a complex system. Per Bak, also writing in the 1990s, cites landscapes as exemplary complex systems (Bak, 1997) and describes how “minor disturbances may lead to events called avalanches, of all sizes. Most of the changes take place through catastrophic events rather than by following a smooth gradual path.” (Bak, 1997: 1). Bak’s use of ‘catastrophic’ here denotes a sudden large change rather than a disaster, but it is worth recalling that such ‘avalanche’ phase transitions can indeed lead to landscape disasters, as for example in multiple flooding events across the world as our climate continues to change.

Rod Barnett uses the term ‘bifurcation’ as synonymous with ‘phase transition’. He points out that, in landscapes, they are not especially unusual, and that, in the normal course of events, “A bifurcation can lead a single system into a distribution that none could have foreseen.” (Barnett, 2013: 45). It is this quality that gives landscape the capability “to generate new patterns of organisation” (Barnett, 2013: 28). A very localised example of this would be when a river, such as the Bollin, running through sandy soils, breaks through the banks of a deep meander and forms an ox-bow lake, with the river itself taking a new course, and forming a new boundary between local authority areas, parishes and neighbouring farms. Over the border in to Derbyshire, in a limestone karst landscape, a river might suddenly disappear underground or emerge in a new location as the action of the water exploits gaps in the bedrock, changing the course of the flow. On a larger scale, whole new land masses can be created at sea by deposition of material during storms (reference here), or as a result of volcanic activity. These land forms can and do appear within a matter of hours. Whether the process and its results are perceived by humans to be destructive or constructive, the landscape has the capability to self organise afresh, generating new ecosystems. Such phase transitions could be triggered by the interactions of any number of the many open systems which combine to make up the landscape, for example in the case of a bush-fire in the Australian outback, which could be triggered by a combination of several factors such as a lengthy drought, long-term land management policies and the act of discarding a single cigarette butt.

Consider then, the landscape of Ashley. Its many physical and social systems are intimately connected to each other and influence each other in countless ways. It may seem to the present generation of Ashley residents that, despite the previous construction of transport infrastructures, the essential rural character of the place has not changed much for hundreds of years. This might make it difficult for inhabitants to conceive that it could ever change in any very significant way, and hard to accept that a proposed transport megaproject could soon be built. Many of the ongoing changes to the place have emerged gradually over time and have been prompted by change agents perceived to be from within the parish itself. The Vicar leaves to take up a new post, a farm tenancy ends, a tree blows over in a gale. A potential revolution in the quality of everyday life, caused by political decisions made in Westminster, seems perhaps overly dramatic and unlikely. However, Ashley is a complex adaptive system like any landscape, and the possibility of a phase transition is inherent. A significant flood event, for example, would not be out of the question, given the parish’s river boundaries, high water table and existing minor flooding problems. The coming of the HS2 line seems, at the time of writing in spring 2017, to be very likely, albeit in changeable political times. The increased level of complexity brought about by this event, or even just the anticipation of this event, has the potential to tip this landscape in to phase transition, from a rural to an urban condition, as changes in the various open systems of the parish culminate in the removal of its green belt status. This paper, in common with my PhD thesis, uses the term ‘cascading development’ to describe an emergent process of exponential development of land in a local area where a landscape intervention, such as HS2, makes a change so disruptive that a cascading effect is produced.

Crucially, it is not just the actual construction of the infrastructure that could cause such a phase transition, but a number of other, earlier, related events, for example the first announcement of the alignment of the route, or a visit by HS2 officials to the local area. Even a ten-minute talk given by an academic researcher one evening at St Elizabeth’s Church, or an hour’s walk through the countryside for research purposes, could likewise tip the balance of the system in to a new phase through the butterfly effect, as described by Lewin (1993) and now in common use.

Figure 2 indicates just one possible scenario for cascading development in Ashley and its immediate surroundings. There is no way of knowing for certain what the post-HS2 outcomes for the landscape will be, and there will also be no way of identifying with any certainty what will have triggered any phase transition that does occur. The ongoing economic growth of Greater Manchester and the airport, for example, could trigger a phase transition in adjacent landscapes, but it would probably not be possible to separate the effects of this growth from the effects of the commencement of operation of HS2 services, or

from the construction of the line itself. This is an imagined future which indicates one possibility over a thirty year period from 2018, and is not a forecast. It is reasonable, however, to propose that a scenario like this is possible for many rural places along the length of the HS2 line.

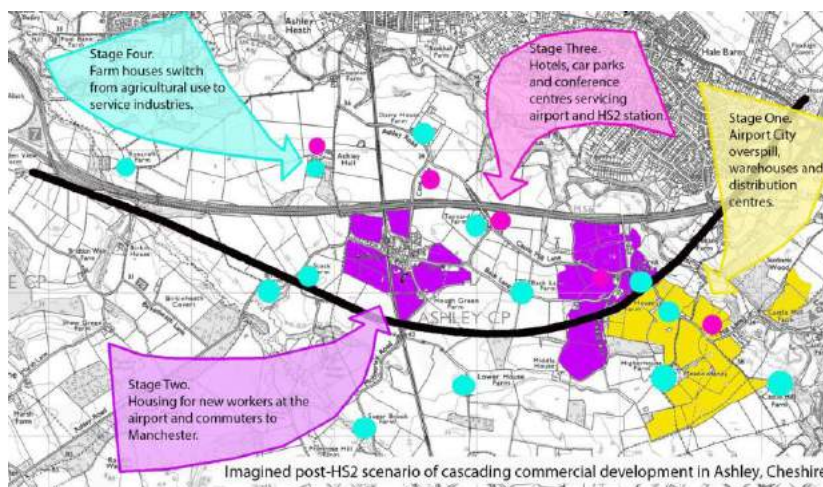

Figure 2. Author's own image, base map as figure 1.

Error! Reference source not found. shows the growth of Manchester airport and airport city such that, when the HS2 station opens at the airport, this tips the balance and causes Ashley to be removed from the green belt. A phase transition to exponential economic growth occurs, and Ashley becomes a hotspot for science parks, distribution centres and service industries such as hotels, conference centres and car parking, which service the demands of this growth. London is now only a one-hour train journey away, and Birmingham can be reached in just over 30 minutes, so commuting long distances is less of a barrier to growth. New housing is required locally to accommodate new workers. Planning permission for this will be easier to get as the rural character is lost to light-industrial development. The local landowner is keen to develop and so the village, bounded now on all sides by motorway and railway, quickly trebles in size. Farm land severed by HS2 and land contaminated by use over four years as a construction compound becomes available for development. Eventually, the island of farm land now trapped between Ashley village and Greater Manchester, succumbs to continued demand for new homes and opportunities for huge profits for developers. Existing domestic and farm buildings in Ashley become divorced from the agricultural functions of the land as farm land is developed and remaining land is drawn back under the control of the landowner and farmed by contractors rather than tenant farmers.

This scenario may sound extreme, but illustrates exactly the kind of growth desired by the UK government when they published 'Rebalancing Britain, from HS2 Towards a National Transport Strategy' (Department for Transport, 2014). This document suggests that the very first priority for the government is to reduce the pressure on Londoners of the capital city's high house prices, a congested public transport system and high costs of office space (£110 per square foot), by developing land in the North and Midlands.

By contrast, it points out that "commercial property prices in the North are nearer £28 per square foot. And yet businesses are more reluctant to move there" (Department for Transport, 2014: 12). HS2's promised short journey times, then, are presented as an opportunity to shift the pressure for development elsewhere:

"In London it will ease the pressure on commuters by adding 18 new train paths per hour into the capital. In the Midlands and the North it will make cities more competitive by connecting them better to the global market ...Put simply, cutting the journey time ... makes it more likely that more businesses will base themselves in the North and that existing firms will prosper...The effect should be transformational." (Department for Transport, 2014: 13)

It seems reasonable to conclude, therefore, that phase transitions to cascading development of housing and business premises in the North and Midlands, far from being the unintended consequences of HS2, represent the aspirations which have driven the project from its early stages. Furthermore, rural locations

such as Ashley, with existing transport infrastructure and in close proximity to both a growing city and a high speed station, will be the landscapes most likely to experience such transitions.

Complexity theory, then, can help landscape professionals and researchers to understand what may happen to a landscape, and why it could occur. This paper proposes that the most important issue arising from this understanding is the likelihood that the future of such places will probably be determined by the commercial interests of big business, in particular property developers such as the major house building companies. As pockets of land severed by the new railway become available, it is therefore timely to ask what will stand between local rural landscapes, each with their own distinctive identity and history, and exponential profit-making land development? And in studying the implications of complexity theory for public engagement with a transport megaproject, what glimpses might there be of simple solutions?

3 UNDERSTANDING SOME ANSWERS

Complexity theory leads us to begin to understand landscape at every scale as a continuously evolving whole, greater than the sum of its parts and comprised of a limitless number of interacting open systems. Compare the fluidity of this landscape condition with the operation of most public consultation exercises, which attempt to operate within a complex emergent field and yet themselves are inflexible, top-down 'snapshots' of public opinion. Such processes tend to start too late, finish too early and be determined by adherence to statutory requirements rather than motivated by a true desire to access the expertise held by citizens about their local landscapes.

3.1 WHY STATUTORY ENGAGEMENT PROCESSES ARE NOT THE ANSWER

Since the announcement in January 2012 of the Government's decision to go ahead with phase 1 of High Speed 2, an enormous amount of literature has been generated that communicates various aspects of the scheme to a number of different audiences. The document that communicates intentions to members of the public who live along the proposed route is the Environmental Statement (ES) for Phase 1. This is the main source of information through which the public are consulted about their landscapes and responses to it have supported members of parliament in considering the effects of the proposals. The complete 50,000 page ES includes written and mapped information about the impacts of the proposals on places along the route and also presents digital visualisations of changes to landscapes. It is the only collated source of accurate information regarding the future of those landscapes and indeed constitutes almost the whole of the Hybrid Bill that enshrines HS2 in law.

Individuals and groups had 23 days to respond to the contents of the ES by submitting a petition to parliament. If the petition was judged valid then petitioners presented their evidence in person, in parliament, to the Commons select committee. 1,925 petitions were received. A similar petitioning process occurred in the House of Lords in April 2016, during the second Lords reading of the Bill, when 820 petitions were accepted. None of these petitions to the Commons or the Lords had the potential to stop HS2 entirely or to substantially affect the route or stations, as this is beyond the power of the select committees.

The petitioning system is an adversarial one. When you speak in front of the select committee; "The Promoters [Department of Transport] have a similar opportunity to present counter arguments against your case." (House of Lords, 2016: 2). This means that some of the most senior barristers in the country, representing the power and weight of Parliament, are set against the petitioner, who presents to several officials, including the Chair, members of the House of Lords or Commons, at least one Queen's Counsel (an eminent lawyer) for the Department of Transport and various other HS2 officials. The Lords' own final report on the process stated that "Time and again during our proceedings, we encountered difficulties with the current procedure. It became abundantly clear to us that petitioners found it cryptic and complex to understand, and labyrinthine to navigate." (House of Lords Select Committee on the High Speed Rail (London - West Midlands) Bill, Special Report of Session 2016–17: 8). There have been detailed criticisms of this combative and inflexible top-down consultation system, dependent as it is on a document of vast scope and impenetrable structure (Bynoe, 2016, Phillips, 2017). It is also based on a model which attempts to meet statutory requirements for consultation by disseminating information to inhabitants in such a way as to create the least possible public resistance to proposals.

Much has been learnt about such consultation in the field of innovative technologies. Initiatives towards engaging the public ‘upstream’ of developments in science and technology, rather than later on in the process, can be understood as a reaction to the ‘Public Understanding of Science’ (PUS) model, launched by the British Royal Society in 1985 (Bauer, 2009, Joly and Kaufman, 2008, Demos, 2004). This model has been widely criticised for addressing an “undifferentiated entity called ‘the public’, which was to be educated and informed in order to secure support for innovation and reduce social resistance to technology.” (Joly and Kaufman, 2008: 2). The assumption that the public are a single unit of people with a coherent experience, and furthermore that they can be designated as ‘uneducated’ for the purposes of the consultation clearly does not stand up to scrutiny, and neither does the assumption that increased education on a particular topic will in fact lead to greater support for that issue. The PUS model “assumed that if people had all the information, and were able to understand probabilities, they would be more supportive of science” (Bauer, 2009: 4). Bauer, of the London School of Economics, finds that, on the contrary “on controversial issues there is no correlation at all” (Bauer, 2009: 4) between degree of knowledge about a scientific topic and inclination to support that technology.

This model, “in which lay people are conceived as passive and empty recipients of information” (Joly and Kaufman, 2008:2) still has powerful influence over the thinking and policy of all kinds of organisations, public and private. In the case of high speed rail, any public engagement based on such a deficit model would be highly unlikely to increase popular support for infrastructure proposals. On the contrary, it is possible that the more people learn about the probability of cascading development proposals in the wake of core infrastructure development, the greater the likelihood of objections being raised.

In these circumstances, to deliberately draw the attention of citizens to likely future developments would not be in the commercial and/or political interests of powerful stakeholders. An example of this might be the construction of a high speed station at Manchester Airport, adjacent to Ashley. HS2 Ltd confirmed that this is their intention on the 15th of November 2016 (HS2 Phase 2b Command Paper: 39). Land development pressure and increase in values as a consequence of this decision will be significant: such stations require public transport links, car parking, increased road traffic capacity and hotel accommodation for example. These will be built largely on green field sites within Greater Manchester; immediately to the east of Ashley’s parish boundary. None of these developments will gain popular support from residents in Ashley, many of whom are tenants and not property owners, so have nothing to gain from knock-on effects on land values, and a great deal to lose in terms of agricultural livelihoods, landscape character and tranquillity. The temptation for a government department to minimise ‘education’ about such likely developments must be significant. Sherry Arnstein’s influential Ladder of Participation (Arnstein, 1969) places ‘manipulation’ on the lowest and least desirable rung of the ladder, with ‘therapy’ just above it. The function of both is to educate people in to a view that the proposed plan is best. Arnstein’s ladder does not extend below ground in to the cellars of public consultation, where it is possible to imagine that an additional rung, perhaps called ‘obfuscation’, would denote a desire to avoid educating a public about matters that will affect them. Efforts towards genuine public engagement may also be hampered by “the pro-technology belief system, the inertia of administrative power, the intense industry lobbying” (Wang, 2016: 16). In such circumstances, it seems reasonable to assume that the Department for Transport’s own engagement strategy will not be sufficient to secure a meaningful voice for inhabitants in the futures of their own, emergent, landscapes.

3.2 INTERIM CONCLUSIONS: CASCADING ENGAGEMENT WITH LANDSCAPE

If the public engagement strategy of a central government department is, in its present form, too top-down, unwieldy and unresponsive, then perhaps local planning procedures might offer a framework for engagement with landscapes on the massive scale required by such revolutionary changes. The possibilities offered at the Parish level by Neighbourhood Planning legislation in the UK form an ongoing element of this research in Ashley. Initial findings, however, indicate that there is a likelihood that land ownership patterns and the business interests of developers will have very significant influence over this outwardly democratic exercise (Phillips, forthcoming).

In contexts such as those described here, it can be difficult to imagine a strategy for public engagement that could possibly hope to respond to complex challenges with any hope of having positive outcomes for the landscape. It could seem that the scale of resources and advance preparation needed to answer these problems render the goal of citizen-led participation in a transport megaproject entirely unrealistic.

However, just as the landscape emerges from very simple low-level interactions between systems, it might be possible for effective public engagement to do the same. As this PhD research develops it will investigate how public engagement with landscape could be encouraged to cascade just as development does. This idea seems to offer the possibility of a fluidity of response that could have a power commensurate with that of the challenges in prospect. It also raises a number of questions that I would be very happy to discuss with conference delegates. An important consideration, for example, is whether a landscape phase transition could, theoretically, be 'steered' in any way. I am also interested in whether citizens could/should routinely initiate their own landscape proposals. I will consider what the role of the landscape professions should be, and what might constitute the rules of engagement for professionals, inhabitants and government. I want to know how citizens could participate in a process that begins with simple interactions but embraces evolving complexity, setting the agenda from the beginning and iteratively rewriting that agenda to respond to emerging circumstances. Work in Ashley suggests that prioritising an embodied experience of the landscape is crucial as a means of understanding the requirements of that landscape, so how should this finding be applied? In all of this the aim will be to achieve fuller understanding of complexity, and a 'reflective capacity' rather than simplistic consensus about the long-term future of local landscapes.

ID 1424 | HOW TO APPROACH URBAN COMPLEXITY, DIVERSITY AND UNCERTAINTY WHEN INVOLVING STAKEHOLDERS INTO THE PLANNING PROCESS

Jossé-Miguel Fernández-Güell¹
¹Universidad Politécnica de Madrid (UPM)
josemiguel.fernandez@upm.es

1 CHARACTERISTICS OF CONTEMPORARY CITIES

Complexity, diversity and uncertainty are three key attributes of contemporary cities which mark their recent evolution and strongly condition the task of urban planners and public officials (Fernández Güell et al., 2016; Fernández Güell, 2006; Camagni, 2003).

The first common feature of all large and medium-sized cities is the high level of complexity of the operational processes that take place within the city and in its hinterland. Complex systems such as the climate and the economy are characterized by being spontaneously self-organizing and adaptive to changes that happen in their context (Holland, 1995; Stacey, 1995). Just as well, it is widely accepted that cities are one of the best examples of complex systems (Portugali et al., 2012; Allen, 1997). As a rule, complex cities experience unpredictable non-linear dynamics and they are capable of self-transformation in order to adapt to changing contexts. Therefore, urban problems are multidimensional and complex since they emerge in an intricate dynamic network of relationships from societal, economic, environmental and political issues.

The operational complexity of cities has been a recurrent handicap for urban planners because it complicates urban analysis and policy making. In the past, planners have tried to deal with complexity with either sophisticated mathematical models or just plain narratives, in both cases without much success. Despite its challenges to analysts, the phenomenon of urban complexity should not be obviated or simplified in excess; on the contrary, it should be conceptually understood as much as possible. The understanding of complexity can facilitate a more informed and evolutionary vision of cities than the standard reductionist and static approaches of many planning processes.

The second feature inherent to any big and medium-sized city is social diversity. This important, but elusive feature has been analyzed by well-known authors from different perspectives such as architectural design (Alexander, 1965), neighbourhood fabric (Jacobs, 1961) or participatory process (Innes and Booher, 1999). As a matter of fact, diversity is not just about ethnic or geographic origin. It is also about social diversity, different cultural expressions and multiple economic interests. Basically, urban diversity is generated by the disparity and heterogeneity of local and supra local agents who intervene in the socioeconomic activities of a city. In addition, cities are diverse because they are inhabited by a wide spectrum of citizens who are not as well organized as large stakeholders, but who have the right to be involved in city affairs.

Diversity and governance are intrinsically linked. In a democratic urban community, political decisions are the outcome of diverse interest groups with different levels of power, with the elected politician as the

catalyst for local consensus. On the one hand, a high level of diversity complicates the governance system for concealing multiple interests, but on the other hand, urban diversity may have positive effects on social cohesion, economic performance and social mobility. In brief, diversity is an important asset of cities in so far as conflicting interests of urban stakeholders are accommodated by mutually satisfactory negotiations.

The third attribute of the urban realm is contextual uncertainty, which influences most decisions regarding city development. All kinds of changes constantly affect cities, generating growth, stagnation or decline. Changes obviously bring a large dose of uncertainty to planners' forecasts (Klosterman, 2013; Abott, 2005). All those responsible for foreseeing the long-term evolution of a city are limited by current forecasting tools. Most of these difficulties are due to the highly complex and dynamic nature of contemporary cities, which prevents the precise and reliable foresight of events. This situation is aggravated when the city operates in a turbulent and changing context such as economic recessions or natural catastrophes.

Faced with the difficulty of foreseeing the future, many planners simply give up long-range planning and focus on contingency planning, which means an unconditional surrender to unexpected changes in the urban context. Although the future remains unpredictable, urban development can be foreseen and alternatives can be designed. Without the ability to anticipate the future and interpret alternative scenarios, cities are in a weak position to face coming challenges. Therefore, by learning to manage uncertainty we might be able to prepare for the future and try to shape it actively.

Finally, it is important to note that the three above mentioned urban features retrofit each other. For instance, a city with a high level of diversity augments its operational complexity while the accelerating rate of socioeconomic change intensifies the degree of uncertainty and complexity of cities.

2 NEED FOR A FRIENDLIER APPROACH TO URBAN COMPLEXITY

2.1 PREVIOUS ATTEMPTS TO APPROACH URBAN COMPLEXITY

Since the 1960s, a traditional approach to deal with urban complexity has been systems theory. The pioneer work of Ludwig von Bertalanffy on General Systems Theory (1968), Jay W. Forrester on Systems Dynamics (1961) and Charles West Churchman on Systems Approach (1968) opened the door to specific contributions toward a systemic understanding of the city. In that respect, the works of John McLoughlin on the application of systems approach to urban and regional planning (McLoughlin, 1969), Jay Forrester on urban dynamics (Forrester, 1969) and Ira Lowry on transportation modelling (Lowry, 1964) are well known. These innovative contributions to the understanding of urban systems produced the first generation of "large-scale urban models" in the 1960s and 70s.

These early attempts to understand urban systems raised great expectations in the planning field, but they had dubious practical results. In fact, the planning literature has recorded recurrently how the application of sophisticated quantitative models during the 1960s in urban renewal programs of large American cities was a resounding failure (Lee, 1973; Brewer, 1973). At that time, large scale urban models emerged as part of an effort to modernize planning and make the field more scientific; however, they were severely criticized. In short, they demanded large volumes of data and offered little detail, they did not behave reasonably with respect to variables for which no data were available, they reinforced command-and-control planning, and indeed they were very expensive (Batty, 1994; Lee, 1994). And above all from our present perspective, early large scale urban models were unable to interpret and simulate complex urban functions.

Three decades after the failure of those early experiences, the Institute of Santa Fe, in New Mexico, began to work with the concept of complex adaptive systems (Gell-Mann, 1994; Kauffman, 1995; Waldrop, 1992). Soon the Santa Fe scientists realized that the city was one of the most complex adaptive ecosystems because it encompassed a multitude of different agents interacting among themselves and the environment. Researcher Geoffrey West considered that the city exhibited capabilities for creating emergent structures and for self-organization (West, 2010). This new concept certainly enriched the original systems approach, but it further complicated urban analysis, making very difficult to predict the evolution of the city.

More recently, the science of complexity driven by smart city initiatives has embraced an integrated systemic approach that brings together a broad spectrum of powerful techniques and concepts that may be applied to the urban context. These include agent-based modelling, cellular automata, network theory, multi-scale thinking, field theory, statistical physics, and scaling theory. The new integrated approach intends to address transdisciplinary issues such as adaptability, robustness, resilience, regulation, and conflict in the urban realm. Nonetheless, little progress has been done in developing real integrated smart projects as some researchers admit (Mattoni et al., 2015; Lombardi et al., 2012).

In brief, after the early models of the 1960s, urban planners have dealt with complexity using narratives, conceptual models and sectoral simulation models, but most of the time they have carefully avoided large integrated quantitative models (Roo and Silva, 2010). Nevertheless, as cities evolve, an understanding of urban dynamics, networks and complexity is becoming increasingly important for planners to successfully guide their visions and policies.

2.2 TOWARDS A NEW APPROACH TO URBAN COMPLEXITY

Most quantitative approaches based on systems theory, while academically interesting, are not always easy to implement in a collaborative process with stakeholders from multiple professional backgrounds due to the high level of technical skills required as to their limited capacity to sketch out complex issues (Carlisle et al, 2016). Confronted with these circumstances, planners should be capable to develop more qualitative and friendlier conceptual frameworks in order to interpret city's complexity in a more holistic way and, at the same time, facilitate effective involvement of local stakeholders along the planning process. Accordingly, the new conceptual framework should fulfil four basic requirements.

Firstly, planners should be able to display the complex nature of cities by depicting all major sectoral systems, local stakeholders and functional relationships in a comprehensive and holistic manner. Conceptual maps and process diagrams could help to structure complex phenomena by displaying graphically all the variables of a problem and the role of diverse stakeholders.

Secondly, planners should develop new communication tools that facilitate the involvement of local stakeholders in the process of collaborative planning when analyzing complex urban issues. These tools should enable the search of consensus among urban stakeholders as well as the management of conflicts and dissent among them.

Thirdly, planners should incorporate foresight tools into the planning process to produce holistic future visions of the city. These tools would enable them to act in co-evolution with the ever-changing urban context. By co-evolution we understand the continuous reconfiguration of actor-networks and city systems as a consequence of continuous societal, economic, technological and environmental changes.

Fourthly, planners should develop innovative research approaches capable of handling fuzzy interconnected problems with the aid of collective intelligence and qualitative tools, instead of trying to solve clearly defined problems through standard quantitative tools. These approaches should respond creatively to fuzzy agendas based on a process of evolving collective intelligence.

In brief, a new model framework based on the former premises could provide conceptual support for spatial planners who are currently struggling to gain a holistic understanding of a city's structure and operations, while it evolves in an uncertain context.

2.3 A NOVEL CONCEPTUAL FRAMEWORK

One way to deal jointly with the complexity, diversity and uncertainty that are intrinsic to contemporary cities is to conceptualize the city as an evolving functional ecosystem, capable of adaptation and self-organization in response to context changes (Fernández Güell et al, 2016). Additionally, the systemic approach should be reinforced by foresight tools as part of the planning process, thus helping planners and stakeholders to look beyond their short-term problems.

Thus, a city may be regarded as a complex ecosystem of connected elements or parts with common purposes, in which human activities, linked by communications, interact as the system evolves dynamically in a given socioeconomic and physical context (Berry, 1964; McLoughlin, 1969). In other words, a city is built from multiple singular initiatives taken through time by a great number of players who are tightly interconnected among themselves. In this ecosystem, any spatial or structural alteration to one of the elements can modify the other parts of the system.

The technique of concept mapping (UN-Habitat, 2007) was used to explain the complex operation of a contemporary city. A schematic model was designed in which the urban ecosystem was synthesized and visualized as a set of different interrelated subsystems (see Figure 1).

Urban demand subsystem. This subsystem, composed of citizens, economic stakeholders, societal institutions and visitors, is placed in the centre of the model. All the demand segments place a number of requirements on the resources, services and infrastructures provided by the urban subsystems so that they can live and work in a city under good conditions.

Urban supply-side subsystems. From the supply side, the societal, economic, environmental and political subsystems of the city strive to interpret and satisfy requirements from demand segments. Each subsystem is described by its resources, operating agents, the services that are provided and the technology that is used.

Figure 1 – A city's functional system (Author's elaboration)

Spatial subsystem. The societal, economic, environmental and political subsystems request specific physical conditions from the spatial subsystem in order to operate properly. Thus, the so-called spatial subsystem, regulated by urban planning, is responsible for providing basic infrastructures, transport systems and a wide range of community facilities and housing units.

Technological subsystem. All the previous functional subsystems and demand segments are serviced by a technological subsystem made up of multiple platforms, which ideally should be horizontal in nature, although they may only operate for a single sector.

External trends. Finally, the overall urban system is subject to external change factors such as demographic transformations, economic cycles, technological innovations or environmental impacts, which affect its functional balance. Foresight studies provide a wide range of techniques for identifying and assessing all kind of trends.

Although it may be perceived as reductionist, this systemic conceptualization of the city has several advantages: it displays a simplified, intelligible abstraction of the inherent complexity of our urban reality; it emphasizes functions and processes rather than spatial patterns; it expresses schematically the dynamic evolution that a city may undergo over a given period of time; it critically analyzes the diverse relationships

between urban components; it provides the bases for decision-making processes; and it exposes the dominance or dependence of stakeholders over functional subsystems.

This systemic approach can help to achieve a better understanding of the underpinnings of the urbanization process and establish a common ground for collaboration among local stakeholders.

2.4 RESEARCH METHODOLOGY

A new systemic approach to cities was developed and validated with various Spanish experts in city sciences and stakeholders over a four-year period. Research was based on a mix of consulting and academic activities which progressively added value to the final research product. The chronological sequence of the validation process was roughly as follows.

The author's personal experience for many years in university teaching and leading consulting projects showed the need for a comprehensive user friendly systemic approach to cities which could be useful not only for professional urban planners but also for a wide range of urban stakeholders. A preliminary systemic model began to take shape during 2013 as the result of desk analysis.

In 2014, a foresight exercise financed by a multi-national consulting firm was undertaken to envision how Spanish cities should desirably evolve towards the horizon 2030 in order to avoid urban development malpractices that generated a real estate bubble during the 2000-2008 period (Fernández Güell & Collado, 2014). This exercise involved four stages. First, a systemic conceptual model was developed to understand the city in a holistic way. Second, a foresight exercise was undertaken using scenario design and visioning. Third, the resulting desired vision for Spanish cities and its foreseeable impact in the urban functional system was discussed with diverse urban stakeholders around Spain.

In 2015, the systemic conceptual model was submitted to the judgement of academics and urban professionals at presentations in two international conferences and subsequent publications in scientific journals. As a result of those external assessments and fruitful discussions, additional refinements were incorporated into the urban functional system.

By the beginning of 2016, the usefulness of the systemic model was validated in the city of Madrid. Preliminary research outcomes –functional system and vision's implications-- were shared with and validated by various Madrid urban stakeholders and planning officials through personal interviews. By mid 2016, confidence was gained about the usefulness of combining a systemic and foresight approach to make the foreseeable evolution of cities more intelligible to wider audiences.

3 IMPLEMENTING THE CONCEPTUAL FRAMEWORK TO DISPLAY THE RECENT AND FUTURE EVOLUTION OF SPANISH CITIES

In order to check its operational feasibility, the proposed urban functional system is implemented to characterize the recent evolution of Spanish cities. Firstly, the model is used to explain the real estate bubble experienced during the 2000-2008 period; secondly, it displays the crisis experienced by most Spanish cities during the 2009-2014 period; thirdly, it envisions the desired future urban development model in the 2030 horizon. The above mentioned retrospective and prospective exercises are supported by secondary sources and specific contributions made by experts in the last three years of continuous research projects.

3.1 THE REAL ESTATE BUBBLE (2000-2008)

The urban functional system shown in the conceptual framework was used to characterize the development model followed by most Spanish cities during the 2000-2008 period, when the country enjoyed a long economic bonanza that nurtured a huge real estate speculative bubble. The successes and excesses made at that time constitute an interesting experience to study before formulating the future

model. The following retrospective analyses are synthesized from secondary sources (Gaja I Díaz, 2015; Naredo and Montiel, 2011; Jiménez, 2009) and contributions made by experts.

In those years Spanish cities were operating as follows (see Figure 2).

Urban demand: Its major segments were fragmented and scarcely connected among themselves. Businessmen behaved opportunistically with short-term actions, contemplating the city just as a chess board in which they could easily make multiple speculative and profitable deals. Regarding citizens, most of them were self-satisfied with the socio-economic context, so they were unconcerned with urban issues. Tourists would arrive at city destinations expecting all kind of facilities and services to fulfil their highest aspirations, regardless of the environmental or social impacts they might cause.

Economic subsystem: It showed good performance indicators in growth and employment, but it also suffered from low productivity levels and excessive financial leverage. Except in big metropolises, like Madrid and Barcelona, most municipal economic bases were dominated by small and medium enterprises in mature industries which had low technological intensity and were mainly oriented to the national market.

Societal subsystem: The social fabric of many Spanish cities revealed the tensions generated by the progressive ageing of urban populations, the wave of scarcely qualified immigrants from developing countries, and the emergence of new family structures. As a result of the previous tensions, social capital was not significantly strengthened in the cities.

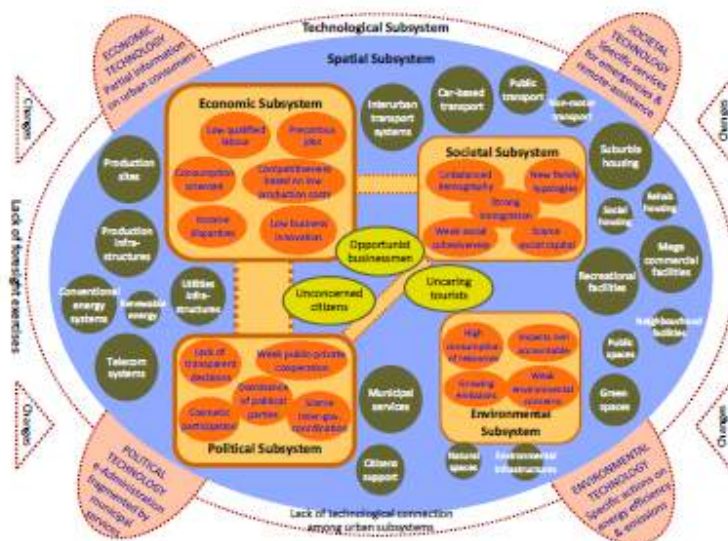

Figure 2 - Spanish cities functional system in the pre-crisis period (2000-2008) (Author's elaboration)

Environmental subsystem: It was relegated to a secondary position within urban priorities during this period. The prevailing economic dynamism gave impulse to the aggressive urbanization of urban outskirts as well as to the construction of large transport infrastructures and commercial facilities. Due to rapid urban growth, numerous environmental impacts occurred in the environs of cities.

Political subsystem: At that time, local governments held positions very closed to the economic subsystem. There was an evident collusion of interests between economic stakeholders and local politicians in big real estate operations, favoured by the lack of transparency in the municipal decision making process. This state of things gave place to numerous episodes of corruption.

Spatial subsystem: Cities were overbuilt increasing their ecological footprint. Large areas were urbanized in the city fringes, big transport infrastructures were built in most metropolitan areas, costly commercial mega facilities were developed in the suburbs and more houses were built than needed.

Technological subsystem: During those years, Spanish municipalities made a significant effort to improve their management systems by incorporating new information and communication technologies (ICTs) to satisfy sectoral needs of specific municipal services.

External trends: Few foresight exercises were drawn during this period. Scattered initiatives, mostly sponsored by sectoral stakeholders, were undertaken to foresee the future evolution of the Spanish society. Some municipalities carried out vision and scenarios exercises as part of their strategic plans.

Not all the city functional subsystems were effectively interconnected during this period. A strong relationship was developed between the economic and political subsystems due to their shared common interests. The societal subsystem had weaker connections with the economic and political realms; in fact, connections were activated on intermittent bases according to pressing needs such as political elections or labour unrest. Regarding the environmental subsystem, it operated in a rather isolated mode because other sectoral policies did not show much concern for environmental issues.

3.2 THE URBAN CRISIS (2009-2014)

By 2009, macroeconomic indicators showed that the economic crisis was in full swing, producing a tough shock to most Spanish municipalities. At that point, it was clear that previous urban practices have aggravated the intensity and scope of the recession, generating a huge real estate bubble.

Urban demand: It was strongly hit by the economic recession. Citizens, faced with long-term unemployment and diminishing social protection, blamed politicians and speculators for their economic misfortunes. Angered citizens turned into social activism, giving strong support to new social movements, which in turn created new political parties. Most businessmen were stranded by the depth of the crisis and the changing economic global context. Despite an initial decline in tourist arrivals, visitors kept choosing Spanish destinations because of their competitive prices, good facilities and lack of safety problems. Though demand segments suffered severely during this period, they were not able to establish links to develop joint actions.

Economic subsystem: The crisis evidenced the fragility of the Spanish economic fabric. Small and medium sized enterprises were particularly affected, generating a huge volume of unemployed people. Those businesses with export opportunities in foreign markets had a chance to survive, while the rest were forced to foreclose or undercut their operations to a minimum. Most local economies faced a profound reengineering process of their economic activities in order to improve their low level of productivity and lack of innovation.

Societal subsystem: Against all odds, the social fabric of Spanish cities resisted the crisis thanks to the strength of the family unit. Family regrouping took place to help the unemployed. Immigration flows reversed and young Spaniards began to leave the country in search of job opportunities abroad. Fertility rates hit records low, aggravating the ageing of urban populations. To counterbalance spending cuts in public services, self-organized citizens began to take grass roots initiatives to provide social coverage to the needy. Social capital seemed to strengthen in cities with big social problems.

Environmental subsystem: As a result of the crisis, the health of the environment became one of the first priorities of politicians and citizens. As a counter reaction to the former real estate speculation spree, a general consciousness emerged in favour of diminishing environmental impacts, caring about emissions and recovering natural spaces. Due to the economic recession, the ecological footprint growth was slowed.

Political subsystem: Widespread economic scandals and political corruption hit hard traditional political parties, opening the door to the emergence of new political groups. Citizens expressed their discontent with traditional power structures by organizing sit-ups in public squares and by supporting social movements. Local governments were blamed by their lack of transparency and accountability in their decision-making processes. Citizens demanded more empowerment and open participation.

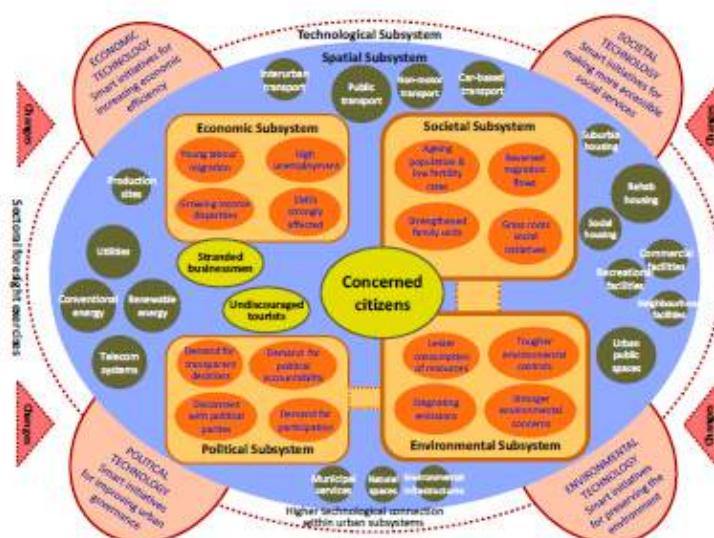

Figure 3 – Spanish cities functional system in the crisis period (2009-2014) (Author's elaboration)

Spatial subsystem: The excesses of the previous period left numerous scars in the Spanish cities. It was common to observe unfinished building skeletons, undeveloped urbanized lots, empty toll highways, oversized airport terminals, underused high-speed trains, and plenty of flats for sale. Traffic congestion diminished and large commercial projects were abandoned. Rehabilitation appeared as a reasonable alternative to new residential development, but the lack of public support slowed down many projects. All kind of large infrastructure projects were revised and many were either delayed or dismissed.

Technological subsystem: Limited by cut spending and diminishing revenues, local politicians found in the so-called smart city initiatives an alternative path for modernizing their cities by reducing emissions, improving energy efficiency and facilitating public participation. These initiatives were promoted by high-tech corporate business and by the European Union through its Smart Cities and Communities Programme. Nevertheless, most smart projects operated under the format of technological silos without much interaction among government departments and other city systems.

External trends: Multiple forecasts, dominated by pessimistic visions, were drawn during the crisis years as a reflection of the Society's awareness about the present problems and the coming challenges. Mostly private organizations developed future scenarios for anticipating the evolution of sectors such as energy, transport, industrial production or environment. Nevertheless, few municipalities were interested in carrying out foresight exercises to foresee their development alternatives.

An overview of the urban functional system unveils that abrupt changes happened in regard to subsystems interconnections. The economic and political subsystems no longer enjoyed privileged links among themselves and gained some sort of isolation respect the other urban subsystems. Instead, the societal subsystem gained momentum and tried to establish stronger links with the environmental subsystem as well as with the concerned citizens. Nevertheless, radical changes were taking place among citizens and local stakeholders that would certainly determine future patterns of power relationships within the urban realm.

3.3 THE FUTURE VISION (2030)

If Spanish cities had to recover in a near future, despite amending past mistakes, they should be able to anticipate and assess the foreseeable impact of forthcoming change factors. Thus, a foresight exercise was due to envision the model of the future city in the 2030 horizon.

After successive discussions with stakeholders and experts, it was agreed that the future desired vision was to be guided by five driving principles (Fernández Güell & Collado, 2014): (1) create an equitable and cohesive social fabric; (2) develop an innovative, competitive and resilient economic base; (3) preserve a healthy and sustainable environment; (4) establish a collaborative and transparent governance system; (5)

build a compact and sustainable urban structure. Those five principles support the urban functional system which displays the desired future vision for Spanish cities (see Figure 4).

All the functional subsystems will be tightly interconnected among themselves and they will take into account the needs, demands and aspirations of the diverse urban demand segments in pursuit of a more integrated model. City managers will avoid dominant positions among the subsystems by establishing relatively well-balanced positions among demands and urban functions. This will compel urban planners to maintain fluid communications and negotiations with different stakeholders.

Vision of urban demand: In the year 2030, Spanish cities will be inhabited by citizens, businesses and public organizations capable of facing problems and challenges in a creative and innovative way. Business will be very demanding on location requirements, but at the same time they will show a collaborative attitude with public officials for improving the city. Citizens will be empowered to exercise their rights and they will be very much involved in public debates. Tourists will show high expectations regarding the environmental quality and social cohesiveness of city destinations.

Vision of the economic subsystem: In 2030 will be more balanced than in prior times. Economic development will be intelligent (based on knowledge, innovation and creativity), sustainable (efficient use of resources and concern for the environment) and cohesive (high level of employment and social

responsibility). Sectors with well articulated clusters of business, technology centres, advanced services and entrepreneurs will flourish and will be more resilient to economic downturns.

Figure 4 – Future vision of Spanish cities functional system (2030) (Author's elaboration)

Vision of the societal subsystem: In the future, it will handle significant challenges such as the ageing of population, the emergence of new exclusionary pathologies, and a growing multicultural society. Cities will establish a new social pact among generations and genders so as to provide adequate assistance to the most needed and handicapped. Resources will be redistributed in an equitable and efficient way to attend social needs and minimize social gaps.

Vision of the environmental subsystem: In 2030, Spanish cities will prosper in economic and social terms, but at the same time they will reduce their ecological footprint by diminishing the consumption of energy, water, soil and other natural resources. Success will be due to technological innovations which will minimize environmental impacts, but also to the growing environmental consciousness of citizens who will have significantly reduced their consumption levels.

Vision of the political subsystem: Advanced governance will be a must in the cities of the future. Local administrations will be more intelligent, innovative, transparent, accountable, participative and inclusive because citizens will be more empowered and socially active as ever before. The increasing involvement of citizens in city matters will give rise to an improved and responsible political class, capable of responding to social demands with adequate policies.

Vision of the spatial subsystem: In 2030, cities will shape their physical elements according to strict sustainability criteria. Spanish cities will opt for compact and complex urban models over sprawl models.

Urban mobility will be dominated by public transport and non-motorized modes. Carefully designed public spaces and community facilities will foster the social encounter of citizens.

Vision of the technological subsystem: The effective development of truly Smart Cities will require the coordination of numerous agents and technologies as well as the long-term involvement of local stakeholders. In this visionary model, the relations among demand segments and functional subsystems will be supported by complex technology platforms which will supply fluid communications in real.

External trends: Cities will scan constantly the context in which they are operating. Scanning will mean to monitor and anticipate all the geopolitical, societal, economic, technological and environmental change factors that may affect the city's development. Those foreseeable changes will be analyzed not only by advanced quantitative models but will be contrasted by experts who will give qualitative opinions.

In brief, the forthcoming challenges will impel cities to interconnect and coordinate their functional subsystems. Consequently, the city of the future will have to be planned and managed under a holistic approach, making sure that all urban functions and city agents operate in an integrated and related way.

4 CONCLUSIONS

4.1 IMPLICATIONS OF THE PROPOSED APPROACH

Implications for comprehensive policy making. The proposed systemic model can be used as a transversal tool to coordinate strategies and actions among the different public bodies --either intra-municipal or supra-municipal-- involved in the urban planning process. On the one hand, coordination is necessary among multiple sectoral units within a single municipality when formulating comprehensive urban policies. On the other hand, complex cities require intense and continuous efforts to coordinate public actions, whether be vertical (national, regional and local levels) or horizontal coordination (various municipalities within a metropolitan area). Just as well, this model can provide useful insights to urban analysts before gathering data and running sophisticated mathematical models that tend to oversimplify complex realities.

Implications for collaborative planning with local stakeholders. An intelligible systemic approach can be of great help for facilitating stakeholders' involvement into the planning process. In fact, participant stakeholders along the research process expressed their support for the systemic model. Firstly, they welcomed the graphical display of the structure and functionality of complex urban systems to which they could easily refer to and understand. Secondly, participants gained an improved insight into the relational complexities of cities. Thirdly, the conceptual model eased the collaboration among diverse stakeholders and public officials. Fourthly, the proposed approach appeared to be user friendly for decision makers and stakeholders, and quite manageable for technicians.

Implications for foresight studies. Both the systemic and foresight approaches used along the research process worked well together to envision the dynamic evolution that a city may undergo over a given period of time. Confronted with the display of the city functional subsystems and their evolution over time, consulted experts were capable to assess the accuracy of past and present situations as well as the plausibility of the projected future vision. In brief, the conceptual framework provided systematic guidance on the foreseeable evolution of the urban functional system by mapping intelligible future visions.

Implications for innovative educational processes. Jay Forrester (1995) suggests that systems thinking should be introduced in planning schools so that students can familiarize themselves with integrative approaches to urban complexity. Systems thinking could provide a unifying basis to connect mathematics, environmental, economic, social and urban studies, which will help students to break down boundaries between disciplines. Nevertheless, explaining to university students the concept of urban complexity is not an easy task for any professor. Therefore, the proposed conceptual framework is a useful first step for students to grasp urban complexity, before analysing in-depth the functional relationships among urban subsystems.

4.2 LIMITATIONS OF THE PROPOSED APPROACH

However, in its present state of development, the proposed model has several limitations. First and foremost, it is just a generic and conceptual framework that needs to be applied to real cities in order to test rigorously its feasibility. This test will enable researchers to check the plausibility of the approach and will provide planners with a road map for improving urban analysis.

Second, more exploratory work should be done with stakeholders' involvement in interpreting the functional system to guarantee that they can add value into the planning process. Further work needs to be done in identifying appropriate methods of enquiry to better understand network interrelations among stakeholders. Likewise, the degree to which this kind of foresight exercise facilitates capacity building among key urban stakeholders remains to be checked.

Third, the conceptual framework, as it is right now, does not contemplate the possibility of plugging in quantitative models that would certainly enrich the whole approach. A concurrent use of quantitative and qualitative tools would improve the accuracy of the method. Thus, quantitative tools could be employed to support and lend coherence to the process, but they should never drive it because the method would lose its eminently qualitative nature and would discourage stakeholders' involvement.

The above mentioned limitations expose clear opportunities for further lines of enquiry that bring together academicians and professionals working in urban planning. Execution of further research will enhance the potential for incorporating a systemic approach and foresight tools as an undisputed work package in the urban planning process.

1 PREFACE

The self-similarity (fractal characteristics) of the unique gully landform of Loess Plateau has been demonstrated adequately. Urban spatial distribution rooted in the landform also has an obvious feature of self-similarity, to forms a relatively stable and harmonious relationship between human being and nature over the past thousands of years. With the rapid development of energy industries and urbanization in Northern Shaanxi, the soil erosion and other ecological problems are getting intense. The contradiction between loess gully landforms, which is a regional and critical ecological factor, and urban spatial development becomes sharper. It brings a tremendous impact on existing relationship between human being and nature. With the help of fractal theory, this research made a coupled correlation study between the topography, which in Northern Shaanxi energy-rich region with fractal characters, and the urban spatial form, so as to explore a realistic way for urban spatial development adapted to landscape environment in Northern Shaanxi. Hopefully, this paper will provide a reference for other research about urban spaces in ecologically sensitive areas.

2 FRACTAL FEATURES OF LANDFORM OF LOESS PLATEAU AND URBAN SPATIAL FORM IN NORTHERN SHAANXI

Loess Plateau in Northern Shaanxi is a typical area of the Loess Plateau in China which located at latitude 34°10' ~ 39°35', longitude 107°30' ~ 111°15', including area among north of Guanzhong Plain, south of the Ordos Plateau, east of Ziwuling, and west of the Yellow River in Northern Shaanxi. Its plateau elevation is about 600 to 1900 meters, its northwest terrain is high and southeast terrain is low. Its total area is about 89,327 square kilometers, accounting for 43.2% of the province's land area and 18.4% of the total area of the Loess Plateau[1].

From the perspective of administrative divisions, Northern Shaanxi includes 1 district and 11 counties of Yulin and 1 district and 12 counties of Yan'an (Table 1). The total population of Yulin City in 2014 was about 3.75 million people, and the total area was about 44,000 square kilometers[2].

city	center city	county
Yulin	Yuyang district	Shennu, Fugu, Hengshan, Jingbian, Dingbian, Mizhi, Wubu, Qingjian, Zizhou, Jiaxian, Suidi
Yan'an	Baota district	Yanchang, Yanchuan, Zichang, Ansai, Zhidan, Fuxian, Ganquan, Luochuan, Yichuan, Huanglong, Huangling, Wuqi

Table 1 -The Scope of Administrative Division in Northern Shaanxi

2.1 FRACTAL FEATURES OF LANDFORM OF LOESS PLATEAU IN NORTHERN SHAANXI

The terrain of Loess Plateau in Northern Shaanxi gradually reduced from northwest to southeast. The forms of the surface are plateau, beam, hilly and ditch, so the features of Loess Plateau in Northern Shaanxi is fractal. Based on literatures of hydrogeology and geography and surface matter composition, the form of Loess Plateau in Northern Shaanxi was divided into six categories which were sand-loess

transition area, loess beam and hilly area, loess hilly area, loess long beam area, loess plateau and broken loess plateau (Figure 1). From the intuitive form of view, the form of Loess Plateau in Northern Shaanxi shows self-similar structure which repeated by valley and plateau and valley[3](Figure 2).

Figure 1 -Six categories of the form of Loess Plateau in Northern Shaanxi

Figure 2 -Luohe in Huangling county of Yan'an, Shaanxi (Image source: http://www.taiwan.cn/taiwan/roll/201409/t20140920_7400890_5.htm)

By using grid algorithm, this paper measured six types of the form of Loess Plateau in Northern Shaanxi which has been characterized by trench lines, and the results are as followings (Table 2) : 1) fractal dimensions of different areas in same type of landform were not exactly the same but pretty close which were in a digital interval. 2) fractal dimensions of different types of landform were with a large difference and the landform can be sorted based on FD from small to large as following: sand-loess transition area < loess beam and hilly area < loess hilly area < loess plateau < loess long beam area < broken loess plateau. The reason that caused result above is that different types of landform have different surface roughness. The slope of sand-loess transition area was slow, so the contours were sparse and the fractal dimension was the lowest compared with fractal dimensions of five other types of landform. Loess beam and hilly area and loess long beam area usually have both beam and hilly, so the surfaces are complex and different and the fractal dimension was high. Compared with loess plateau, broken loess has both beam and plateau which are under the erosion at the same time, so the geomorphic fragmentation was greater, fractal dimension was higher.

categories of the form	FD of the landform	Interval of FD
sand-loess transition area	1.0019	1.0-1.2
	1.0241	
	1.0571	
	1.0803	
	1.1847	
loess beam and hilly area	1.3553	1.3-1.7
	1.6153

2.2 FRACTAL FEATURES OF URBAN FORM OF CITIES IN NORTHERN SHAANXI

By using grid algorithm, this paper measured fractal dimensions of urban boundary and urban land of 25 cities in Northern Shaanxi.

First of all, based on the form of urban boundary, these 25 cities were divided into five types which were narrow stripes city, branching band city, curved strip city, broken strip city and lumpy city. By using grid algorithm, this paper measured fractal dimensions of urban boundary(Table 3) and sorted the results by ascending sequence(Figure 3).The results showed that with the ever-increasing dimension of fractal dimension, there were corresponding regular changes in the form of urban form. In the lower part of the fractal dimension, the corresponding boundary morphology were mostly long strip and curved strip which indicated that the boundary shape of these two types of towns was relatively simple. In the higher part of the fractal dimension, the corresponding boundary morphology were mostly branched and stripped which indicated that the boundary shape of these two types of towns was more complicated. The fractal dimension of the bunker town was uneven and the rule was weak.

City	Wuqi	Yulin	Huanglong	Hengshan	Yichuan	Shennu	Zhidan	Wubu	Ansai
FD of urban boundary	1.2	1.216	1.268	1.355	1.362	1.378	1.379	1.387	1.387
City	Luchuan	Qingjian	Yan'an	Zichang	Fuxian	Jingbian	Dingbian	Jiaxian	Fugu
FD of urban boundary	1.399	1.441	1.441	1.445	1.445	1.452	1.462	1.463	1.471
City	Ganquan	Yanchuan	Huangling	Mizhi	Suide	Zizhou	Yanchang	—	—
FD of urban boundary	1.491	1.494	1.501	1.511	1.52	1.576	1.59	—	—

Table 3 -Fractal dimensions of urban boundary of 25 counties

Figure 3 -Corresponding relationship between FD of urban boundary and form type

Secondly, filled the town boundary and measured fractal dimension of urban land. The result showed that the fractal dimensions of the urban land were basically between [1.3-1.6], and a small number of fractal dimensions of the urban land were basically between [1.6-1.85](Table 4). The incremental order of fractal dimensions were as followings: fractal dimensions of long strip city<branched strip city<curved strip city <broken strip city<lumpy city(Figure 4).

City	Wuqi	Yulin	Huanglong	Hengshan	Yichuan	Shennan	Zhidan	Wubao	Ansai
FD of urban land	1.3	1.701	1.339	1.398	1.535	1.492	1.425	1.365	1.669
City	Jingbian	Dingbian	Jiexian	Fugu	Ganquan	Yanchuan	Huangling	Mizhi	—
FD of urban land	1.614	1.847	1.56	1.49	1.618	1.51	1.603	1.605	—
City	Luochnan	Qingjian	Yan'an	Zichang	Zizhou	Yanchang	Fuxian	Suide	—
FD of urban land	1.489	1.68	1.42	1.471	1.685	1.713	1.449	1.46	—

Table 4 -Fractal dimensions of urban land of 25 counties

Figure 4 -Comparison between FD of urban land and form type

At last, based on the fractal dimension increment, arrange the fractal dimension of urban land and urban boundary of 25 cites (Figure 5). Increase of fractal dimension of urban boundary (0.39) was slightly smaller than the one of urban land (0.55) which indicated that fractal dimensions of urban land fluctuated greatly. The reason might be that fractal dimension of urban boundary only represented the complexity of the form of boundary, and fractal dimension of urban land represented the complexity not only of the form of boundary but also of the filling with internal land. Thus fractal dimensions of urban boundary may be close, but fractal dimensions of urban land are usually different given that different cities have different layouts of land.

Figure 5 -Comparison between FD of urban land and urban boundary

3 FRACTAL COUPLING RELATIONSHIP BETWEEN URBAN SPATIAL FORM AND LANDFORM

Different from city in the plains, the development of city in gully area is always limited by the ups and downs of the mountain, geomorphic structure and other external space environment. The typical fractal features of the loess plateau in Northern Shaanxi determine the narrow and long characteristics of the landform, valley and the mountain undoubtedly have obvious binding and guidance on the form of urban spatial form. In the typical gully region of the Loess Plateau in Northern Shaanxi, the valley is often very narrow, cities in this area often appear band shape and grow with the river bend or extend along the river valley, so they highly coincide with the characteristics of landform (Figure 6). The urban spatial forms in Northern Shaanxi inherit the morphological characteristics of valley, thus they also form dendritic system with different scales, and the form of urban land and landform have coupling similarity on different scales.

Figure 6 -Coupling relationship between urban land and landform of Ganquan county (left)and Fuxian county (right)

3.1 FRACTAL COUPLING RELATIONSHIP BETWEEN FORM OF URBAN BOUNDARY AND LANDFORM

Land boundary is one of the important characterization elements of urban spatial form, also is an important interface between urban and natural landform. Forms of urban boundary are different because of different types of landform where the cities located. The coupling relationship between boundaries and landform of cities in different sizes is different, even the cities are located in the same type of landform.

Perform a linear fit of fractal dimensions of urban boundary and corresponding landform of the 25 towns(Figure 7). The result showed that correlation trend between fractal dimensions of urban boundary and landform in sand-loess transition area was negative(except Yulin). Correlation trend between fractal dimensions of urban boundary and landform in three types of hilly areas was discontinuous and in general the former moved up and down around the latter. Correlation trend between those two in loess plateau was basically proportional.

Figure 7 -Comparison between FD of landform and urban boundary

Based on the fractal dimension increment, arrange the fractal dimension of urban boundary and landform. The result showed that when fractal dimensions of urban boundary became larger, distribution of fractal dimensions of landform had no obvious rule(Figure 8). When fractal dimensions of landform became larger, distribution of fractal dimensions of urban boundary showed a downward trend(Figure 9). Judging from those tow results, fractal dimension of urban boundary was influenced by fractal dimension of landform, and the former changed in the subsequent changes.

Figure 8 -Comparison between FD of landform and urban boundary based on the former

Figure 9 -Comparison between FD of landform and urban boundary based on the latter

Combined with the chart and the actual situation analysis, there are four points in the relationship between the form of urban boundary and landform in Northern Shaanxi: 1) the original construction of the town and the landform were the most closely related. In a certain watershed, the urban boundary along the ditch line showed the fractal characteristics. 2) urban construction land tended to select the water system developed flat valley which showed that water system had restrictions on urban boundary. 3) when the social factors such as traffic weakened, the coupling between urban boundary and landform increased. 4) the relationships between landform and urban boundary of Yan'an and Yulin were relatively weak, mainly due to the influence of various factors such as economy, society and traffic, and the urban boundary gradually deviated from the original form determined by natural factors such as landform in the process of urban development.

3.2 FRACTAL COUPLING RELATIONSHIP BETWEEN FORM OF URBAN LAND AND LANDFORM

Fill urban boundaries of 25 cities and the resulting patterns were the forms of urban land. Measured those forms of urban land by using grid fractal algorithm and compared with fractal dimensions of corresponding landform (Figure 10).

Figure 10 -Comparison between FD of landform and urban land

It can be seen from the figure that there was no obvious linear relationship between fractal dimensions of landform and urban land of 25 cities, whereas corresponding relationship in same type of landforms was obvious: 1) there was a negative correlation between those two in sand-loess transition area. 2) correlation trend between fractal dimensions of urban boundary and landform in three types of hilly areas was discontinuous and in general the former moved up and down around the latter. 3) correlation trend between those two in loess plateau was basically proportional.

Figure 11 -Comparison between FD of landform and urban land based on the latter

Figure 12 -Comparison between FD of landform and urban land based on the former

Figure 11 and 12 can be obtained by increasing the order of urban land fractal dimension and landform fractal dimension respectively. When fractal dimensions of urban boundary became larger, distribution of fractal dimensions of landform had no obvious rule. When fractal dimensions of landform became larger, distribution of fractal dimensions of urban boundary showed a downward trend.

3.3 SUMMARY

In general, most of the towns, except for individual towns, have similar fractal characteristics in land form and boundary morphology, and are negatively correlated with topography in fractal dimension. In addition, there are corresponding relationships between the scale of urban land form and the complexity of landform, that is, the more complex landform broken, the smaller the scale of urban land use, the greater the contrary, which in the sand -loess transition zone and other hilly areas of the performance was very obvious.

4 "GROUP + NETWORK -LIKE" FRACTAL -MIZHI URBAN LAND SUITABLE SHAPE MODEL

4.1 OVERVIEW OF MIZHI COUNTY AND STUDY REGION

Mizhi County is located in the eastern part of Yulin City, Shaanxi Province, the middle reaches of Wuding River, longitude 109°49'-110°29', latitude 37°39'. East-west length of administrative area is 59km, north-south width is 47km, and the total land area is 1212km².

The landform of Mizhi county is the area of the transition from sandy beach to loess landform, and it has the characteristics of typical loess hilly and gully landscape. Gully and beam and hilly staggered in this area

and the surface fragmented. The area of central Wuding River valley is flat and its agricultural production conditions are better.

Affected by economic development and traffic and other external factors, urban boundary began to break through the original fractal state. River traffic and land conditions and other leading factors became obstacles to growth of urban boundary inheriting fractal landform.

Focusing on the area of Mizhi county as the main study region, and extending the area of 20km square as the "fractal characteristics and performance evaluation of urban and rural spatial form"(Figure 13). The study area extends north to Zhenchuan town of Mizhi county, extending southward to Shilipu township, extending eastward and westward by about 10 km to the end of the subsurface watershed.

Figure 13 -Study region of Mizhi county

Figure 14 -Urban and rural land use status of study region Table 5 -Fractal dimensions of urban land of 25 counties

4.2 FRACTAL CHARACTERISTICS OF CURRENT SITUATION

The land of the study area is composed of the three trenches of valley, sub-ditch and the tributary ditch. This system can be analogous to the tree:valley is the main trunk, sub-ditch for the branch, branch ditch for the tip, thus forming three levels of "trunk -branches -shoot"(Figure 14). The total construction land use situation in the study area is shown in Table 5.

According to the results of radius fractal dimension calculation (Figure 15), the fractal fit degree R^2 of the study area was 0.992, and the fractal characteristics were not obvious. The radius dimension $D = 0.941$, which was much smaller than 2, showed that the density of land use circle in the study area was decreasing from the center to the periphery, which was consistent with the current situation of development along with valley (i.e. "strong backbone and weak branches" form). In addition, the radius dimension 0.941 was low (less than 1), indicating that the construction area of the study area was still concentrated in the county center (i.e. Yinzhou town), the surrounding township construction land proportion was low, therefore the spatial utilization and integration of the outer area of Mizhi county (including sub-ditch and The use of land within the trench) should be strengthened.

Figure 15 -Radius FD of study region

According to the results of grid fractal dimension, the fractal fit degree R^2 of the study area was 0.991, and the fractal characteristics were not obvious. The grid dimension $D = 1.501$, which was between 1 and 2, belongs to the normal range, but the dimension was low, which indicated that the spatial development in the study area was immature, and the land form did not reach the stable saturation state (Figure 16).

Figure 16 -Grid FD of study region

In summary, due to constraints of the slope, water and a large number of unavailable land, Mizhi urban and rural land tended to spread along the large and loose strip, resulting in the overall land of small scale, discrete layout and weak fractal characteristics of urban and rural space. Therefore, it is necessary to combine the spatial potential and actual situation of the study area, to rationally expand and guide distribution of urban and rural land, and to improve the fractal dimension of urban land, so as to optimize and enhance the overall form of land use .

4.3 SUITABLE FRACTAL PATTERNS OF MIZHI

Based on the research on literature and cases of urban and rural development in the Loess Plateau of Northern Shaanxi, the future development of urban and rural spatial form in the study area should be based on three basic structures: shape and scale of valley, shape and scale of sub -groove, shape and scale of branch ditch. Based on the organization of these three types of structures, this paper summarized eight developmental forms of urban and rural spatial patterns for the study area (Table 6).

Spatial configuration	①monopodial structure	②linear and crumby structure	③fish-bone structure	④point-axis structure
Land layout				
Spatial configuration	⑤cluster agglomeration structure	⑥linear and leaf-like structure	⑦feathery structure	⑧uniform net-like structure
Land layout				

Table 6 -Spatial configuration of urban and rural land of Mizhi county

Although the above configurations can not cover all the land forms, they represented the main spatial development paths for cities in the loess plateau gully area and had a guiding significance. By comparing the fractal dimensions, three kinds of relatively good spatial configurations were obtained.

First, the divergent structure of the group presented a better balance and filling because of its high grid fractal dimension: the cluster of patches in the channel ensured the balance of the whole structure and was easy to form a multi-core group pattern. The radius fractal dimension of the configuration did not meet the fractal standard, indicating that the concentration of the center and the periphery of the city was poor: the dilution of the land in the subsurface was not enough, so that the land use efficiency in the small watershed was low and the synergistic effect was insufficient(Figure 17).

Secondly, the branch-like structure exhibited a superior central agglomeration and peripheral diffusivity due to its high radius dimension. The full development of urban space in the subsurface formed a relatively independent dendritic or pinnate small watershed unit, which was organized as a central green axis to ensure the protection of the ecological environment and cultivated land. The end-like dendritic or pinnate space structure was not conducive to the small watershed between the traffic links and functional layout, and was not conducive to building agglomeration centers of urban and rural land. In addition, the point-like configuration and the uniform mesh configuration had similar problems and were more prominent: excessive expansion of the space skeleton and decentralized land layout led to higher infrastructure costs and made it difficult to gather the formation of urban centers (Figure 18).

Thirdly, The zonal vein shape had the advantages of grid fractal dimension and radius fractal dimension, and had more comprehensive spatial occupying effect. The segmental layout in the channel ensured the balance of urban space, and the layout of the network in the limited area was more easily integrated with the gully terrain, thus forming a multi-level space system. This structure not only protected the efficiency of urban space development, but also alleviated the pressure of urban and rural development on the ecological environment of the valley (Figure 19).

Figure 17 -Cluster and divergence structure

Figure 18 -Feathery structure

Figure 19 -Linear and leaf-like structure

Based on those three kinds of urban and rural fractal space development strategy, the suitable model and optimal configuration of urban and rural land in Mizhi research area can be outlined. The spatial form of the configuration is "group + veins"(Figure 20), that is, based on the expansion of both the valley and the channel, the urban form continuously expands as the self-similar veins and its scale grows from small to large. Its scale of land can be up to 40km² and its fractal dimension is 1.673 which is relatively suitable judging from perspective of fractal cities. Besides, this form of urban and rural land will have good spatial filling and equalization and high land use rate.

Figure 20 -Cluster + net-like structure 5

CONCLUSION

With 25 counties as samples, this paper made a coupled correlation study between topography and urban spatial form based on GIS and fractal dimension calculation. The main conclusions are as follows: (1) The higher fractal dimension of land form goes, the lower fractal dimensions of urban spatial boundary and urban land become. Hence the urban spatial form inversely coupled with land form under fractal perspective, which means they are spatially complementary. (2) Based on sample study of Mizhi county, this paper had come up with the suitable urban spatial mode "leaf-like network mode" which requested territory of county and city growing along with main valley and then extending along with sub-valley and finally becoming continuous and dense and netty land use.

The exploration above showed that many ideas and methods in fractal theory have wide application prospect in urban and rural planning and design, and can provide feasible means and ideas for studying the order logic of complex objects. At the same time, fractal planning and design should be guided and supported by the theory and method of urban planning, thus expanding the application and practice of fractal theory in urban and rural planning.

onurtumturk@gmail.com

1 INTRODUCTION: BEHAVIOURAL SCIENCES AS AN EMERGING DESIGN PHILOSOPHY

The expeditious rise of the Modernism discourse -and its contributions on the architecture and urban design theory and practice at the beginning of the 20th century -has given much of its place to harsh criticisms and brand-new questions in the following years. According to Lang (1987), major developments arising from the Modern Movement such as unprecedented growth in human knowledge, major social changes, and increase in the standard of living made design praxis difficult rather than making it easier. Lang legitimizes this speculative and critical point of view with the assertion of having the technological ability to construct buildings, neighbourhoods, and cities in a wide variety of ways without fully understanding the ramifications of designing for human behaviour. Within this critical approach, after mid-1900s a new field of environmental studies – generalized as behavioural sciences -has emerged in the context of man and environment relationship which deals with the complex systematic interactions between the people and built environment.

Behavioural sciences which is dealing with the subject of human actions is a generic term that includes anthropology, sociology and psychology and even sometimes politics and economics (Bashiri, 2015). It is a comprehensive design philosophy which takes the human needs, preferences and values as the basis to satisfy the human needs and to eliminate environmental restraints and stresses. According to Carl Jung (1958), “people are as much a product of the physical environment as that of the social environment”. Moreover, according to Lang (1987), “the physical world, of which the built environment is a part, is locked in an evolving relationship with the social and cultural worlds of people. [...] Architects and urban designers are primarily concerned with changing the physical world so that it better fits a set of human needs”. For the fields of urban design and architecture, it is a crucial need to use the behavioural sciences and environmental psychology as a methodological tool. Architecture and urban design -as disciplines dealing basically with enhancing the quality of human life – are concerned fundamentally with understanding what lies behind the nature of environment. While questioning the mutual interaction between man and environment, according to Rapoport (1977) there are three general questions which constitutes the main specifications of behavioural sciences and its concerns over man and environment relationship:

- “1. How do people shape their environment – which characteristics of people [...] are relevant to the shaping of particular environments?*
- 2. How and to what extent does the physical environment affect people, i.e., how important is the designed environment and in which contexts?*
- 3. What are the mechanisms which link people and environments in this two-way interaction?” (Rapoport, 1977)*

In the light of all these fundamental questions, behavioural scientific approaches develop an understanding about the impact of designers’ work on people’s lives especially when they design environment for people whose behaviour patterns and values are different than their own. This situation represents the complex nature of man and environment relationship and the natural issue of uncertainty. The fact that while the design professions have much in the way of normative theory, they are weak in positive theory or explanatory theory results in the erroneous conclusions about the impact of designers’ work on people’s lives. Indeed, the failure and problems of contemporary urban spaces are caused by the fact that design research and theory is not sufficiently empirical – which means we as designers need a comprehensive positive theory to be value-free, to avoid bias, to look for alternative explanations and to apply the rules of scientific method to observation and explanation. Therefore, according to Lang (1987), search for a positivistic approach is a crucial need and behavioural sciences offer the design professions much to help us develop both positive theory and an understanding of our normative theories. This issue leads

architects and urban designers to the abandonment of 'absolutist positions' on what constitutes good design and the adoption of a 'relativist position'. This means that the design professions require a broader and more explicit understanding that they currently have of both the person environment relationship and the process of design.

Considering that the fundamental purpose of behavioural sciences is to develop positive theories, it is clear that these sciences have an important role in the development of theoretical foundations of design in various ways. If the position of behavioural sciences in architecture be considered as a model for professional architects and urban designers, it will lead to the success of the design. If designers use the help of environmental psychologists and direct their design towards creating environments that meet human needs, then the built environment can satisfy aspects of human needs such as survival, safety, belonging, esteem, learning and beauty and so on. In general terms, using the behavioural sciences in the design process increases the quality of the final product and process' itself.

2 COMPLEXITY AT THE ROOTS OF MAN-ENVIRONMENT RELATIONSHIP

It is still certainly valid in architecture and urban design theories that built environment is most crucial determinant for human behaviour patterns and life quality of the space. According to Lang (1994), while the quality of the built environment is certainly a major attribute of environmental quality, it is also tempting to go beyond this level of thought to consider the built environment, as the Modernists did, as the independent variable in the relationship between physical and social worlds – social behaviour being the dependent variable. However, via the help of developed literature on 'complex nature of human behaviour and also complexity of the urban space', it can be easily stated that the interaction -or the relationship -between man and environment is not simple as that. In other words, human behaviour is not a direct result of the effects of the urban space; or the urban space is not a direct outcome from the behaviours of its users. Interrelationships between these two phenomena do not represent a simple linear process. Indeed, man and environment relationship is much more complex and consists of intricate, dynamic and nonlinear processes.

As extraordinarily complex beings, humans and their individual and collective behaviour patterns can only be understood via the relational model which is more complex than the organismic and role models. According to this behavioural scientific model, "the human being is seen as both a subject and an object, as a succorer as well as a succorent". People are individuals who are the sum of their roles in society and need to be seen in relationship to others. To fully understand the implications of this complex model of people for urban designers, we need to understand how human beings experience the environment, and what motivates the way they experience it (Lang, 1987).

In addition to the complexity of human beings, all human settlements have complex patterns within which other meta-patterns-or micro patterns-exist. Moreover, all these patterns emerge under the dynamic process of urban change. At this point, Lang's criticism over "the Modernists' failure to understand the richness of human needs, the richness of the environment, and the complexity of the relationship between people and environment" is mentionable to open up a discussion about how recently developed complexity theories can help us to understand the complex interaction between man and environment as the main research question of this paper. This criticism takes its roots from the criticism of four basic theoretical positions (a free-will approach, a possibilistic approach, a probabilistic approach and a deterministic approach) about man-environment relationship. According to Barlas (1994), with the advent of ecological and environmental psychology, architectural determinism and simple behaviourist approaches was seriously questioned and challenged. The current approaches to the analysis of man-environment relations are probabilistic – which means it is based on an understanding of the dynamic interplays between human and spatial behaviour -in nature (Lang 1987, Lang et al. 1974). "Accepting the probabilistic approach would mean to acknowledge the 'uncertainty' concerning man's motivations, knowledge and decision making modes" (Barlas, 1994).

While Jon Lang's and more recent behavioural scientists' strong emphasis over the complexity issue related with man-environment relationship is seminal and very influential in that times, their approach to the concept of uncertainty in complex systems is substantially 'naïve' due to the lack of comprehensive literature about the complexity theories. According to Lang (1987), designers will always be making decision with uncertainty and so, behavioural sciences may reduce this uncertainty but will not eliminate it.

While Lang's point of view about his acceptance of the uncertainty as a concept which cannot be eliminated totally is worthy to note, a critical perspective should be developed to the issue of reducing uncertainty in order to raise a discussion. With the development of complexity science and its effects on architecture and urban design, concept of uncertainty cannot be seen as a drawback for design process or product. The fact that cities are complex systems which essentially contains various uncertainties, reducing the uncertainty seems unreasonable. Instead, designers should learn how to deal with uncertainty by using it as a design input: which means they should learn to 'design with uncertainty'. Within this context, complexity theories will help designers to develop better behavioural scientific approach to the fields of architecture and urban design.

3 EMERGING PARADIGM OF COMPLEXITY

Complexity science is a field that grew from chaos theory and the study of fractals in the 1980s. After 1990s, theory of complexity has led to the different scientific studies for urbanism, geography and architecture, and theorists studying in this field have increasingly directed their attention toward the dynamic processes and global patterns that emerge from the collective interactions of a system's individual components (e.g., Cowan, Pines, & Meltzer, 1994; Holland, 1995). Pierre Frankhauser who is a French geographer studied the urban complexity by conducting multiple studies of urban built surfaces, that there was a real geometric structure to them, and that it is possible to extract the fractal dimension of an urban area by analysing the built and unbuilt zones. According to Helie (2007), he thus proved that the city is a complex structure with a geometric order, and not simply a mathematical anomaly. Michael Batty studied complexity simulation methods, such as cellular automata, agent-based models, and catastrophe models. With his overarching work, *Cities and Complexity*, he showed the output of cellular automata as morphologically similar to cities. Last but not the least, Nikos Salingaros has taken a more material and less analytical approach to urban complexity. He explained the concept of 'urban web' as a set of connections between physical spaces that are differentiated and complementary and which cannot be subdivided in sub-sets.

Although most of the principles of complexity theory have originated in the physical and natural sciences, Gell-Mann (1995) states that "even more exciting is the possibility of useful contributions to the life sciences, the social and behavioural sciences, and even matters of policy for human society". According to Eidelson (1997), "many areas of the behavioural and social sciences have already attracted the attention of complexity investigators; among these fields are social networks, organizational development, economic instabilities, urban development, political transitions, international relations, social movements". As a transdisciplinary collection of concepts from different scientific fields of studies such as physics, economics, sociology and ecology; complexity theories and complex systems has prepared a background for urban design and architectural theories. According to Eidelson (1997),

"it has taken time for planning to adopt complexity thinking beyond metaphor or common usage of the term, but we now appear to be at a tipping point where complexity planning is exploring methods of engagement with bottom-up phenomena, structural and functional co-evolution and resultant adaptable and self-organisational systems, rather than the question of whether cities are complex". (Eidelson, 1977)

In the context of all this theoretical background, complex systems are basically considered as the aggregates involving many components generating a recognisable global (collective) behaviour and large-scale order which are not controlled centrally, but generated by many local interactions (Caliskan, 2013). In addition to this definition, they are adaptive, unpredictable and generative systems including continuous information processing and adaptive feedback loops. In order to challenge the conventional views on urban planning and design, to understand the complex and nonlinear nature of man-environment relationship and to develop better approaches in terms of the behavioural sciences, searching for models of complexity and the various kinds of complex systems is a crucial necessity.

3.1 COMPLEX ADAPTIVE SYSTEMS

As a general term, 'complex adaptive system (CAS)' derived from the complexity theories and it means "a 'complex macroscopic collection' of relatively 'similar and partially connected micro-structures' formed in

Lastly, an overlapping feature in the context of environmental adaptation of human behaviour can be observed in CAS. Several investigators have found the concept of fitness landscapes useful in analysing the adaptation and coevolution of complex adaptive systems (e.g., Gell-Mann, 1994b; Kauffman, 1993; Wright, 1986). Heylighen and Campbell (1995) have used a fitness landscape approach in describing how systems evolve through the twin processes of variation and selection.

While the behavioural or social scientist faces many challenges in translating complexity theory principles into their own domain, a considerable value in simply uncovering similarities between specific aspects of dynamical systems and human social behaviour can be expressed according to the assertions above. As a result of the greater complexity of human behaviour and accordingly spatial organization, it can appear as if deterministic causal laws do not govern social phenomena. Instead, the complexity perspective also illuminates the interplay between the fragility and stability that characterizes many of the phenomena explored by behavioural and social scientists (Eidelson, 1997). Within this perspective, it can be trustfully stated that complexity theory would generate some important theoretical insights and research findings in the agenda of urban design and architecture.

4 DESIGNING WITH THE UNCERTAINTY: A SPECULATIVE APPROACH TO COMPLEXITY

After giving all the related theoretical literature for behavioural sciences, complexity of human and spatial behaviour, complexity theories and overlapping attributes of behavioural sciences and complex adaptive systems, a critical question of 'can design process be managed under the uncertain conditions which are natural results of complexity' can be raised. At this point, remembering the Lang's and other important behavioural scientists' approach to uncertainty would be appropriate to enlarge the discussion. According to Lang (1987), "designers will always be making decision with uncertainty and so, behavioural sciences may reduce this uncertainty but will not eliminate it".

If there are some certain key words that seems to fit perfectly our ever-changing and dynamic urban space, these would be complexity and uncertainty. Indeed, the concept of complexity's itself is "a state of uncertainty within collective action" (Caliskan, 2013). As our world changes dramatically and unexpectedly, societies have started to experience uncertainties in all fields of their social life. According to Murray (1961), a fundamental definition of uncertainty is "liability to chance or accident", "doubtfulness or vagueness", "want of assurance or confidence; hesitation, irresolution", and "something not definitely known or knowable". With the rapid growth of understanding of complex adaptive systems in recent years, it is realized that ecological, human and urban systems having dynamic and ever-changing behaviour and structure cannot be understood fully by means of conventional approaches and theories. As a conventional approach to the problem, according to Pahl-Wostl (1995), uncertainty and lack of predictive capabilities equal ignorance. Such a point of view is very inadequate to deal with the complex environmental problems. As Wilson (2002) stated that if we conceptualize complex urban systems from the complex systems perspective, we are likely to approach the uncertainty problem in a way very different from the conventional.

In a Newtonian world, the stability of cause-and-effect relationships makes it possible to pursue reductionist science and makes us to intervene in the system with predictable outcomes. However, what is problematical about complex systems in this regard are their pervasive nonlinear, causal relationship (Holling, 1987). According to Levin (1992), "at any time a large number of factors may influence the outcome of a particular event, each one to a greater or lesser extent; at another time, the strength of those same causative factors on the same event may be very different". The result is a decline in predictability which means a system which is dynamic, changing and full of uncertainties. The idea of working with uncertainty is not new in the planning context. Rittel (1973) introduced the challenging concept of 'wicked' problems to the planning debate. "Contrary to 'tame' (manageable) problems which could be defined clearly, wicked problems have no clear start, end or ultimate solution because they are intrinsically uncertain, non-linear and complex". The complexity sciences, rediscovered Rittel and embraced his 'wicked' problems fully (Conklin, 2005) as wickedness represents precisely the fundamental uncertainties observed by the complexity sciences in the real world. Moreover, Christensen (1985)'s work referred to a type of complexity allowing variation in types of planning issues, a variation which depended on uncertainty.

In order to bridge with concepts from the complexity sciences such as non-linearity, emergence, path-dependency, transitions, co-evolution, adaptivity and self-organisation, uncertainties should be used as a design input rather than seen as obstacles for design process. By allowing uncertainties, designers can avoid from the static, fixed and linear thinking mechanisms which are not useful to manage complex systems. Instead, they can achieve more incremental, adaptive, dynamic and complex solutions to the complex problems of our age. As it is known from the related literature, complexity concepts from evolutionary biology, social sciences, psychology and ecology have played a significant role in demonstrating cities are evolving open systems due to the influence of biological cognitive agents – human beings with their dynamic behavioural nature -on multiple urban processes (Allen, 1997; Batty and Marshall, 2012; Holling, 2001; Portugali, 2016). According to De Roo and Silva (2010), “temporal dynamics and ‘wicked’ problems posit the fundamental issues of uncertainty and unknown unknowns”. Uncertainties are a product of the interactions and interdependencies between elements and dynamic environments and as such are an intrinsic part of how urban systems and networks function. In the context of complex systems’ natural capability of adaptation and co-evolution through the processes of variation and selection, designers should benefit from errors, random behaviours or most importantly uncertainties. In fact, Kelly (1994) views “honour your errors” as a guiding commandment for effective adaptation. He advises that by nurturing small failures, a system can make large failures less probable. That is, small cracks can prevent larger fractures. Indeed, errors and uncertainties are often renamed innovations when they lead to a better problem solution or a more adaptive path. “Furthermore, tolerating minor mistakes and allowing uncertainties for variabilities instead of trying to correct or eliminate them also frees a system to focus on more important and more urgent functions” (Kelly, 1994). For urban designers, architects, social and behavioural scientists and theorists, issue of complexity and uncertainty seems exciting to experience new paths and methods of design and to develop novel strategies for more diverse and complex systems. However, at this point, what remains unclear, is how can we cope with – or rule -the uncertainties to meet the needs of human beings by developing behaviour sensitive approaches?

The answer to this vital question is actually lying deep down in the well-known theory of urban design and architecture.

4.1 RECURSIVE PATTERNS: PERCEPTIBLE ORDER OF UNCERTAINTIES

The fundamental characteristics of complex systems leads difficult questions to answer: How can designers cope with the uncertainties while they are trying to sustain human needs in the environment without predicting the consequences of their actions? If we are living in the world of complexity, would accepting the uncertainties as undefeatable mean that we have no rational basis for design?

Even if complex systems contain uncertainties and emergent behaviours, there is ‘perceptible order’ in these systems. This understandable order refers to dynamic, characteristic and recursive patterns in architecture and urban design theory. Holling (1987) states that “I would describe this order as recurring similar patterns, never quite the same, sometimes startlingly novel because of the changing and adapting elements of the system, but also usually distinguishable from patterns in other systems”. According to Christen (2009), “pattern is the repetitive configuration of the physical entities in space or that of the events in time. Moreover, Holland (1992) suggests that learning in this kind of environment is based on the identification of recurring system patterns. The checker board game that he uses as an example of pattern learning is a relatively simple example of a complex adaptive system. It presents a limited and stable set of possible system states and patterns; the criteria for successful intervention in the system are fairly clear and the time and resource costs of learning are relatively low (Wilson, 2002).

For the behavioural scientist, Nowak et. all (1994) have recommended looking for regularities or patterns rather than focusing solely on uncovering one-way causal links between variables; bidirectional causality, in which each variable is simultaneously both a cause and an effect, is commonplace in complex systems. Within these observed patterns of behaviour, it may be possible to detect signs of nonlinearity and dynamism. From the behavioural scientific point of view, according to Rapoport (1977),

“the environment is a series of relationships among elements and people and these relationships are orderly – they have pattern. The environment has a structure and is not a random assemblage of things. It both reflects and facilitates relations and transactions between people and the physical elements of the world. These relationships in the

physical environment are primarily spatial – basically objects and people are related through separation in and by space”. (Rapoport, 1977)

Therefore, concerning with the behaviour of the form and recursive patterns on the space would lead us understanding nature of complexity and dealing with the uncertainties at the roots of human behaviour and space's itself. From this point of view, recursive urban patterns can be considered as the vital systematic relationships in a complex system. This idea of systematic relationship refers to the idea of Jacobs (1961) – city as an organised complexity. Jacobs (1961) presents the multiplicity of choice experienced with the emergent diversity of the urban elements (i.e. street, block and building) as the source of urban complexity. Within all this perspective, urban patterns can be considered as the key factor for learning to deal with complexity and designing with the uncertainty as a natural result of the state of being complex.

4.2 ON PATTERNS AS 'THE ATOMS OF ENVIRONMENTAL STRUCTURE'

In order to evaluate environmental design as a rational process and develop a scientific approach to the man-environment relationship positive design models and methodologies must be specified. According to Lang (1987), one of the most influential model has been proposed by Christopher Alexander (1964). His approach consists of decomposing a problem into components that are as independent of each other as possible, establishing a hierarchy among them, and then finding patterns of the environment that meet the requirement of each component of the problem.

In 1966, Alexander and Poyner – in their extraordinary work: “The Atoms of Environmental Structure” - argue that the critical aspect of environmental problem-solving is the satisfaction of basic behavioural tendencies and that the nature of the design process is the determination of tendencies and of possible conflicts between tendencies in different environment-behaviour settings. The work of Alexander and his colleagues on the understanding of the structure of design problems, the translation of behavioural findings into form statements, and the development of a pattern language for the description and cataloguing of environment-behaviour patterns continues to advance at a rapid rate (Moore, 1970). These continuous and dedicated studies created ‘the form-behaviour approach’ – which relates behaviour to form - to the environmental design studies; and later on, they are modified into ‘a pattern language’ approach. The form behaviour approach has focused on ways to identify form-behaviour problems and to translate behavioural understandings and behavioural research into testable form ‘patterns’. Alexander and colleagues (1977) stated that urban space is mostly generated by the recursive patterns and these perceptible patterns are organized in an interconnected and hierarchical system that allows for infinite combination – which points out the complexity and unknowability of certain ends. Ulrich (2006) describes patterns as:

“It is important to realize, according to Alexander, that patterns are not arbitrary design ideas but can and need to be identified and verified through careful observation. Furthermore, patterns become meaningful only within a hierarchy of interdependent patterns, in which each pattern helps to complete larger patterns within which it is contained, and in turn is further completed by smaller patterns that it contains. Each pattern has a well-defined place in the overall network of patterns; together, they constitute a pattern language, a vocabulary of design that consists not just of words but of mental design images”. (Ulrich, 2006)

In general terms, pattern languages address to two different needs; firstly, a way of controlling a complex system – which is urban space and its relationship with the human behaviour, and secondly a design tool which helps the designer to build a coherency. Moreover, as a generative system, pattern language has the ability to generate unlimited number of combinations to deal with the complexity at the roots of manenvironment relationship. According to Nguyen (2015), “pattern languages help us to tackle the complexity of a wide variety of systems. Each "pattern" represents a rule governing one working piece of a complex system, and the application of pattern languages can be done systematically”.

When the form behaviour approach and the concept of patterns are evaluated in the context of behavioural scientific studies and the complexity sciences, they offer seminal and overarching point of views. According to Salinas and Mehaffy (2006), “the pattern language contains rules for how human beings interact with built forms, codifies the interaction of human beings with their environment, and determines

how and where we naturally prefer to walk, sit, sleep, enter and move through a building, enjoy a room or open space, and feel at ease or not in our garden". The pattern language is a set of inherited tried-and-true solutions – containing the concept of 'uncertainty' - that optimize how the built environment promotes human life and sense of well-being. It combines geometry and social behaviour patterns into a set of useful relationships, summarizing how built form can accommodate human activities. Besides, pattern languages which genuine and defines an adaptive design method have evolved, and, as with all evolved systems, they have developed an extraordinary degree of organized complexity (Salingaros and Mehaffy, 2006).

In short, revisiting the form-behaviour approach as a methodological tool to cope with uncertainties arising from the complexity and emphasizing the contribution of patterns in this context leads to introduction of behavioural data into the design and planning process. Moreover, this approach creates a basis for a shift from linear and static methods of behavioural sciences to the dynamic, adaptive and complex ones. According to Marshall (2009), "we no longer see the universe as an entirely predictable, deterministic place. We now see it more as a complex; sometimes chaotic place, but one where we can still find patterns in the complexity".

Modern urban planning has succeeded in eliminating complexity with its reductionist approaches, running away from the uncertainties and leaving it's behind the empty and disastrous urban environments for us to live with. Therefore, the pursuit of complexity models to cope with uncertainties and developing the form-behaviour approaches to apply them should be the main concern for the fields of urban design and architecture.

5 CONCLUSION

After mid-1900s, the expeditious rise of the Modernism discourse has led to the harsh criticisms and brand-new questions. In the way of searching for new answers to these vital questions, behavioural sciences - a comprehensive design philosophy which takes the human needs, preferences and values as the basis to satisfy the human needs and to eliminate environmental restraints and stresses - has emerged in the context of man and environment relationship. However, behavioural sciences' deficient and limited point of view about the issue of man and environment relationship should be questioned in the context of emerging new paradigms. Contrary to the very first approaches in behavioural sciences, human behaviour is not a direct result of the effects of the urban space; or the urban space is not a direct outcome from the behaviours of its users. Interrelationships between these two phenomena do not represent a simple linear process. Indeed, man and environment relationship is much more complex and consists of intricate, dynamic and nonlinear process which is full of uncertainties.

Within the general context of this paper, a critical perspective is developed to the issue of reducing uncertainty – which is a general approach of 'conventional' urban planning and design - in order to raise a discussion. With the development of complexity science and its effects on architecture and urban design, concept of uncertainty cannot be seen as a drawback for design process or product. The fact that cities are complex systems which essentially contains various uncertainties, reducing the uncertainty seems unreasonable. Instead, designers should learn how to deal with uncertainty by using it as a design input: which means they should learn to 'design with uncertainty'. In that sense, complexity theories and complex systems – which are basically considered as the "aggregates involving many components generating a recognisable global (collective) behaviour and large-scale order which are not controlled centrally, but generated by many local interactions" - will help designers to develop better behavioural scientific approach to the fields of architecture and urban design (Caliskan, 2013). In order to challenge the conventional views on urban planning and design, to understand the complex and nonlinear nature of man-environment relationship and to develop better approaches in terms of the behavioural sciences, searching for models of complexity and the various kinds of complex systems is a crucial necessity. With this fundamental aim, the question of 'can design process be managed under the uncertain conditions which are natural results of complexity' has been raised.

In order to bridge with concepts from the complexity sciences such as non-linearity, emergence, path-dependency, transitions, co-evolution, adaptivity and self-organisation, uncertainties should be used as a design input rather than seen as obstacles for design process. By allowing uncertainties, designers can avoid from the static, fixed and linear thinking mechanisms which are not useful to manage complex

ID 1524 | WHAT IF LARGE INFRASTRUCTURE PROJECT PROCESSES ADOPTED A COEVOLUTIONARY CHARACTER? DISCUSSING THE MERITS AND CONSEQUENCES FOR THE OOSTERWHEEL LINK PROJECT, ANTWERP

Suzanne Van Brussel¹
¹Ghent University
suzanne.vanbrussel@ugent.be

1 INTRODUCTION

In the quest for a more sustainable mobility, present mobility planning approaches do not prove effective. In particular in the case of large infrastructure projects (LIPs) this becomes manifest; realising LIPs has become tremendously difficult these days, resulting in many stranded projects. Previous LIP-research has shown that complexity is behind these struggles, in all its facets. Although decision makers often still focus merely on financial, technical and legal issues of complexity (Flyvbjerg, 2007; Priemus, 2007), it becomes increasingly clear that the influence of social and organizational complexity is heavily underestimated with respect to planning processes and procedures, see Figure 1 (Hertogh & Westerveld, 2010).

Figure 1. Views of complexity from multiple LIPs: Betuwerooute, Gotthard, Löttschberg, A73-South and HSL-South.
Source: Hertogh and Westerveld (2010, p. 175, figure 4.8)

The social component of complexity relates to the number and representation of the actors and the alignment of their (conflicting) demands. Often, the decision making process is still in the hands of vested planning actors favouring backroom politics. The organisational aspect of complexity, that is closely connected to the social component, focuses on the (power) relation between the stakeholders, the responsibilities, the appropriate scale levels, etc. The fact that up till now – with respect to LIPs – the focus stays on the financial costs, the risks and opportunities relating to the progress in time, and the technical aspects (Flyvbjerg, 2007; Priemus, 2007) points towards the prevailing technocratic planning approach, towards the notion of the (mobility) planner as engineer. While this planning perspective used to pay off, more recently however, other mobility planning approaches have been sought for, since “complexity strikes back if it is neglected” (Salet, Bertolini, & Giezen, 2013, p. 1989). Hence, the central question here is: (1) What can such new complexity embracing mobility planning approach add to LIP planning processes? , and (2) What does this mean for the actors and their roles? We hereby also consider recent attempts to work with complexity in the policy fields of mobility and spatial planning, and what they have obtained so far.

The paper is structured as follows. Chapter 2 gives a brief overview of why we need to grasp complexity in the planning process and to which extent these ideas are already implemented. In chapter 3 we test these ideas and planning approach with vested planning actors in the case study of the Oosterweel Link. But first we have to take you through the project history of this case. Chapter 4 presents the discussion and final conclusions on what coevolution can add to LIP-planning processes.

involved are the Flemish government, the Flemish parliament, the City of Antwerp, the project management team appointed by the Flemish Government (i.e. BAM), and the activist groups or citizen movements. We also shed light on other protagonists in the story that took the role of game changers: the governor of the Antwerp province and the intendant (respectively in beginning of the project and in most recent project years).

3.1 THE OOSTERWEEL LINK STORY

3.1.1 ONCE UPON A TIME AN OPTIMISTIC AND FUTURISTIC INFRASTRUCTURE STORY STARTS... (1995-2005)

In 1995 the Flemish Agency for Roads and Traffic launched the start of a new masterplan to counter the structural congestion in and around Antwerp. The completion of the Antwerp ring road with the Oosterweel Link (Figure 3) was perceived the crown jewel of the masterplan that would solve all problems. The Oosterweel Link was conceived as a combination of a tunnel with a double deck viaduct called 'Lange Wapper'. The governor of the Antwerp province, Camille Paulus, was in favour of these infrastructure designs. To define the precise route of the LIP a study was carried out by ABM (Atenco, Belgroma –

Grontmij, and Maunsell). This study came up with 6 plausible routes, but in the end a 7th possibility was added, a combination of parts of the previous options. The City of Antwerp, the Port of Antwerp, the province of Antwerp, the Flemish administration and some other institutions approved this 'optimised medium route', which later became notorious as the 'BAM-route'. Only this route would be further studied and elaborated (Verhoeven & Ysebaert, 2008).

Figure 3. The Oosterweel Link section (red).
Source: Het Nieuwsblad, March 4, 2009,
http://www.nieuwsblad.be/cnt/dmf04032009_049

In 2001 a consultancy consortium (TV SAM) was commissioned by the Flemish Government to elaborate that route. To promote the masterplan and to acquire the necessary support base a States-General was organised by the governor, bringing most vested institutions and agencies together, but only little publicity was given to it. By 2003, a management company was established (BAM, Beheermaatschappij Antwerpen Mobiel) to take over the project management and to replace the role of the Flemish administration in fulfilling the framework agreement with TV SAM, as a private company that functions independent of political interference. A close collaboration between the consultants of TVSAM and BAM started. When determining and securing the route of the LIP in a regional implementation plan (GRUP), they preferred to follow the (at that moment still optional) environmental impact assessment procedures.

3.1.2 THE AWAKENING – AFTER HAVING SEEN THE MODEL AND THE COST INCREASE... (2005-2009)

Figure 4. Model of the Lange Wapper dubble deck viaduct skimming over the City of Antwerp without and with underlying urban fabric. Source: (right) <http://4.bp.blogspot.com>; and (left) <http://www.bavo.biz/img/images/langewapper%2012.jpg>.

When the BAM, in 2005, eventually showed the model of the Oosterweel Link to the press and the Flemish parliament, it caused a lot of commotion and reactions were almost unanimous enthusiastic. But it was met with great resistance afterwards, during the public inquiry of that procedure where the model was shown for the general public for the first time. stRaten-generaal, an activist group, came with its own alternative route suggesting to alleviate the city from transit traffic and complete the ring road much further away. The City of Antwerp was alarmed and wanted to buy time before making a decision. An extra study of the alternatives was launched: the Horvat study (carried out by Horvat). In addition to the BAM-route with the

Lange Wapper viaduct, this study also took into account the tunnel variant of the BAM-route (called Horvat-route) and the alternative of stRaten-generaal. The research took only two months after which one concluded that a tunnel option was more expensive than a viaduct. Hence the approval was given for the viaduct landmark and the tunnel option was abandoned. Building consortia were notified for designing, elaborating and implementing the BAM-route.

Figure 5. Tunnel variant of the Oosterweel Link on the BAM-route (Horvat). Source: http://www.nieuwsblad.be/cnt/dmf04032009_049

Finally four consortia were retained for submitting their 'best and final offer'. An independent quality division ('kwaliteitskamer'), existing of national and international experts in the field and chaired by the governor, was established to examine and criticize these BAFO's and advise the management company BAM on their final decision. Soon preference was given to the offer of the Noriant consortium and the other consortia were excluded, though their final offer was criticized by the quality division for not being the most economical, nor most qualitative one. It appeared that the governor had an eye to the architectural beauty of the Lange Wapper viaduct for his province (Penris & Peumans, 2007).

In parliament they had difficulty to accept that alternative routes were still taken into account during the environmental impact assessment (EIA, MER), while the building consortia had to finalise their BAFO's according to the BAM-route. In addition, by absence of valid competitors, the total cost of the Oosterweel Link proposal could increase from 0.6 to 1.3 billion euros. This raised many questions about the communication and the transparency of the BAM and the opposition towards the deal with Noriant grew from then on. The precise roles and relations between TV SAM and BAM remained vague and the budgetary resources for the conducted research were repeatedly questioned. In response, BAM commissioned PWC and Deloitte for an external audit of TV SAM. The commission decided to follow the dossier more closely from then on. From 2005, regular progress reports were to be presented by BAM in

the parliamentary commission and also the Court of Audit of Belgium monitored the made progress (Peumans & Penris, 2005). Nonetheless, due to the accumulated delays and compensation measures, the total cost estimates continued rising. Therefore, at the end of 2007 the Flemish Government established a price cap for the project of 1.8 billion euros (Penris & Peumans, 2007, p. 7).

3.1.3 FROM LANDMARK TO ... SCRATCH? (2008-2012)

In 2008, Ademloos ('Breathless') a new civil movement stood up to put the harmful environmental health impact of such an infrastructure project on the Antwerp citizen on the agenda. Ademloos came up with the aspect of health and air quality and was experienced with communication strategies, whereas stRaten-generaal mainly focused on the technical aspects (e.g. alternative route), and quality of life issues in general. A fruitful collaboration between the two civil movements had started, whereby each organisation remained faithful to its own specialty.

Under the pressure of an increasing opposition against the Oosterweel Link project, the Flemish government decides to have all alternative routes for the project studied once more (L.B., 2010). In July 2008, when Arup/Sum starts the investigation of which the stakes are high. However, when in March 2008 the results of this study are presented, none of the proposed routes excels the others regarding all measured aspects. Consequently Arup/Sum proposes to elaborate an alternative route itself, whereby the third crossing of the river Scheldt is located more northerly, similar to the proposal of stRaten-generaal. The Flemish government approves this additional work, but does not want to wait for the conclusions and has instructed BAM to continue on the chosen path. While Arup/Sum is elaborating its alternative route (Arup/Sum-route), according to their decision of March 28, 2009, the Flemish government instructs the BAM to file the building permission for the implementation of the Lange Wapper. But due to the Arup/Sum study the final agreement on the routing of the project was postponed for the next legislature.

Soon after the decision, the civil movements launched a petition against the BAM-route of the Oosterweel Link project and together they managed to enforce a referendum. Their support base grew steadily (Moolenaar, 2008; Verelst, 2011, pp. 163-165,185). On October 18 (2009) on their first public event they victoriously terminated the Lange Wapper chapter in the Oosterweel Link story as the majority of the citizens voted against the viaduct in the referendum (Vandenbergh, 2009). The civil movements criticized that their proposed route was not taken into account properly in the EIA (projectMER), which they could only consult much later when the damage was done. Besides, the building consortia were already notified to elaborate an infrastructure design for the Lange Wapper viaduct on the BAM-route while the environmental impact assessment, comparing the different alternatives, was not yet concluded.

In July 2009, completely unexpectedly, the further research of Arup/Sum concludes that the studied Arup/Sum-route tunnel alternative is technically feasible and economically viable. But more important, that at all levels their alternative performs better than the Lange Wapper viaduct on the BAM-route. Swayed by the growing civil opposition the City of Antwerp organises a referendum at October 18 (2009) that results in the rejection of the Lange Wapper viaduct (Brinckman, 2010). Consequently as the permits and plans were delivered precisely for the viaduct structure, the procedures of the regional spatial implementation plan and the associated EIAs (and their public inquiries) had to be redone for the tunnel-variant on the same route. Because of the referendum the project had changed substantially and a new full-rebidding was unavoidable. This compromised the financial agreement that was already made with the building consortium Noriant for the Lange Wapper (Dendooven, 2010; Verstraete, 2010).

In 2010 the Flemish government promised to take a final decision in the Oosterweel case running through the alternatives once more and include them in the environmental impact assessments. This fits within the launch of a new Masterplan 2020, that has a broadened scope and looks for a total and multimodal solution for mobility and includes mitigating measures compensating for quality of life aspects.

In the meantime, the civil movements elaborate their alternative the 'Meccano-route', an optimization of the Arup/Sum-route (that in turn was based on the previous stRaten-generaal-route). Together with Forum

2020, a group of influential experts and managers in Antwerp, they have their Meccano-route studied by an independent research institute (TML). The results of the TML study comparing Meccano-route with the BAM-route are favourable to the Meccano-route (Yperman & De Ceuster, 2010). In response, the Flemish

administration instructed the Flemish Traffic Agency to investigate the TML-study (Grispen, 2011). It seemed like a cat-and mouse game with high stakes.

In 2012 a new research institute (Anteagroup) is entrusted to carry out the environmental impact assessment, in which in addition to the BAM-route (tunnel variant) and the Meccano-route, five other alternatives are included (one of which is the Oosterweel North-route), see Figure 6. The implementation of the tangents A102 and R11bis is already incorporated in the Masterplan 2020 at that moment.

Standaard

3.1.4 A NEW BREATH FOR THE ANTWERP CITIZEN (2012-2015)

Since air quality and environmental health has entered the debate in 2008, the theme of (partially) capping or tunnelling some major roads would never disappear. Through research by design, the City of Antwerp looks into the feasibility and impact of capping (parts) of the city road network. In November 2012, Ringland, a new civil movement in Antwerp stands up and launches the idea of capping the southern ring road. It is the dawn of a new era of civil opposition.

In 2014 Anteagroup finalises the EIA (planMER Oosterweel) on the basis of which the Flemish government decides on February 14 to follow the chosen path of the BAM-route (stated policy, 'beslist beleid'). To refrain from further legal actions Noriant received a settlement of 37.19 million euros (Moen, 2014), a measure that was met with dismay in parliament.

On the same day of the Valentine's decision of the government, the Ringland initiative officially arose, proclaiming the capping of the ring to ameliorate the liveability and health of the citizens, in combination with a new concept for the ring road structure. This implementation alternative to the southern part of the ring road was partly inspired by the capped M30 in Madrid and suggested earlier by stRaten-generaal. Beyond problem solving, Ringland (the land on the ring road) was especially well-developed and presented as an opportunity for enhancing and managing a qualitative and liveable urban growth. First the concept was elaborated within the urban planning and architecture office Stramien. Using appealing

representations of this concept (Figure 7), Peter Vermeulen, the leading urbanist of this office, and his Ringland entourage steadily gained ground. The civil support base reached even further than the Antwerp city. The other activist groups joined the new spirit and collaborated with Ringland. The opposition to the BAM project gained a more positive public image.

Figure 7. Ringland, the concept. Source: Ringland

In three months' time, by the end of 2014, Ringland had collected more than 100 000 euro, by symbolically selling the land on the surface of the ring (4m² for €20). Ringland spent this crowd funding money on extra

research: a mobility study, a cost benefit study and a liveability study (E.D.M., 2015). StRaten-generaal and Ademloos launched an online call to publicly vote for Ringland and, thus, against the spatial implementation plan of Oosterweel (GRUP Oosterweel) (Ademloos, 2015). Embracing social media, finally over 15.000 statements of objections were obtained. This gave the opposition groups the right to speak in the Flemish Parliament on July 2 (De Standaard, 2015).

In the field however, the preparatory works already started in the end of 2015 (B.B.R., 2015). As the opposition parties and many citizens support Ringland, the government decided to establish an 'intendant' (an idea prompted by Ringland itself); this external person should harmonise the Ringland and the BAM project, bring all actors together and look for opportunities to pursue a maximal capping of the ring road within the project margins as negotiated with the BAM. For the latter reason opposition groups were sceptical and expected little room for manoeuvre for the intendant, thus little outcome.

In the end of 2015 and the beginning of 2016, Ringland starts a new campaign and launches the Ringland Academy, bringing together a wider group of experts and professionals beyond the core Ringland team. They offer ad-hoc inputs into Ringland's activities, contribute to ongoing study work, and develop projects related to one of the core-themes of Ringland. The Curieuzeneuzen air quality citizen science project has been one of the main outputs of the Ringland Academy up to now. Aside from its objective to better understand air quality problems in Antwerp, Curieuzeneuzen was created to sensitize and trigger Antwerp citizens (and politicians) about their living environment and the urgency for action with respect to traffic-related air pollution. As such, Ringland manages to increase its support base by inventing themselves over and over again.

3.1.5 WORKING WITH THE INTENDANT – LANDING OR STRANDING? (2016-...)

In the end of 2015 after public tendering, Alexander D'Hooghe is selected as 'intendant' or mediator; he is a professor at the MIT and experienced with participatory processes, e.g. in the 'Rebuild by design' initiative in the aftermath of the passage of hurricane Sandy in New York. In January 2016, he starts inviting all stakeholders to hear and discuss their ambitions and values in the story. Within six months he should deliver an ambition paper, in which the outlines for a maximal capping of the ring road are formulated and supported by all stakeholders. Some find his mandate too limited, as the BAM and the Flemish Government only commissioned the investigation of the capping options, leaving an inquiry of the mobility system underneath out of discussion. During his mandate he gained the trust of all stakeholders and the privately and confined or 'safe' atmosphere in which the 'super workshops' took place to elaborate opportunities, collaborate and discuss a possible compromise payed off quite well already. For the southern part a political compromise was reached and supported by all stakeholders (City of Antwerp, the civil movements, the Flemish administration and the Minister) (Huyse, 2016; Van Ginneken, 2016). For the northern part the debates and private meetings are still ongoing at the time of writing. Stakes are high, as the three civil movements already collected enough signatures to enforce a second referendum in

Antwerp, in case the government would not postpone the submission of the building permit for the Oosterweel Link till after the intendant finishes his work within the different workshops (Huyse, 2016; Vermeulen & BELGA, 2016). It seems that a compromise is in the making, the intendant and the major stakeholders still elaborate a new option – a combination of the BAM-proposal (Oosterweel Link but 'light' version) and that of the citizen movements (a capping of the whole ring road and the completion of the ring further north of the city)(see Figure 8), but it is not sure if the project will land or strand in the coming weeks (Brinckman, 2017).

Figure 8. Compromise proposed by intendant. Source: Brinckman (2017)

3.2 ROUNDTABLE OUTCOMES – THE OOSTERWHEEL LINK PROCESS FROM THE STAKEHOLDERS’ PERSPECTIVE

Figure 9. Participants roundtable Complex Infrastructure projects – Universiteitsclub UA, Thursday May, 26 2016

3.2.1 COEVOLUTION? IDENTIFYING CLICK-MOMENTS

In the roundtable we confronted the participants with the whole project history again, just like we took you through the project in the previous section. The challenge was to bring the key-stakeholders¹ in the process together (Figure 9), to hear about how they perceived the encountered complexities, and to see if they could sympathize with each other's perspectives and decisions at several crucial moments in the project process. To cope with the encountered complexity, we focused on a coevolutionary approach, incorporating elements of the 'dynamic management' as proposed by Hertogh and Westerveld (2010), in which sufficient flexibility is guaranteed, but in which the omnipresent urgency to act can also be responded to (focus on control on several moments). The various stakeholders could see the merits of such approach and were asked about how they perceived the coevolution in the process. They ended up with identifying key-moments or 'click'-moments (as some proposed) that were decisive for the rest of the (coevolutionary) process. However according to the civil movements some of these click-moments were ambiguous as they seemed to leave some possibilities open for alternative options.

As a first click-moment all participants identified the moment in the 2nd round, in 2008, in which the results of the Arup/Sum alternatives assessment were presented and the moment had potential. The alternatives were assessed and compared based on various criteria. When the bureau proposed to conduct a follow-up study because it was concluded that none of the proposed routes excelled all the others, the Flemish government made the 'fatal mistake' to make of this moment an ambiguous click-moment according to the roundtable participants: the government commissioned Arup/Sum to carry out this further research (i.e. non-click but open), while at the same time the BAM was commissioned to prepare the building permission (i.e. click). The roundtable argued that the government should have taken a break and set the Oosterweel Link procedures 'on hold'. By the made decision trust was compromised and polarisation increased. Everyone agreed that a pause was not sufficient, one should have switched to a co-creative approach already back then.

A second click-moment, in particular concerning the civil movements was the decision of the Flemish government in 2011 to assess all alternatives once and for all in a final environmental impact assessment. At that moment, the civil movements cherished hopes that all their suggestions and supplied ideas would be taken into account seriously. However, after a while this feeling of trust disappeared by lack of sustained communication, which is – according to the administration – inherent to the formal procedures. Also the transparency with which the alternative options were adopted and modelled in the assessment was criticized. Not all alternatives were taken into account on the same grounds. This prompted the civil movements to file a legal complaint as their last hope.

¹ Also the Alderman for Mobility of the city of Antwerp (K. Kennis), the governor of the Antwerp province (C. Berx), and a representative from VOKA (the Chamber of Commerce, representing the Flemish entrepreneurial sector) were invited and willing to join, but were eliminated after a doodle round of checking agendas.

For some roundtable participants the exact click might have happened a bit earlier: on the moment that the Flemish government decides on the 'optimised medium-route' (the later BAM-route) already in round 1. Some argue that once the political choice is made, one should respect that decision and one cannot call that into question over and over again. Otherwise the project stagnates and opposition increases. But not all participants agree with that, as they argue that the process was not transparent enough, not well-communicated, there was no participation at all and thus no broad support base as the project was steered completely internally. Besides, on various moments unfair treatment of alternatives or decision made with conflicts of interest, made these decisions unstable. Furthermore, the enduring protest against the project has broadened the project scope: quality of life aspects, a redesign of the mobility system, the aspect of air quality and the concept of capping, etc. were initially not on the agenda.

The civil movements argue that it is only logical that the process has to be redone, since the project scope has more than doubled. But the participants representing the administrations replied that the question is rather 'how long can the government as client last without a solution?' They point out the risks of taking more than you can actually handle, of overcharging the project. Because that would make the project fail. As such they are in favour of not questioning previous decisions. But there is no lacking sense of urgency, but according to some, although the problem is clear, the problem solution(s) and precise objectives are not (!) and are still frequently questioned. Is a third crossing of the river Scheldt actually necessary and solve the problem? Even that is questioned, so, how can we decide already?

A final indicated click-moment is the decision of the Flemish government to definitively choose for the BAM-route (see round 4). However this felt for all roundtable participants also as a quite ambiguous click as the government had just appointed an intendant (this idea was prompted by Ringland) to align all actors and build a broad support base for the capping (cf. idea of civil movements) of the Oosterweel Link project (on the BAM-route). Most participants had at the moment of the round table just started an intensive and private cooperation process guided by this intendant, the mandate of which was according to the civil movements and most experts in the debate too limited. Wasn't this also a moment for a pause to alleviate the ongoing processes of this intendant?

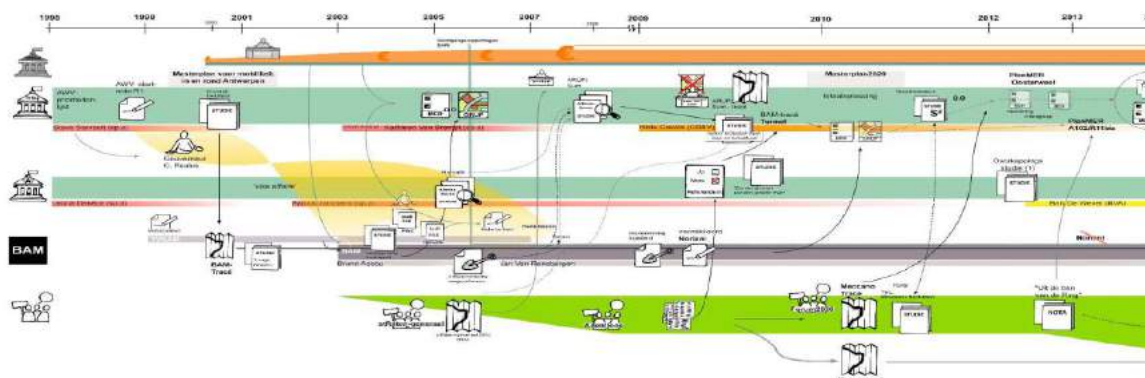

4 DISCUSSION AND CONCLUSIONS

Realising large infrastructure projects (LIPs) has become tremendously difficult nowadays and many projects strand. Although decision makers often still focus merely on financial, technical and legal issues of complexity it becomes increasingly clear that the influence of social and organizational complexity is heavily underestimated with respect to planning processes and procedures, also in the case of the LIP Oosterweel Link. Since complexity in its many aspects seems behind all those LIP-struggles, we need to switch from the prevailing and often linear technocratic planning approach to an approach that holds in the encounter with complexity. That is why we wanted to explore the coevolutionary character of the whole process. We hosted both vested and civic actors of the Oosterweel Link case in a round table discussion and confronted them with the project history again. The discussion proved successful with respect to (1) acknowledging the encountered complexity and the utility of a coevolutionary perspective in this respect and (2) understanding the made choices and identifying the crucial moments that made or broke this coevolutionary process. What did coevolution add to the LIP Oosterweel Link? What did it imply for the actors' roles?

The participants argued that the key for working with complexity is to release the process and to shift focus from project output or implementation towards the process of co-creation. They identified click-moments where coevolution flourished or got stuck in the case. Furthermore, they agreed on the necessity of a more integrated way of working, implying a less fragmented government. There should be a balance of interaction from the beginning on and control (decisions or 'clicks' should also be made in case of a broad support base). The importance of a mediator or intendant was acknowledged in this case to balance between interaction and control. It seemed more difficult for the participants to decide on the best moments and powers for control: what the click-moment includes and who finally decides.

From a coevolutionary perspective, observing all (inter)actors and agendas at stake (Figure 2), we could oversee the merits of the various rounds of opposition and delay. Thanks to the first citizen movements and their opposition, the project's scope incorporated the liveability aspects, environmental (and) health aspects. Though there were some moments of convergence, the conflict model prevailed in those rounds.

When Ringland came into the debate, this steadily changed. The three citizen movements closely collaborated, but kept their own 'specialties'. Ringland actively addressed the government and project management team BAM with its capping ideas, and had in the meantime built a substantial support base. By carrying out studies and establishing the Ringland Academy, it also gained the support of many academics and experts in the field. Ringland prompted the need for a mediator (or intendant) to align all stakeholders, herewith inviting themselves and the citizen movements to the decision making process, mediated by the intendant. Since then a cocreated or coevolutionary model dominated, based on trust, transparency and interaction. A first compromise was signed between all involved parties and the concrete elaboration, engagements and planning procedures are currently seriously being discussed. Soon we will see if the project finally lands...

ID 1585 | DECODING AND MANAGING CITIES: TOWARD A COMPLEX AND DYNAMIC SYSTEM APPROACH

Giovanna Mangialardi¹; Angelo Corallo¹; Nicola Martinelli²

¹University of Salento; ²Polytechnic University of Bari

giovanna.mangialardi@unisalento.it

1 INTRODUCTION

Due to the rapid growth of cities and their social, cultural, economic and technological evolution, the policies and legislative instruments need to adapt to this change. By 2050, United-Nations estimate 6.4 billion people¹ are expected to be living in cities (Riffat et al., 2016), with relevant consequences on resources, emissions and services². In spite of this, the development of Europe's cities and the relations among them constitute one of the most important driving force for the future of Europe (Rotmans and Van Asselt, 2000).

The complexity of the urban phenomena needs to be investigated in an integrated manner, through the management of the systems and processes making up the city. Indeed, the city is recognised in literature as a complex, open and adaptive system, that evolves in time and space (Portugali et al., 2012), (Healy,

¹ The recent report by the United-Nations (2014) estimate 3.9 billion urban population in 2014 itself.

² http://ec.europa.eu/eurostat/statistics-explained/index.php/Urban_Europe_%E2%80%94_statistics_on_cities,_towns_and_suburbs

2006). Its components (i.e. buildings, infrastructures, human agents etc.), with own lifecycle, interact among them and are not predictable linearly, not even separable, but are based on the principle, attributed to Aristotle, that "the whole is greater than the sum of the parts". Furthermore, the cities, as "systems within systems of cities", should take into account the interdependencies with their territories. Each city should study both the relationships within itself but also with the urban boundaries, urban region, in an inter-scalar vision.

Facing the complexity of above mentioned urban challenges, traditional methods and planning techniques appear obsolete and static, ever more characterised by the highly diverse and intertwined ways of how the community actually uses the urban space (Zhong et al., 2015), (Faludi and van der Valk, 2013), (Healey, 2006), (Hartman and De Roo, 2013), not contemplating the dynamic and complex behaviour of the city, as recommended by the main United Nations conferences on the development issues of the cities in the world (i.e. Rio Earth Summit in 1992, Habitat at Istanbul in 1998 or at Quito in 2016).

In order to obtain a resilient city, adaptive to urban dynamics, defining new strategies of urban governance are required to support cities to manage the continuous change and the interrelation between city systems (spatial and human), trying to "unravel" urban complexity.

For the authors, an opportunity for a paradigm shift could reside in through the interoperable platform as methodological conceptualization, enabled by the Information Technologies. In this work the methodological and technological framework BIM-based (Eastman et al., 2011) is described as an opportunity to decode and manage the urban dynamics complexity. The innovative use of the Urban declination of the Building Information Modeling (BIM) methodology, already consolidated for building application, and other interdisciplinary approach to cover technological gap (like Product Lifecycle Management – PLM or Geographic Information System - GIS) (Terzi et al., 2010)(Maguire, 1991), could assist to better understand the planning issues, that are in the most case complex "not only because the problems themselves are ambiguous and difficult to define, but also because they involve multiple stakeholders with multi-attribute preferences" (Lai and Huang, 2016).

Starting from the analysis of a case study based on the absence of an integrated management, that represents as the complexity of an urban transformation reflects its impact on the urban system, the objective of this research is to propose a methodological framework able to model and to simulate the interrelations between the main "actors" and components involved (i.e. stakeholders, officials, business people and citizens), by digitalizing and by making clear the processes. In fact, usually, a urban transformation/construction project "involve complex sets of relationships between parties under different professional background in order to achieve complex goal. The complexity of these projects are resulting from a thousand of documents and drawings that being used manually, that could lead to mistakes in construction process, drawings are not updated, delays, cost overrun, etc." (Latiffi et al., 2014).

Moreover, the systematized and integrated management of these relationships produce data, which are processed into information and then knowledge (historical, present and future) (Innes and Booher, 1999), enabling predictive analyses or different simulation for the best and participate solution. Moreover, this study shows how the proposed interdisciplinary approach referring to the organizational and dynamical aspects of a city sub-system and network as a whole, may improve the management of the "city-system", by arguing that there is the necessity to change the way we think, by integrating "system thinking" (De Roo, 2012).

The present paper is structured as follows: Section 2 gives a brief review of the state of the art and of the literature for decoding and managing cities. In Section 3, it is presented the research aim and methodology. Section 4 is based on the description of the criticalities of an actual urban process: the student housing in Bari, useful for highlight the actual process problem that are overcome by the description of the efficient solution framework in Section 5 "toward a complex approach: preliminary result on the innovative model for complex urban management". Finally, in Section 6 it is provided conclusions and discussions about possible extensions of the current formulation.

2 DECODING AND MANAGING CITIES

"The processes that drive spatial and economic urban change are increasingly interconnected and interact with multiple levels of scales" (Hartman and De Roo, 2013) and it is impossible to predict all the criticalities. As a complex system, the city is dynamic (Batty, 2008), in contrast with the static vision of the urban plans and it is an open system (White et al., 2015) because of the continuous interactions with multi external agents. In an ideal vision, the future urban system should be so resilient to adapt to potential disturbances, by learning from the past experiences to better plan and simulate the future action. Furthermore, the improvement of a single sub-system that composes a city not significantly increases the resilience and sustainability of the urban system. A "system-of-systems" approach is necessary that at the same time strengthens individual sub-systems as well as the overall system of a city. The "management of complex systems such as cities requires the use of innovative, sophisticated planning tools that can assist in monitoring current conditions and projecting future developments. It also requires a well-structured participatory process of creating social support by stakeholders for long-term city visions" (Rotmans and Van Asselt, 2000).

Moreover, cross-disciplinary research approach for analysing complex dynamics of cities are needed. In detail, the know-how in the industrial engineering sector, characterized by integrated approaches¹ with great experience in complex processes and actors management, may be useful to decode and systematize the urban processes, by leading to a „smart city" with a global vision and a local action. For example, in the manufacturing industry, for decades collaborative 3D modelling, visualization and simulation of complex products have been used to anticipate and test the behaviour of complex systems before prototypes pass into production, taking into account the interaction between stakeholders, by finding bottlenecks system and optimizing processes, time and costs.

By carrying this knowledge to the urban phenomena could be strategic, even though cities are not a complex product but are composed of integrated and interrelated systems like a complex system. Nowadays, the tendency is to customise product complex lifecycle management platform, or building lifecycle management tools, oriented toward the city understanding and management, by providing the foundation for the virtual technology used to create urban environments and objects, such as buildings, utility, mobility systems and infrastructures.

An example is "Virtual Singapore: A Platform to Solve Emerging and Complex Challenges"². The National Research Foundation (NRF), Prime Minister's Office of Singapore, and Dassault Systèmes are cooperating to find solutions that give Advanced information and modelling technologies through a

collaborative platform based on a realistic and integrated 3D model with semantics and attributes in the virtual space. The tools and services development address the emerging and complex challenges Singapore faces thanks to a rich data environment and visualisation techniques that will be used in a collaborative manner by Singapore's citizens, enterprises, local administrator and research community.

Another study of Xu et al. (2014) explains the potential benefits of CIM, City Information Modeling, a framework of integrating BIM technology into GIS with the goal of bringing great benefits to the urban construction and city management.

So, there is the need for a perspective system and strategic approach, by integrating the cross-disciplinary academic insights and the latest practical innovations, to enable resilient and sustainable urban system, looking towards the industry 4.0 technologies and focusing on the asset management.

The following paragraphs, starting from a case study, aims at providing an integrated approach for future planning and management within the urban complex system through the design of an innovative framework based on the integration of collaborative and technological approaches.

1 PLM - Product Lifecycle Management as holistic approach for complex product in manufacturing industry

2 <https://thebimhub.com/city-management/>

3 RESEARCH AIM AND METHODOLOGY

The current approach used for the management of urban transformation process is not considered sufficient to decode the complexity. Starting from this consideration, this research aims to propose a customized BIM based methodology for the urban management. The work is based on a case study analysis, wicked example of management of an urban transformation, to demonstrate how “systems thinking approach” can improve the management and planning processes. In particular reference to an urban subsystem case study, the research highlights the necessity to insert and integrate the subsystem in a greater complex system (in an inter-scalar vision), by avoiding the compartmentalised action, by reaching resilient and sustainable actions.

The first phase illustrates the weaknesses of actual process and how an innovative framework can improve the understanding of system components and complexity. It consists in an empirical inquiry based on a qualitative method that investigates phenomenon within a real context: the interrupted construction site of a student housing in Bari, South Italy.

This research deepens the urban transformation conflicts, and how they arise in the context of cities development. The survey is done strategically for understanding sociological and planning processes and interactions within actors at different levels and with environmental, economic and political domains.

A qualitative research on project management processes is carried out. Data collection, which began in September 2016 and finished in March 2017, involved analysis of project history, the documents (project plans, contract documents, reports) and semi-structured interviews with stakeholders. Face-to-face interviews with the principle actors of the process involved unstructured and open-ended questions, by covering a range of topics related to the multiple reasons for the site construction interruption, the involved actors and interactions with external actors, the information exchange method, documents management, and used technologies. In this way, the researcher had the possibility to record a lot of information for rebuild the long period of the project, started in 1996, by analysing the criticalities, bottlenecks and responsibilities. From the data collected, a process workflow and information management were mapped, and the set of information was systemized of the whole period.

The second phase shows the proposed innovative and integrated framework BIM-based in order to “unravel” the urban complexity by the systematization all the process, by identifying the urban subsystem, the involved actors. Strong emphasis was put on the interaction among different domains involved in a planning transformation, to exceed the sectionalized approach. The new vision proposed for an urban transformation is scalable at the whole urban system.

4 DESCRIPTION OF A CURRENT URBAN PROCESS: THE STUDENT HOUSING IN BARI

The analysed project is a university residence, which construction was interrupted. The building is located in the south-west of the Mungivacca district of the Municipality of Bari, Puglia Region, South Italy, and it is part of a larger “Integrated Urban Renewal and Recovery Program” aimed at promoting a functional and social mix. (Figure 1). The project process started in 1996.

Figure 1 – The Student Housing, Mungivacca District, Bari, Puglia Region, South Italy¹

The case study includes all the requirements for a complete and complex reflection: lack of a clear and programmed management, multiple strategies change, planning and constructive mistakes, until the possibility of rethinking the project for respond to new urban needs, by including the social and economic analysis. The general project of urban renewal, nowadays recognised as a successful intervention, was addressed by the municipal administration to strengthen the student vocation of the district, through an organic urban regeneration characterized by the use of available areas for services, green and university facilities for the creation of an integrated system for leisure and social exchanges.

The construction started in 2011, envisaged the realization of an extensive building for 100 student apartment, with university facilities. The project started about twenty years ago, promoted by the Autonomous Institute of Public Housing - IACP (nowadays named ARCA²). The work had to be completed by September 2012, but due to different unforeseen developments ("persistent obstacles to a rational and rapid execution"), they have been prolonged over time, until the construction site blocked in 2015. Due to the construction stopped, the ARCA requests confirmation from ADISU, the Regional Agency for the University Study Right, in mid-2016, of the actual need for the approximately 300 bed places for non-resident students. At the end of September 2016, the ADISU denied this need due to the "declared" full coverage of the current student bed places demand.

This change of plans, in addition to the problems connected with the abandonment, has an influence on the other systems of the city: the hypothesized formation of an Academic Corridor (Wivel and Perry, 2013) is compromised, structured on the theme of old and new university residences in this urban quadrant (Martinelli et al., 2016), along the strategic axis of Bari – Taranto; waste of public money; impairment of the quality of public space; a sense of urban deprivation and insecurity.

The described case is a clear example of public and/or private "absence of management" and due to the high number of stakeholders involved, the complex process has slowed down until the construction site blocked, by producing misalignment between "demand and supply", but also misalignment with urban regeneration policies. This case would have required a dynamic approaches and project feedbacks, which in our institutional contexts and in our traditional process are completely absent.

In this regard, in recent months the involved authorities, including the Puglia Region, the ARCA, the Municipality of Bari and other stakeholders, have been forced to rethink these student housing by

¹ Source: Rielaboration of the authors from Google Maps and <http://www.arcapugliacentrale.gov.it/a-p-c/patrimonio-immobiliare/progetti-e-interventi/1-nuove-costruzioni/3-mungivacca> (on April 2017).

² The new name of the Authority for public housing of the Apulia Region "Regional Agency for the house and for living" <http://www.arcapugliacentrale.gov.it/a-p-c/patrimonio-immobiliare/progetti-e-interventi/1-nuove-costruzioni/3-mundivacca>

changing their original destination, targeting their social housing, in response to the new housing and urban needs (ie young couples, separated parents, elderly people, immigrants, etc.)¹. But despite this, there aren't the appropriate methodologies and tools to take on this changes as rapidly as possible and in an efficient manner, by optimising time and costs.

It emerges, therefore, the need to analyse these changes through the lens of complexity, arguing on the integrated analysis (Schwaninger and Koerner, 2004) of the urban systems and the phenomena dynamic, on the integration of new needs, new targets, and the involvement of various public and private actors who will inclusively have an active part in the process, from the initial planning phases to the management. The authors believe that an alternative hypothesis is now made possible by the use of new models that provide new technological infrastructures to support urban complexity and the continuous evolution of the city , as described in the following paragraph.

5 TOWARD A COMPLEX APPROACH: PRELIMINARY RESULT OF THE INNOVATIVE MODEL FOR URBAN MANAGEMENT

Starting from "interrupted" example for misalignment between urban policies, action and socio-economic changes, in the current context of public policy uncertainties under the effects of the global crisis, the proposal is to trace models backed by ICT tools, which can help the decision makers to formulate strategies that respond to new economic and social urban needs based on clear public-private management processes and active community engagement. The research intends to contribute methodologically to reinventing the process, making it dynamic, optimizing the resources employed, and operating urban regeneration actions that will produce benefit both for the community and the private. The framework, named Urban Common Data Environment, scalable to other urban transformation intervention and in general to the management of urban subsystems, is based on the use of a BIM/PLM/GIS as Methodology, Technological Platform and tools, deployed on the urban scale, in an interoperable and inter-scalar vision.

In detail, Building Information Modeling (BIM) is "a set of interacting policies, processes and technologies generating a methodology to manage the essential building design data in digital format throughout the building's lifecycle", according to Succar (2009). It is centred around an Information Model, which is the virtual representation of the physical characteristics, that in the present research is extended to other urban subsystems. The enabling technologies of BIM methodology are not yet mature enough to handle maintenance phases.

Product Life-cycle Management (PLM) is a strategic business approach for the effective creation, management and use of corporate intellectual capital, from a product's initial conception to its retirement (Amann, 2002). It is useful for the methodology because offer a robust base for the standardization of the whole process, with particular attention to the maintenance phase, technologically weak in BIM methodology.

The Geographic Information System (GIS) (Maliene et al., 2011) is a system designed to capture, store, manipulate, analyse, manage, and present spatial or geographic data, that enables the scalability to the BIM methodology to the urban scale, creating a standard for the data exchange.

The main platform objectives are the complex urban action process management, the interaction between the actors involved, the creation of a cognitive/informational knowledge base that will cover the various phases over time, overcoming the sectorial vision. It is hypothesized, as exemplification, its application at the integrated management of the whole conversion process of student accommodation.

At the center of the process there is the structure digitization, according to a three-dimensional information model that allows the definition of spaces according to the technical-functional requirements, by guaranteeing the storage of all the necessary data and by enabling participation thanks to the strong communicative capacity of the 3D model, via feedback systems.

¹<http://ricerca.repubblica.it/repubblica/archivio/repubblica/2017/04/06/le-case-per-studenti-in-totale-abbandono-socialeBari04.html> <http://www.lagazzettadelmezzogiorno.it/news/home/409870/appartamenti-per-studenti-in-realizzazione-a-bari-gestiti-dal-costruttore.html>

The platform will allow all phases project tracking by enabling active involvement of all public-private actors for conversion/management, through the requirements collection, digitization, and maintenance. The benefits are numerous:

- a single referential system to ensure management;
- improved business and resident participation, the interoperability between the actors involved (managing body, PA, administrators, associations, resident, etc.) and used technologies;
- the ability to make transparent every action and every economic investment by simulating the various solutions and interactions with other systems (infrastructure, mobility, utilities, services, etc.) and dimensions (economic, environmental, social);
- the ensuring compliance with the legislative framework and time limits and the ability to identify the "bottlenecks" of the process in a clear and univocal way;
- archiving information and facilitating maintenance phases;
- increased transparency, reliability, scalability and sustainability of services.

The innovative framework is based on a collaborative model for managing urban complexity in a System of System approach. The integrated platform will link the stakeholders from all city domains in a urban common data environment and will enable access to a single informative DB linked to the 3D urban model, which constantly and dynamically will update with new process data. This framework will be managed by the strategic figure of the city manager (Sancino, 2008) for the urban management and as a Decision Support System for city administration. In addition, the authors consider the management as central phase in the whole process for the important investment and the complexity of action. It will follow the PAS methodology of Asset Management. Figure 2 explains all the process, actors, level, and city subsystem.

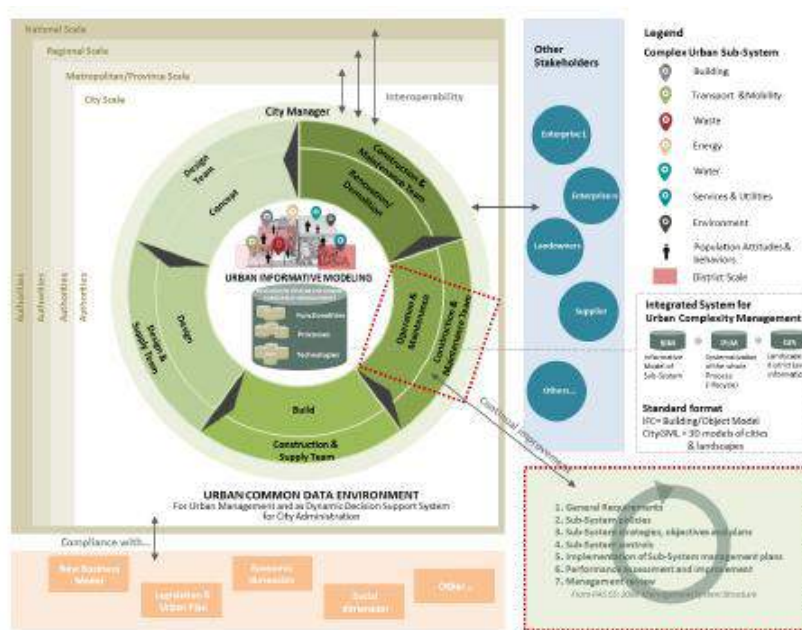

Figure 2 – The Integrated Framework: the Urban Common Data Environment

6 CONCLUSION

The research highlights as innovative and integrated approaches are needed to improve the quality of urban planning and consequently of the urban space and services, shifting the attention to the management of cities, by adopting the complexity lens.

Thanks to the specific case described, at the district level, it was possible to understand the importance of the relations among different levels, like the national level (for the possible financing), regional level (strategic vision) and local authority (operative vision).

Moreover, it is emerged the necessity to rethink the management of the public action for optimize the process, through innovative technologies, today used or for the Building level (as the Building Information

Modeling, rarely used for the urban scale) or deriving from another discipline like the PLM (that focalizes the attention to all lifecycle, really important for the city maintenance)

Using innovative and integrated platform for decoding the complexity (characterized by human and physical dimension) and manage the city could generate the new virtuous shape of urban regeneration. In addition, the authors believe that a new figure in the city manager is strategic to handle the whole process, with urban, managerial and technical skills.

This proposed methodology is intended as a preliminary phase of a broader study that wants to overcome technological and/or methodological gaps that prevent a full adoption of BIM base technology to the city management.

1 INTRODUCTION

The conception of the Territory, or in other case of the city or the urban as a part of the previous one, as a Complex Evolutionary System, full of diversity and uncertainty due to its continuous transformation, it is clear that it has important implications for Planning. So, if Planning is considered as a way of thinking and future-oriented action based on decisions of a spatial nature taken in the present on a complex and constantly changing system. The main consequence is the impossibility of formulating an all-encompassing and finalist Planning, since it is not possible to intervene on all the elements of the system, which are also in continuous evolution and transformation. Then, in a spatial context of strong uncertainty, due to the non-linear combination of different coevolutionary changes, it is not feasible to formulate a finalist image of the territory, or city, for a future time horizon. Therefore, Planning has to change its traditional budgets and accept that in a complex, diverse, evolutionary and uncertain environment its role will be very different. For that reason, Planning must accept that its fundamental objective will be the formulation of alternative solutions for each spatial problem posed, evaluating different evolutionary trajectories of the territory, in order to facilitate and improve collective decision making.

Thereby, given the impossibility of acting on all the elements of the complex, diverse and uncertain system that is the territory, Planning as a mode of action for collective spatial decision-making has to select on which variables to act or intervene. In this sense, and in order to maintain a certain global vision, Planning has to act on its Spatial Structure, that is to say on the smaller number of elements that allows to obtain the greater knowledge and understanding about the performance and morphology of the territory. Therefore, Planning will intervene in the territory, and in urban space, by transforming the elements of its Spatial Structure, which at the same time and in a coevolutionary way is conditioning and transforming the rest of the elements of the system.

Within the Spatial Structure, a priority object of Planning, Infrastructures are key elements, since they are the framework or skeleton that articulates the Urban System, supporting the relations between the urban and land-use elements. In addition, Infrastructures through their spatial effects condition the location and evolution of Urban Systems components. Therefore, a new model of Planning based on intervention on infrastructures, as the key elements of the Spatial Structure of the Territory, is proposed. The action on the Infrastructures of the Spatial Structure implies a selective model of Planning, in order to transfer series of collective values and interests by acting on key elements of great transcendence and influence on the global set, at the same time as it allows a certain margin of freedom and self-organization for the rest of individual space decisions. Therefore, an infrastructure-based Planning model arises, resulting from the action on the key infrastructure of the Spatial Structure through a process of collective decision-making.

Thus, different Territorial Scenarios are formulated from the spatial effects of infrastructures on land uses and the Urban System in a flexible framework, in order to evaluate the impact on collective values of different solutions in a dynamic context.

2 INFRASTRUCTURES AS KEY ELEMENTS OF THE SPATIAL STRUCTURE OF THE TERRITORY

A simple observation of the Territory, or in its case of the city, shows the existence of a remarkable amount of interrelated physical and biotic elements, which interact with each other, giving rise to phenomena and processes that involve the generation of flows of energy and materials. In a certain sense, this simple observation of the Territory leads directly to its conceptualization as an ecosystem, in which there are a large number of elements, which generate multiple and diverse relations and which, in turn, imply a great number of phenomena and effects of their interaction. That is, it is a Complex System.

The Territory as a Complex System has, among many others, three characteristic parameters such as complexity, diversity and uncertainty. A fourth parameter must be added, spatiality, since all its elements and the relations between them maintain a clear spatial component. Therefore, the Territory is a Complex Space System, which has a great dynamism, diversity and uncertainty. Thus, the Territory as a Complex Space System has a large number of elements, very diverse, and generate multiple relationships, which is a problem for their understanding and intervention on it. For this reason, it is frequent, and it is an intrinsic property of the systems, to distinguish different subsystems, in order to define and particularize both the constituent elements and the relations generated. On the other hand, the elements and relations belonging to the Territory are located in space in a certain way. An own and characteristic space arrangement of the system, very different according to the considered areas, and that can be considered as one, but the greater, of the configurating and defining elements of the system. In fact, much of the relationships established between the elements of the system are conditioned and influenced by this spatial arrangement and by the existence of connection between them. This aspect of the systems leads directly to the idea of Spatial Structure, that is, of the distribution of the parts or components of a system in space.

However, the concept of Space Structure applied to the Territory has a slightly different and nuanced meaning, since in a way it is a simplification of the real complexity and diversity. Thus, in a strict perspective of the term, the Spatial Structure would make reference to all the physical elements of the Territory and its functional relations. Obviously, under this approach it would be almost impossible to both understand and intervene on the Territory. Therefore, it is necessary to make simplifications and abstractions that allow a global understanding of both their physical configuration and their operation, thus emerging the concept of Spatial Structure. Thus, the concept of Spatial Structure is defined as the spatial arrangement adopted by the smallest number of elements that explain the overall configuration and functioning of the Territory as a unitary set within its intrinsic complexity and diversity. In this sense, as formulated, the Spatial Structure is a schematic model of the Territory, and whose elements have been selected based on the scope of work, its spatial dimension and the analyzes that will allow to understand and characterize it (Fig. 1).

Figure 1 – Spatial Structure of Milton Keynes. Source: Bosma and Hellinga, 1997)

Infrastructures play an important role in the configuration and formation of the Spatial Structure of the Territory, being both one of its main elements and the support that links the different elements of the Urban System and Activities, on the one hand, and the relations established between these, on the other hand. Hence, if the Spatial Structure is the representation of the spatial arrangement of the main elements that shape the Territory and the relations established between them, the Infrastructures are the ones that provide the interlocking of the Territory and the interrelations between the elements of the system. Therefore, if the Spatial Structure is observed from a broad perspective, beyond the simple arrangement of elements in space, as a set of physical and virtual interrelations between them, Infrastructures would be one of the main elements, either as a union of physical relationships, either as the support of virtual and physical relationships.

Therefore, there is a clear relationship between Territory, Spatial Structure and Infrastructures. However, a couple of issues should be specified in this relationship. On the one hand, the need to carry out simplifications, generalizations and abstractions in order to reduce complexity and uncertainty in the understanding of the Territory, both the Spatial Structure and, in particular, the Infrastructures. On the other hand, it is obvious that changes and modifications occurring in any of the three elements modify the remaining two. Thus, in this sense, a trinomial is formed between Territory, broadly understood, Spatial Structure and Infrastructures. A relationship of bidirectional nature two to two and circulate between the three, in which the modifications in one of them affect the next one and this one to the rest, that again resets to the first one.

Hence, the Trinomio Territory, Infrastructures and Spatial Structure is a clear example of the nature of the first as a Complex System, in which are present the properties, or rather characteristics, of connectivity and interdependence of its elements. Thus, in Complex Systems, such as the Territory, there is an important interconnection between its elements, with a significant degree of connectivity, which varies with different properties such as diversity, intensity, density and quality of interactions (Mittleton-Kelly, 2003)

and which gives it a remarkable interdependence between the different elements. This connectivity and interdependence means that a change in one element implies the affection over other related elements, assuming its transformation to a greater or less degree and intensity (Fig. 2).

Figure 2 – Trinomio Territory, Spatial Infrastructure and Infrastructure (Source: Sánchez-Rivas, 2016)

On the other hand, it is also necessary to clarify that a Complex System such as the Territory has a high multidimensionality. Hence, it has very different dimensions such as physical, socioeconomic or cultural, that interact and affect each other. In this sense, if one considers from a perspective related to the understanding of that which at a certain scale represents the essential elements of the Territory, the Spatial Structure is rather a cultural approximation. Thus the relations between the elements of the Trinomial are deployed in at least two dimensional levels: a purely physical one, related to the physical elements of the System, and a cultural one, in a certain way, related to the simplified and abstract understanding Of the functioning of the System through its Spatial Structure.

Infrastructures, particularly those of transport, are one of the fundamental elements that shape the Spatial Structure of the Territory and, as such, it is obvious that their transformations and evolutions must involve both global changes and in the different subsystems of the Territory (Settlements, Environmental System, ...). Consequently, the variations in the Infrastructure System generate a series of effects that imply changes in the Spatial Structure and its components. However, this relationship is bidirectional and the Infrastructures themselves are modified by the existing transformations in the other elements that shape the Spatial Structure of the Territory and, above all, by the evolution of land uses. In the background, this is a circular relationship, more than bidirectional, in which land uses determine the location of activities, which require transport infrastructure, and then, in turn, create opportunities for locating activities through the differences of accessibility, in such a way that changes in the land uses are generated (Wegener and

Fürst, 1999). The vast majority of the spatial effects of infrastructures have in common, in addition to the attraction and expulsion of activities, two underlying processes of great importance in the current configuration of the Territory: the rupture of the friction of distance, on the one hand, and the increase and multiplicity of connections between elements of the Spatial Structure (Fig. 3).

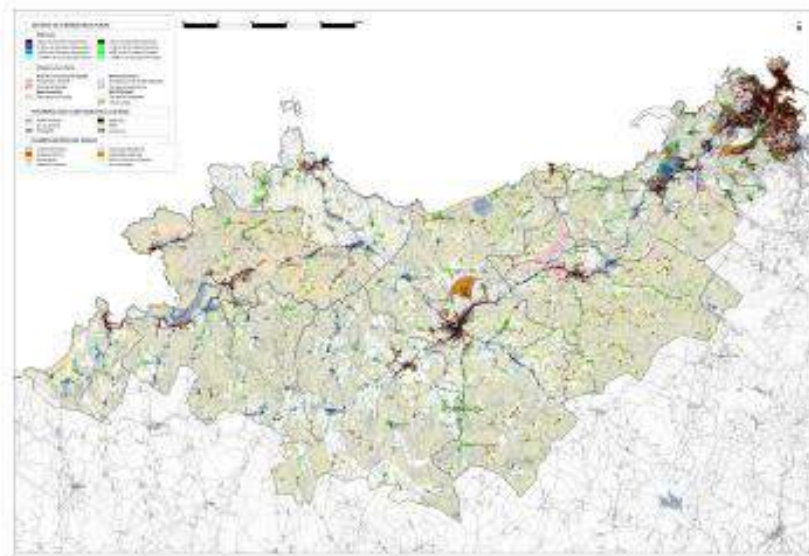

Figure 3 – Spatial effects of a road in Galicia (Source: Sánchez-Rivas, 2016)

Considering these spatial effects, in particular their connectivity and their attractiveness, it is possible to distinguish four major conceptual visions about Infrastructures within the Spatial Structure and, by extension, the Territory. These four conceptual visions are: articulation, axes, poles or nodes as centralities and barriers as limits. In this way, the articulation refers to its spatial arrangement and how Infrastructure link with each other and with the rest of elements. The axis refers to the generation of linear patterns of spatial arrangement. Meanwhile, polo as centrality refers to the concentration of other elements, for example land uses, around an Infrastructure. Finally, the barrier as a limit refers to the impossibility on the part of the organizational patterns of other elements to cross or continue after an Infrastructure.

Therefore, the Infrastructures are one of the main elements of the Spatial Structure of the Territory. Thus, they are configured as the main support of both the communication and union between the rest of elements and their relationships, providing their cohesion. At the same time, Infrastructures, through their configuration and their characteristics, are what give the Territory much of its structure, its morphology and its properties, particularly those related to connectivity and accessibility. From this point of view, the Infrastructures are raised as the central element, or at least to the highest level, of the Spatial Structure of the Territory.

3 PLANNING AND INFRASTRUCTURES. COMPLEXITY, UNCERTAINTY AND EVOLUTION E INFRAESTRUTURAS.

If Infrastructures have a vital importance in the configuration of the Spatial Structure of the Territory and, above all, to generate processes and spatial dynamics of urban development, it is undoubted that this importance must also be transferred to the elaboration of Planning. However, capturing or incorporating the dynamic processes of change and transformation that generate and catalyze Infrastructures is not easy for Planning (Dupuy, 1998). This difficulty has arisen, to a great extent, in the very conceptualization and practice of Planning. In particular, due to the difficulties that the instruments and tools of the Planning have found difficulties to incorporate the dynamism of the existing space processes in the reality (Sánchez-Rivas, 2014a).

Then, these difficulties have been related to the disregard of the spatial effects of the Infrastructures in the Structural Models proposed by the Planning (Graham and Marvin, 2001; Sánchez-Rivas, 2016). Due to this, the reality of the planning practice has shown the existence of important discrepancies between the Planning, mainly between its future final image formulated through the intervention on the Spatial Structure, and the final trajectory of development and real evolution of the Territory, especially in terms of the impacts that the spatial effects of the Infrastructures have had on it. This situation can evidently lead to the bankruptcy of Planning and its delegitimization as a useful and effective instrument to formulate a Territory more in line with the vision and interests of society. Therefore, Planning seems to be unable to integrate Infrastructures and their spatial effects and, therefore, is doomed to failure.

Truly, there are two major reasons for Planning to integrate from the outset Infrastructures as a central element of its future Spatial Structure. First, and obviously because of its importance within the configuration of the Spatial Structure and as support of the relations between the different elements of the Territory. Second, and less evident, the need to incorporate Infrastructures as elements that generate spatial dynamics of great importance for the configuration and operation of the Territory based on their spatial effects and their impact and influence on the rest of the elements. In this sense, the disconnection between Infrastructures and Planning results in the first failure of the determinations of the second and, obviously, a clear discrepancy between the reality of the Territory and the Structural Model formulated by the second.

Indeed, the utility of Planning is linked to the greater convergence with the real evolution of the Territory, or at least with the Structural Model formulated as a future aspiration of its Spatial Structure. And for this, Planning must be able to model in some way the spatial dynamics of change and transformation that occur in the Territory. In this sense, it is necessary that Planning considers in its Structural Models, and consequently in its proposed future Spatial Structure, both the Infrastructures and their spatial effects. Therefore, it is essential and necessary the integration of Infrastructures and their spatial effects in Planning, in order to respond to the dynamism and continuous transformation of the Territory.

However, considering the dynamism of the Territory, in particular through the spatial effects of Infrastructures, involves increasing both the complexity and the uncertainty. Therefore, the opening of important questions about the nature and the capacity of Planning to intervene in the Territory. In this sense, if a fourth element is added to the Trinomio Territory, Infrastructures and Spatial Structure, Planning, forming a Tetrahedron, can be more easily understood the difficulties of the latter to establish finalist determinations. Thus, if the transformation of one of the elements of the previous Trinomio implies the modification of the others, the introduction of Planning also implies its transformation. A relation that is

not unidirectional, but it is bidirectional with each of the elements, since the modifications in one change the others and, therefore, the starting point of the Planning, leading to its revision (Fig. 4).

Figure 4 – Tetrahedron Territory, Spatial Structure, Infrastructure and Planning (Source: Sánchez-Rivas, 2016)

In this way, if the complexity and uncertainty of the Territory, due to its continuous transformation, implies the impossibility of an all-encompassing and finalist model, capable of intervening on all its elements, Planning must evolve in its forms, objects and instruments. In this sense, and taking into account the complexity and diversity of the Territory and existing interdependencies, and without questioning the need to formulate some form of future-oriented intervention, logic indicates the need to establish a certain selectivity about what allows to reduce the uncertainty within a joint and global vision, that is to say on the Spatial Structure. At the same time, considering the key role of Infrastructures within the Space Structure, mainly due to its capacity to generate effects on the rest of elements, implies the centrality of the first in Planning processes. Therefore, Planning has to intervene in the Territory by transforming the elements of its Spatial Structure and in particular on its Infrastructures.

Consequently, faced with the complexity and uncertainty present in the Territory, the hope of an all-encompassing Planning seems to be just that, a hope broken by reality. In addition, such Planning would imply transferring to the Territory dichotomies in some sense moral and ethical between freedom and authoritarianism in spatial decision making, which could not be consistent with the view of Planning as a community collective action that expresses spatially a series of values and interests from consensus.

If from a position linked to political ethics is intended to maintain a series of values related to freedom in making spatial decisions, both collective and individual in a multi-actor environment such as the Territory, the possibilities of Planning really pass through a sort of selectivity of the elements on which to intervene and by a certain abstraction. In a certain way, this approaches a relative, if not complete, incrementalist vision of Planning, by developing small strategies focused on specific issues or elements in order to reduce uncertainty. However, this is not a pure and hard incrementalism based fundamentally on small interventions and strategies on concrete elements, but when performing on the Spatial Structure exists a certain global intentionality. Above all, if this action is posed with relatively holistic pretensions of understanding and global intervention through the spatial effects generated by the elements of the Spatial Structure, which allows, and implies, the possibility of using macro strategies that can be reached by disaggregating them micro-strategies on concrete elements.

Therefore, Planning has to be linked to a structural vision of the Territory, in which it acts in a way that combines a macro strategy in which microstrategies are integrated around the elements of the Spatial Structure, as real physical essence and as an abstract model, based on the spatial effects generated by Infrastructures and their capacity to catalyze and condition urban development. In this sense, Infrastructures are an element whose appearance, use and management is usually collective, with which the priority object of Planning as a mode of collective action on the Territory, while in urban development, especially land uses, there is a greater individual component, although also in some cases collective, that responds to a spatial decision making that experience shows that it does not usually come from a previous planning process. Therefore, Planning has to move towards a model based on the intervention on the elements of the Spatial Structure, in which Infrastructures and their spatial effects play a central role as a collective expression of the values and interests of a given society or community. At the same time, the continuous transformations of the Territory require that Planning to be transformed continuously, that is, to evolve towards different states or situations.

At the same time, accepting that Planning has to focus its action on the elements of the Spatial Structure implies that the achievement of a collective desired future for the Territory is the result of the spatial effects that the elements of the previous one generate on others. In this way, to a large extent, Planning has to be based on establishing Structural Models in which the intervention on the elements of the Spatial Structure allows to lead the development and the transformation of the rest through the spatial effects generated mainly by Infrastructures.

Then, this model of Planning involves considering the existence of dynamic processes of adaptation to the conditions generated by the spatial effects of the Infrastructures that shape the Spatial Structure. In addition, it involves considering, as in the reality of the Territory, the existence of elements that come from Planning processes along with others that could be described as spontaneous, which in a certain way do not stop being a sample of the freedom of individual decision and self-organization carried out by different actors present in a multi-actor context.

In this sense, as opposed to other paradigms of understanding of the Territory, incapable of integrating the processes of transformation and change existing in it, the paradigm that interprets the Territory as a Complex Evolutionary System allows to consider both issues. In a context of complexity of the Territory and of continuous transformation and fragmentation in spatial decision making, the application, or rather extension, of the concepts of Evolution Theory has been shown as a model of useful and adequate understanding, being able to incorporate both the existing dynamism and the presence of elements from different origins (Marshall, 2009), whether these are the result of local spatial decisions or a more or less centralized planning. Thus, it influences the need to consider Planning as an evolutionary cultural construct, which adapts to the changes that have occurred in the Territory, whether these are the result of its determinations or not. In a way, it is a coevolutionary paradigm, in which two or more elements evolve adapting to the transformations of the other or others. In this sense, there is a Coevolution on two levels. One at the level of the Territory, physical, where the different elements that comprise it coevolve, for example Infrastructures and land uses, on the one hand, and another on a cultural and abstract level,

between the Territory, understood as a complex system, and Planning understood as a mode of action, in which both co-evolve from the transformations of the other. Therefore, a new paradigm opens in the relationship between Infrastructures and other elements of the Territory, on the one hand, and Territory and Planning, on the other hand, Coevolution.

Thus, at a physical level, there is a Coevolution between the different elements that shape the Territory, using the term in a generic way to refer to the different subsystems, and Infrastructures. A Coevolution that in particular occurs between the urban development and the Infrastructures based on the spatial effects that they generate and the "evolution with" of both, through different processes of mutual adaptation over time. Along with this physical Coevolution, there is also a coevolution at the cultural level between the Territory and Planning in which both condition the paths taken by their temporal changes in a given period of time. Therefore, there is no doubt that between the Territory, Infrastructures, by extension Spatial Structure, and Planning there is a Coevolution, which is complex and which not only concerns these two dimensions but is deployed in multiple elements already two levels. In the background this is a consequence of the multidimensionality of Complex Systems and the absence of a single solution, due to the interaction of multiple connected and interdependent causes. This situation implies a great uncertainty and the inability to univocally design, predict and control a Complex System such as the Territory, in which different coevolutionary processes are taking place.

Therefore, the Infrastructures take an important role as central elements of the Spatial Structure of the Territory, which, to a great extent, is the object of action of Planning. Thus, fundamentally through the action on Infrastructures and through their spatial effects, Planning intervenes on the rest of the Territory, in particular on those of its Spatial Structure, transforming it and thus catalyzing the change in the rest of the elements in a coevolutionary way. Due to this, Planning has to incorporate new tools, instruments and concepts that allow to consider and to consolidate this mode of intervention on the Territory through the coevolutionary effects of the Infrastructures with the rest.

The conception of the Territory as a Complex System full of diversity and uncertainty, in which it is not possible to intervene on all the elements present in the same, it is evident that it has to have important consequences for Planning as a mode of future-oriented action and intervention and towards the transfer to the Territory of a series of values and interests. The main consequence is the impossibility of proposing an all-encompassing and finalist Planning, since it is not possible to intervene on all the elements that shape the Territory, due to its continuous transformation, which adopts a coevolutionary approach in which elements influence on others, generating spatial dynamics of change according to different mechanisms. In this context, two issues seem to be fundamental to Planning. First, the translation of a series of values and collective interests into the Territory is a consequence of the action on a few essential elements, which generate adaptive and coevolutionary changes in others, in such a way that the whole is transformed in a certain direction. Second, in a context of strong uncertainty due to the non-linear combination of different evolutionary changes, which are also continued over time, it is not feasible to formulate a finalist image of the Territory for a given time horizon and much less an optimal solution, because there will be multiple paths and solutions resulting from different possible alternatives (Batty, 2013). For this reason, Planning must accept that its fundamental objective is the elaboration of alternative solutions for each spatial problem posed, evaluating the different trajectories that the resulting changes generate in the Territory in order to facilitate and improve the collective decision making, while allowing a certain margin for individual locational decisions, which will obviously be conditioned by the interventions on the Spatial Structure and its spatial effects formulated by each proposed solution.

Therefore, the evolutionary paradigm of Planning and in particular its coevolutionary approach poses a Territory in continuous transformation, in which coherence is neither possible nor intervention on all its elements nor the formulation of finalist images. In a certain way, this is a Planning in continuous elaboration and revision, which explores different trajectories of its evolution, both due to the different interventions proposed collectively on the Spatial Structure of the Territory, and by the emergence of self-organizing patterns resulting from the individual decisions of location of activities. Thus, within the context of the revision of the forms of Planning, the evolutionary paradigm is linked to a nonlinear model, circular in some way, in continuous process of elaboration and based on the future scenarios resulting from the different solutions and interventions, in order to allow a collective decision making that is much more participatory, open and integrating of the different values and interests of the agents in a multi-actor context. A Planning model whose intervention on the Territory has to focus on the Spatial Structure, and in particular on Infrastructures from a coevolutionary perspective with the land uses, to which the former

condition through their spatial effects, through microstrategies projects inserted in a global macro-strategy framework. Obviously, this centrality of the interventions of Planning on the Infrastructures supposes the opening of new perspectives for these, mainly as far as the formulation of alternative scenarios of evolution of the Territory based on them and their spatial effects.

4 TOWARDS A NEW INFRASTRUCTURE-BASED PLANNING MODEL

The emergence of new forms of Planning, in particular from the evolutionary paradigm and its coevolutionary approach, opens new perspectives for the consideration of Infrastructures in this matter. In this way, the opportunities presented by multiscale, the multi-layered division that intersect, the simulation and the formulation of future scenarios allow to contemplate Infrastructure from a dynamic approach through the concept of network and its spatial effects, surpassing the static approach as structural elements. All this makes it possible to respond to the new demands derived from the network - territory and from the new complex spatial structures present today such as Metropolitan Areas and Urban Regions, characterized by the existence of relational geographies (Healey, 2007) due to the connection to Transport Infrastructures and of multiple spatio-temporal trajectories. Thus, through the analysis and continuous cross-linking of different scales of Infrastructure with each other and with other different territorial subsystems, considering the compatibility of their spatial effects in different future scenarios, it is possible to provide a flexible, strategic, structural and project response to enable taking collective decisions on the Territory. At the same time, the use of future scenarios makes it possible to overcome biased and unidimensional visions of Transport Infrastructures as channels of communication to cover their multiple natures and uses, in particular as structuring elements of the Territory and as a collective space. In this sense, Planning can consider the different alternative roles that Infrastructures adopt in terms of their multidimensionality and with that to evaluate the incidence that their spatial effects generate on the Territory, adapting, coordinating and compatibilizing of several territorial systems. This new approach to Infrastructure-based Planning must consider the different roles an Infrastructure can play and the impact its spatial effects have on the Territory from a coevolutionary perspective with the rest of the subsystems. In this way, Infrastructures regain a leading role in the elaboration of Planning. Therefore, a new approach to Infrastructure-based Planning emerges.

Thus, taking into account the main spatial and physical effects, such as the attraction and expulsion of activities, the rupture of the friction of distance and the establishment of multiple relationships between the elements of the Territory, Infrastructures may take on different roles regarding the configuration of the Spatial Structure, whether this perspective refers to the understanding as to the intervention on it. In this sense, from a conceptual point of view of the Structural Models oriented towards Planning, these roles are four: articulation, linearity, centrality and limit. Each of them has different effects and implications at different scales. At the same time, Infrastructures can take various roles based on its multidimensionality.

The capacity of the Infrastructures to communicate and organize the different elements of the Spatial Structure to achieve a coherent and efficient set is behind the role of articulation. Thus, Transport Infrastructures are those that through their organization provide the physical support to structure the rest of the Territory. So, one of the main roles that Transport Infrastructure can adopt is the articulation of the future Spatial Structure proposed by Planning. In a way, by articulation is meant the different structural morphological models that can be adopted by the Transport Infrastructures, generating different effects in terms of the spatial distribution of accessibility and connectivity, which affects the organization of the Urban System, global and regional scale, and in the implementation and management of land use and activities, on a metropolitan and urban scale (Fig. 5). Each of these structural models of articulation provides different spatial configurations and distribution of accessibility and connectivity, privileging some points on others when establishing relationships and implement activities, ranking the Territory. These structural models can adopt different morphologies and typologies, from star configurations, radioconcentric, squares, crosses, directional meshes, etc., which have been experimented by Planning on several occasions, such as in the Director Scheme of Paris of 1965, the Greater London Plan, the Plans for Copenhagen and Stockholm.

Figure 5 – Two different morphologies as articulation role of transport infrastructure (Sánchez-Rivas, 2016)

The capacity of Transport Infrastructures to extend accessibility and connectivity through the Territory, radiating the urban condition through certain directions, is behind its role as linearity, as Axis or Corridor. Transport Infrastructures characterized by their linearity provide, throughout their guideline, accessibility and connectivity in a continuous way, in the case of roads, or in a discontinuous way, in the case of railway systems and motorways. An accessibility that generates the attraction of diverse activities and uses of the land, in such a way that being supported in the infrastructure they are located of continuous way, or with a certain discontinuity (Fig. 6). The use of the linearity of the Transport Infrastructures as the driving axis of the urbanization has been a resource very used by Planning, from the pioneering proposal of Linear City of A. Soria to the most sophisticated elaborations of the “Finger Plan” of Copenhagen of 1947 or the system of transverse tangent axes of the Director Scheme of Paris of 1965 or the most recent ones of Curitiba. In these linearities, public transport systems tend to become very important throughout their directive, since they have a greater efficiency, by minimizing their travel and maximizing the population served, and also by matching accessibility throughout the route. The notion of Axis refers fundamentally to a single guideline; however, on the other hand, in recent times, there has been a complexation of the morphological model of this linearity with the juxtaposition of different Transport Infrastructures and their effects towards the concept of Corridor. This is configured as a tape of variable width that encompasses different typologies and functionality of the Urban, Environmental and Infrastructure Systems over a large extent, forming or forming part of notable territorial areas of Metropolitan Areas and Urban Regions. Planning must try to order and structure these Transport Infrastructures in an integrated way with the land uses, due to its advantages in the efficiency and effectiveness of the collective transports and the provision of infrastructures of urban services, in order to maximize the population served and minimize construction costs avoiding an indiscriminate extension in all directions.

Figure 6 – Corridor and Centralities structure by the effect of Port and motorways in Metropolitan Area of A Coruña (Sánchez-Rivas, 2014b)

The capacity of Transport Infrastructure to generate privileged points of the Territory, due to its high accessibility and connectivity, implies the establishment of important territorial centralities (Fig. 6). Thus, nodal Transport Infrastructures such as an Airport, a Port or a Railway Station, in which access to both the

same and the service developed therein is performed in a specific and determined node of the network, are configured as Centralities of high connectivity and accessibility, attracting and concentrating activities and uses of the soil, and making possible the establishment of multiple relationships. These nodal centralities are the points in which the dynamism of the current network originates and must be considered from this perspective as such by Planning. In a way, it is not anything new, since current experiences such as Transport -Oriented Development (TOD) or older ones such as the Stockholm Plan of 1952 consider these nodal centralities as the key points of their management, both at the regional or metropolitan level as well as local scale in terms of land use and activities.

The capacity of Transport Infrastructures to separate different realities in terms of their model of urbanization in the Territory from the barrier effect is behind its role as Limit. A Limit role under which two main objectives lie: the containment of urban growth and decentralization to avoid an ungovernable extension of the city, on the one hand, and the monumental and symbolic closure of the city, on the other hand. Alongside both reasons are other functional reasons linked to the distribution of cross-border traffic flows. Thus, certain Transport Infrastructures, especially roads such as Rings, Bypass and Orbital, structure and generate attractive effects on land uses, while also acting as boundaries between different forms of urbanization, preventing an indiscriminate extension of the urbanization and emerging from them a network articulation of the Urban System. The clearest example of the use of a Transport Infrastructure as an element of closure and containment of the city is represented by the orbital highway of the Greater London Plan of 1944, also associated with another tradition of great importance as the green belts.

Therefore, this new model of Infrastructure – based Planning of a structural and co-evolutionary nature tries to intervene on the Spatial Structure, that is to say on the Territory, through the different roles that Infrastructures can adopt, generating different spatial effects on the other elements, in particular on urban development. This model opens new perspectives and opportunities for Infrastructures, where the consideration of their multiple natures and uses, especially as configurators of the Spatial Structure, is key to the creation of great projects for the planning of the Territory.

5 CONCLUSIONS

Undoubtedly, the emergence of new forms of Planning such as the one based on the evolutionary paradigm and its coevolutionary approach, implies the opening of new and very interesting perspectives for Infrastructures in the elaboration of the previous one, especially as regards its integration and the consideration of the dynamism conferred on the Territory through its spatial effects. In this sense, the conceptual visions of Infrastructures based on their spatial effects, in particular, and in a co-evolutionary way with the land uses, seem to be adequate tools for proposing alternative Structural Model of great potential. In this sense, these Structural Models will be able to intervene on the Territory in a context of complexity, fragmentation and multiple actors, that continuously evolves in a non linear way, through the exploration of different future paths for an appropriate collective spatial decision making.

Planning within the framework of the evolutionary paradigm is not an all-encompassing instrument, which seeks to define and completely design and to the last detail of the Territory, allowing the existence of other processes of change and transformation of the same that could be described as spontaneous or emerging. At the same time, Planning from an evolutionary perspective internalizes that the change and transformation of both the elements that make it and the global set is produced by adaptive changes, largely coevolutive, to the transformations that occur in other elements, whose influence is established through the spatial effects generated. In this sense, the spatial effects generated by Infrastructures are of great importance because of their capacity to condition urban development, in particular land uses.

Hence, against a traditional static Planning, this new model based on Infrastructures, in particular through four major roles that can adopt (articulation, axis and corridor, pole or node as centrality and limit), along with the consideration of its spatial effects, it would be possible to intervene in the territory by defining a global macro strategy as a spatial framework resulting from selective microstrategies on key elements of the Spatial Structure. Thus, at the same time that collective decisions are transferred to the Territory, a certain margin is allowed for local decision-making, conditioned indirectly through the spatial effects of Infrastructures in coherence with the global framework, being possible to integrate those emerging dynamics resulting from processes of self-organization.

ID 1661 | CONCEPTUALIZING SELF-ORGANIZATION IN URBAN PLANNING: TURNING DIVERGING PATHS INTO CONSISTENCY

Beitske Boonstra¹; Ward Rauws²

¹Ghent University; ²University of Groningen

beitske.boonstra@ugent.be

ABSTRACT: Within the realm of urban studies and spatial planning, the concept of self-organization receives increasing attention in understanding spatial transformations and related planning interventions (De Roo et al, 2012; Portugali, 2011). In exploring the potential of self-organization, various scholars however introduce diverging interpretations of the concept, consequentially leading to different understandings of what the concept can offer to planners. In the first part of the paper, we show that the different interpretations have their foundation in two distinct epistemic positions: One is a critical-realist interpretation of complex adaptive systems (Byrne, 2005), resulting in a planning focused on pattern recognition and formulating guiding conditions (Portugali, 2011; Rauws, 2015). The other includes a post-structuralist interpretation of emerging assemblages (Cilliers, 1998; DeLanda, 2006), leading to a planning focused on personal style and situational behavior (Boonstra, 2015). The potential synergies between the two epistemic positions has so far remained unexplored, while aspects of both perspectives simultaneously are at work in spatial transformations. Therefore, the second part of the paper explores their complementarity and discusses how to turn the two positions into consistency with one another – meaning how they can mutually reinforce each other without losing their individual epistemic strengths. Based on this exploration we suggest planners to act adaptively and differentiate in style in response to the situation at stake, among others by means of pattern recognition. On a conceptual level the paper shows how planning scholars can make sense of the diversity of ongoing processes of self-organization in the context of spatial transformations.

1 SELF-ORGANIZATION IN URBAN STUDIES, SPATIAL PLANNING AND GOVERNANCE

In attempts to better address some of the multiplicity, fuzziness, fluidity, fragmentation and resource interdependency contemporary spatial planners face today, and to move beyond command-and-control governance or the pursuit of consensus, planning scholars are increasingly turning their attention towards the complexity sciences (Portugali, 2011; Boelens & De Roo, 2014; e.g. Duit & Galaz, 2008; Byrne, Geyer, Gerrits, Batty, Bettencourt, De Roo, Teisman, Hillier, Van Wezemael). What complexity sciences bring to planning is the research on the evolution of phenomena. Instead of a Newtonian conception of the world based on reductionism, determinism and predictability, complexity sciences portray a world view of non-linearity and spontaneity as a consequence of the interconnectedness and changeable nature of a countless number of interacting elements (Waldrop, 1992; Cilliers, 1998; Heylighen, 2008; Rauws, 2015). As such, notions from the complexity sciences can assist planners to conceptualize their role in a world which is in continuous change and perform more situation-specifically and adaptive to these ongoing non-linear processes (De Roo, 2016).

In the debate on complexity and planning, especially the concept of self-organization has increased in popularity over recent years (De Roo, 2016; Boonstra, 2015; Rauws, 2015; Zhang, 2016). In general, self-organization is defined as the spontaneous emergence of order out of disorder (Prigogine and Stengers, 1984; Cilliers, 1998). Due to rich interactions between elements within a system and with the system's environment, self-organization processes fuel the emergence of new systems states from within a system itself. As such, self-organization is a spontaneous, autonomous, and locally driven process (Cilliers, 1998; Heylighen, 2001; Teisman et al., 2009; Prigogine and Stengers, 1984). Urban studies and planning scholars consider self-organization a helpful concept in for instance understanding underlying mechanisms of urban dynamics and spatial transformations (Allen, 1997; Batty 2005; Portugali, 2000). It been applied to slum and informal urban development [Barros & Sobreira, 2008; Silva & Farrall, 2016], spontaneous emergence of patterns in traffic flows (Kerner, 1998), pedestrian movements (Helbing et al., 2001), or the emergence of civic initiatives in spatial development (Boonstra, 2015; Rauws, 2015).

The understanding and application of the concept of self-organization has however been far from uniform. To begin with, at least two schools of thought can be distinguished, respectively building on the 'hard/natural' sciences and the 'soft/social' sciences. Originally, self-organization has been well defined within the hard and natural sciences (Zhang, 2016). Starting with the work of Ashby on cybernetics and investigators entangled in their own systems of observation (Ashby, 1947), this scholarship has been expanded by amongst others the mathematical work of Hermann Haken on synergetics (1977), the study of thermodynamic systems in states of becoming by the Prigogine Group (Prigogine et al., 1977), and the work of biologists Maturana and Verela (1974) on the reproduction and self-maintenance of ecological systems. The perspectives on self-organization offered in these studies, have been translated into research on, for instance, infrastructure systems and urban networks (Batty & Longley, 1994; ADD), evolution of cities (e.g. Allen, 1997; Portugali, 2000; Batty, 2005), and urban planning and design (e.g. Engelen et al., 1993; Batty, 2007; Yamu & Frankhauser, 2015). Many of these studies build on quantitative, analytical models, addressing power laws, fractals and the like in simulating urban dynamics. Reflecting on the development of Complexity Theories of Cities, Portugali (2011) distinguishes at least four achievements: a theoretical basis for understanding the emergence of networks out of local interactions, acknowledgement of circular causality and non-linear effects, attention for the self-maintaining and self-renewing capacity of cities, and the importance of diversity and variability for urban vitality.

At the same time, serious efforts have been made in addressing self-organization from a soft and social science perspective, as such contributing to a more profound understanding of 'social complexity'. In various contributions, self-organization is seen as an explanation of the spontaneous emergence of a collective social result, for instance social norms, a new dominant discourse, a social organization, out of the interactions by and communication between individual agents. Examples are the work of the sociologist Luhmann (1984; 1997) on society as a self-referential system consisting of several 'structurally coupled' subsystems, Giddens' structuration theory on the dialectical relationship between self-organization and institutional rules, individual actions and institutions (Giddens, 1984) and the work of Fuchs (2003) on the emergence of social movements. These studies have inspired planning scholars in the role of frontrunners in the transition towards renewable energy (Frantzeskaki et al, 2013), rethinking interactive planning approaches (Van Assche, 2007) and analyzing dilemmas in heterarchic governance processes (Jessop, 1997). These and similar studies often have a qualitative and often explorative nature, focusing on narratives, discourses and power-games, addressing the qualitative issues of complex agents (Portugali, 2011), but according to Byrne (1998) and Byrne & Gallagher (2014) can have a quantitative dimension as well. WIDE RANGE OF METHODS in VARIOUS DOMAINS (Byrne & Gallagher, 2014; Byrne, 1998).

The two views on self-organization originating from the 'hard/natural' and the 'soft/social' sciences are often considered fundamentally different. Whereas 'hard/natural' self-organization is understood to result in the spontaneous emergences of (often physical) patterns in space, 'soft/social' self-organization is understood to result in the emergence of forms of human organization or coherent groups of people without central coordination. We argue however, that this divide between the human (social) versus non-human (natural) world is problematic to planners. Because human settlements – the main concern of spatial planners – are not mere natural phenomena, nor only physical and materialist entities. Human settlements, including cities, are artifacts with agents – and their actions and behavior are products of intentions, plans, social and cultural norms, political pressure etc. (Portugali, 2011). As such, cities require a hybrid understanding. Moreover, a divide between the natural and the social ignores the holistic perspective that is offered by the complexity sciences. As advocated by Urry (2003; 2005a; 2005b; 2006), complexity sciences stress the importance of objects and nature as part of our social worlds, making an analytical division between nature, objects, people, social systems undesirable. Complexity sciences intrinsically address processes of spatial ordering (Thrift, 1999), but also related to the dynamics of a rapidly changing environment, urban life, and changing societal opinions (Van Wezemael, 2012: 93-94; De Roo et al., 2012: 2). Hence, a complexity perspective can assist planner in reuniting the material world and the social world, offering an integral and rich account of the issues they deal with.

Therefore, we do no longer wish to continue on the distinction between hard/natural and soft/social sciences. We do however acknowledge that the interpretations and the subsequent use of complexity – and more specifically self-organization – can differ significantly among scholars. The aim of this paper is therefore analyses the interpretations self-organization at a deeper level, looking at the epistemic traditions in complexity and their ontological bases. In the first part of the paper, we explore the different interpretations of complexity by elaborating on the two major epistemic traditions that have emerged within

the theories of complexity since the 1970s (Hillier, 2010), one from a Critical-Realist ontology and one from a Post-Structuralist ontology. We identify the key characteristics of self-organization mechanisms in accordance to these epistemic positions, and discuss their implications for understanding spatial transformations and related planning interventions. We illustrate these differences along the example of a regenerated shopping street in the city of Rotterdam, the Netherlands. In the second part of the paper, we once again exemplify the differences between the two epistemic positions, but we also start to explore their complementarity. We speculate on how to turn the two positions into consistency with one another – meaning how they can mutually reinforce each other without losing their individual epistemic strengths. Based on this exploration we suggest planners to act adaptively and differentiate in style in response to the situation at stake, among others by means of pattern recognition. On a conceptual level the paper shows how planning scholars can make sense of the diversity of ongoing processes of self-organization in the context of spatial transformations.

2 THE CRITICAL-REALIST EPISTEMIC TRADITION

2.1 A CRITICAL-REALIST PERSPECTIVE ON COMPLEXITY

The first ontology that stand behind a specific understanding and application of self-organization is critical-realism. To elaborate on this ontology, we draw on the work of Roy Bhaskar and scholars that further expand his proposal (Sayer, 1992; Collier, 1994). Critical realism embraces the idea that reality has an objective existence outside human construction and cognition (Layder, 1990; Danermark et al., 2002). Critical realists, however, also postulate that knowledge about reality is not directly available to us, but is produced by knowable actors in the social world (Pratt, 1995). For this reason they oppose a view on 'knowledge' as something fixed and pre-determined. Instead knowledge is considered to be subject to revision and modification, mediated by filters of language, sense making and social conventions. Descriptions of reality are affected by both the conceptualizations, values and interests of the observer (i.e. the researcher) and those that are observed (i.e. actors that are part of processes of self-organization) (Danermark et al., 2002). According to Bhaskar, system boundaries drawn by observers are always artificial and limit the possibility to gain a comprehensive understanding of how the system functions. As such, explanations of reality are considered partial at best.

But despite the mediating role of human interpretations, the understanding of reality can still be enhanced through research. Considering the complex social world critical realists take the position that an intersubjective account of reality can disclose some of its real complexity (Alvesson & Sköldberg, 2009). Critical realists aim to confront explanations of reality with human perceptions and experience in order specify, adjust, reject ideas on the structures and mechanisms that give shape to reality (Danermark et al., 2002). Bhaskar distinguishes three layers in how one can understand the world; the empirical, the actual and the real (Sayer, 2000). The first concerns personal experiences, the second is about the events, processes and behaviours that are subject to observation. The third level is the domain of the underlying mechanisms that produce these events, processes and behaviours. It is especially this third layer that is of scientific interest to critical realism: the observation, research and analysis of the mechanisms underlying the occurrence of reality (Gerrits, 2012). But in contrast to universal truths, critical realists regard generalisations of causes and mechanisms to have a limited scope in space and time. Any generated knowledge is local, and explanations are understood to be contingent, meaning they are temporal in time and local in place (Byrne, 2005; Gerrits, 2012). Temporal cause and effect relations do exist and can sometimes even be known, but the potential conjunction between local conditions and recurring patterns does not necessarily imply any general laws (Gerrits, 2012).

To conclude, critical realists depart from the position that reality exists outside human construction, but that this reality can only partially and temporarily known. The subjective interpretations of reality, the impossibility of comprehensively mapping a system, and the changeability of relations, imply that knowledge includes provisional explanations of what generates, produces or enables certain events (Sayer, 1992). This critical realist ontology fits well the complexity theorists attempts to search for causal relations between events and elements, while acknowledging that complexity is a real, non-constructed, property of the social world, and since it is emergent through interaction, as such non-decomposable. Reality and complexity cannot be compressed without losing some of its aspects (Gerrits, 2012; Morcol, 2001).

2.2 CHARACTERISTICS OF SELF-ORGANIZATION FROM A CRITICAL-REALIST PERSPECTIVE

A critical realist perspective on self-organization is offered by theories on complex adaptive systems (CAS). CAS theories have been developed within the hard sciences, such as physics, chemistry and mathematics, which traditionally embrace a positivist view. However, moving beyond linear causality and full determinism means that the positivistic ontology does not provide a sound basis for CAS theories. The ambitions of positivists to identify universal laws and mechanisms, to produce universal frameworks of understanding and to assume a high degree of predictability, are considered unrealistic in complex world. In contrast, complexity science emphasizes the changeability of relations and configurations, complex causality and a high degree of unpredictability. Therefore, Archer et al. (1998) and Danermark et al. (2002) argue that CAS theories require a critical realist stance, or what some refer to as a complex realist stance, as a synthesis of critical realism and complexity science (Reed & Harvey, 1992; Byrne, 1998; Gerrits, 2012).

In CAS theories self-organization processes have a prominent role. They are considered to be a key mechanism in the system's adaptive capacity. It involves the spontaneous transformation of a system due to the uncoordinated interactions between system's elements or actors. This means that through their behavior, actors or elements unintentionally contribute to a change of structure or function on system level. Self-organisation from a CAS perspective includes the spontaneous formation of patterns or structures at a global level out of the interactions between agents at the local level (Heylighen, 2008). Hence, the 'self' of self-organisation refers to the 'unplanned' emergence of organisation 'by itself' or 'spontaneously' (Rauws, 2016). In this process of spontaneous organisation various phases can be distinguished: 1) the occurrence of a symmetry break, (2) reaching a critical point, (3) followed by a non-linear process of adjusting behavior by independent agents, resulting in (4) spontaneous patterns emerging at specific times, revealing the complementary actions of all agents together (De Roo, 2016; Rauws et al. 2016).

Complex adaptive systems are considered as open systems, being sensitive to changes in their environment, that evolve through feedback and feed-forwards loops with sub-systems and supra-systems (Holland, 1995; Wolfram, 2002). This means that these systems are dynamic as they continuously adapt to their environment, resulting in non-linear trajectories of development. Self-organize happens through feedback loops that either stabilize or disrupt the system. Feedback loops can be positive, when they reinforce and amplify initial changes, and lead to dynamism (also called feed-forward loops (De Roo, 2012)). Feedback loops can also be negative, when the reaction of the system is opposite and suppresses the initiated change. Such feedback loops lead to stability (Teisman et al., 2009: 12; Heylighen, 2001: 8-9).

Whereas critical realism allows for the acknowledgement of subjective interpretations of reality, the impossibility of comprehensively mapping a system, the changeability of relations, and the contingency of knowledge, it does study these feedback loops and emerging patterns, and searches for contextual conditions that explain this emergent behaviour.

2.3 A CRITICAL-REALIST PERSPECTIVE ON SELF-ORGANIZATION IN CITIES AND PLANNING

With the aim to better understand the volatility and interconnectedness of urban systems, also planning scholars have adopted CAS theories in analyzing the development of neighborhoods, cities and regions, as examples of such self-organizing complex adaptive systems. The critical-realist perspective is evident in the way CAS theories are used to explain the emergence of urban form (Thrift, 1999: 32). Well-known examples can be found in the work of Peter Allen (1997; 2012), Paul Krugman (1996), Michael Batty (Batty, 2005; Batty, 2013; Batty & Marshall, 2012), Bill Hillier (2012), and Juval Portugali (2000; 2006; 2011; 2012a; Alfasi & Portugali 2007). What is common to the various applications is that they connect to the epistemology of the Santa Fe-tradition. All concern the emergence of large-scale, macro-structures from the interactions between individuals and collective entities. For instance according to Allen (who was, for a time, part of the Prigogine group in Brussels (Thrift, 1999: 32)): "Spatial structures of cities, regions, and urban networks emerge from the continuous interaction between individuals, their goals, their aspirations and the macrostructure that they have allowed to emerge" (Buijs et al., 2009: 97). According to Portugali (2000), the city is a reciprocal product of the initiatives of actors, influenced by personal/individual motives (caused by their environment) versus spatial developments that are in their turn the product of

collective actions. The outcomes of such self-organizing processes manifest themselves in specific urban forms and patterns (morphological or functional), physical growth, the emergence of new socio-spatial groups as a result of geographical settings or characteristics such as houses, lots, and housing blocks (Portugali, 2000), or the spontaneous emergence of economically specialized districts (Krugman, 1996). Other examples are the spontaneous emergence of patterns in traffic flows (Kerner, 1998, Chowdhury & Schadschneider, 1999), pedestrian movements (Helbing et al., 2001), urban land transformation (Webster & Lai, 2003, Barros, 2005), and informal settlements (Silva & Farrall, 2016). (Wagenaar, Gerrits, Rauws, Bettencourt; Weidlich, Helbin; Pumain; Batty, 2013).

In this understanding of complex adaptive systems, both the physical aspects (e.g. infrastructure, buildings or transport vehicles) and social aspects (e.g. organisations, actor-networks or institutional codes) of self-organizing processes, are considered as properties of a real world. Sense making by actors greatly enriches the dynamics of these urban systems (Portugali, 2011). There is no collective ambition amongst actors to establish a transformative change though. Instead, the emergence of new spatial and/or institutional configurations is a result of actors that act on the basis of individual ambitions, but nevertheless produce a collective output. The nonlinear aspect of self-organization relates to the uncertainty to what extent a spontaneous pattern will emerge: will there be a minimal response, or will the pattern be massive, or will it be something in between. No one can tell.

The incentives for feedback and feed-forward loops are seen as part of the system, and can come from both individual citizens and professional planners. Professional planners, and their predictions and plans, can make the plan and reality bend toward each other (Portugali, 2012b: 231), and intervene when self-organizing processes head in an undesired direction (Krugman, 1996; Rauws, 2015). This leads to a planning in which pattern recognition and condition planning are crucial. The recognition of emergent patterns at a system level should reveal any underlying structures, which can then be influenced by changing conditions to such an extent that the outcomes of the self-organizing processes can be steered towards a socially desired direction (Rauws, 2015).

3 THE POST-STRUCTURALIST EPISTEMIC TRADITION

3.1 A POST-STRUCTURALIST PERSPECTIVE ON COMPLEXITY

The second ontology that leaves its marks upon the understanding and application of self-organization is post-structuralism. Post-structuralism is a philosophical and sociological thinking that is not necessarily a coherent whole to be captured under one denominator, but much more a complex web of thoughts and mutual influences. The work of several, predominantly French thinkers in the second half of the twentieth century can be considered as its' core: Gilles Deleuze, Michel Serres, Jacques Derrida and Jean-François Lyotard (Ieven et al., 2011; Belsey, 2010). An important threat that runs through the work of these thinkers is the explicit rejection of representation. Representation is simply impossible, according to Deleuze, due to the complexity and heterogeneity of relationships (Romein et al., 2009: 60). It is therefore not the thing or its representation that deserves attention, but rather its becoming, individuation, and differentiation. The only way in which representation is interesting, is when it is performative, when the representation is a becoming in itself that affects and encounters (Posman, 2009; Huyghens, 2009; Oosterling, 2009). This also resonates with Lyotard's notion of presence and representation. According to Lyotard, representation of the real is impossible due to the heterogeneity of meaning: Of what is meant, who means it, and to what the meaning is assigned. According to Lyotard, looking for representation is nothing more than an attempt to achieve the impossible, namely to bridge all these irreconcilable elements (Parret, 2011). In the world, becomings are happenings, and it is these happenings that people communicate about and seek representations of, in order to transform this elusive happening in the here and now into a conceivable presence that can last. However, these representations themselves are also happenings that become and affect. For instance, an artwork is interesting not so much for what it represents, as for what affects it induces by being present at a certain time and place. This is what both Lyotard and Deleuze regard as post-representational (Parret, 2011). In other words, for the post-structuralists, truth in society is not so much an issue, but the appearance of it is (Belsey, 2010).

Between post-structuralism and complexity theory strong resonances exist, especially between the works of Ilya Prigogine, Gilles Deleuze, Michel Serres, Jacques Derrida, Jean-François Lyotard, Bruno Latour

and Isabelle Stengers (Cilliers 1998, Thrift 1999, DeLanda 2002, 2006, Morçöl 2005, Hillier 2007, Van Wezemael 2012). Although Deleuze has been criticized for not fully understanding the terms from the natural sciences he was making use of, the natural sciences – including the work of Ilya Prigogine and Isabelle Stengers – have been a major sources of inspiration for his work (Thrift, 1999; Prigogine & Stengers, 1979; Christiaens & De Ronde, 2009). Deleuze's notion of the "fold," for instance, has linkages to the "refiguring of 'internal' and 'external' processes" that complexity theory makes use of (Thrift, 1999: 56). Complexity notions are also apparent in the work of Jacques Derrida (Cilliers, 1998). Notions of difference, becoming, and order not as a law but as exception and emergent property, are crucial elements in these post-structuralist works (Thrift, 1999).

3.2 CHARACTERISTICS OF SELF-ORGANIZATION FROM A POST-STRUCTURALIST PERSPECTIVE

Even though the notion of self-organization is not so explicitly used within post-structuralist thinking, the shared ontologies between complexity and post-structuralism (Van Wezemael, 2012; Hillier, 2007: 54) allow the development of a post-structuralist understanding of self-organization as well.

Self-organization from the post-structuralist perspective would then refer to what could be called the emergence of a relational "self". According to Deleuze, individuals and their identity are historically constituted entities, which are not a given but are defined progressively (DeLanda, 2002, 10, 26). The emerging self thus never stands alone, but exists and co-evolves within a network of relationships and interactions, 'always playfully changing in an unpredictable way' (Cilliers, 1998). Moreover, according to Lyotard, individuals and their identity, the selves, are constructed in a web of meaning and relationships: "A self does not amount to much, but no self is an island; each exists in a fabric of relations that is now more complex and mobile than ever before." (Lyotard, 1984). Also Derrida elaborates on how we distinguish ourselves and our surroundings: by describing what it is not (difference), by remembering the absences and that which has been excluded (trace) and by relating to what it resembles (la meme) (Berns, 2011). The self thus never stands alone, but exists and co-evolves within a network of relationships and interactions.

One way of describing the emergence of such relational selves is by actor-network theory (Callon and Latour, 1981; Callon, 1986; Law, 1986; 1992; Latour, 2004; 2005), as this theory describes how actor-networks evolve from fairly unstructured beginnings (comparable to the lack of central agency, distributed control, and dynamic boundaries from the complex adaptive systems) into organizational closure, placing emphasis on the relationships that constitute the network (Cilliers, 1998: 112). Actor-network theory can be considered as post-structuralist as it does not take the system as a starting or an end point. Instead, processes are understood as ever-evolving and performative, in a constant process of making and remaking, without clearly identifiable beginnings, delineations, final ends, or outcomes. Instead of seeking an underlying truth or structure of systems, the post-structuralists rather focus on relationships that constitute systems – or preferably: actor-networks. Systems or actor-networks are performative, and meanings and actions proliferate in unexpected ways, depending on the relations being established (Murdoch, 2006).

An actor-network is formed along a process of translation. This process happens in four sequential steps, described by Callon (1986) as problematization, interessement, enrolment, and mobilization, and by Latour (2004) as perplexity, consultation, hierarchization, and institution. The problematization phase refers to the first phase in the emergence of an actor-network. An actor delineates a problem, and aims at making others see this problem too, and convincing them this problem needs to be addressed by new ways of doing, or a new type of knowledge or organization – a new self becomes visible and renders identity. The next phase is interessement, a phase in which the initiating actor looks for allies, and tries to establish connections between them and the network. By this, validity is given to the problematization and the alliance it implies – the new self acquires credibility. The third phase is that of enrolment, in which the specific roles of the interested actors are negotiated, consolidated, and defined. A common identity is determined and set – the new self acquires stability. During the subsequent fourth phase, the end result of translation, mobilization, the actor-network has proven to be strong enough to remain together and can now exercise the power to follow through. A new type of order has emerged, one in which certain entities within the network control the others – the self is being recognized and acknowledged, and is no longer

questioned. The actor-network has become a black box, whose content is taken for granted (Latour, 2004; Callon, 1986). From here, new translations will start again, either when the black box starts becoming an actor in itself, or when the black box is opened due to changed circumstances. Then, a new problematization phase will emerge. The focus of these actor-networks is therefore not on stability, nor on the individual elements within an actor-network, but on the action of actors in the associations they form. Boundaries of an actor-network are emergent and performed, and impossible to specify, as inside and outside continuously shift along the various phases of translation (Cilliers, 2002: 82; Hillier, 2012: 58-59).

The perspective of self-organization adds a dimension to the translation in actor-networks is that emphasizes the “self” of an actor-network. Instead of merely following and tracing ever evolving actor-networks with all their fluidity, openness and transformability, and without clearly delineating any boundaries of the actor-network. The emphasis on the self enables to see some of the internal drivers, the matters of concern and the intentionalities of the actors that operate within, or work on constituting an actor-network. Self-organization as a process of expanding a self, and appropriating an environment in favor of the establishment and maintenance of the self.

3.3 A POST-STRUCTURALIST PERSPECTIVE ON SELF-ORGANIZATION IN CITIES AND PLANNING

From the post-structuralist perspective, the study of self-organization is not concerned with emergent patterns or conditions, but rather by the interactions among people, things, places, goals, etc. and the materialities, consolidations and affects created by these interactions. This wide-open process of self-organization leads to frequently changing structures, dependencies, and interactions, which are often only temporary, set up for a particular reason. Lack of centralized control then refers to the multiple actors involved in projects, developments or initiatives, of which each one has some degree of power to act, invest or withdraw, and to appreciate and enjoy the benefits of any results (cf. De Roo, 2012: 159). Self-organization is not a property of the system as a delineated entity, but the expression of the interactions and relationships between individual actors and non-human factors that over time form networks around specific situated issues.

In a post-structuralist view, spatial planning and governance are seen as performances of representation – and not seeking representations or underlying structures per se. The performer and the context of performance are entangled in heterogeneous processes of spatial becoming, performance of social practice and space go hand in hand (Murdoch, 2006). Self-organizing actors are actively engaged in producing representations and becoming of representations as attempts to understand and influence spatial becomings. Translations happen when an initiative, project or actor aims at achieving or changing something in the environment, adding new activities, new uses and new physical objects to an existing spatial configuration. And as the actor-network perspective includes human and non-human elements, both the people who were important in the materialization of an initiative as planning-related factors, such as a site, architecture, planning documents, procedures, legal settings etc are addressed. Spatial planning itself can be seen as a process of network-building, in which entities of various kinds are assembled in ways that allow the network to undertake certain functions (Boelens, 2009; 2010).

The perspective of self-organization as emergent actor-networks for spatial initiatives opens up to an understanding of various networks which are planning simultaneously. When translated to planning, this post-structuralist view on self-organization can be used to explain ongoing struggles to establish meaning, identity and over whose reading of space should take priority. The focus lies on transformations, and the identification of actor-networks and trajectories through which various actors are forming relational space – and relational selves. From there, collective creations emerge over time, influenced by power laden and relational stakeholder networks (Innes & Booher, 2002; 2010), politics that intersect in improvised practices and performances, and affect (such as emotions, desires, imaginations) and – following Deleuze & Guattari’s notion of the way in which any conceptualization comes with its creators’ unique signature – with the specific style brought in by individual and collective actors (Hillier, 2007: 223; Deleuze and Guattari, 1991). As such, the post-structuralist perspective on self-organization as the establishment and emergence of relational selves in the context of spatial becoming and spatial planning, also opens up awareness of spatial actors and interventionists to the individual level and role of the individual – including

the individuals styles and affects felled and performed among and between actors. It opens up an awareness of the situational context, felled and experienced in the here and now.

4 ILLUSTRATION: THE TRANSFORMATION OF THE NIEUWE BINNENWEG, ROTTERDAM

We can further clarify the two epistemic perspectives with the empirical illustration of a urban transformation in the city of Rotterdam in the Netherlands. In the center of the city, we find the Nieuwe Binnenweg. The best days of the Nieuwe Binnenweg directly followed after the Second World War. Whereas bombings had devastated the city center of Rotterdam, major shopping facilities settled on this street which connecting the devastated city center with neighborhoods that had survived the bombings. When in the decades that followed the city center was step by step rebuilt, the Nieuwe Binnenweg gradually lost its function as central shopping destination. At the beginning of the 2000s, this street had become strongly deprived (Naafs, 2012). The main economic activities that took place in the street were sex and drugs related, and the street had turned into a hot spot for criminal activities. Most of the real estate located on the street was privately owned, and occupied by entrepreneurs who solely focused on their own (short term) profits. Many buildings were vacant and the public space was badly maintained. The public authorities mainly targeted their interventions and investments toward the surrounding streets and residential buildings (social housing). The street itself had turned into an area which residents and visitors of Rotterdam avoided.

Today, however, the Nieuwe Binnenweg stands as an attractive shopping and business street again. Economic activity on the street has a hybrid contemporary character: entrepreneurs mix shopping, business, hospitality and community activities, are specialized in sustainability, local production, design and lifestyle, vintage and re-use. The entrepreneurs in the street share a strong collective identity, which radiates to its surrounding area and has made the neighborhood much more attractive, not only for entrepreneurs and visitors, but also for residents. Analyzing this transformation process helps to further clarify the different readings that critical realism and post-structuralism offer, as well as the practical implications these two different readings bring to planners.

4.1 THE TRANSFORMATION OF THE NIEUWE BINNENWEG FROM A CRITICAL-REALIST POSITION

What happened in between halfway 2000s and today, can be described according to the critical-realist understanding of self-organisation from a CAS perspective as follows. What happened in between halfway 2000s and today, can be described according to the critical-realist understanding of self-organisation from a CAS perspective as follows. After the deterioration that set in when the newly build city center of Rotterdam became completed, several conditions started to trigger its regeneration. A new policy was instated in Rotterdam with a zero-tolerance attitude towards (street) crime and drugs related nuisances. Major spatial interventions in the city (including the rebuilding of the city center and the transformations of major former harbour areas) were declared finished and the attention of the city drifted elsewhere. Just before the financial crisis hit in, economically the city center of Rotterdam started to do really well, and the Nieuwe Binnenweg cautiously started to profit from this developed as well. And when the financial crisis did hit in, the Nieuwe Binnenweg had enough empty buildings to accommodate new and experimental economic activities (sharing economy, cooperative work spaces, pop-up shops etc.) against low rent or no rent at all. One of the major characteristics of the Nieuwe Binnenweg was the dispersed private land ownership – in contrast to the surrounding streets that mostly accommodate social housing – giving the local authorities limited space for manoeuvre to invest and intervene in a way that tackles deterioration.

The street appeared to regenerate itself through a series of uncoordinated and relatively independent actions by the public authorities, by various, individual shop-owners and by local community groups. Some decorated the public space, others transformed the function of their shops from retail to food and beverage, and again others organized social events to attract new visitors to the street. These activities and investments were triggered by a symmetry break (e.g. the rise of online shopping/changing in rental legislation/economic crisis). Over time, these actions result in changing spatial patterns on a wider scale,

resulting in a structural change of the function and structure of the street (e.g. the shopping street becomes a public 'living room'/ street in decline to hipster hang-out). Typically, structural change is unpredictable in the sense that it cannot be deduced from the sum of all actions. Also, the activities and investments were not centrally coordinated, let alone that they are part of a blueprint plan for the revitalisation of the street. Hence, a CAS perspective on self-organisation emphasises the spontaneous and emergent character of structural change of urban systems by analysing processes of pattern formation.

In the context of urban development, the critical-realist CAS perspective on self-organization thus implies the absence of a collective ambition amongst actors collectively to realise a particular urban transformation. Instead, the emergence of new spatial configurations is mainly driven by actors' actions that are based on individual ambitions. Therefore, this type of self-organisation covers the emergence of urban developments out of uncoordinated and relatively independent actions (e.g. transformation of a shop into a bar or café) by multiple actors (e.g. shop owners). These actions are a response to a trigger for change (e.g. the rise of online shopping). Over time, these actions result in changing spatial patterns on a wider scale (e.g. the shopping street becomes a public 'living room'). Typically, these patterns are unpredictable in the sense that they cannot be deduced from the sum of all actions. Thus a complexity-inspired understanding of self-organisation, from here on simply referred to as self-organisation, emphasises the spontaneous and emergent character of urban developments.

Conditions were created to attract new businesses. Businesses with a creative or hybrid profile were given start-up funding, and real estate owners were encouraged to lower their rents – arguing that vacancies would be more costly than low-rent use. Also conditions were created that would stimulate real estate owners to renovate their buildings, by giving them a choice: either renovate your building, or sell it to a collective trust. In both cases, the real estate owners would be financially compensated with municipal funding (Interview Frank Belderbos, 2014).

Slowly, a new mix of craft industries, design shops, hubs for creative entrepreneurs, bars and lunchrooms and other hybrid economic activities, often in combination with on-line businesses, and highly attractive to young urban residents emerged (Interview Frank Belderbos, 2014).

4.2 THE TRANSFORMATION OF THE NIEUWE BINNENWEG FROM A POST-STRUCTURALIST POSITION

What happened in between halfway 2000s and today, can also be read from a post-structuralist perspective of self-organization. Then, the transformation of the Nieuwe Binnenweg would foremost be described as a matter of relationships being established in order to establish a sense of a collective self among actors and factors in and around the street.

Actors actively engaged in making representations started in the early 2000s, when several businesses who identified themselves as the "remaining decent businesses" (in furniture and quality food) in the western part of the street started to address the deterioration of the street to the municipality, while pleading for policy to improve the connectivity of the street to the city center (Interview Frank Belderbos, 2014). Meanwhile, in the eastern part of the street (closer to the city center), several businesses started to address the same concerns. However, instead of addressing the municipality directly, they first made attempts to establish networks among themselves. The owner of a shoe store wanted to renovate her building, and managed to get the neighboring shop owners on the same line, and enrolled a well-known architect to draft a renovation-plan. Based on this plan, the municipality was asked to co-finance the renovation, to which the municipality surprised but happily applied with a funding mechanism for civil initiatives. From there, other interactions between the municipality and the local businesses emerged as well: a local hairdresser learned that the transport-agency planned a renovation of the tram-line, a year before the municipality planned the renovation of the street and pavement. He managed to organize a simultaneous renovation, and knew how to engage the restaurants and bars in this part of the street to take the opportunity to expand their terraces, bringing increased activity to the street. Other networks established between the local businesses, the city authorities and other shopping areas in and around the city center emerged as well – both in the form of city-wide events as in the form of structural deliberations. In 2011 the local businesses in the eastern part voted in favor of a Business Improvement District (Naafs, 2012).

In the western part of the street the local businesses were less organized (the local business association was run by the sex-industry and showcased little concern on the quality of the street itself), and the problems of deterioration were much more significant. Here, the municipality became an active stakeholder in establishing networks with and among businesses, helping them to bring forward their ideas and to develop a sense of collective identity. First, in 2002, a “safety-agent” was posted in the street. His main job was to establish networks among businesses, residents and diverse departments within the municipality in order to organize projects that would increase the safety, sense of ownership and livability in the neighborhood. In an empty building on the Nieuwe Binnenweg he established a meeting-center for businesses, he gathered ideas and opinions about the street and tried to stimulate both residents and businesses to take initiatives that would improve the neighborhood (Interview Marcel Dela Haije, 2013). In 2008, a “regeneration-agent” was posted in the street as well. His main job was to interest the local businesses to participate in a collective regeneration-program – targeting both the renovation of the individual buildings as the refurbishment of the street and its public space. For this, not only networks had to be established among businesses and residents, but also with the transport agency and the local housing associations, and with European funds that would complement the financial resources the municipality could offer (Interview Frank Belderbos, 2014). Efforts were also made to strengthen the – at first hardly active – business association in this part of the street (Interview Frank Belderbos, 2014; Interview Marcel Dela Haije, 2013).

During this period, both actors from the western and the eastern part of the street actively engaged in making representations of the street, in attempts to create a sense of a common identity that would also generate a new image of the street to outsiders: the ragged, messy, rough but at the same time cultural, stylish and diverse character of the street – highlighting the authenticity of the street in comparison to the more mainstream and commercial city center. In the eastern part, the businesses engaged in art projects, organizing events, advertisement and marketing – all to give extra exposure to the street and its businesses (Naafs, 2012; Interview Frank Belderbos, 2014). In the western part, the safety-agent, the regeneration-agent and a retail-manager – together with and sometimes even on the initiatives of local businesses and residents – engaged in attracting additional creative businesses, bars and restaurants to the street, but also facilitated art-projects such as poetry on buildings, the production of books about the street and the neighborhood, and the organization of events (Interview Frank Belderbos, 2014; Interview Marcel Dela Haije, 2013). From a post-structuralist perspective, these representations also account as performances and happenings through which new affects are created among actors.

Today, the Nieuwe Binnenweg has a much more solid image to outsiders, and the street and its economy have become more nested in the surrounding neighborhood – no longer being a nuisance to the neighborhood, but its main attraction instead. Moreover, among the businesses a sense of collective identity has emerged that is performed through two solid and active business associations that work in close cooperation with the city authorities (Interview Frank Belderbos, 2014; Ondernemersvereniging Binnenweg, 2010). However, this identity is not something given, but something that needs to be maintained and continuously developed further. Today, the focus still lies on establishing relationships. Not only in maintaining the business associations and their relationships with the city authorities, but also on improving the interactions and relationships between the eastern and the western part of the street – that somehow got to share the same collective identity but are not necessarily well-connected in their governance (Interview Frank Belderbos, 2014; Interview Marcel Dela Haije, 2013).

In addition to this account largely focused on the process of establishing relationships and a sense of a collective self through the creation of representations, this post-structuralist narrative on the transformation of the Nieuwe Binnenweg also illustrates the before mentioned ongoing struggles over whose reading of space takes priority, and the importance of style. The struggle over whose reading of space takes priority is for instance evident in the western part of the street, where local businesses had to be convinced from scratch on the benefits of a collective approach to the street – as opposed to their usual way of pursuing mere individual interests. It is also evident in the attempts undertaken by several actors to transform the image of the street from sex-industry, drugs and criminality towards creativity, culture, style and urban activity – by forcing out businesses who did not fit to that latter image. A third struggle over reading of space takes place in the eastern part of the street. Here, the initial positive cooperation between the local businesses and the municipality was damaged when the local businesses started to develop a different vision on the future of the street than the municipality. Whereas the municipality blamed the local businesses for not taking into consideration the entire neighborhood and accused them of a lack of professionalism, the local businesses blamed the municipality for taking its hand and responsibility away

from the street now that the established Business Improvement District was generating its own financial resources – and thus damaging the still very fragile economic profile of the street (Naafs, 2012).

The importance of style becomes evident as the actors involved in the transformation of the Nieuwe Binnenweg describe their own activities and attitudes. They all describe their work as a continuous pushing, pulling, networking and communicating, trying to establish connections. But perhaps even more importantly, all emphasize the importance of encouraging ownership, intrinsic motivations and initiative among others than themselves, stating that their role should eventually be no longer necessary (Interview Frank Belderbos, 2014; Interview Marcel Dela Haije, 2013; Naafs, 2012).

5 COMPARING THE TWO APPROACHES

Following these descriptions of a critical-realist and a post-structuralist understanding of self-organization would be, and what it would mean for planning, at first hand the understandings indeed seem to be fundamentally different and therefore perhaps also incompatible (see table below).

Critical-realism / CAS	Post-structuralism / STS (ANT)
Reality has an objective existence outside human construction & cognition	Rejection of transcendence, the social is constructed
CAS – Complex Adaptive Systems	STS – Science and Technology Studies (Actor-Network Theory)
The “self” of self-organization refers to “by itself”; spontaneous emergences within a system	The “self” of self-organization refers to the emergence of a relational and networked self
Individual uncoordinated actions lead to unintended unforeseen collective outcomes; the planned versus the unplanned	Multiple actor-networks are planning simultaneously, struggling over whose reading of space takes priority

Indeed, the literature claiming that the critical-realist and post-structuralist understandings of complexity are incompatible, is redundant. To put it more bluntly, accusations fly back and forth between the two ontologies. Whereas critical-realist do call into question the claim of value-free observations, they distance themselves from – in their words – postmodern view that denies a coherent, unified real world (Alvesson & Sköldberg, 2009). By some, the post-structuralist understanding of complexity is even called “fashionable nonsense” and “an abuse of science” (Sokal & Bricmont, 1999), accusing the post-structuralists of abusing strict mathematical entities, or physical and brain processes such as chaos, entropy, order, disorder as mere loose metaphors, in city planning leading to nothing more than architectonical kitsch (Portugali, 2011). Another accusation made at post-structuralists is that in a post-structuralist perspective on cities nothing is stable, true or that nothing matters for more than a second (Portugali, 2011). On the other hand, protagonists of the science and technology studies are caustic against any sciences who speak of the “world” or “nature” independent of relationships, and accuse them of “pretentious arrogance” and “narrowmindedness” (Stengers, 2003: XX). Such scientists, according to Stengers (2003), refuse to see themselves as part of the ‘event’ of science. Bruno Latour adds to this his AFKEER of researchers who either take social aggregates (which system definitions essentially are...) as a given and that subsequently look for underlying structures or contextual conditions that explain its emergent behavior. According to Latour, such conditions and structures explain nothing, and the only thing they do is that they abstain actors and make them irrelevant: actors only fulfill a function, they simply realize a potential that was already there as any agent in the same position would be forced to do the same. As such, research based on such pre-assumptions tends to put a veil over what is actually happening, and will thus only come with pretentious, false or at best impartial explanations. Such research is considered by Latour as completely incompatible with his science and technology studies (Latour, 2005).

Based on the theoretical elaboration on the concept of self-organization and the subsequent empirical illustration of self-organization in urban transformation processes earlier in this paper, we can now even further deepen the divide between the two positions, and bring the divide down to five major points of difference:

Difference 1: Dynamic Systems versus (emerging) Actor-networks

Difference 2: Planner is observer of emergences versus Planner is actor in emergences

Difference 3: Unintentional non-linearity versus Non-linear intentionality

and the configurations they represent can be compared and thus help to understand the various ways in which things have come to be as they are, the various ways in which they might be different, and – with luck and the wind in the right quarter – how any intervention or changed condition might produce one possible future rather than another (Byrne, 2005). Thirdly, collective needs and desires underlie many planning interventions. One can think of cities that want to fight the consequences of climate change or which have a societal ambition to reduce urban inequalities. Thus the system level is of importance as is it at this level that some consequences of spatial developments manifest themselves and because some needs and desires are collective ones. A critical realist position on self-organization aids planners to identify possibilities to influence systems dynamics by creating conditions for development that can enable or constrain reconfiguration processes (Alfasi & Portugali, 2007; Moroni, 2015; Rauws, 2015).

However, with its focus on patterns and conditions CPR has a blind spot for the motivations underlying the behaviour of individual actors. Although CR acknowledges the importance of local interactions by agents, and the role of sense-making and perceptions, the wheeling and dealing of individual actors is easily overlooked. Emphasis is placed on the emergence of spatial form, the spatial outcome of urban development processes, and less on the actual doing and acting within these processes (cf. Portugali, 2011). Moreover, in the critical realist perspective of cities as complex adaptive systems, it is almost obvious to claim that self-organizing processes – which are often market or civic-led – especially take place in cities that do not have planning or zoning entities (Krugman, 1996). As such, the critical realist position allows – or even strengthens – a dichotomy between planned versus unplanned development, placing the planner or planning scholar at a safe distance from the actual happenings that take place (Boonstra, 2015). Lastly, a real pitfall for researchers who take a critical realist position on self-organization, is to pick social aggregates (the systems they observe) or the collective (on whose behalf they apparently act) too carelessly and without reflection. Only when – beside the study of underlying structures – sufficient attention is paid to personal experiences and events, processes and behaviours (cf. Bashar – see section 2), and thus the critical realist ontology is applied thoroughly, this pitfall can be avoided. Because as urban transformations that are fuelled by self-organization processes are a product of the interactions between individual actors, a comprehensive understanding of what drives these individual actors and how they relate to each other is crucial. To avoid the mentioned pitfall, PSP can offer a complementarity and crucial position to the analysis of urban self-organization processes.

PSP on self-organization focuses on the perceptions, associations and relations individual actors and how these feed into the emergence of actor networks. It analyses how dominant readings of reality emerge out of the interactions between actors, in turn affecting the meaning of these interactions to these actors and their consequences for their actions. PSP put emphasis on associations, actor-networks and controversies ‘in the making’.

The performative, relational-oriented view of PSP is relevant to planning in two ways. Firstly, planning is an act of intervention. The post-structuralist position takes this act of intervention seriously as it places emphasis on the actors: anyone who changes anything for anyone is perceived as an actor, and thus regarded as relevant while studying urban development processes. It is thus also open for unexpected actors, and provides insights on the interpretations and motivations of actor in relation to a specific situation. A PSP on self-organisation offers methods to identify these and trace them over time. As such it enables us to understanding how particular readings of reality are emphasised, gain influence, direct action, and are overtaken by other reading again. Secondly, PSP sees action as performative, and thus opens up to the acknowledgement of style and affect. Awareness of this enables planners to not only map the interpretations and motivations of other actors in an emergent actor-network, but also enables planners to adjust their style of operating in this actor-network. This way, the professional planner can more closely align with the involved actors and might be more effective in influencing which reading of reality will dominate over others. Moreover, in order to connect, align, and respond, one first needs to know one’s own perspective and position, and the frames through which the world is observed. Only then is one able to see others, and only then can the empathy with other planning actors grow. Frames that follow from this self-consciousness, can give actors clear and stable ambitions, and consistency to their actions, without losing the capacity to affect, to be inspiring, manifold, and flexible (Loepfe 2014; Van der Stoep 2014). Awareness of such selves and frames is especially needed in moments of uncertainty, as these selves and frames can provide a feeling of consistency. Without that feeling, “quick closures” become very probable (Loepfe, 2014: 209-210). Thirdly, PSP opens up the perspective of planners as actors within an (emergent) actor-network. Planners are not mere observers of spatial transformation processes, or

instigators of general conditions that stand far away from the individual agents within a spatial system, but become actively engaged themselves.

However, with its focus on stylist and relational performances, building only on a PSP on self-organisation would mean that the aggregated effects and collective needs and desires are largely ignored. The same can be said about the opportunities to influence these by generating enabling and constraining conditions. A PSP standpoint easily becomes relativist. And an easy pitfall is that system definitions or any form of representation or aggregations is made, even though actors in the cases continuously make these. Only when PSP is applied thoroughly, and frames, references, representations etc. are regarded as actors too, this pitfall is not taken.

6.2 SOME CONSISTENCY AT LAST

It is the complementarity of both perspectives on self-organization that motivate us to explore how diverging paths in the debate on self-organization and planning can be turned into consistency. We believe that acknowledging and utilizing this complementarity will allow scholars to more comprehensively grasp the complexities of urban self-organization processes. At the same time it offers planning practitioners a wider set of action perspectives on how they can relate to self-organization processes.

While looking again at the case descriptions of the transformation of the Nieuwe Binnenweg from the two positions, can distinguish various moves planners can take. First, the CRP enables planners to identify emerging socio-spatial patterns by recognizing early warning signals identify global trends that can function as amplifiers (Rauws, 2016). Through pattern recognition, and by looking at emerging patterns, planners can also identify global or local trends that can have a potential influence on the area of their concern. Or they can recognize and identify purely emerging trends within the area itself. Next, pattern recognition in combination with PSP enables planners to identify emerging actor coalitions that co-evolve with these patterns and map the consistencies and inconsistencies in the representations actors produce in the ongoing development process. In the light of supporting vitality and liveability of places, planners could, for instance, be concerned about the influence of particular initiatives on socially and environmentally “just” urban landscapes (Hillier, 2011). They could also be concerned about inconsistencies that emerge out of a fragmented development within a certain territorial environment (Rauws & De Roo, 2011). The way in which both global and local economic and political processes triggered the deterioration and the revival of the Nieuwe Binnenweg are illustrative.

Second, planners can anticipate the impact of these trends through condition planning, and respond to the developments by implementing rules and regulations that enable positive effects and mitigate negative ones. While such a response can be seen as reactive, planners can also proactively trigger self-organizing development processes guided by various conditions. But with help of PSP, planners do not only influence such processes from a safe distance (either from town hall or the desk in a university building), but as active agents within the local area itself. The case of the Nieuwe Binnenweg shows how important the role of those matchmaking agents can be in the actual regenerations. The case of the Nieuwe Binnenweg also shows how condition planning (financial tools to trigger individual landlords, subsidy programs for civic initiatives) and the active networking of individual agents (the safety-agent and regeneration-agent and several individual shop owners) can (or perhaps should) go hand in hand.

Thirdly, PSP makes visible how patterns become recognized and how people start behaving accordingly – the new emergent pattern becomes an actor itself. The emergent collective identity becomes acted upon – whether called enslaving principle or black box, it is no longer put into question. What PSP additionally brings into perspective is the style with which such representations are performed, or the style with which active agency within the emerging actor-networks is performed. Being open to such stylist performances, enables planners to look for more consistency in an area – consistency in the sense of moving in the same direction and a mutual strengthening of (individual or autonomous) actions and initiatives. Not because frameworks or conditions dictate such direction, but by actively empathizing with the emerging selves (be it individuals, actor-networks, projects, initiatives, collective identities, discourses etc.), and without forgetting about others’ and one’s own perceptions, intentions, representations.

Together, these perspectives for action can foster a process of continuous adaptation. After all, self-organization processes and planning rules and regulations are co-constitutive, and therefore the

development of monitoring, evaluation and learning activities is essential. By emphasizing the complementarities between the CRP on self-organization and the PSP on self-organization we do however not suggest that both perspectives should be merged. This would not only be unrealistic, as they build on different epistemological and ontological standpoints, it is also unnecessary. Planners have a strong tradition of pragmatism (cf. Dewey), focusing on 'what works', and we argue that depending on the situation at stake one perspective can be more informative than the other (cq De Roo, 2012?). Combining the two positions of CR and PS allows and perhaps enables planners to become adaptive in their ontological preferences according to the situations and challenges they face. Then, stylistic performances and pattern recognition, planners as individual agents and as the ones who create conditions can go hand in hand. And moreover, planners can start become aware of the style with which patterns are recognized, and the patterns in style that are created. This requires that planner scholars and practitioners become aware of the differences and complementarities. This paper offers a framework to boost this awareness.

However, we fully realize that propagating a combination of post-structuralism and critical realism in planning practice has quite some consequences, and it more easily said than done. Therefore we propose to continue research on the combination of the two ontologies in two ways. The first way is by including pragmatism to the combination and diversification of styles, the second way is to go deeper into the issue of representation and pattern recognition in a way that relates to both post-structuralism and critical realism. Such can for instance be found in the topic of embedded cognition.

ruicolacopt@gmail.com ; jabreu@tecnico.uLisboa.pt

1 INTRODUCTION

What drives people into a city? Some cities seem able to attract workers and residents, sometimes tourists, eventually all of these. Some are commuter towns. And some are, to some extent, in between those. Christaller (1933) considered the city to be the centre of a market area, and Lösch (1954) further elaborated on that theory. Location theories date back to von Thünen (1826), but close to the 21st century, Krugman (1991) posed a relevant question: why is it that in such a large, fertile country like the U.S.A. “the bulk of the population resides in a few clusters of metropolitan areas?”. The question was later emphasized, with Clarke (2003) and Jayne (2006) assuming postmodern cities as places of consumption.

Jacobs (1961) had long hinted at why people live in cities: “Not only do public characters spread the news and learn the news at retail, so to speak. They connect with each other and thus spread word wholesale, in effect.”. The city was presented as more than just a market centre – it was an organic system, whose complexity couldn’t be modelled at the time.

But modelling complex systems has evolved significantly, with the focus, in some cases, having shifted from “how to” to “how well”, as more data becomes available and models become more sophisticated. “What scientists really need to know is exactly how well (or how poorly) their models perform over a broad range of conditions and criteria” (Costanza, 1989). Even though results still can’t provide absolute certainties, they can prove to be relevant for research.

Therefore, this paper aims at contributing to research on modelling a complex system, by identifying factors that might explain retail spatial distribution, and analysing its effects on a city, with Lisboa being used as a case study.

Relevant insight on the subject has been provided by a number of authors, but the works of Mullins (Mullins et al., 1999) in relating households’ location and consumption spaces, Borck (2007) in linking city size and measures of consumption and social interaction, Porta (Porta et al., 2009) in modelling the relationship between street centrality and commercial density, and Sevtsuk (2014) in identifying location patterns in retail and food establishments, were essential to this paper in the way they approached data and presented results. Using density surfaces to represent data relied heavily on the work of Thurstein-Goodwin and Unwin (2000) and Batty (Batty et al., 2004), as will be seen.

The paper starts with an overview of retail spatial distribution in Lisboa, but eventually focus on neighbourhood-scale retail: amongst retail, neighbourhood-scale promotes a relevant role in aiming for more sustainable communities – it encourages interaction between neighbours, walking instead of driving, and can help generating local employment (Sevtsuk, 2014). It’s a key element of neighbourhood liveability and thus fundamental in the context of the contemporary – postmodern – city. Its resilience helps maintain a neighbourhood’s vitality (Barata-Salgueiro and Erkip, 2014).

The location of retail establishments in the city of Lisboa, in two different periods (1995-2002 and 2002-2010) is analysed, and quantitative relationships with demographic factors are therefore established. Spatial analysis is used to uncover spatial patterns, and spatial regression analysis for correlating data.

1.1 CASE STUDY

An opportunity to analyse the evolution of the retail structure in Lisboa was presented when a geo-referenced database pertaining commercial establishments, and referring to several years between 1995 and 2010, was made available by the City Council. Considering that, around that period, the National Institute of Statistics (“INE”) had conducted 3 national population and housing censuses (“Censos”), trying

to establish a relationship between commercial activity and demographic data also became feasible. Therefore, the demographic data used on the analyses refers to the censuses of 1991, 2001 and 2011 (INE, 2014, 2014a and 2014b), while for commercial data, 1995, 2002 and 2010 were used (CML, 2016).

1.2 SPATIAL ANALYSIS

A geo-referenced database of establishments containing 14.673 locations in 1995, 16.092 locations in 2002 and 17.035 location in 2010 was used to analyse spatial distribution of establishments. Establishments were compared both globally, disaggregated into “sectors” (“retail” and “restaurant”) and into 10 types of activities: Foods (non-prepared: includes groceries and similar establishments, excludes restaurants, cafes, bars and similar establishments); Personal Use Items (mainly clothing and clothing accessories); Household Articles;

Health and Hygiene items; Leisure items (sporting goods, bookshops, music stores, etc.); Repairs (all sorts of repairs); Other items (all other items non-included in the remaining types); Restaurants and similar establishments; Cafes and similar establishments; Bars and similar establishments”. The first seven types were considered the “retail sector”, while the remaining three were considered, globally, the “restaurant sector”.

A zoning system was defined considering the following:

1. Commercial locations were available as point features. Point density was used to create continuous surfaces, by calculating “a magnitude-per-unit area from point features that falls within a neighborhood around each cell” (ESRI, 2016);
2. Demographic data was available as polygon features. INE uses a zoning system of statistical subsections (“subsecção estatística”), with each polygon corresponding to a block in urban areas (INE, 2014c). Since their limits varied between 1991, 2001 and 2011, the polygon features were converted into points, and then into continuous surfaces, by using the process previously described for commercial locations;
3. Finally, a grid of 150m x 150m polygons was created (meaning an area of 22 500m², similar to the average size area of INE’s statistical subsections), to which all data was then related, allowing for an OLS-type regression to be modelled.

1.2.1 POINT DENSITY

Since data with this level of disaggregation has an “intrinsic granularity” with variables presenting “extremely high variances, with a pre-dominance of zero values and hence extremely non-normal frequency distributions” (Thurstain-Goodwin and Unwin, 2000), and considering the final purpose of modelling a regression, using continuous density surfaces presented itself as a way to both go around this problem and better identify patterns “by smoothing the data to iron out the inevitable discontinuities that take place from data that are originally represented by land parcels and/or the fine scale postal geography” (Batty et al., 2004).

Density surfaces were produced for establishments and a set of demographic indicators. In commercial establishments, density represents the number of point features found at a fixed distance (radius) around each cell, per unit area (km²). For demographic factors, the value of the variable being analysed served as the weight for each point feature.

1.2.2 COMMERCIAL DIVERSITY

To examine the diversity of commercial activity within each grid cell, an index based on Shannon’s entropy was used (Song and Knaap, 2004).

$$\text{Entropy} = - \sum \frac{[P_j \times \ln(P_j)]}{\ln(J)}$$

with P_j being the proportion of establishments of type j , and J the total number of establishment types, for each grid cell. This index varies between 1 and 0, with 1 representing a perfect balance between all J types found at cell level.

Entropy was calculated using the disaggregated data for the 10 establishment types.

1.3 SPATIAL REGRESSION ANALYSIS

Regression analysis was used to test if the location of one type of establishment relies on the presence of other specific types. For this purpose, ordinary least squares regression was used.

The purpose of linear regression analysis is, as known, to find a (linear) relationship between a dependent variable and a set of explanatory variables:

$$y = X\beta + \varepsilon$$

with data consisting of n observations, and y being vector of $n \times 1$ scalar responses, X an $n \times p$ matrix of predictors (with p being the number of predictors), and ε a $n \times 1$ vector of unobserved scalar random variables (errors).

One establishment type was considered the dependent variable (Foods), with the remaining used as dependent variables (predictors). Variables accounting for demographic factors (population, ratio of younger residents (under 13yo) and older residents (over 65)) and economic activity (with primarily non-residential buildings posing as a possible source of information for job location) were also included in the model. An additional variable, "Activity within Malls", was calculated by dividing the density of establishments located within malls by total establishment density. All variables represent densities (as explained in Point Density) or ratios of densities.

A classical OLS regression was performed, with a considerable number of variables being significant at the 99 percent level. But diagnostics for spatial dependence (Lagrange Multiplier) signalled for significant spatial autocorrelation, making the OLS results unreliable (Anselin, 2005; Sevtsuk, 2014).

To overturn the bias, a spatial lag model was used. Having set a weights matrix, the model runs an implementation of the previously mentioned function:

$$y = \rho W y + X\beta + \varepsilon$$

where y is an $n \times 1$ vector of observed dependent variables, W is a $n \times n$ spatial weights matrix that describes adjacency relationships, and ρ is the spatial autoregressive parameter (lag).

The general model fit was improved when compared to classical OLS, as was indicated by a higher value of R-squared, and analyses was made possible.

2 RESULTS

2.1 SPATIAL ANALYSIS

2.1.1 POINT DENSITY

"Eventually, a range of resolutions is necessary to adequately describe the fit of models with reality" (Costanza, 1989). Transforming points to surfaces by using point density required the choice of a radius. Smaller radii added to the resolution (but increased the difficulty in discerning patterns), and larger radii implied significant data loss (though revealing patterns that could be relevant at regional scale), as shown on Figure 1. Finally, a radius of 300m was considered appropriate, and density surfaces for commercial activity were created. Figure 2 present total establishments variation between analysed periods.

Figures 3 and 4 present the variation for the restaurant and retail sectors, as previously defined.

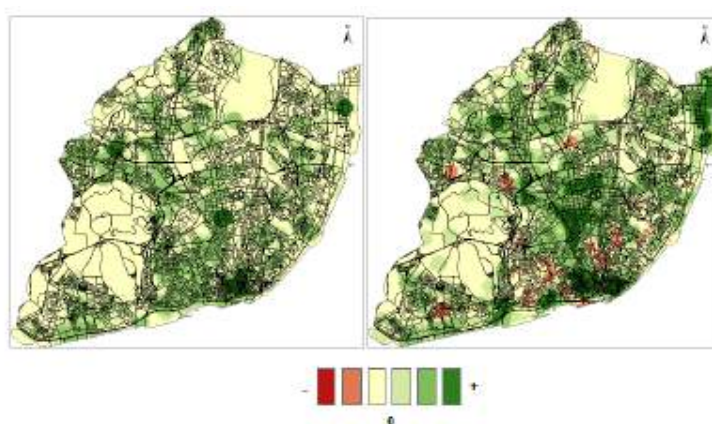

Figure 3 – Restaurant Sector – Density Variation: 1995 to 2002, and 2002 to 2010 (left to right)

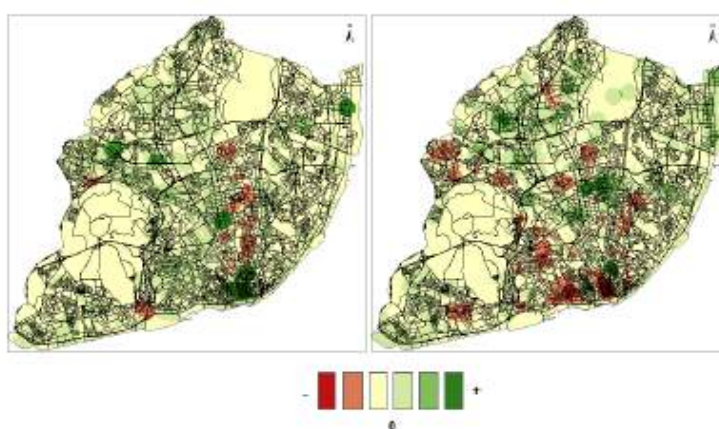

Figure 4 – Retail Sector – Density Variation: 1995 to 2002, and 2002 to 2010 (left to right)

Analysed separately, the two sectors show different trajectories: while on the period between 1995 and 2002, the impact of the shopping malls is noticeable in both sectors, the restaurant sector is, in general, growing steadily, while retail, outside shopping malls, shows significant growth only in Baixa-Martim Moniz, and therefore contributes for most of the losses in total commercial activity observed in Figure 2 in this period.

As for the following period, the restaurant sector shows significant growth mostly all over the city, while in retail, the traditional street-level commercial areas that hadn't been affected between 1995 and 2002 suffered losses in this period. Alvalade showed persistent loss throughout both periods. As for Baixa, it gained almost 60 personal use items stores between 1995 and 2002; and lost roughly the same number in the following period, along with several other types of retail. They also explain for the losses in Figure 2, only for this period.

Personal use items was indeed the most affected commercial type at street level: from 6.2% of total stores located at malls in 1995 it went to 27.8% in 2010 – 712 stores, amounting to 45% of retail located in malls in 2010, and explaining in part of what happened in Baixa and Alvalade.

Tables 1 and 2 contains a summary of the 10 types of commercial activity, both total and located in shopping malls, thus presenting a general overview of the studied period.

Year/Variation		1995	2002	Variation	2010	Variation
Type	Description	Total Number	Total Number	2002-1995	Total Number	2010-2002

Table 2 – Establishments located in Malls - Total Number and Percentage, 1995, 2002 and 2010

Foods present both a persistent decrease (Table 1), and a very low percentage of activity inside malls (Table 2). This may indicate not only the direct competition from malls, but also a lack of characteristics that would allow these establishments to locate inside malls, which is consistent with the activities within this type (groceries, butchers and bakeries, amongst others), that are important at neighbourhood level but don't have the scale to compete directly with the supermarkets that serve as anchors in Colombo and Vasco da Gama. Visually, the effect is as displayed on Figure 5.

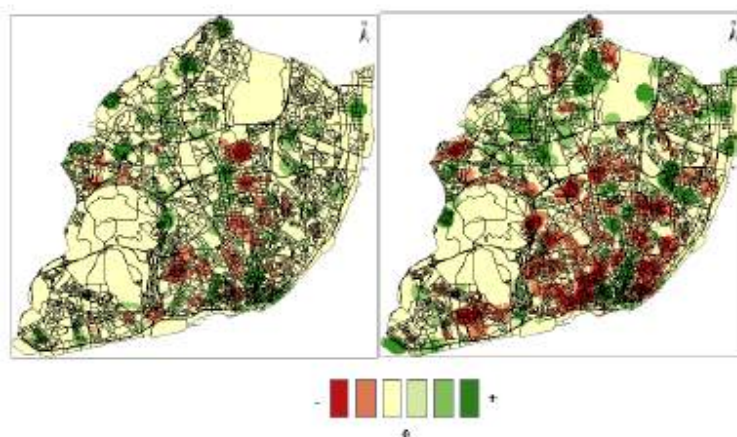

Figure 5 – Foods – Density Variation: 1995 to 2002, and 2002 to 2010 (left to right)

Vasco da Gama and Colombo are visible on the first period (the malls in Saldanha don't rely on supermarkets as anchors). Another phenomenon, though, becomes noticeable in the second period: "old Lisboa" losing this type of activity while "new Lisboa" gains it. Marked in tones of red and orange are the older neighbourhoods in town, with Bairro Alto-Baixa-Martim Moniz appearing as the exceptions (south in green). Upper north, Lumiar /Alta de Lisboa and northeast, Parque das Nações, show positive variation. A preliminary conclusion about Foods can be made: they are needed, to some extent, in residential areas that are still developing, since they provide for daily necessities. Figure 6 compares variation in Foods and Population in this period, with the correlation being obvious.

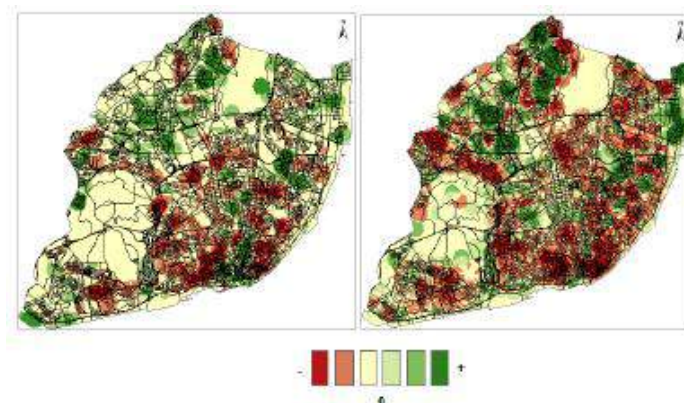

Figure 6 – Foods (left) and Population (right) – Density Variation: 2002 to 2010 (Foods) and 2001 to 2011 (Population)

2.1.2 COMMERCIAL DIVERSITY

Commercial diversity, here measured by entropy, is high at cell-size level, with some small variations between 1995, 2002 and 2010. This doesn't necessarily indicate a good balance of commercial types in Lisboa, but an overall good mix of establishment types at cell-size, for the types taken into consideration. Since cell-size was based on the average area of a statistical subsection, which corresponds to a city block, one preliminary conclusion would be that at block size, activities tend to mix. The analyses on diversity produced the results shown of Figure 7.

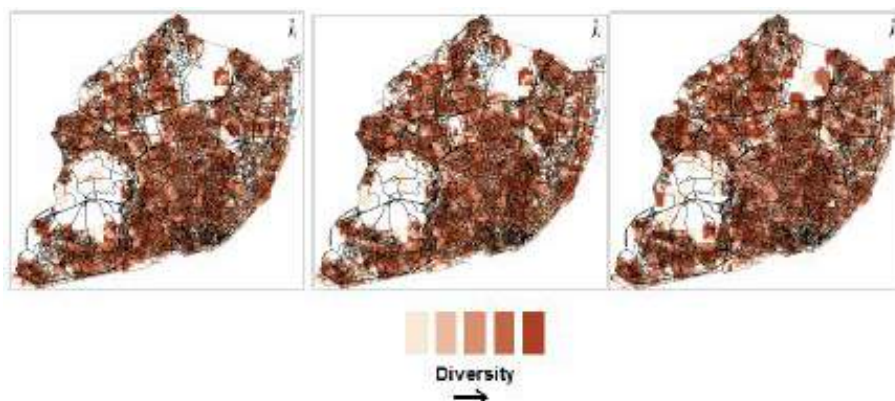

Figure 7 – Commercial Diversity: 1995, 2002 and 2010 (left to right)

Figure 8 presents Commercial Diversity in 2010 and Establishment Density for that same year.

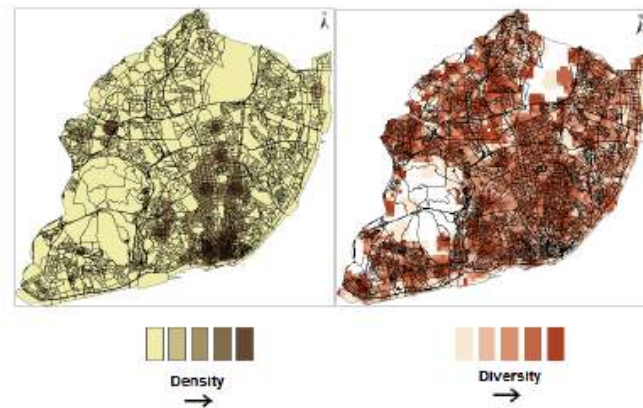

Figure 8 – Establishment Density and Commercial Diversity, 2010 (left to right)

Adding to the previous conclusion, Colombo presents high density but lower diversity. To a lesser degree, the same happens with Vasco da Gama and the smaller malls at Saldanha. Malls offer high density at block size; street level commercial activity, a more balanced distribution.

2.2 SPATIAL REGRESSION ANALYSIS

Regression was focused on Foods, considering the analyses that had been made to this point. The results are presented in Table 3.

Variable	OLS			Spatial Lag		
	coefficient	t-statistic	p-value	coefficient	z-statistic	p-value
ρ (lag)	--	--	--	0.876	142.93	0.000

Likelihood Ratio Test	--		--	4340.779*		0.000

Note: OLS: Ordinary Least Squares. LM (Lagrange Multiplier).

*Entries presented are Values.

Table 3 – OLS Model – Classic OLS Regression and Spatial Autocorrelation (lag) for Foods, 2010-11

The lag model presents a variable for the spatial lag term of Foods, ρ (lag). Its coefficient parameter (Rho) reflects the spatial dependence inherent in sample data, measuring the average influence on observations by their neighbouring observations. It has a positive effect and it is highly significant, which must be taken into consideration when examining the results. Still, controlling for spatial dependence allows for an analysis, focused on the lag model results.

Personal Use items, Repairs, Other items, Restaurants (and similar) and Cafes (and similar) present a positive and significant relation ($p < 0.001$). A negative and significant relation is found with Health and Hygiene.

With the % Activity within Malls also being significant and negative, and considering both the values on Table 2 and the preliminary conclusions about Foods, and commercial diversity, one might establish a relation between these types: except for Personal Use items, these are the types of activity one might find at street level, and block size. This relation, though, requires a similar analysis to be done on the other types. It's a finding pending further investigation and opened for discussion.

As for the relation with Personal Use items, the part of that activity still occurring outside malls is so relevant at neighbourhoods like Alvalade, Campo de Ourique, and the areas surrounding Avenida de Roma and Avenida Almirante Reis, that it might be sufficient to establish a significant relationship with Foods.

Foods is significantly related with Population, but with a very small coefficient. This might be explained by a bigger density of establishments being found in older, less dense areas. The relation with % older than age 65 (and the lack of it with % younger than age 14) also point to that conclusion.

Relation with Primarily Non-Residential Building is significant and negative, which is consistent with Foods being necessity type goods and thus, more related with residential type occupation.

Regression analysis, as said, was used to test if the location of one type of establishment relies on the presence of other specific types. Having made that point, to some extent, the spatial lag model was run using the same variables, but with data from 1991 (demographic) and 1995 (commercial). Table 4 displays the results (along with those displayed on the previous table, for spatial lag in 2010-11).

Variable	1991-1995			2010-2011		
	coefficient	t-statistic	p-value	coefficient	t-statistic	p-value

Table 4 – Regression results with Spatial Autocorrelation for Foods, 1991-95 and 2010-11

Table 4 allows for yet another approach to change in Foods in a period of 15 years (before and after the shopping malls from the late 90's). Foods maintains a positive and significant relation ($p < 0.001$) with Restaurants (and similar), Cafes (and similar) and Repairs. Personal Use items weren't relevant in 1995, nor were Other items. As for Personal Use items, one might risk concluding it was a clustered activity, with that cluster having been displaced to shopping malls, and the remaining activity resisting in traditional, street level commercial neighbourhoods. The relation with Other items is very interesting: this type was created to include

all types that couldn't be included in the other 9 categories. It includes, for example, "Bazars", which in 1995 were just 69 (out of 2129) and in 2010 were already 311 (out of 2383). These are stores selling

miscellaneous goods, from clothes to household articles, to souvenirs and snacks (the smaller ones), usually managed by immigrants, with a large community settled Intendente-Martim Moniz-Mouraria (these amount for the biggest part of the positive variation on retail that can be observed east of Baixa in Figure 5, in the 2002-2010 period). It's a street level activity that almost didn't exist in 1995, but since then, was able to present itself as relevant at block size and eventually contributing to neighborhood liveability.

The relation between Foods and demographic data shows an aging population, as demonstrated by % older than age 65 in 1991: it was significant, but negative.

Shopping malls weren't relevant, and Relation with Primarily Non-Residential Building was significant and negative, although with a smaller coefficient (which might show increasing detachment between commercial activity and other economic activity).

3 CONCLUSIONS

This paper originally intended to present an overview over retail on a period that encompasses 3 decades: a longitudinal analysis on patterns that would visually reveal some expected changes (like the emergence of malls) but also some that weren't quite so obvious. Being able to visually identify the importance of an immigrant community on the resurgence of a neighborhood was unexpected.

A general conclusion is that retail maintained its relevance (10.834 establishments in 1995, 11.385 in 2010), but with a significant part of the activity being transferred to malls (almost 14% of total in 2010). In sum, it went from 10.474 establishments at street level to 9.807 – a loss of 667 units.

As for the restaurant sector, it showed persistent growth, both inside and outside malls: from 3.893 establishments in 1995 to 5.650 in 2010. From 14.241 at street level to 14.994 – a gain of 753 units.

The first conclusion, though, is that between 1995 and 2010 there was a transference of activity, from street level to malls, and a transference of importance, with the growth in restaurants amounting for the losses in retail.

Now, considering that Foods and Personal Use items amounted for the largest part of retail in 1995 (more than 40%), if Foods had displayed the same behaviour of Personal Use items (which, as said, changed from approximately 6% located in malls in 1995 to almost 28% in 2010), the effect of malls on retail at street level would have been even more impressive. One can't say that Foods served as an anchor for retail at street level, but they had a relevant part in maintaining traditional commercial activity. An unexpected contribution came from Other items: Bazaars became relevant (from 69 to 311) and presented themselves as a viable, street level commercial activity (only 10 located inside malls in 2010).

A second conclusion is that Foods and Other items held a significant part in holding retail at street level. Since Restaurants and Cafes presented themselves as parts of the "mix" of street-level activity, directly related with Foods and Personal Use items (along with Repairs), it's reasonable to state that, at block level, these types amount for a significant part of the commercial diversity in Lisboa. But with the restaurant sector growing steadily, what's the risk of losing retail activity to restaurants? And at what point will it pose a threat to neighborhood liveability? With developing neighbourhoods accounting for the bigger part of positive variation in the retail sector, and this "mix" being positively correlated with population older than 65, what are, specifically, the risks for neighborhood liveability in the old parts of Lisboa?

The third conclusion is that there might be a risk for sustainable retail systems at street level, especially in the older neighbourhoods of Lisboa, where traditional street retail still persists.

Further analysis, with recent, more disaggregated data, would be important in determining the extension of the described phenomena. The availability of other types of data (e.g. space syntax or actual employment) would also help in building a more robust model, even if considering that "as far as the laws of mathematics refer to reality, they are not certain; and as far as they are certain, they do not refer to reality" (Einstein, 1923).

1 INTRODUCTION

By its content, the article is an integral part of a more comprehensive research on the complexity and sustainability of urban structures and systems. It is focused on identifying the forms of activity and possible procedures of operationalisation and transformation of the urban functions acting in the everyday life of the inhabitants in the observed space.

In studying the complexity, for the purpose of this article, it was necessary to define the basic notions that are applied in the process of analysis and generating the manifest dimensions of this phenomenon. As a starting point, a precondition is set according to which the identity of the notion can be identified identically in social and technical sciences.

Accordingly, the basics are urban fabrics, generically followed by urban structures and constructs, and then finally spatial systems and configurations. In our considerations of complexity phenomenon, we use the following definitions of notions.

Urban fabrics is a set of natural and artificial elements of components in the form of built and unbuilt parts of the observed space. It covers structures with elements of substructure and suprastructure, and all forms and types of ecostructures and infrastructures that connect them functionally and spatially.

Urban structure (city) is a set of urban fabrics of the observed part of area that makes an administrative, functional and spatially connected entity.

When in the consideration of urban structure (city) the people are included, their public and private needs, which are realized in the appropriate types of functions (institutions of public and private sector) and executed by appropriate processes, urban constructs appear. Urban construct is an urban structure connected with people, functions and processes in the observed area.

Spatial system is a set of urban structures connected with the hierarchy of functions and roles in the observed area (conurbation, region).

When in the spatial system the processes are included, which are generated by the people with their public and private needs realized in the appropriate functions (public and private sector institutions), then configurations arise.

Therefore, in our considerations, the urban structure is not only seen as a group of interconnected components of settlements made up of artificial fabrics and natural elements, but as urban constructs created by the complex acting of economic, social, functional and spatial relations. These connections arise as a result of the needs realized inside and outside the components of the observed space by urban fabrics.

The urban system is not only considered as a sum of inhabited spaces of different sizes and characteristics (Vresk, 1984; Grgurević, 1990), but as a spatial configuration. The realisation of these connections, relations and features is observed vertically, hierarchically - according to the rule of the "size order" of the inhabited area, horizontally - towards distance between them, and co-evolutionally towards the functional relations and transformations that urban systems turn into a spatial configuration.

The functions analysis in urban planning and spatial planning refer to their dual role in space. Once is a facility of the components with features of attractors in the space (relational paradigm), and in next case it is a subject of complexity research within the components of urban structure or systems by the function flow diagram.

As an attractor, the function affects the size, intensity and frequency of relations between spatial entities, and as a paradigm, the function is interpreted by algorithms that simulate activities in the process of realisation of functions in the observed area. The function paradigm has the role to link the parameters obtained at the level of the relational paradigm and the processes being explored at the next level of research.

The purpose of this paper is to clarify the role of urban functions in the observed space and to point out the contribution of the functional paradigm to the possibility of operationalisation of complexity and sustainability of urban constructs and spatial configurations.

For the relational paradigm of complexity, a thesis was set up that in the geographic administrative area, included in the research of urban structure and system, there are not two inhabited spaces of the same characteristics. Therefore, the relation matrix must give a greater number of combinations without repeating than the observed area has functionally and administratively organized independent populated places at regional level.

For the functional paradigm, the axioms were set, that the function paradigm of complexity at a higher level - region depends on:

- sum of the categories of settlements hierarchy located in the observed space,
- the category in which the considered inhabited area belongs according to the concept of nodality and centrality,
- the number of functions that take place in the inhabited area for their own needs and the needs of people in other inhabited environments,
- the number of inhabited places of lower rank in the surroundings of the observed inhabited space that supports functionally and institutionally, defining the gravitational space and the intensity degree,
- distribution of functions in a space that plays a significant role in analysing and generating processes in the observed space.

2 STARTING POINTS FOR THE ANALYSIS OF FUNCTIONAL PARADIGM

The assumption is that the purpose and aim of this work can be achieved by the application of different scientific (logical and mathematical) methods.

From the previous research, the purposefulness of the application of the inductive method in the generative procedure has been confirmed, and for the analytical processes, it is appropriate to use logical deduction. By one component it expresses axioms that can be used to calculate the scalar value of the functional paradigm, and the other component (control) determines the way in which the deduction is applied in the axioms. Because of this, any changes in the axioms are followed by well-defined changes in the algorithm.

The implementation of the research in this paper should contribute to the illumination of the complexity of the different origins of causes and consequences resulted from the activities in the observed space for the purpose of defining the condition in this area. Operationalisation of functions can be accomplished by linking and deducing to a common denominator of the influence of economic and social connections and relations that realize in the space through the artificial and natural structures of the observed space.

For the purpose of this research, the following axioms were set:

- all components of particular urban structures and systems do not have the same capacities to meet the living and other functions in their immediate environment;
- all components of structures and systems do not have the same functional facilities for everyday and occasional needs of their inhabitants;
- The diversity of social, cultural, sports, administrative and other functions of inhabited areas depend on their size / population and the structure disposition of inhabited places in the observed space.

In the elaboration of the relational paradigm, there is a common statement for the relational, functional and structural (organisational) paradigm, but it should be repeated here: Criteria, indicators and benchmarks of complexity and sustainability in urban planning and spatial planning are determinable. For their determination, in the analysis it is necessary to include a larger number of variables and relations depending on the size and components of complex urban structures and systems (Petrović et al., 2014).

3 ANALYSIS OF ELEMENTS OF FUNCTIONAL PARADIGM

Functional paradigm elements are the parameters obtained by parameterisation of component relations and algorithms compiled of flow diagram of components functions of urban structures and systems. The relational paradigm shows the size of the interaction between components of urban structures and systems for a particular observed function.

In order to carry out the operationalisation of functions of urban structures and systems, their algorithmisation is carried out by using the results of relations parametrisation of urban structures and systems. By this process, conditions for quantitative and qualitative operationalisation of functions are achieved.

In order to carry out algorithmisation of urban functions, their features are considered to establish an analogy between the occurrence, by which some function or phenomenon is manifested in the space, and the flow diagram of the observed function in the algorithmisation process.

3.1 CHARACTERISTICS OF URBAN STRUCTURES AND SYSTEMS FUNCTIONS

The functional paradigm expresses the forms in which the parameters of each observed functions are manifested, as well as their effects in the observed space. In simple urban systems, the functions can be manifested autonomously, and can also act interactively in the space. In both cases, the effects of functions are summative.

In interactive functions, interaction mechanisms can be conductional and correlational. In the first case, a co-occurrence event causes linear changes in execution of the function. In the second case, the change (covariance) that is the result of joint action should be observed with more attention because it produces additional effects that are a consequence of joint action, but are not interactive actions. Relating to time the functions from the aspect of duration can be discrete and continuous, and from the aspect of metric, they can be deterministic and unpredictable (random).

Functional paradigm shows the operator actions and effects on changes in the input sizes of some functions processed by operand of the observed component of the urban structure or system.

3.2 FLOW DIAGRAM OF THE URBAN FUNCTIONS SIMULATION

The flow diagram of the simulation of urban functions should encompass as many information as possible about the way of realisation of the function or process. But at the same time for the purpose of operationalisation, it is necessary to reduce it to a limited number of parameters by the "reduction of information".

Through the abstraction, diagram should visualize the manifest dimension of the observed phenomenon, and by graphic interpretation, it should, as much is possible, simulate the dynamism of function relations in the space. Although the function flow diagrams are interpreted in reduced form, they can in its essence simulate complex relations. The most important is to set up correctly and exploit the operational nature of a diagram that simulates the material reality of possible events expressed by scalars.

3.3 ALGORITHM CHARACTERISTICS OF THE URBAN FUNCTION SIMULATION

In the process of functions algorithmisation, urban fabrics are treated as function operands in the observed component of structure or systems. Operands are manageable values and they have inert characteristics. In the functions processing, users and service providers are treated as operators of functions. Function operators perform the transmission or transformation of input value, and may have stochastic characteristics and have changeable characteristics. These transformations, as a consequence of functions processing, may have linear or complex characteristics.

In this kind of research, the diagram has two roles: one is to edit, record, transmit and process information and another is a creative role by which model of actions and processes is abstractly generated, that are manifested in space in real physical dimensions and scales.

To make an algorithm, as a means of recording procedures for solving problems of functions operationalisation, appropriate for computer processing and simulation of urban functions, with the generally accepted algorithm characteristics (discreteness, finality, determination, and massiveness), it should also have the characteristics of sequencing, graphical interpretation and compatibility with computer software languages.

3.4 METHODS USED IN URBAN FUNCTIONS SIMULATION

Since in the research, starting from the ideation, through the definition and interpretation comes the operationalisation of the state of space - as the ultimate aim of the study of the complexity of urban constructs and spatial configurations, it is necessary to apply various methods appropriate for the multidimensionality of this phenomenon.

The simulation of the functions is performed by the methods of abstraction, analogy and reduction, and is interpreted by the function flow diagrams that show the operationalisation of the appearance (manifest dimensions) of the function using the method of algorithmisation.

Complexity, as an occurrence, is composed of latent and manifest dimensions. These characteristics of phenomenon determines on the mental level - the ontological status of the constituent elements, on the level of definition - the epistemological aspects, on the level of interpretation - the hermeneutical aspects, and on the level of operationalisation of physical - mathematical aspects in the form of quantitative and qualitative indicators (Greco & Sosa, 1999; Portugali et al., 2012; Batty, 2005, 2009;)

The abstraction method, that meets the necessary and sufficient conditions for studying the complexity of phenomena in space, is appropriate to these criteria. According to I. Kant, abstraction is preceded by reflection, and for G. W. Hegel abstraction is "placing a formal identity in which actual differences are abolished in manifolds" i.e. between latent and manifest dimensions. Traditional philosophy distinguishes three degrees of abstraction. In the first stage, the notion, as result of abstraction, is abstracted from individual sensory characteristics. In the second stage, it is abstracted from substance (mathematical terms), and in the third stage notions (result of abstraction) are abstracted from the quantity (Kutleša, 2012, p. 46). At these three levels, knowledge from metaphysics, mathematics and physics is also appropriate as a supplement to urban planning and spatial planning.

By the axiomatisation of the above statements, in the relational paradigm the method of parameterisation of relations was applied, and at this level of research of the functional paradigm of complexity, the method of analogy and algorithmisation of functions was applied. The method of analogy has consistently been applied in the process of interpretation of the flow diagram of the function of urban structures and systems according to the aforementioned their characteristics and the characteristics of the algorithm in the simulation of urban functions¹.

¹ In order to interpret different function flow diagrams by analogy method, for the purpose of this research, works of Howard (2007) and Erdi (2008) were used as a model for analogy.

4 REVIEW OF STUDY RESULTS

Realisation of urban functions in a given area may have different effects on the occurrence of events that characterize the condition in the observed area. They are represented by various types of flow diagrams of function realisation as a tool for application of functions algorithmisation in urban structures and systems.

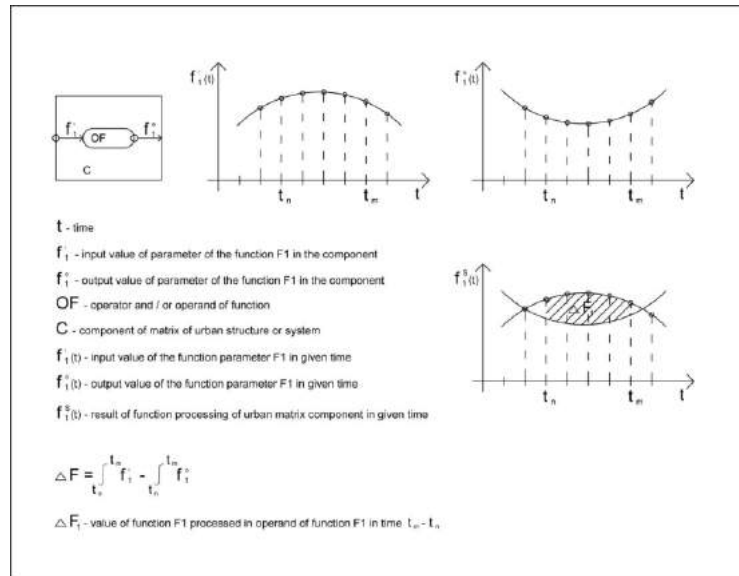

Figure 1 - Scheme of a monofunctional flow diagram of urban functions

Figure 1 shows a scheme of a monofunctional flow diagram of urban functions with arbitrary inputs and outputs, expressed in numbers that can have a positive and / or negative value on the positive part of the abscissa. These function values at this level are viewed as scalar value functions, which can happen discretely and/or continuously.

Linear multifunctional algorithm is characterized by superposition property. The superposition of the input value of the function (cause) results in upgrading the output value of the function (consequence). This rule is valid for the input values of all components functions of urban structures and systems. From there follows a bifunctional or polyfunctional algorithm with parallel processing characteristics of two or more functions that are processed simultaneously according to the co-existence law.

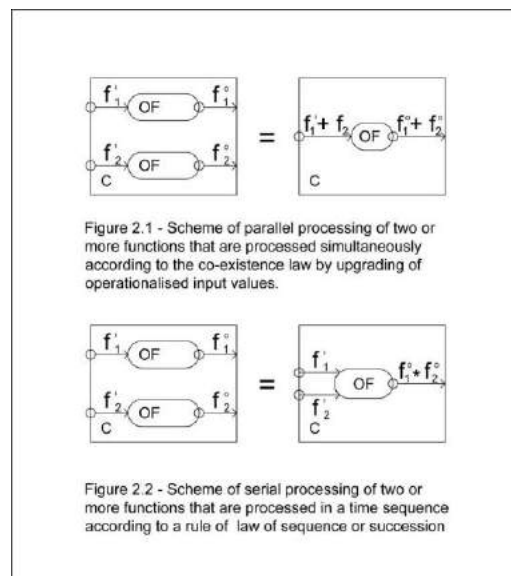

Figure 2 - Scheme of the bifunctional flow diagram of urban functions

Figure 2 shows the scheme of the bifunctional flow diagram of the urban functions in which output values are of different values depending on the subject of the recipient and the service provider of the function - function operator and the urban fabrics as the object of the function operand. They can be constant, but also variable values in space and time of activity of some urban function. A special form of multifunctional flow diagrams of functions in space is an example of serial processing of functions. It takes place in a time sequence according to the rules of law of sequence or succession.

Figure 3 - Scheme of flow diagram of circular causality of urban functions

Figure 3 shows the scheme of flow diagram of circular causality or tangling of urban functions. The third form of functions processing in the components of urban structures and systems results in consequence of acting of the input value of the observed function and the addition resulting from the tangling (Howard, 2007, p 100) of the input value in the observed component. Causes of tangling can be autocorrelative characteristics of the identity of the fabrics component of urban structure or system.

Figure 4 shows the scheme of flow diagram of the reverse effect of urban function. In the flow diagram of reverse effect of the function processing there is not a clear border of the cause and effect because output influences the input. This reverse mechanism¹ affects the dynamics of functions operationalisation, because it can have a positive and negative sign. The negative reverse effect reduces the difference between input and output values and thus stabilizes the effects of function processing.

A positive reverse effect increases the difference from the initial state and thus destabilizes the effects of function processing. (Erdi, 2008, p. 8)

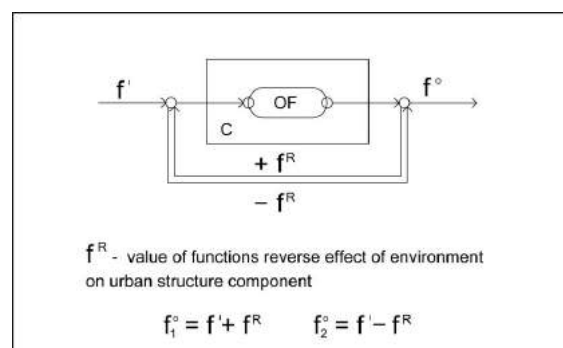

Figure 4 - Scheme of flow diagram of the reverse effect of urban functions

¹ Natural and social systems abound with reverse mechanisms, so there are inevitable in complexity studying.

The output vector from the linear system is obtained by tangling the input vector with the response vector of component to the effects of the input vector. These effects can be precisely determined in linear systems, and in complex systems, they are determined by the probability account, based on the previous state of the system.

The total effect of tangling can be defined either by integral tangling or summative tangling. In this process, the tangling may occur during function processing so that two (or more) output values of functions processing produce a third (or new) value under the influence of the function operator within the component of the urban structure or system. The feedback effect affects the properties of the system so that in the operationalisation of n components of the system, the system generates $n + m$ output components. ($M > 0$). (Erdi, 2008)

Both reverse connections (the negative - dumping and the positive – amplifying) are always found in complex systems. The effect of the behaviour of an element of a structure or system is such that it always changes itself under the influence of the environment. Unlike the linear system where the superposition principle is applicable, complex systems cannot be expressed as the sum of the behaviour of its parts, because even the components of complex systems can be complex systems.

In linear systems, the effect is always directly proportional to the cause, and in complex systems it can be significantly larger, proportional or none. If the growth of the effect manifests exponentially, and with a small increase of the exponent in the finite time, an infinite increase in appearance may occur.

From above mentioned, it can be concluded about the possibilities of operationalisation of the parallel, serial and feedback connections of the component functions of a structure or system, and thus it is feasible for the complex multifunctional system through the reduction process of flow diagram of the function. Reduction is feasible in many ways, and the same methods of operationalisation can be applied at the level of operationalisation of the functional matrix of complexity.

5 CONCLUSIONS

The article identifies the basic notions used in the process of analysing and generating the manifest dimensions of the complexity of urban structures and systems. The dual role of function and the axioms was determined; the possibility of operationalizing the functions of urban structures and systems by their algorithmisation using relation parametrisation is pointed out; the basic starting points of the functional paradigm of urban structures and systems, their components and their interconnectedness, the dynamics of realisation and the possibility of operationalizing the functions of the urban matrix components are presented.

The analysis and generation of components functions of urban structures and systems, their algorithmisation and conducted analogy as well as the simulation of the movement of urban functions in the flow diagram pointed out the role of urban functions in the observed space and the contribution of the functional paradigm to the possibility of operationalisation of complexity and sustainability of urban constructions and spatial configurations.

Urban fabrics as functions operands in the component of structure or system are manageable in size and have inert characteristics. Functions operators (users and service providers, natural conditions and data) perform transmission or transformation of input value and may have stochastic and variable characteristics. These transformations can be linear or complex, which can be concluded from the presented schemes of functions flow diagrams.

If all components of urban structures and systems would be processed just by parallel and serial algorithmisation processes (regardless of their number) all these algorithms could be reduce to one algorithm by sequential addition for parallel and consecutive tangling of output values for serial algorithms of function.

In the process of algorithmisation of functions, beside the parallel connection of the functions operationalisation it is possible to connect them in series. In this case, the output value of

the first function is the input value of the second function in the function flow diagram, and the result of the operationalisation of these two functions is not the sum but the product of multiplication of the two outputs of the function tangling in the observed space.

The basic characteristic of time-invariant linear construct is the transparency of the function process operator and its influence on the output value of a particular function from the observed component of the urban structure or system.

It is important to emphasize that the operator of the tangling of components function of urban structures or systems is commutative, associative and distributive, and the operand is changeable by transforming and intervening into the components constituent elements of the urban structure or system. Since urban fabrics at the observed moment are fixed and invariable in size, limited capacity, linearity manifests itself to a certain load of fabrics by processing all functions at the observed moment.

The phase of their linear characteristics finishes by optimal load of the functional capacity of the components constituent elements of the urban structure and system in the processing of functions. Increasing the functional load of the constituent elements of the urban structures and system components causes the appearance of tangling in the functions processing.

Therewith starts the phase of transformation of urban structures and systems into complex constructs and configurations. Although constructs and configurations have complexity characteristics, their features have not yet ceased to be deterministic. After that limit, by further increasing the function load, the results of the functions processing assume the characteristics of complexity. This firstly results in the variability of the effects of functions processing, and then also in the variability of time needed for function processing. Therewith a possible border between the linearity and complexity of the characteristics of the components of the urban structures and systems caused by the activities of the function operator and the capacity of the operand at the observed moment and time flow, is determined.

Finally, it can be concluded that based on conducted mathematical induction and synthesis, the features of function flow diagram shown in Figures 1 to 4, and the axioms as well as the above conclusions the characteristics of a complex functional paradigm can be defined. The complex functional paradigm has characteristics of parallel, serial, circular and backward processing of functions in discrete and continuous form. This paradigm fully reflects the algorithmisation of the functions of complex urban constructs and configurations.

ABSTRACT: The uncertainties that are part of the development trajectories of cities challenge spatial planners in designing productive interventions. This paper explores how complexity theory can support planners in dealing with these uncertainties intelligently. It presents a dynamic, time-sensitive understanding of spatial transformations that helps to clarify the interconnected and changeable nature of the underlying processes. The paper continues by proposing an adaptive planning approach that strengthens the responsiveness of urban areas to both expected and unexpected changes. The argument is made that adaptive planning first and foremost implies a focus on influencing and creating conditions for development, followed by attention to content and process. Based on an imaginary case of inner-city transformation, the paper distinguishes key conditions for guiding spatiofunctional configurations and supporting capacity building of local actor coalitions.

KEYWORDS: uncertainty, complexity, adaptive capacity, conditions, urban transformation, responsiveness

1 HOW PLANNERS ARE CHALLENGED BY UNCERTAINTIES¹

The certainties we humans so appreciate appear to be illusions more often than we would like. Transformations induced by climate change, technological innovation and social upheavals are well-known drivers of the wicked problems and deep uncertainties we are confronted with (Haasnoot et al., 2012; Van Bueren et al., 2003; Rittel & Webber, 1973). They affect society as a whole and, in particular, policy and decision-makers when designing interventions to guide future developments. Uncertainties are not limited to these examples. Unexpected natural, political and economic events, coincidental confluences of gradual change processes feeding larger transformations and unforeseen societal responses to policy programmes illustrate how the reproduction of uncertainties occurs in many domains and at multiple levels of scale, driving towards a future which is difficult if not impossible to predict (e.g. Pawson et al., 2011; Scheffer, 2009; Walker et al., 2003). People address such uncertainties heterogeneously (Chow & Sarin, 2002). Moreover, social views on which possible future should be aimed for are often unstable (Van Bueren et al., 2003). Accordingly, in trying to engage with the positive and mitigate as much as possible the negative, policy and decisionmakers are continuously challenged by the uncertain conditions in which they operate (Duit & Galaz, 2008; Teisman, 2008).

Spatial planners in urban development processes also wrestle with how to deal with uncertainties in their daily practices. Urban areas, including cities and neighbourhoods, are dynamic, changeable environments that sometimes follow unexpected routes (Batty, 2013). Meanwhile, planners aim to improve the sustainability and liveability of these places through rationally designed interventions. As early as 1969, Friend and Jessop pointed out a set of uncertainties defying planners: regarding knowledge about present and future environments, regarding actor intentions, and regarding value judgement on planning interventions (see also Christensen, 1985). In today's highly connected and information-driven world, the omnipresence and potential impact of uncertainties receive increasing attention in literature on planning (e.g. Albrechts, 2010; Bertoni, 2010; De Roo & Rauws, 2012; Salet et al., 2013; Van Woerkum et al., 2011). The limitations of traditional planning strategies and instruments in dealing with unforeseen developments are also exposed, as these are often based on prediction, stability and risk reduction (e.g. Abbott, 2005; Gunn & Hillier, 2014; Rauws et al. 2014). Therefore, the question that becomes increasingly urgent is how planners can strengthen the responsiveness of urban areas to both foreseen and

¹ This paper includes sections from the author's PhD thesis 'Why planning needs complexity', freely available at: 10.17418/PHD.2015.9789036778

unforeseen change, while at the same time making societally preferred development trajectories more likely.

This paper aims to contribute to this quest by exploring an adaptive planning approach. The approach is based on the idea that planning operates in a world of 'becoming', in which processes of evolution and transformation are ever-present (Tsoukas & Chia, 2002; Byrne, 2005). It aims to strengthen the responsiveness of urban areas to a variety of possible futures by setting conditions for development. As such, it resonates with the debate on strategic spatial planning. Following Albrechts and Balducci, strategic spatial planning offers complementary means to operate in today's complex and dynamic societies, as traditional planning instruments are merely designed for situations of stability (Albrechts, 2010; Albrechts & Balducci 2013). It is presented as an inclusive, action-oriented method for transformative practices that open up new routes of development, including analytical and normative dimensions (Albrechts, 2010). Some of its key elements are: identifying placespecific problems and opportunities in a global context; mapping possibility spaces by analysing spatio-temporal conditions and constraints; creating new arenas for policy articulation by identifying and/or mobilizing actor coalitions across scales and sectors; and shaping places by selective actions on strategic issues that are embedded in and justified by a long-term vision.

The adaptive approach proposed here builds on the strategic spatial planning agenda and offers three main contributions. Starting from a complexity perspective, it exposes some of the mechanisms underlying a world of becoming, such as non-linearity, self-organization and fundamental uncertainty. An adaptive planning approach also stresses the need for places to have sufficient capacity to cope, respond and adapt to change in order to secure their vitality. This is to say that strengthening adaptive capacity itself becomes a main objective of planning interventions. Finally, adaptive planning introduces an additional level of intervention. While the strategic spatial planning repertoire is mainly oriented at fostering desired change given certain conditions, the adaptive planning approach targets exactly these conditions as object of intervention. Put differently, adaptive planning is about influencing the possibility spaces for urban transformation with the aim to support an area in keeping its fit with the dynamic environment. Innovation, the central theme of this special issue, is considered an essential mechanism in this process.

The structure of the paper is as follows. Section 2 introduces a complexity perspective to rethink the nature and character of contemporary urban development processes. Complexity theory helps to clarify the interconnected and changeable nature of the processes underlying urban transformation. Section 3 explores the potential of a condition-based, adaptive planning approach in guiding such transformations. Section 4 discusses what these conditions may comprise. These are illustrated by an imaginary case of an inner-city transformation in Section 5. The paper concludes with a reflection on the role of public planners and an agenda for future research.

2 A COMPLEXITY PERSPECTIVE ON URBAN DYNAMICS

Supporting planners in developing an enhanced understanding of urban dynamics and related uncertainties, several scholars find inspiration in the world of complexity (e.g. Gerrits, 2008; De Roo et al., 2012; Portugali, 2011; Batty, 2013; Loepfe, 2014). Complexity theory is concerned with the evolution of phenomena, rejecting the Newtonian conception of the world based on reductionism, determinism and predictability (Cilliers, 1998; Wolfram, 2002; Heylighen, 2008). These phenomena are often defined as systems or networks of which the components 'are to some degree independent, and thus autonomous in their behaviour, while undergoing various direct and indirect interactions' (Heylighen et al., 2007: 125). Wellknown examples are insect colonies (Bonabeau et al., 1997) and the World Wide Web (Scharnhorst, 2003). Complex phenomena are dynamic, nonlinear – a small change can have a big effect and vice versa – and include interdependencies across various aggregation levels. This implies that they evolve without central coordination and are very difficult to predict and to fully manage.

A key characteristic of these so-called 'complex adaptive systems' (CAS) is their continual evolution towards an optimal 'fit' with their dynamic environment. They are open systems, exchanging information and energy with their environment. For this reason, they are sensitive to changes in this environment, and respond by adapting their configuration. Cities also express this behaviour, responding to various contextual changes, such as demographic pressures, economic trends, and technological innovations (Portugali, 2006). Others argue that this is also the case for other urban units such as neighbourhoods

(Wagenaar, 2007) and metropolitan regions (Innes et al., 2010), in more or less similar ways. As such, portraying urban areas as CAS invites planners to consider ongoing adjustments of an area's configuration as both a source of and a coping strategy to address uncertainties in its development trajectory.

The adaptive behaviour of cities cannot be reduced to a set of clearly distinguishable cause-effect relations when following a complexity perspective. Instead, processes of adjustments are considered to emerge from the interaction between multiple drivers for change at various levels. We already discussed the influence of contextual changes, but cities are assumed to adjust, transform and innovate from within. These local changes include, for example, initiatives by citizens, entrepreneurs, local authorities, and coalitions between these three. One could think of redevelopment projects, grassroots initiatives or start-ups. Unsurprisingly, both contextual changes and local initiatives trigger interventions at system level by city planning authorities. Changes are stimulated, linked, regulated, mitigated, etc., depending on how they relate to the general ambitions of the city, the policies frameworks and dominant power structures. In turn, interventions at system level influence again the impact of contextual trends and the opportunities for local initiatives. Hence, casting cities as CAS emphasises the interrelatedness of changes on various levels, of which some are planned – being initiated by public planners – and others are unplanned. As a consequence, the possibilities for planners to predict and control a city's development trajectory are believed to be limited. Developments emerge partly 'autonomously', beyond the scope of planners, and the way a city's trajectory unfolds is considered to be time-specific and place-specific.

A key concept of complexity theory that helps in understanding the potentially autonomous character of transformations is self-organization. Processes of self-organization can result in a structural change of a system, such as a neighbourhood, emerging out of a number of local initiatives without these initiatives being centrally coordinated (Rauws, 2016). An example could be the transformation of a mixed residential neighbourhood into a 'student town', changing both its function and structure. Triggered, for example, by a growing student population in a city, individual homeowners can decide to rent rooms to students. Meanwhile, private investors might decide to acquire single-family homes and transform them into dormitories. Such uncoordinated, relatively independent actions can, over time, result in changing spatial patterns on a wider scale; shop-owners adjust their range of products and opening hours to meet the demands of the students, bars are opened, and parking lots are transformed in open-air hang-outs and bike sheds. The result is a full transformation of the role and structure of the neighbourhood, embracing its new identity as 'student town'.

Planning is not necessarily absent in such transformations as homeowners and shopkeepers often have to meet certain regulations. However, the transformation at the neighbourhood level is not centrally coordinated nor designed in advance. Instead, it emerges spontaneously and the patterns it gives rise to at system level are unpredictable in the sense that they could not be deduced from the sum of all individual actions.

The (partly) spontaneous character of some urban transformations challenges planners to rethink their strategies in guiding these transformations. From this section we can learn that there are at least three reasons why a complexity perspective can contribute to such a rethinking process:

- A complexity perspective draws our attention to the multiple, interdependent drivers for change on various levels that shape development trajectories. Some of these drivers are the result of planning interventions, while others emerge beyond the range of influence of planners. As the way these drivers feed into each other and in interact amplifies some change processes and dampen others cannot be controlled, uncertainties are partly fundamental. It is important that planners be able to deal with both foreseen and unforeseen change.
- It challenges planners to consider the transformation of urban configurations as ongoing processes. Taking a complexity perspective, urban areas are seen as places that are continuously shaped and reshaped by internal and external forces, always on their way to become. To be able to fully take into account these dynamics in planning interventions, planners should develop a situational understanding of planning challenges. This includes the idea that what should be aimed for and with whom to reach consensus depends on the when and where of a planning issue.
- As change is believed to be continuous, multi-level and situation-specific, a complexity perspective urges planners to focus their efforts on strengthening the adaptive capacity of cities

and neighbourhoods. This would enable urban areas to function well under different circumstances, being responsive to both foreseen and unforeseen opportunities and threats.

3 TOWARDS AN ADAPTIVE APPROACH FOR GUIDING URBAN TRANSFORMATIONS

If we indeed embrace the idea that planners deal with processes of becoming, then how can planning contribute to responsive cities? In other words, how can planners strengthen an area's capacity to react, incorporate and adapt to change, and stimulate those futures that are considered to be more sustainable and liveable? Aiming to do so, the logic of designing an 'optimal' plan and endeavouring to control urban development towards the achievement of this predefined future should be considered undesirable. After all, this would bring us back to an understanding of cities as stable entities in which transformations can be shaped by a series of successive events that can be devised in advance. Alternatively, plans and strategies which allow for continual reflection and adaptation are required in order to support a range of possible emerging trajectories. They should be able to 'seize' opportunities for socially preferred development directions and prevent problematic issues from aggravating (see also Lessard, 1998; Van Assche & Verschraegen, 2008; Van Woerkum et al., 2011). We thus take the position that the focus of planning strategies on reducing or avoiding uncertainties needs to be redirected towards accepting these uncertainties and exploit the opportunities they give rise to.

This poses a series of challenges to planners. For example, how to be ready to exploit opportunities that are yet unknown? How can planners connect their policies and interventions to the on-going interactions at various levels of the urban system concerned? And how to design plans and strategies that effectively support a range of possible future development trajectories? These are complicated challenges, and we certainly do not aim to present an overarching new approach in which all these challenges are tackled. However, in making cities more responsive to change, we argue that first and crucial step can be taken by redirecting the focus of planning to influencing and generating conditions under which development trajectories unfold. We call this an adaptive approach to planning (see also Rauws & De Roo, 2016; Yamu et al., 2016).

A condition-based, adaptive planning approach is about offering a general framework for urban transformation without defining a particular future spatio-functional configuration or configuration of actor relations. The argument is that influencing the conditions under which urban areas transform, rather than defining a specifically desired configuration, generates possibility spaces that allow an area to respond to and profit from a range of possible directions of development. It opens up development frameworks for the 'unplanned', spontaneous ways in which cities and neighbourhoods adjust to and co-evolve with changes at various levels of society (e.g. technological innovations, grassroots movements or demographic trends). We argue that an adaptive planning approach enables planners to strengthen the responsiveness of an area to foreseen and unforeseen change, while securing important societal values.

This adaptive approach is not meant to replace more traditional planning approaches. Instead it can be considered as a valuable addition to the existing repertoire of planning approaches, especially for planning interventions in dynamic urban areas and with a longer timeframe. In line with our argument that planning problems require a situational understanding, the planning approach or mix of approaches that fits best also varies over time and space (Alexander, 2012; De Roo, 2012). Situations can, for example, be differentiated on the volatility of their context, the urgency to act or the level of diversity in the ambitions, interests and commitment of actors involved. An adaptive planning approach is in particular suitable for issues situated in highly dynamic context with variable and overlapping actor coalitions, while for instance an instrumental approach can work well in situations with a high level of urgency, a relatively stable context and rather crystallised networks of actor relations.

Positioning adaptive planning within a repertoire of planning approaches, we touch upon adaptive capacity at meta-level, namely in the governance landscape itself. A further exploration of such a meta-framework is beyond the scope of this article, but more can be found in De Roo (2012) and Zuidema (2014). In the remainder of this contribution, we concentrate on what kind of conditions planners need to focus on when guiding urban developments in an adaptive way, and reflect on the role(s) public planners can have in these development processes.

4 IDENTIFYING CONDITIONS FOR ADAPTIVE URBAN ENVIRONMENTS

The adaptive capacity of urban developments is fostered and constrained by a variety of conditions. These conditions include governmental rules and regulations, the qualities of the existing urban fabric, motivation and capacities of involved actors, economic climate and technological possibilities, political aims and societal desires, and many more. All are conditional to the kind of urban developments that have potential in a particular situation. Unsurprisingly, only a part of these conditions can be influenced or generated by planners. The adaptive planning approach that is proposed here focuses on two categories of conditions on which planners can have a substantial influence: conditions on spatio-functional configurations and conditions for the capacity building of local actor coalitions. The former concerns formal rules and regulations that have to be met when realising an urban development project, such as accessibility to public space or the spatial relations between built structures. They influence on the spatial quality of projects as well as the impact of these projects on the wider urban fabric. We will argue that, when formulated in a particular manner, they can also help in keeping an area open for a range of potential trajectories. The latter includes conditions that increase the possibilities for a diverse range of actor coalitions, traditional and innovative, to establish themselves and contribute to urban transformations. One can think of measures that foster information exchange or increase connectivity between actors. Local coalitions are important if planners want to embrace self-organization mechanisms in urban development and foster a continuous exploration of alternative directions of development in response to ongoing dynamics.

4.1 CONDITIONS FOR GUIDING SPATIO-FUNCTIONAL TRANSFORMATIONS

In this section, we will explore how generating conditions on spatio-functional configurations can be part of an adaptive planning approach. We start by analysing the contributions of Stefano Moroni, Nurit Alfasi & Juval Portugali, and a paper by the author himself coauthored with Matthew Cook & Terry Van Dijk. These three studies were selected as they are among the few that explicitly define conditions for urban development in the limelight of complexity thinking. At a conceptual level, Moroni (2015) explores regulatory instruments that are less reliant on explanation and prediction. Alfasi & Portugali (2007) discuss an alternative for the Israeli planning system by incorporating the idea of the self-planned city.

Finally, Rauws et al. (2014) analyse how Dutch urban development plans can become more responsive to change. A review of their communalities and their differences (Table 1) allows us to construct a preliminary foundation for an adaptive planning approach.

All three approaches share the assumption that urban development is a continual process rather than a sequential one, as in none of them end-states are defined. They also have in common that the complexity and the limited predictability of urban development processes are presented as aspects that should simply be accepted by planners. As such, the conditions introduced in the articles are not prescriptive but mainly have a relational character, offering developmental frameworks that can guide a wide range of possible future development trajectories. Based on the three articles, we analyse the types of conditions that can be distinguished.

From Moroni's nomocratic planning approach, the most generic and liberal of the three, we can derive the importance of securing the quality of life in areas under transformation. Operating in dynamic situations that sometimes follow unexpected trajectories, Moroni argues that planners are responsible for setting conditions that reduce possible negative effects and leave all other possible outcomes open. He refers to these conditions as 'framework instruments' merely meant 'to prohibit individuals from interfering with the private domain of other individuals rather than imposing some active duty or action' (2015: 257) (e.g. avoid producing externalities of type A, B, and C to neighbouring plots). As such, flexibility in urban development process is provided while undesired consequences are mitigated. This is not to say that prescriptive tools, which he calls patterning-instruments, should be fully abandoned. According to Moroni 'framework instruments must be used to regulate private activities, patterning instruments to guide public actions' (2015: 262). All in all, the first type of conditions that we distinguish for an adaptive planning approach is about securing the quality of life under a variety of potential development trajectories.

Introducing urban codes for the 'self-planned city', Alfasi & Portugali also look for ways to increase the flexibility in urban development processes. With their codes on physical qualities (e.g. land coverage),

design (e.g. material), and usage qualities (e.g. accessibility), amongst others, they propose to guide urban change regardless of specific plans. With these codes they aim to increase opportunities for more incremental urban development. However, they add the importance of context-sensitivity in the application of these codes. While Moroni argues that conditions should be as uniform as possible, Alfasi & Portugali introduce the idea of the planning judge. It allows for a more situation-specific guidance of urban areas in transformation, as these judges decide, based on generic-relational rules, whether developments are appropriate in the particular context.

We follow Alfasi & Portugali in their call for context-sensitive flexibility. Some potential positive or negative development opportunities in the short-term are closely related to the particular situation in the 'here and now'. Conditions tailored to this situation may therefore more accurately trigger or mitigate these development opportunities. Of course, the tailoring of conditions for development can limit the adaptive capacity of an area in the long-term as the virtual and actual potentials of situations yet to come are difficult to identify. However, in line with Alexander (2012), we argue that spatially and locally qualified conditions can still have general-relational character. For example, in an area with a growing local economy due to some attractive historical landmarks for tourists, conditions can be tailored in order to utilise the economic and place-making potentials of these landmarks. Meanwhile, these conditions can still be formulated in such a way that they can productively guide a range of potential development trajectories. In this particular situation, a condition for development can, for instance, be that new projects have to contribute to the identity the landmarks provide to the area and that the sightlines to these landmarks have to be respected. This way, the unique potentials of an area are acknowledged and future development trajectories are left open as much as possible as well. In sum, the second type of conditions for our adaptive planning approach is about generating context-sensitive flexibility in the pace and direction of development.

In earlier work, we added a third dimension to the debate by arguing that adaptive planning is as much about triggering societally preferred development directions as about strengthening the responsiveness of urban areas to change (Rauws et al., 2014). The proposal is to combine the implementation of conditions with visionary elements of planning that create a sense of urgency among stakeholders, trigger new initiatives and legitimise public investments. As such, societal ideals can be integrated in an adaptive development framework.

Advancing the argument further, we embrace the idea that adaptive planning includes a normative dimension. In any other way, adaptive planning would be limited to triggering a kind of social Darwinism; strengthening the self-reliance of urban systems to 'survive' in dynamic environments (see also Davoudi, 2012). Setting conditions cannot and should not be done in isolation from societal values, norms and agreements (including political agreements), for example on poverty reduction or protection of vulnerable ecosystems. Collective ambitions on creating a better future – one which is, for instance, believed to be more socially just, economical viable or climate change proof – should also be part of planning frameworks (Rauws & De Roo, 2016). However, a risk of looking ahead is that the produced images and persuasive stories on potential futures are again translated into plans that project a particular future urban configuration. This would undermine the openness of actors to alternative, nonenvisioned trajectories of development. As an alternative, we suggest integrating societal preferences regarding future trajectories in the defined conditions for development. For example, if a city aims to reduce its impact on the environment, energy neutrality can be conditional for new developments or transformation projects. Translating societal preferences into such a qualitatively formulated condition instead of detailed quantitative norms, improves the area's responsiveness to changing demand and unexpected events as well as to unforeseen innovations. In the case of energy-neutral building construction, the latter can, for example, include a new solar energy technique. Hence, the third type of conditions we identify is about stimulating the emergence of societally desired development trajectories.

To conclude, discussing the selected works helped us formulate three types of conditions that we argue to be key for guiding urban transformation in an adaptive way:

- Securing the quality of life under a variety of potential development trajectories
- Generating context-sensitive flexibility in the pace and direction of development
- Stimulating the emergence of societally-desired development trajectories

In combination, these conditions can strengthen the adaptability of an urban area to a variety of possible future spatio-functional configurations, while offering opportunities to foster the emergence of those development trajectories that are preferred over others.

In concluding this section we briefly discuss how conditions on spatio-functional configurations can be established and applied. Who defines these conditions? Is there a hierarchy among them? And how can the 'fit' of a proposed development be evaluated? As the types of conditions that have been identified closely relate to the central values, ideals and ambitions of communities (defined in the widest sense; citizens, entrepreneurs, policy makers, decision makers, etc.), we argue that defining these conditions should be embedded in an open and democratic process involving a diversity of actors. While we acknowledge the extreme difficulty of undertaking such a process (Brand & Gaffikin, 2007), we also believe it is crucial step in establishing a development framework that is inclusive and cross-sectoral, and that receives public support.

We distinguish two aspects that can help in the operationalisation of this process. First, differentiating the degree of generality in the formulation of conditions, and in those who decided on them, based on the spatial scale that is addressed. Conditions that apply to a city as whole can and should be formulated in a more generic way. They can, after being explored and discussed publicly, be determined by representatives of stakeholder groups, following the principles of a representative democracy. Building on Marshall (2009), we suggest that moving towards the more local scale of, for instance, a neighbourhood, communities can decide to further tailor some of the conditions that were established at a higher scale, or set additional ones. This allows them to address the place-specific qualities, problems and opportunities they perceive. The smaller the geographical unit, the more representative democracy principles can be replaced by those of participatory democracy, contributing to a sense of ownership of the process and the place, and unlocking the tacit knowledge of its everyday users. At all scales, the three types of spatio-functional conditions are key, but conditions that are meant to secure the quality of life are often rather universal while those related to generating context-sensitive flexibility and stimulating desired directions of development can expected to be more place-specific. In sum, the proposed multi-stage way to formulate and decide on conditions for development can help in finding a workable balance between the generic and the specific.

The second aspect is about the enforcement of conditions in urban projects. In general, we consider most systems of building permits and development approval that have been developed for traditional land-use planning also applicable to the adaptive planning framework proposed here. A pre-condition for the successful functioning of such enforcement systems is that conditions are formulated and explained in clear and unambiguous ways. For instance by using images, infographics and digital planning-support tools instead of guidelines using technical jargon. However, how to proceed when the open and partly qualitatively-defined conditions result in confusion, or even a dispute between the project proposers and those evaluating its permissibility? For these situations, the proposal by Alfasi & Portugali (2007) to establish some sort of planning judge can offer a solution. In our view, such a judgement can be given by a committee of independent experts, for example consisting of public planners and urban designers from another city. They can weigh the arguments of both parties and decide on which interpretation of the conditions is most appropriated given the situation at stake, and considering the original intentions of the defined conditions. Setting up such an evaluation system offers a way to work with the complexities of urban transformation instead trying to reduce these complexities.

4.2 CONDITIONS FOR CAPACITY BUILDING OF LOCAL COALITIONS

Strengthening the responsiveness of urban areas to change requires more than opening up development frameworks for a variety of possible spatio-functional configurations. The generated possibility spaces also have to be utilised in order to indeed improve an area's fit with its dynamic environment. Therefore, planners have to open up their practices for selforganisation mechanisms in urban development (Boonstra, 2015). As self-organisation processes are unpredictable and not guided by collective intent, planners have to reach out to the diverse range of local actor coalitions which all take part in reshaping the urban fabric.

These coalitions emerge from the temporary, changing and multiple interactions in cities, in which public planners are not necessarily leading. Nevertheless, we argue that enabling these coalitions is crucial in supporting an area's capacity to adapt to changing circumstances. Property owners, citizens, and

entrepreneurs have often valuable (tacit) knowledge on how a place functions and not seldom initiate innovations in response to a shifting context. In other words, contributing to self-organisation mechanisms, these coalitions not only optimise existing urban configurations, but also generate novel ways to use, develop and brand urban areas.

We suggest that planners can support the involvement of actor coalitions in urban development by means of capacity building. Drawing on community engagement and community initiative literature, this concerns influencing the available means, motivation, and social capital of local coalitions, processes of mobilisation, and the responsiveness of formal institutions (Lowdnes et al, 2006; Bakker et al, 2012; Denters, 2016). It is beyond the scope of this article to comprehensively discuss the enabling conditions for these five aspects. Limiting ourselves to a few examples, one can think of providing relevant data on the area and its context, improving the connectivity between actors, and offering support in making the steps from idea to implementation. But supporting the initiatives of various actor coalitions should not result in high levels of inequality and social exclusion. Particular groups may easily organise themselves to defend their interests while others may have less capacity to do so or are quietly excluded (Uitermark, 2015). Such effects might be partly mitigated by including a condition on peer learning, which stipulates that those receiving public support are required to share their knowledge and skills with other emerging coalitions. The challenge for planners is to facilitate local coalitions in developing their initiatives and as such trigger the selfinnovating and self-stabilizing capacity of urban systems, without fostering socio-spatial segregation.

5 CONDITION-BASED DEVELOPMENT: AN IMAGINARY CASE OF INNER-CITY TRANSFORMATION

Based on the types of conditions identified above, this section offers an illustration on how an adaptive planning approach might look like in practice. An imaginary inner-city transformation project is taken as example because of the high level of complexity these projects typically show. Inner-city transformation projects for instance often include fragmented ownership positions, historical functions and structures that one wants to preserve, and a broad range of directly and indirectly involved actors (Healey, 2007; Bosselman, 2012). Taking an inner-city transformation project as an example is also relevant as this kind of projects are increasingly dominant over greenfield development in most Western European cities (Thomsen, 2011). We run a thought experiment to identify what kind of conditions can guide such a transformation project and discuss to what extent these conditions contribute to the adaptive capacity of the area.

Let us assume that our imaginary project concerns a former industrial harbour site. The storyline is that the harbour has lost its functionality as a result of newer and more modern harbour areas elsewhere. Due to its location in the centre of the city, next to the historical heart and the shopping district, the area has the potential to make the transition to a multifunctional, high dense urban neighbourhood. Aiming to increase the attractiveness of the city and to renew its economic profile, the municipality is eager to develop the site. However, the context is far from stable. Next to the long-term uncertainties about how technological, ecological and demographic trends will affect the area, planners also face short-term uncertainties: the various landowners differ in their capacity and willingness to contribute to the transformation, citizens and politicians argue about which projects have priority, and due to a period of economic decline investors are hard to find. How, in such a situation, with multiple uncertainties, would an adaptive approach be of help?

Ideally, urban development projects start by considering how the project can contribute to the central values of the city (e.g. inclusiveness, economic vitality, and sustainability) and its related ambitions (e.g. poverty reduction, boosting innovative businesses or reducing the city's consumption of fossil fuels). To identify potential paths of development, influential contextual trends are identified, actor networks are mapped and distinctive qualities of the area are traced (see Boelens, 2009; Hartman et al., 2011). Traditionally, the next step would be to design an integral plan for the area for the next 10 to 20 years, including a fully developed real estate programme, an estimation of land rates, and a detailed zoning plan.

However, as an adaptive approach to planning aims to increase the responsiveness of urban systems to changing circumstances, demands, and opportunities, a different route is taken.

The starting point for development is the existing urban fabric and the actual and virtual potentials that are seen by actors involved. With actual potentials, we refer to niche developments that already take place in the area. With regard to our former harbour area this can for example include fishing boats converted into houseboats or the transformation of a former warehouse into a fish restaurant. Virtual potentials are about the opportunities, ideas and dreams actors associated with the area or specific spots within this area. For instance, realising heat exchange systems by linking the heat grid of buildings to the harbour water reservoirs, or a coalition of actors who want to turn a shipyard into a music club or theme park. The aim is not to define how these potential developments can be fit into an area's configuration that is envisioned for the longer term. Rather, the objective is to turn these potentials into a first step of an incremental development process. This process is about connecting the current dynamics of the area and its distinctive qualities with the ambitions for the long run, while securing the area's capacity to adjust its pace and direction of development over time.

5.1 SPATIO-FUNCTIONAL CONDITIONS FOR ADAPTIVE INNER-CITY TRANSFORMATION

Discussing a regulatory framework that can guide the incremental transformation of our imaginary case in an adaptive way, we apply the conditions on spatio-functional configurations introduced earlier: conditions that secure quality of life under a variety of potential development trajectories, conditions that increase the context-sensitive flexibility of the development process, and conditions that stimulate the emergence of societally desired development trajectories.

For the first category, the precautionary principle can, for example be a condition for development in relation to safety and environmental issues (Rijswick & Salet, 2012).

Additionally, conditions can be defined for the accessibility of public space, the degree of alienation between buildings, and the financial safeguarding of and spatial reservations for primary infrastructure and services. As we believe that quality of life also includes 'the right to the city' for all socio-economic classes of society, a minimum percentage of social housing per hectare can be another condition. With regard to the second category, generating context-sensitive flexibility, the redevelopment of the former harbour area can for instance be guided by a global land use plan, in which only broad categories of functions are defined. One can also think of allowing the temporary use of existing spaces or pop-up structures for creating temporary new spaces. These temporal developments can stimulate the exploration of alternative configurations, to reduce start-up costs, and to support place-making activities (Silva, 2016). Another option is the implementation of zoning-independent development rights, in which landowners can trade development rights (type of function, density and height). This allows planners to roughly set the programme for the area, without defining the urban configuration.

The third and final category includes conditions that foster the emergence of preferred developments trajectories. These preferred trajectories can be related general societal ambitions, for instance to enable the transition to climate-proof cities, or area-specific preferences, for example strengthening the water-urban interactions. Considering the ambitions for the transformation of the harbour site, a more general ambition to reduce the environmental impact of the city can be translated into the condition that new developments have to be energy-neutral. Area specific ambitions can be reflected in, for example, the condition that all buildings should have a public function on the first floor in order to stimulate that the area becomes a multifunctional extension of the centre area of the city. Another condition can be that building transformations should result in a physical orientation to the water, including a publicly accessible space between the building and the waterside.

This way, the harbour feel of the area is strengthened. In sum, the conditions included in the regulatory framework set the general boundaries for the spatio-functional configurations that may emerge over time, both with regard to quality of life standards and desired identity and qualities. At the same time, a specific configuration is not prescribed, nor is the pace of development. This allows the actors involved to respond in a flexible manner to changing demands, new opportunities or arising threats.

5.2. Enabling adaptive inner-city transformation through capacity building

As argued in Section 4, an additional set of conditions is essential for an adaptive development of the harbour site. These conditions concern the capacity of local actor coalitions to contribute to urban transformations and fuel self-organization. In the context of the harbour site, self-organisation mechanisms may trigger a shift of the area's focus towards leisure development, for example. When various actor coalitions see the area as a potentially attractive place for

bars, shops and recreation activities, such as cooking workshops, an openair cinema or a waterbike rental, their initiatives can collectively result in a spontaneous transformation of the economic profile of the area towards the leisure economy.

To utilize the potential of diverse actor coalitions, conditions are required that support the emergence of surprising collaborations of, for instance, local entrepreneurs and retired fishermen, next to or partnering with traditional coalitions between project developers, municipalities and construction companies. Discussing these conditions, we limit ourselves to the three examples introduced in Section 4: improving the availability of relevant information on the area and its context, fostering the step from idea to realisation, and supporting the connectivity between actors.

The first condition can include the provision of open source data on the history of the harbour area, trend reports on demographics, technological developments and economic pressures on various scales, or an interactive digital map showing the initiatives that have already been launched. This enables a wider range of (potential) local actor coalitions to explore development opportunities for the area. The second condition concerns fostering the transition from idea to realisation. Here one can think of providing analyses of best practices in harbour redevelopment. This can inspire actors and help them to identify successful transformation strategies. Another possibility is to create experimental zones where prototypes can be tested. The third and final condition concerns increasing the connectivity among actors, as this can, among other things, boost the emergence of new (innovative) actor coalitions. Implementing an online platform where supply and demand of space or services can be matched during the transformation of the harbour site can increase actor connectivity. Also, the appointment of 'matchmakers' who are responsible for coaching local coalitions and updating them on other initiatives and networks in the harbour area can be of help. Finally, alternative forms of financing projects can increase connectivity. In the harbour case, crowdfunding, for example, can be used for the creation of a temporary, manmade beach on one of the empty industrial plots in the area. Or a business development zone can generate collective financial resources to upgrade the public space. Hence, we argue that a combination of conditions can enable the emergence local coalitions that play a role in urban development, contributing to the selfinnovating and self-stabilising capacity of the harbour area.

To conclude, urban development trajectories, such as the transformation of a former, innercity harbour area, often involve many uncertainties. In this section, we illustrated how a condition-based, adaptive planning approach may improve the responsiveness of the area in dealing with these uncertainties. The main principle behind the approach is that the conditions generated for development, increase the area's capacity to deal with and benefit from a variety of potential spatio-functional configurations, as well as actor coalitions and their initiatives. The specific way in which the conditions have been operationalised for the presented case indicates that they are situation-dependent to a certain degree, despite their generic and relational nature. This teaches us that conditions for adaptive urban development should be embedded in processes of structural monitoring and learning. Only in this a way can the balance between the generic and the specific be recalibrated from time to time, allowing for development frameworks that support an area's adaptive capacity in the long run.

6 EPILOGUE: IMPLICATIONS FOR THE ROLE PLANNERS AND A FUTURE RESEARCH AGENDA

In response to the uncertainties that challenge planners in guiding urban transformations, this paper explored an adaptive planning approach. Starting from a complexity perspective, emphasis was laid on how the changeable nature of the multiple and interdependent processes underlying urban transformation give rise to non-linear development trajectories. In such a dynamic context, keeping a fit with their environment is key for urban areas in securing their vitality over time. Therefore, an adaptive planning approach is focused on strengthening the responsiveness of urban areas to both foreseen and unforeseen change, and aims to enable urban areas to function well under different circumstances. We argue that this approach requires a shift in the focus of planning strategies; from content (i.e. what) and process (i.e. with whom) towards conditions for development.

We discussed conditions for spatio-functional configurations and for capacity building of local coalitions which allow planners to develop frameworks for adaptive urban transformation. But what does conditions-

based guidance of urban change imply for the role of public planners? We argue that an adaptive planning approach invites planners to adopt the roles of trend-watchers, matchmakers and facilitators alongside their more traditional roles as experts or mediators. As trend-watchers, planners are required to keep an eye on contextual trends, as well as on emerging local initiatives, and to develop proposals for adjusting conditions for development when necessary. As matchmakers, planners are expected to link emerging projects and local coalitions, and to point out opportunities, synergizing new projects with existing urban functions and structures. As facilitators of urban change, planners are requested to promote innovation and experimentation, and to coach the local coalitions that propose them. Planners, by taking up these roles, can co-create the city with traditional and non-traditional actors in urban development.

Exploring an adaptive approach to planning also brings forward issues that require further research. For instance, to what extent and in what way can powerful actors be moved to cooperate to the opening-up planning systems, when they run the risk of weakening their own positions? A better understanding is also needed of how an adaptive planning approach works out for actors less well-organised or skilled: with the open development framework, planners face the risk of primarily serving the interests of well-informed elite. Furthermore, a recent study by Savini (2016) on urban development projects in the Dutch city of Amsterdam showed how actors tend to undermine the adaptive capacity generated in development frameworks by signing contracts under private law, with an aim to increase their legal security. How to overcome these barriers when moving towards a more adaptive approach to planning? We invite practitioners and academics to further research these issues, with an aim to developing a comprehensive theory on adaptive planning, its opportunities and its practical limitations.

ID 1730 | REGIONAL RESILIENCY: EXPLORING THE EMERGENCE AND RESILIENCY OF TWO REGIONAL INITIATIVES IN THE NETHERLANDS

Alda Alagic¹

¹Gent University

alda79260@gmail.com

ABSTRACT: In the past few decades we have observed a proliferation of regional initiatives labelled in various ways. Some refer to city-regions, appealing to some kind of territorial coherence of adjacent cities, others to learning -, creative -, or competitive regions, ascribing to the region human abilities to learn and create. Even though such regional initiatives are very distinct from each other in their appearance and process of development, most of these initiatives are results of actor networks with some kind of common interest crossing the administrative boundaries of cities. As such, from an actor-network perspective, it can be argued that regions emerge through network activities between various actors who in first place prioritise meaningful (economic) relations above spatial scale and fixed demarcations. In the same line, regions are thought as a landscape of perpetual overlapping processes of becoming. Such regional processes develop at a certain grade of complexity and uncertainty of how relations (re)assemble and how do they become resilient. Consequently the dynamic context of changing relations also implies a different role for planners in regional initiatives. Even though it seems impossible to plan for such complex and volatile regional processes, planning activities occur and regional concepts emerge in co-evolution with other socioeconomic processes. In this paper we will explore the emergence of two regional initiatives in the Netherlands and their resiliency. More specific we want to address the meaning of the regional concepts in relation to the resiliency of regional initiatives. One, Brabantstad, is a governmental initiative concerning five midsized cities in the province of Brabant. The other, Eindhoven-Leuven-Aachen-Triangle, is a cross-border regional network including Flemish and German cities Leuven and Aachen. With the help of Assemblage Theory and Actor Network Theory we will investigate which conditions lead to more (or less) resilient and robust regional initiatives and their capacity to transform their context.

1 INTRODUCTION

Contemporary regionalization processes, which involve various stakeholders with different economical interests, political differences, and cultural challenges, encompass much more complexity than the mere material and administrative construction of clearly defined regional territories. Such intertwined territorial and social formations influencing each other leads us to the debates about post-structural space conceptions and linkages between the social and the material constellations (Amin & Thrift, 2002; Massey, 2005; Murdoch, 2006; Urry, 2002). The post-structural conceptualization of space is based on the idea that space is produced within heterogeneous networks and that different conceptualizations and meanings of space can exist next to each in a constant process of becoming (Boelens, 2009; Murdoch, 2006; Rydin & Tate, 2016). This means that the post-structural concept of space prefers agency and the act of constant (re)assembly of networked space above predefined structures (Boelens & de Roo, 2014; Farias & Bender, 2010; Van Wezemael & Silberberger, 2016).

From the perspective of post-structural concept of space and organization, resilience is linked to the agency of the actors, which is the main instrument to increase the resiliency of an emerging regional initiative (Brown & Westaway, 2011).

In this paper we want to address the conditions of regional resilience by investigating two case studies in the Netherlands; a cross-border regional initiative Eindhoven-Leuven-Aachen-Triangle (ELAT) and a governmental collaboration of representatives of the province and five middle-sized cities in the province of North-Brabant (Eindhoven, 's Hertogenbosch, Tilburg, Breda, and Helmond). Using the translation process from Actor Network Theory we can describe and analyze the process of emergence of the two regions. We will then relate the case studies to the theories of resilience in order to research the real meaning of the regional concepts and conceptualizations emerging during the process itself.

2 RESILIENCE OF REGIONAL ASSEMBLAGES

In resilience thinking there is a difference made between equilibrant (engineering) (Holling, 1973), ecological and evolutionary interpretations (Boschma, 2015) of the term. According to the equilibrant approach, resilience is defined as the ability of a system to quickly return to its original state after a shock or disaster (Peterson, Allen, & Holling, 1998). The main focus of such approach is to define the desired functional equilibrium and to develop a mechanism, which allows the parts of the system to find their way back to the original state after unforeseen event(s).

From this perspective and in relation to regions, the focus mainly lies on economic resilience and the capacity of regions to address problems generating longterm success and how regions recover from external shocks reestablishing former states of equilibrium (Christopherson, Michie, & Tyler, 2010). The ecological interpretation of resilience emphasizes the existence of multiple equilibriums and a system moving from one to another (Holling, 1973, 1996). Even though different from each other, both engineering and ecological concepts of resilience acknowledge the existence of equilibriums to which systems bounce back or forward. Contrary to such linear processes regional initiatives develop in seemingly chaotic and volatile trajectories with characteristics such as emergence, self-organization, co-evolution, and uncertainty (Van Wezemael & Silberberger, 2016). Due to its linear and normative approach, both engineering and ecological approach are insufficient to describe resilience in heterogeneous and highly dynamic processes such as emerging regions. Such regions are in the continuous complex processes of becoming, transforming, and confronted with highly uncertain outcomes (Allen, 2011; Anderson & McFarlane, 2011; Farias, 2011; Farias & Bender; McFarlane, 2009; Van Wezemael, 2008). From the perspective of perceiving regions as complex, relational and heterogeneous, its resilience cannot be conceptualized as the ability to return to the 'normal' state of affairs. Resilience should rather be conceptualized as the capacity of the region "as the ability (...) to change, adapt, and, crucially, transform in response to stresses and strains" 302 (Carpenter, Walker, Anderies, & Abel, 2001; Davoudi et al., 2012, p.: 302) without slipping into a new regime or identity (Walker, Salt, & Reid, 2006). From that perspective regional resilience is not a static and fixed quality but 'a dynamic capacity to move between a range of adaptive states without crossing a threshold of no return' (Dovey, 2017; p. 486). However governmental policy and therefore also spatial planning, as one of the main instruments to put political concepts into practice, emphasize the equilibrant resilience and the absorption of shocks and maintaining functions of the system and less on the ability to transform and adapt (Davoudi, 2016; Davoudi et al., 2012).

From the perspective of co-evolving regional processes, resilience thinking is related to various aspects of social organization and in particular the role of humans as integral elements that give shape to processes through which social and spatial structures are transformed, adapted or maintained (Dwiartama & Rosin, 2014). Hence ideas of regional resilience can be linked to the concepts of learning-, creative-, selforganizing regions in which the need for partnerships, alliances, collaboration and shared concerns are perceived as crucial in order to achieve resilience through combined actions (Cole & Marzell, 2010; Ross & Berkes, 2013). Here Actor Network Theory Theory (ANT) offers a distinctive approach to the study of regional processes aimed at achieving resilience (Dwiartama & Rosin, 2014). ANT goes beyond the dichotomy of social natural actors and proposes that both human and non-human actors are capable to influence the development of regional systems represented as actor-networks by forming relations and enrolling other actors (Dwiartama & Rosin, 2014). According to ANT, agency is not only attributed to humans but also to non-human actors such as objects (buildings, vehicles), nature (animals, rivers, or weather). As such, the concept of agency, extended beyond the human intentionality, in ANT offers several advantages in to studying resilience in regional initiatives (Dwiartama & Rosin, 2014).

Instead of focusing on demarcated sites of action (e.g., neighborhood, city, region, state) or specific aspects of social interaction (e.g., legislation, spatial planning), ANT focuses on the relationships between actors and the way these relationships shape, transform, and/or influence the network of related actornetworks. As such it allows us to think the region as a 'global entity -a highly connected one- which remains nevertheless continuously local' (Latour, 1990; p.6).

ANT proposes that agency only exists when actors are related to each other not in the mere sense of its existence, per se, but that there is an evident amount of energy and time poured into the relationship. Additionally an actor is distinguished as "any thing that does modify a state of affairs by making a difference" (Latour, 2005, p. 71).

Resilience from the point of view from ANT is seen as an ongoing process, generated by associations between actors within actor-networks and their efforts to remain indispensable, change or transform the actor-network according to their interests. Hence when we talk about a region with resilience and its capacity to act and respond rapidly to the unexpected (Innes & Booher, 2003), in reality we are talking about actor-networks with capacity to connect, act, and respond to the unexpected events. We propose to research the adaptive capacities within regional processes making use of the translation process from ANT.

Additionally, and based on existing research, adaptive regional resilience can be defined on the characteristics of: 'stability', 'self- organization', and 'innovation' (Peng, Yuan, Gu, Peng, & Ming, 2016), 'robustness', 'redundancy', 'rapidity' (Tempels, 2016), 'diversity' and 'redundancy' (Dovey, 2017). In the following we discuss the characteristics of resilience through the translation process of ANT. To be more specific, in the translation process and as part of the problematisation phase (Callon, 1986), the capacities of actors are described as the capacity of the lead actor to recognize and precisely describe an emerging controversy as well as to propose an innovative solution (Venturini, 2009). In addition, such actors could also be capable of mobilizing existing in order to convince them to accept the proposed solution and forming new (regional) external relations in order to solve the problem (self-organization). External relations are crucial because the emergence of a controversy (problem) is actually proof that existing actor-network relations have not prevented its emergence and that a solution must be searched elsewhere (Boonstra & Boelens, 2011; DeLanda, 2006). In the emerging regional process an Obligatory Passage Point (OPP) can emerge (Rydin, 2013). During the intereseement phase negotiation and consultation with other actors occurs whose identities and roles are translated and enrolled through the OPP (Callon, 1986). Translations of identities is crucial in order to make sure that all actors pursue the same regional idea and behave accordingly to the terms of enrolment in order to achieve stability. An OPP is an important mechanism to direct self-organization corresponding with reproduction, confirmation, creation, re-creation of self, and self-maintenance (Boonstra, 2015). During the enrolment phase the amount of actors increases while the relations are further stabilized. To successfully enroll actors beyond the initial problem definition and solution, the lead actors must be capable of adapting and transforming the regional idea and concept in order to align interests of not only increasing amount of actors but also diverse set of actors (A. A. Alagic, L. Boelens, & M. Glaudemans, 2017). Through enrolment of as much as possible actors thinking and behaving in accordance with, by the lead actors, proposed concept of the region, the region in fact gains robustness. However, the characteristics that can increase regional resilience are also linked to diversity and redundancy (Dovey, 2017). The diversity of enrolling actors increases the capacity of the regional network to adapt because its parts are able to react to stress in various ways. As such diversity is linked to redundancy as the capacity of the actors to 'perform in different ways by moving forms and functions around so that actors can perform a multiplicity of functions' (Dovey, 2017). In fact this would mean that not only the region gains resiliency by heterogeneous set of actors but also that the process of enrolment must allow for actors' identities and roles to stay or become heterogeneous in order to increase their modes and radius of agency (A. Alagic, L. Boelens, & M. Glaudemans, 2017; Van Wezemael & Silberberger, 2016). In other words hybrid identities of the actors in which they can perform different roles in different setting are desired condition for achieving resilience. For spatial planning in relation to resilience, the existence of heterogeneous identities and interests is in fact a stumble block for its insufficient ability to include and accommodate different sets of knowledge (Innes & Booher, 2010; Rydin & Tate, 2016) due to the tendency of formal planning to develop methods and models in order to optimize the efficiency of the systems (Dovey, 2017). According to ANT and during the enrolment phase, the lead actors are rendered invisible through spokespersons speaking on behalf of the whole regional network and a set of inscriptions (Rydin, 2013). The inscriptions in the form of statistical data, contracts, policy and strategy documents, or laws 'allow the lead actors to execute power through space and time without their

continuous effort and labour' (Rydin, 2013), in order to maintain achieved and further induce stability and robustness of the region. Maximal robustness is achieved during the mobilization phase the regional relations become institutionalized and taken for granted, while focal actors govern from a distance.

3 INTRODUCTION CASE STUDIES AND METHODOLOGY

For this research and for two case studies we have conducted a total of twenty six (26) in-depth interviews. Both cases include actors from Eindhoven and some of them were aware of both regional initiatives and were asked to reflect on both. We have focused on emerging controversies, research questions and solution propositions conceptualized by the lead actors (Venturini, 2009). Additionally we have looked at developed strategies on how and which actors are enrolled during the process and what effect they provoke within the regional actor-networks and further regionalization. Our goal was to find what kind of conditions contribute to the regional resilience and how these conditions emerged or how the participating actors created these particular conditions. During the interviews the actors were asked to reflect on their role and activities within the actor-network and how the relations between them and other actors started, evolved, and which materials/objects played a role in the assembly process. This way we were able to retrospectively 'follow the actors' (Latour, 2005, p. 12) as the actors revealed the traces "in their weaving through things they have added to social skills so as to render more durable the constantly shifting interactions" (Latour, 2005, p. 68).

4 CASE STUDIES ANALYSIS

4.1 EINDHOVEN – LEUVEN – AACHEN – TRIANGLE (ELAT)

During the 1980's Philips, based in Eindhoven, encountered a major controversy. It was losing its leading global position in microelectronics due to a changing context in which technological innovations were generated more in open actor-networks of inter-firm alliances (Chesbrough, 2003). Due to Philips' dispersal in the previous years it has set up factories and laboratories in among others also Louvain (BE) and Aachen (GER). Philips' external relations in these two cities would prove to be crucial for the emergence of ELAT, a cross-border high-tech region including actors from three cities and three different countries. The solution for Philips' controversy of 'how to implement open innovation' included consultation and enrolment of representatives from Interuniversity Microelectronics Centre (IMEC) from Louvain. IMEC already accomplished to set up and implement an open innovation environment in its laboratory and Philips' representatives saw the opportunity for learning and exchanging identities.

However Philips during the knowledge exchange process with IMEC, Philips also learned that in order to achieve an open innovation environment a broader set of diverse actors and tacit knowledge was needed. At the same time leading actors from the region of Eindhoven were confronted with controversies of declining local economy due to declining power of Philips and shifting central government's policy to focus on the its major cities in stead of equal distribution funding (Ministry of Economic Affairs, 2004). As solution for these issues regional reorganizations was proposed and resulted into the set up of a regional development agency Brainport Development. Lead actor the mayor of Eindhoven consulted the local educational institutes (Fontys Hogeschool and Technical University Eindhoven) resulting into an advisory board (for the municipality) advocating the Triple Helix idea in which is proposed to set up networks between academia, government, and business actors to foster technological innovation. To facilitate the emergence of such networks, Brainport Development organized round tables around the idea of Business and Technology Communities (BTC). The BTC meetings became the Obligatory Passage Point of a diverse actor-network pursuing relational intensification among technological firms and between local government and technological firms in order to achieve technological innovation and thus first step towards an open innovation environment (A. A. Alagic et al., 2017). During these meetings the representatives of Philips advocated and promoted the idea of an open innovation environment to other participants¹ through their successful collaboration with IMEC in Leuven and thus an already existing regional axis of technological innovation between the two cities (R. Harwig, 2012). Additionally during these BTC meetings Philips

¹ (technological firms, academia, municipality, SRE, Brainport development)

representatives also achieved to convince others of the importance to enroll actors from Aachen where Philips had facilities. Specifically this idea was presented as a regional concept of regionally interconnected high tech campuses in the three cities. During the negotiation process of such ideas, roles were discussed and developed resulting into a set of actors intensively travelling to the other two cities (Louvain and Aachen) in order to convince eligible actors of the value of an open innovation environment through intensification of relations between the three campuses (R. Harwig, 2012). The regional concept and goal transformed once again portraying a regional triangle between the three cities. With this newly translated regional idea the lead actors applied for Interreg IIIB funding allowing further assembly of the regional concept (T. v. Lier, 2012). During this phase, the role of focal actors transferred to the three mayors of each city who appointed spokespersons and strategies were developed to further intensify the relations (R. Harwig, 2012). This resulted into an array of divers effects, newly emerging actor-networks, influencing the existing relations and reassembling existing relations into new actornetworks.

For example, two KIC locations were assigned to consortia formed as part of ELAt regionalization process (T. d. Bruijn, 2012). Spatial effects include the emergence of high-tech campuses in the three cities with aligned developmental strategies. On the high-tech campus in Eindhoven, a jointventure action between various actors resulted into Holst Centre, in which the identity of IMEC was translated into an open innovation environment for the development of sensor technologies (R. Cuyvers, 2012). Eventually, cross-border regional network ELAt merged with the governmental cross-border initiative Top Technology Region (TTR)¹ (T. v. Lier, 2012). The main reasons were that the Interreg IIIB funding for ELAt stopped and that the Dutch central government saw the opportunity to implement the success of ELAt into the more bureaucratic provincial initiative TTR (T. Hommels, 2012). Dutch central government supported the peripheral Dutch province of Limburg to initiate the TTR network with its direct cross-border neighbors in first place to reverse its economic decline (D. Plees, 2012; T. Hommels, 2012). Left without (European) funding, focal actors of ELAt, the mayor of Eindhoven supported by other two mayors, merged ELAt with TTR against strong resistance of the spokespersons (P. Scholmeesters, 2012).

4.2 BRABANTSTAD

Around the same period (1990's) on the territory of the Dutch province North Brabant a new governmental network emerged including the representatives (mayors) of the five middle-sized cities² and the province of North Brabant. As such this regional network functions as some kind of a middle layer between the official administrative entities (province and municipalities). However the regional network Brabantstad does not strive to judicially institutionalize the relations, meaning that the network does not have any juridical powers over certain territories as the focal actors have over the province or the cities. The main controversy that triggered this kind of regional thinking and reorganization of existing actors into a newly formed regional initiative was a combined set of issues raised in that particular period.

The first one was the policy shift of the national government from equal distribution of central government's funds to one supporting the big cities (Janssen-Jansen, 2004). With the central government's intention to focus on support of the country's major cities the middle-sized cities began to fear to be left out of funding and support (P. v. Ree, 2014).

Secondly, this change of context in which the emphasis of national policy is directed towards the main urban nodes and their performance, perceiving the cities as the central places of socio-economic dynamic, also challenged the relation between the province and its main five cities. Unlike the provinces of North-, South Holland, and Utrecht, the province of Brabant is traditionally seen as the province of the farmers (Janssen-Jansen, 2004). At that point the Province of North-Brabant faced a reality of lacking strong and reliable relations with its major cities and therefore a lack of effective alignment and coordination of interests (J. Janssen, 2013).

¹ Cross-border initiative of six adjacent provinces with their deputies as representatives: Limburg (NL), North-Brabant (NL), Limburg (BE), Flemish-Brabant (BE), Liege (BE), Northrhine Westfalia (GER)

² 3 Brabantstad: an alliance between the mayors of Tilburg, Eindhoven, 's Hertogenbosch, Breda, and Helmond and the Deputy of the province North Brabant

Thirdly, the formation of a parallel regional initiative City Region Eindhoven (SRE) in 1993, as technological core of the province and the country, formed a serious candidate to become an official province (Haran, 2010). From that perspective, SRE formed a challenging threat to the institutional power and territory of the province of North Brabant in line of the ongoing discussion about the role of the provinces. Every now and then, it is proposed to reassemble the provinces into greater territories or to decentralize their power to smaller regional units (Haran, 2010; Janssen-Jansen, 2004). Additionally, the Ministry of the Economic Affairs adopted a view that North Brabant consists of two different socioeconomic urban networks, namely the west and the east wing (Haran, 2010). According to this conception, the east wing of Brabant with the city of Breda is perceived as an economic entity oriented towards economic activity around the harbors of Rotterdam and Antwerp, while east wing's forces tend to concentrate around the technological innovation hub of Eindhoven supported by a strong manufacturing industry in the surrounding (Haran, 2010).

Concluding, the Province of North Brabant faced a possibility that it could lose its magnitude of influence on its whole territory, especially the cities.

Faced with the challenges and the threats outlined, the Royal Commissioner Frank Houben consulted scientists, urban planners, architects, and policy experts who he commissioned to write a manifesto on the future of North-Brabant. Various interviewees mention this manifesto as a turning point for the set up of the regional network Brabantstad. The main conclusion of "Manifesto North-Brabant" was that "the future is knowledge and the cities; not just agriculture" (Broess & Grijzen, 1997) having in mind that the province of Brabant has a centuries old farmers identity. To act in line of an urban future, Brabant and its people, therefore, must first deal with their traditional conception of romantic countryside as basis of their identity.

The manifesto further notes that the policy of EU is focused on regions while at the same time large parts of the Dutch sovereignty are transferred to the EU-agencies, that it is inevitable that the future socioeconomic developments will mostly benefit city-regions (Broess & Grijzen, 1997). It is pointed out that from this European perspective on cities and city-regions, that the future of Brabant depends on the relations between the Brabant cities. Armed with such arguments to rethink 'Brabant's rural areas as a mold of the big city' (p.32) and combined with claims that an alliance between the cities would prevent unnecessary competition towards third parties such as the central government and the European Union the Royal Commissioner Frank Houben started to regularly meet with the mayors of the five cities.

From various inter-consultation between the chairman of the province and the five mayors, the idea was born to create a city-network (A. v. d. Broek, 2013). It was assumed that this network could solve the controversies of provincial territorial instability of the province, lack of funding for the individual cities and prevent unnecessary competition between the cities by aligning their strategies towards third parties. On one hand the province was building a relation with the cities and gaining their trust and loyalty in order to prevent possible assembly of new regions on its territory and therefore keeping Brabant whole. On the other hand the main motive of the actors to collaborate seems to be an opportunity to form a strong lobby towards the central government and European Union, which would increase their chances for more financial means. As part of the translation process (intersement), the focal actor delegated its role to a spokesperson establishing a Programme Bureau Brabantstad at the province of Brabant. Additionally, through the work of the Programme Bureau representatives, lower layers of the municipal and provincial lead actors (administrative officers, planners, strategic advisors, etc.) got enrolled and take part in formalized consultations and meetings. The consultation between the participating actors is formalized through a fixed annual agenda of multilateral meetings called Brabantstad Tuesdays. These meetings function as OPP through which the enrolled administrative officers are informed immediately of the ideas and agenda of the lead actors for which they possess the tools to implement in the individual cities. Also Brabantstad is represented by a lobby delegate at the headquarters of the EU in Brussels.

Regional conceptualization of Brabantstad is based on the metaphor in which the territory of the province is represented as a tapestry mosaic in the shape of green landscape patches in-between a patchwork of dense five urban cores and smaller patches of villages with their own sociospatial characteristics. This metaphor is also part of the spatial development strategy in which is stated that the existing patchwork of separate zones should be maintained and further reinforced meaning that the cities should become more densified and the green patches should keep and develop their green, agricultural and leisure characteristics. Regional patchwork concept is emphasized, reinforced and maintained through various strategic documents and regional studies and designs commissioned by the Programme Bureau. Another

regional concept and developmental model of Brabantstad focuses on the three corridors: Rotterdam - Antwerp axis, Amsterdam - Den Bosch - Eindhoven axis and Rotterdam - Breda - Tilburg – Venlo corridor. Further the spatial strategy involves improving connections to the three corridors and the cities in order to improve Brabantstad as a daily urban system (Noordanus, 2014).

Even though Brabantstad was acknowledged as strategic urban network in the Fifth National Policy Document on Spatial Planning, still one of the controversies was not yet settled and not all ministries perceived it as a whole urban network resulting into contrasting policy and funding towards the participating cities (Haran, 2010). In ANT term it can also be stated that the network insufficiently developed enrolling strategies in order to convince the external relations of its existence and relevance. However, it can be argued that Brabantstad achieved the mobilization phase in ANT terms based on two initiatives undertaken by the actor-network. In 2007, the actants managed to formulate and execute a concerted agenda of projects in Brabantstad. The agenda was backed up with financial means put together by the cities and the province resulting into an investment plan named Meerjaren Programma (1 billion euros). Secondly, in 2008 and part of the same concerted agenda, the regional network of five cities decided to apply for the title of European Capital of Culture in 2018. Even though, the jury decided to award Leeuwaarden with the title and subsidy to represent the EU in 2018, the application alone is seen as an achievement for Brabantstad. The process of application is conceived by its actants as a positive development of the network mainly due to the fact that the divers actants showed the ability and will to align various interests of the different cities into one common strategy and plan, presented in the bid book Brabantstad 2018.

5 ANALYSIS RESILIENCE STABILITY

"Formation of Brabantstad is seen as a solution to the emerging controversies (territorial, power and funding at stake) of the lead actor Province of North Brabant. The solution for the controversy is sought in ways to return to the previous state: coherency and integrity at provincial level. From that perspective the actor-network Brabantstad is focusing on the equilibrist resilience. Internal stability is further enforced through exclusion of other actors (smaller municipalities and non-governmental actors). Main mechanism for this exclusion is the formation of a strong OPP (Programme Bureau + formalised meeting structure) where identities of the actors are constructed and controlled.

Also by focusing on the development on physical infrastructure, Brabantstad is in fact striving to increase its internal stability. Spatial planning is playing a crucial role in this element of self-organisation and consultation among planners from different cities increases the knowledge and interest alignment in the plans. However the planners stay within their traditional professional boundaries following the ideas and policies from above by executing the central state, provincial and municipal agendas. Consultation among the planners has not resulted into new regional concepts or enrolment of other than by the OPP selected actors.

Formation of ELAt occurred in a much more rhizomatic way. The solution for the controversy on how to create an environment of open innovation did not start with a pre-defined regional concept but developed through building relation with eligible actors.

5.1 SELF-ORGANISATION

Self-organization is best understood as a relational process in which the actors search for more order. In relation to adaptability in a changing context self-organization must be dynamic to handle the change. Changing context provokes action in organized systems as we observe that provincial lead actors are forced to transform their relation to the actors from the cities.

From the perspective of the characteristics of self-organization (reproduction, confirmation, creation, recreation of self, and self-maintenance) the idea of Brabantstad is reproduced in the governmental networks through meetings of lead actors. Created regional concepts are further reproduced through concerted agenda and execution of local building projects. However these building projects are result of local agenda's, which were bundled under the name of Brabantstad. As such the projects served local leading actors and not specifically regional concept Brabantstad. Recreation and self-maintenance are

achieved through publication of regional concepts, commissions of design projects as well as a fixed annual agenda of meetings and consultation with each other.

ELAt actors on the other hand show capability to involve different and distant actors through creation of enrolment strategies, which include alternating regional concepts. As the actor-network grows, the actors learn from each other and recreate each other's identities in their own environment. As example, Philips resettled a whole research department to IMEC in order for their employees to collaborate and learn.

IMEC's (Louvain) open innovation identity is recreated in Eindhoven by the set up of Holst Centre on the high tech campus. DSP Valley, a networking platform originated in Louvain, is recreated in Eindhoven as well. This all has contributed in the intensification of the relations and creation of a distinctive region on the axis of the two cities.

5.2 INNOVATION

Brabantstad actors focus on predefined regional strategies and developmental models (daily urban system, corridors, zoning). Such models prioritize certain actors above others and do not allow different knowledge to enter the network, which in fact is crucial for innovation. The political landscape of the region is not transformed. The distribution hierarchy of administrative power stays the same in which the roles of participating actors and their distribution of power is locked in the centuries old model and procedures. The leading actors can translate the ideas of Brabantstad through the usual provincial and municipal procedures but do not develop strategies to involve the inhabitants, the ones that in fact evaluate them through democratic voting, into the decision making process of Brabantstad. The conceptualization of Brabantstad as a patchwork of divided green and red zones is bounded by administrative borders and as such serves as a representation (from above) of the territory of the province of Brabant. In other words it is as a spatial metaphor used to seduce actors in certain direction of spatial development without addressing their functional relations and interests.

Focal actors of ELAt show capabilities to develop innovative strategies in order to enroll other actors. Innovative and alternating regional conceptualizations are crucial part of such strategies. It is evident that for successful enrolment process regional concepts must co-evolve with the transforming actor-network. In addition, entering actors (through OPP) with their specific knowledge alternate the context and in relation to other actors generate innovation (technological, policy, spatial concepts, etc.) further stabilizing the network. However the leading actors fail to develop innovative strategies to enroll financial means after the Interreg funding stopped.

5.3 ROBUSTNESS

A complex actor-network is robust if it keeps its basic functionality under failure of some components. In Callon's words robustness is accomplished through successful translation or when as many actors are enrolled as possible.

One of the main controversies to be solved by the province of Brabant could in fact be interpreted as to increase the robustness and coherence of relations on its own administrative territory. The translation strategy to enroll the leading actors (mayors) of its subordinate cities involved the concept of a region (the province) perceived not by its administrative borders but various regional concepts such as a patchwork of green and red zones, daily urban system, metropole, and corridors. It could be argued that such regional planning concepts were presented as proof of an existing common shared region as strategy in order to seduce the mayors to align their interests and begin to act as a unified and coherent region. Additionally this would increase the magnitude of influence of the province as well as prevent the possible break-up of the province into a west - and east flank or the formation of a new administrative region surrounding Eindhoven. This has worked as so far as the lead actors have aligned their lobby strategies towards the central government. It has been argued that the alliance has not achieved anything substantial for the region as a whole except an effective network of city representatives who successively lobbied for each other's individual projects subtracting financial means from the national state and the European Union ((Janssen-Jansen, 2004) ELAt achieved a certain level of robustness through translation phases, which enrolled more and more diverse and spatially dispersed actors. The main condition for increasing its

robustness was the successful enrolment of Interreg IIIB subsidy. The financial support allowed the leading actors to further assemble the external actors, contract a full time project leader, increase the mobility of spokespersons, develop common strategies, documents, and a website. However, once the funding stopped after four years ELAt was merged with another initiative, which in fact meant the end of ELAt. This means that the lead actors failed to develop strategies to increase robustness by enrolling eligible actors to continue the funding in some way.

6 CONCLUSIONS

In this paper we aimed to research how resilience is built in emerging regional initiatives by researching the conditions which contribute or obstruct resiliency. More specifically our goal was investigate what role the spatial planning plays or could play in this process. From our analysis we observe that resiliency is not only a matter of sum of all parts but that it includes a form of collective agency which becomes from "... interactive, co-ordinative and synergistic dynamics of their transactions" (Bandura 2001:75–76, Ross and Berkes 2013:26).

This collective agency is an actor-network property and emerges through the relations between its members. With ANT we were able not only to research the relations between the human participants but also their relations to emerging technology, regional concepts, administrative borders, built environment, policy documents, etc.

By analyzing the process of becoming of the two regional initiatives we have discovered that the leading actors focus on different interpretation of resilience and that spatial planning plays a crucial role in both. Challenged by a controversy including the competition of a newly formed city-region Eindhoven and the central government perceiving the province as consisting of two separate economic zones, the province of Brabant initiated Brabantstad in order to increase its internal stability and coherence. As such the main goal of the lead actor seems to be to return to the original state of a unified province. From that perspective, Brabantstad is building on the equilibrist resiliency, which is aimed at developing strategies to maintain and/or return to the 'desired' equilibrium. In that process lead actors use the already existing regional concepts (daily urban system, corridor development) and conceptualizations coming forth out of the process (Brabantstad Mosaic Metropole) to underpin and reinforce the territorial unity of the province and its borders. The type of strategies that are developed and the fact that only governmental actors are enrolled reveals that the eventual goal of Brabantstad is to keep things together and prevent new regional actor-networks to affect the existence of the province. The translation process develops in a strict and linear process directed through the Program Bureau Brabantstad. Identities and roles are defined by the six leading actors and translated to the lower levels of administration.

In the case of ELAt, we observe a much more rhizomatic and heterogeneous regionalization process in which regional concepts co-evolve within the assembly process and serve as a strategy to bring regionalization further, induce emergent actor-networks, and enroll distant actors. Here we observe that roles and identities also emerge as result of the regionalization process and that they are not predefined and imposed by the lead actors. During the assembly process certain borders emerge such as the triangle of the three cities revealing the desired spatial location of the actors and the enrolment of actors connected to the technological innovation. After ELAt merged with the provincial TTR regional initiative, we observe similar regionalization process as Brabantstad. The leading actors of the provinces emphasize their territorial administrative borders and focus on reproduction and reinforcement of these borders through internal organization of relations.

From this perspective, the pursuance of resiliency in regional planning depends upon how resilience is conceptualized and promoted by the leading actors. However in the case of ELAt we see that the regional concepts contribute to the pursuance of different interpretations of resilience and could perhaps be more studied and applied as instruments in achieving regional resilience.

T19 | RESILIENT AND SUSTAINABLE TERRITORIES

CO-CHAIRS: RICHARD SLIUZAS; ADRIANA GALDERISI; TERESA CÁLIX

The increasing frequency and severity of natural and human-induced disasters, often linked to extreme weather events, causes considerable losses and damages in cities and regions worldwide. Urbanization trends and planning processes oriented to the development and management of human settlement systems of various sizes and forms generate multiple environmental concerns - from the degradation and fragmentation of natural ecosystems to the more and more frequent climate-related hazards – and may drive increased exposure of human settlements to a local mix of hazard factors within a short time span. Moreover, cities all over the world are more and more often threatened by significant social pressures related to poverty, conflicts or to increased migration flows and temporary human settlements, such as refugee camps. Disaster risk reduction (DRR) and the building of resilient communities and settlement systems feature strongly in international fora such as Rio+20, the Sustainable Development Goals and UN-Habitat's New Urban Agenda. The on-going process towards the implementation of the Sendai Framework for Disaster Risk Reduction 2015-2030 clearly identifies the decisive importance and role of land use and spatial planning in making resilient and less vulnerable territories and communities in combatting current and future natural, technological, na-tech, socio-economic and socio-technical hazards.

But how can planning contribute to realization of these agendas, particularly at sub-national level?

Land use and urban planning are more and more frequently identified as key non-structural risk mitigation measures to avoid exposure in most hazardous zones and to reduce exposure and vulnerability in already built areas. Even so, risk reduction, climate adaptation are often still addressed through sectoral approaches and tools, with limited integration into land use and urban planning processes. Moreover, in many countries the response to the more frequent disasters is still mostly reactive rather than proactive.

This track addresses ways and means to more effectively integrate DRR and Climate Adaptation through urban and territorial planning and to promote urban regeneration strategies contributing to fairer policies of welfare and hospitality. In line with the conference theme, we encourage contributions that engage with collaborative and proactive approaches as well as with adaptive planning practices, capable to reduce and manage current and emerging risks, through multi-stakeholder engagement and dialogue. We welcome papers of a theoretical, methodological or an applied nature focused on the multidimensional concepts of the resilience and sustainability of territories in the face of environmental and social challenges focusing, above all, on natural and technological risks. Moreover, as the dissemination of risk information through education is a crucial issue in the implementation of the Sendai Framework, we also are seeking contributions that discuss innovations in planning education related to DRR and/or sustainability. Deliberations around social justice in planning, which includes the topics of integration and social cohesion, for improving cities' resilience in the face of current and future environmental and social challenges, are also encouraged.

ID 1315 | A MODEL FOR THE PURSUIT OF ROBUST URBAN FORM

Tony Hall¹

¹Anglia Ruskin University

273ach@gmail.com

1 INTRODUCTION

The starting point of the argument to be presented here is that the physical structure of urban areas lasts from many decades to several centuries. Without rebuilding, it can constrain, or even prohibit, specific urban activities that are thought desirable and being planned for. In contrast, economic and social forces will change markedly over the same time period and it is desirable that the physical structure should be designed to cope with these changes.

Growth of settlements is the norm rather than the exception and, at the very least, there is no basis for assuming that a city will never expand beyond its existing limits. As urban areas expand, it becomes necessary to retrofit them by inserting new, and adapting existing, buildings and by renewing and extending the infrastructure. Increases in residential density will result and will require similar retrofitting. If, therefore, a city is to be planned it must be robust: it should be designed to accommodate change, particularly the expansion of infrastructure, on a continual basis.

Although, at first sight, very long-term physical planning of robust form may seem like a tall order, it will be argued that it is feasible. A theoretical and normative model of robust urban form can be derived, or deduced, from two sets of planning goals - pursuit of quality of life and pursuit of sustainability (Hall, 2015) - and it will be shown that it has some remarkable properties.

2 DERIVATION OF THE PED-SHED

A sustainable goal of minimising use of energy leads to the planning criterion that activities should be located such as to minimise the need to travel. This then leads on to a sequence of further locational criteria, arranged in order of priority. A first priority would be no travel. In practice, this would imply no more movement than would be expected within a building or between adjacent buildings. In other words, mixed land uses would be immediately adjacent to each other in two dimensions or overlay each other in three dimensions.

Obviously, not all activities could, or should, be located so close together. Parks and playing fields would not fit and an attempt to combine retail, commercial and residential activities within an excessive extension of three-dimensional megastructures would militate against a high degree of quality of life. As a second priority, therefore, urban form should permit uses to be located within walking distance of each other. A walking distance can vary between 300 and 700 metres in length, and a typical length is 400m. However, we will wish to talk about an absolute maximum for the extent of development, and to explore its consequences for urban form in general, and so we need a robust figure that would not normally be exceeded. Urban design guidelines commonly suggest an average of 400 metres and maximum of 800 metres radius (Llewelyn Davies et al, 2000).

The resulting form is not a new idea and is referred to in the technical literature as a ped-shed. (Unfortunately, there appears to be no suitable alternative that is problem free.) The structure of a typical 800m radius ped-shed is illustrated diagrammatically by Figure 1. There is some, but not complete, equivalence here with the work of Calthorpe (1993) and many other proponents of the neighbourhood principle (Walters, 2007).

Because of the of both the desire to minimise the need to travel and likely economic pressures on the supply and value of land, the residential density can be expected to decrease with distance from the centre. The absolute density levels within each ped-shed would be determined by the distance of the pedshed as a whole from other urban centres and the socio-economic pressures resulting from this. Nonresidential uses permitted in the settlement would be expected to be concentrated in the mixed-use core.

3 LINKING UP PED-SHEDS

There are clearly limits to what facilities could be contained within one 800m-radius settlement. Adoption of a maximum distance implies that, once such a settlement has been constructed, further development would require additional ped-sheds. The pursuit of sustainable travel now requires, as the third level of priority, that walking gives way to travel between the ped-sheds not dependent on the private motor vehicle. They should be linked by a high-grade public transport corridor, ideally a frequent-service fixed-track facility, each stop at the centre of the mixed-use core. This creates what is often known as a beads-on-string form. If a facility is not within walking distance, then it can be reached by walking combined with public transport. Although travel in total is not minimised, the form adopted means that it can still take place in the most energy efficient manner. The form does not necessarily compel the use of walking and public transport but that it does ensure that anyone without private motor transport is not disadvantaged.

Open land would surround each ped-shed and would thus be within the walking distance of all dwellings. This would not only minimise travel to outdoor recreation but also make it available to those without access to a car, especially children. The green areas between the strings could be substantial and would not only allow ample room for recreation. Such land could also have a significant role to play in urban agriculture and the management of storm drainage.

As with the ped-shed, the beads-on-string idea is not in itself new. Similar ideas have been set out by Peter Hall (Hall and Ward, 1998), Hildebrand Frey (1999) and the Urban Task Force (1999), amongst others. However, the following proposals previously set out by this author (Hall, 2015), have not been commonly advocated elsewhere.

3.1 THE DESIGN OF ROAD PROVISION

Within the ped-sheds, motor vehicle access would be permitted but a low speed environment would favour safe and pleasant movement by foot and bicycle. All the roads, therefore, should have frontage access and speed limited to a maximum of 50 kph or, in some neighbourhoods, 30 kph. Local buses within 50 kph roads could supplement the public transport provision. Higher-speed roads, with no frontage access, would be located outside the ped-sheds and would permit vehicle speeds up to, or even in excess of, 100 kph. They would link the ped-sheds and could carry higher-speed long-distance buses in addition to private cars.

Some may be motorways but others may just be two-lane roads. The point is the access restriction. This implies a two-level road hierarchy for motor vehicles:

- urban streets with low speeds, limitations on heavy vehicles, active frontages and enclosure of space;
- motor roads with higher speeds, surfaces supporting heavy vehicles, no necessary building frontage and restricted access.

3.2 NON-RESIDENTIAL PED-SHEDS

Park-and-ride facilities around public transport stops pose a particular problem. The space taken up by the parking of cars is in conflict with the principle of bringing other uses closer together with pedestrian access. The solution is to locate park-and-ride facilities around dedicated public transport stops away from residential ped-sheds. This would have the further advantage of allowing direct access by the higher-speed roads.

Warehouse and distribution centres and park-and-ride facilities should be located outside of residential ped-sheds. The same would go for all other space-hungry, low-intensity commercial and manufacturing uses, such as very large hospital and educational complexes. They, like park-and-ride facilities, should have their own stop on the quality public transport network. This leads to a non-residential ped-shed containing a combination of such uses, as illustrated diagrammatically by Figure 2. It would also be possible to have a ped-shed that was, say, half non-residential and half residential, or similar proportions.

3.3 DEALING WITH RESIDENTIAL DENSITY

What will be the number of people living in a residential ped-shed? The threshold of population needed to support specific facilities is a perennially difficult one because it is subject to change over time. For example, variations in the economics of retailing affect the support for different types of shops. The catchment areas of schools may be affected by changing educational theories and economics. Moreover, there can be different threshold populations for different types of facility.

The robust solution is that it is the area that is fixed and the density that should vary according to the number of people required to support the facility provided. This contrasts with the more usual approach of density being regarded as fixed and uniform and the number of people required for the catchment area generating the area of the settlement. Different densities in different beads (i.e. ped-sheds) would support a different mixture of facilities. The variation would not just be between ped-sheds but could change over time through the process of redevelopment. Services not found within one ped-shed could be reached by easy travel to another nearby or to a city centre.

4 A THEORETICAL CITY MODEL

Supposing we were to base an entire city on the beads-on-string form, what would the result be? Such a whole-city model would be an idealised form, not an actual city plan, but it would create a theoretical model whose properties could be examined (Hall, 2015). For our model, a radial structure will be adopted, with arms or fingers radiating out from a central point. This is not, in itself, novel and similar suggestions have been made by other authors and for particular cities. The innovation proposed, and pursued, here will be to insert additional radial “arms” between others where space allows, with these arms being served by branches from the public transport lines, as shown in Figure 3.

It is possible to explore different spacing of station stops and separation of the radial arms. The author has examined these (Hall, 2015) but space precludes a full discussion here. The optimum solution was found to be a line of 800m radius ped-sheds with a minimum separation of at least 200m between them and at least 200m between the radial forms. This produces the city shown by Figure 3, extending to a maximum radius of approximately 10 km. Note the emergence of circular or orbital public transport routes at 3.6 km and 9 km radii from the city centre.

There is green space within walking distance of all residents. Outside of the city centre, substantial non-built-up areas between the beads-on-string are created. As the extent of the city grows so these areas become largely enclosed on all sides with only narrow connecting strips between them. As such, they are not really green wedges in conventional planning parlance, as these normally remain open-ended as the city grows.

The term that will be used here for the non-built-up areas will be green enclaves. Starting 4 km out from the centre, each one is approximately 5.5 km long and varies in width from 0.5 km to over 2 km, with a total area of approximately 560 ha. These are areas that can accommodate a wide range of uses (other than continuous built-up areas). This has the great advantage of accommodating roads for motor traffic and railway lines for high-speed passenger and heavy freight movements, in addition to the recreational facilities and urban agriculture.

At first glance, the diagram may appear very uniform, as though all the ped-sheds would be the same, but this would not necessarily be the case. What is being presented is a long-term physical structure. Residential density would vary over the city in both space and time, as could the quantity and scale of nonresidential uses. Many of the ped-sheds could be at a much higher residential density than adjacent ones and could incorporate local centres with significant shopping, commercial and social facilities. Furthermore, a number of the ped-sheds would not be predominantly residential but might have all, or a major part of, their area devoted to manufacturing or distribution activities, or to large-scale health or educational provision or to park-and-ride facilities. These spatial variations would be subject to change over long time periods. What of the city centre in Figure 3? It is not a continuous built-up area, as in most cities.

However, the central ped-shed could reach very high densities and contain a very wide range of uses, as could the ped-sheds adjacent to it. The central ped-sheds could be brought closer together than the outer

ones but, whether they are or not, the prospect is of a larger central area composed of higher-density urban neighbourhoods, or quarters, separated by parkland while still constituting an integrated whole. Note also that an intercity railway line passing through the city could be accommodated within the green enclaves, with a main station within the central ped-shed.

Figure 3 also shows the roads for motor vehicles where they are outside the ped-sheds. There would be the two-level road hierarchy already proposed: slow speed with active frontage within ped-sheds and higher speed with restricted frontage outside. The separation of 200m between the ped-sheds offers major advantages. Major roads can pass between the ped-sheds permitting circular routes around and throughout the city. We are immediately presented with a most remarkable result. It is possible to drive over the entire city at a reasonable speed on roads designed for the motor vehicle even though the city has been laid out to facilitate walking and use of public transport. A possible objection that readers may now raise, though, is that these roads are severing the green enclaves and creating barriers to the movement of their users. One response is that this is certainly going to be no worse than the situation in existing cities.

However, there is the more important point that, although these roads may be subject to access restrictions, not all of them will be the same. Some may, indeed, be motorways with several lanes in each direction. On the other hand, and at the other extreme, many may have just one lane in each direction carrying mainly local traffic. This will, as with the population density, vary both within the city and over time. In large parts of the city, especially at the extremities, the severance will be very minor. Moreover, the large size of the green enclaves must be taken into account. They are not types of local park but areas up to 2 km wide.

Another important property of the theoretical model is that it is extendable while retaining access to public transport and green space. There is no fixed outer boundary. The land that cannot be built on is within the city rather than around it. Figure 4 shows the city expanded to a radius of approximately 20 km.

We now have another set of green enclaves. These larger enclaves, starting 9 km out from the centre, are approximately 10 km long and also vary in width from 0.5 km to over 2 km, each having a total area of approximately 1800 ha. What can now be seen is how the inner ring of green enclaves can now accommodate express rail lines providing faster services from the city centre from the outer areas and retrofitted as the city expands. There is now another orbital public transport route at a radius of 18 km from the centre.

5 CITY EXPANSION AND NETWORKS OF CITIES

Although the theoretical city model appears to be able to expand indefinitely while retaining its sustainable characteristics, allowing for retrofitting of infrastructure as it expands, this is, of course, a theoretical concept. In reality, the city would encounter other settlements as it expands and would eventually meet other large cities. Cities could be strung along the transport corridor to create a higher level of beads on string form. Notwithstanding the ability of each theoretical city model to expand sustainably in a radial direction, would indefinite expansion be a good idea in reality? Figure 5 shows two 20 km radius cities with their centres approximately 40 km apart. As they merge into each other a higher concentration of ped-sheds results such that another city could be said to emerge, but in an unplanned way. In particular, there would be no new radial public transport routes to a new centre unless retrofitted on a massive scale. This is not in line with the intention of designing the planned robust city.

Figure 6 shows 20 km radius cities with a gap of approximately 10 km between them. Additional ped-sheds are allowed along the line of the inter-city route but not otherwise. Radial expansion is restricted in favour of the building or expansion of other cities. The Figure shows how the cities could possibly be arranged on a regular lattice that could be extended. What is happening here is the use of the theoretical model to explore the properties and consequences of a developing megalopolis i.e. an arrangement of a considerable number closely packed and interacting cities. Merged cities already exist in North-western Europe and North-eastern America. In rapidly developing countries, such as China on the Yangtse and Pearl River estuaries, at the time of writing, ever more extensive megalopolises are emerging. A method for making this process of agglomeration a planned one could have considerable practical potential.

6 IMPLICATIONS FOR PLANNING PRACTICE

Implementation of the proposals made in here does not necessarily require the construction of complete cities, and complexes of cities, on the lines of the theoretical model. There are much more prosaic applications of the ideas that could be readily absorbed into day-to-day planning practice. Urban extensions can be designed using the beads-on-a-string form proposed and, indeed, it can lead to a useful step-by-step method is available leading down from the strategic to local design criteria (Hall, 2015).

There are significant implications for the preparation of development plans in that the emphasis on physical form does not necessarily require the preparation of detailed master plans a long time in advance of development. Detailed two-dimensional maps and three-dimensional perspectives are essential for short-term planning but they are not required for the long term. Long term plans could be based on a formula, or criteria-based approach, as used in our theoretical model, for both for the location of development and the expression of design qualities, with physical detail shown only where and when required. These criteria could then be carried over from one plan period to another to achieve the long-term physical consistency.

The same locational principles could also be used to manage and plan for expansion “upwards” or, more properly, urban intensification. Levels of residential density could be related to walking distance from public transport nodes (Hall, 2015). The idea of high-density development around major stations is, of course, nothing new and is a policy that is widely implemented. What would be different here is to have a policy for the location of low and intermediate densities, and identification of areas where there would be no increase. This is not to say that these lower levels would not change over time but that the change would be put on a rational basis. Increases in density would be related to improvements in accessibility.~

7 CONCLUSIONS

Taking stock of the theoretical city model, it can be seen to have some remarkable, and to a certain extent counter-intuitive, properties.

- The robust city does not require limits to growth placed around its periphery. It could, in theory, continue to expand without limit while still successfully pursuing quality of life and sustainability.
- This does not mean, however, that there are no limits on the extent of urban areas - far from it. What it means is that non-built up areas or green enclaves would lie between the radial routes rather than being in the shape of green belts around the city. They would be similar to green wedges but would not necessarily be spatially open ended, as a green wedge concept would normally be. What is important is that the shape and size of the green enclaves would not be arbitrary but a necessary and systematic consequence of the locational principles of development.
- The green enclaves would provide the space for the retrofitting of infrastructure.
- Although the locational principles are based completely, and explicitly, on facilitating walking and the use of public transport, the resulting city form would also permit, rather unexpectedly, almost unrestricted access by motor vehicles across the city. Their speed would be limited within predominantly residential ped-sheds but this would not be the case when travelling between them through the green enclaves. They would be able to access park and ride facilities and commercial warehousing, distribution and manufacturing centres with little restriction.
- The same principles guiding the expanding structure of the city could also be applied to growing complexes of adjoining cities. They would be linked by transport corridors but separated by extensive green areas.

The planned robust city appears to work perfectly. Why then do we not find it in practice? Even where a planning regime is very interventionist and has proper regard to the design of physical form in the long term, the argument of this book presents two significant challenges at the local political level.

- The protection of the green enclaves.
- The cost of providing quality public transport corridors contemporaneous with new development.

Overcoming these obstacles is, in effect, a necessary consequence of having a city that is genuinely planned. The choice before us is between a city with a planning system and processes but which is not

actually planned in any strategic sense and the planned and robust city as argued here. What is remarkable about the model is the advantageous implications of restricting development to within walking distance of public transport nodes. It results in quality movement about the city for motor vehicles as well, although such vehicles would have to accept significant speed restrictions within built-up areas. It permits the city to expand in a planned manner with room for the retrofitting of infrastructure within the existing boundary as the city grows. In more common parlance it allows the city “live and breathe” as it grows.

ABSTRACT: For the development of urban areas within existing urban systems, which concentrate on sustainable ways of energy supply and therefore essential cooperative planning processes, interactive software systems holding digital city models can enable visual driven support. The offered visual support provides a communication basis for the interdisciplinary actors within these complex planning processes. Within an interdisciplinary research project a visual planning and decision support system, named the 'URBEM-Visualization', has been developed. This system allows to geographically pinpoint information of urban systems within a multi-dimensional city model. Thus, it offers multi-scale and cross-domain handling of information within different calculation scenarios regarding energy supply. Based on a development area in Vienna, located at the train station "railway station Vienna West", which offers high potential for a sustainable agglomeration and the use of built grid infrastructures, a "planning test run" is evolved. Within this planning test run, new designs of housing developments and different possibilities for the electrical and thermal energy supply related to building energy demands are evaluated, analyzed and visualized. Based on this planning test run the paper exposes how visual interactive decision support strengthens the cooperation of the interdisciplinary planning team as well as the planning process. Furthermore, this interdisciplinary consolidation facilitates a rethinking process, changing historical driven top-down planning processes. It shows how visual output of simulation data regarding energy supply networks allows the design of new feedback-loops of information flows and how this can supply decision makers in early stage planning processes.

KEYWORDS: decision support tool, visualization, cooperative planning process, cross-domain grid simulation

1 INTRODUCTION

1.1 MOTIVATION

The United Nations forecast of 2014 shows a population of 8.5 billion people up to 2030 (United Nations, 2014) on the earth. The forecasts also report about 60% of the population in 2030 (Statista, 2017) will live in cities worldwide. Due to this rapid growth of urban agglomerations worldwide, planners are facing complex tasks for setting up plans, measures and actions to gain sustainable development within urban settlements in a resource-conserving manner. Against this background, urban development within defined city limits is a constructive approach to reduce soil sealing, arising damages of the soil function as well as the possibility to use existing supply infrastructures in the fields of mobility and energy. This can cause a reduction of CO2 emissions due to energy savings in construction, maintenance and usage. The formula 'Inner development before external development' by Bernd Scholl proclaims to reduce further settlement spread and declares to improve the quality of the built stock (Scholl, 2007: 3).

In practice, this ambition means a big challenge for planners and complex planning processes. Within these processes, the cooperation of interdisciplinary domain experts, the connection of domain specific calculation and simulation models as well as the spatial visualization of their outcomes has to be structured and handled. For the support of planners facing the mentioned needs, a digital spatial visualization provides a communication base.

Furthermore, the visualization allows to create multi-scale system overviews as well as long-term simulation and analysis of the impacts based on performed actions. If the visualization is embedded in a digital environment, it enables decision and planning support.

Within the doctoral college URBEM (Urban Energy and Mobility systems) conducted from 2013 to 2016 at TU Wien (cf. Bednar et al., 2016) the URBEM-Visualization prototype has been developed. The URBEM Visualization constitutes a web-based planning support system. This approach focuses on a test run, the 'URBEM-Planning and Development Run' (UPDR), using the URBEM-visualization as a decision and planning support tool for a sample region located in Vienna which holds high potential for redensification. Within the UPDR interdisciplinary domain experts simulated outcomes for the technical infrastructure grids within this region and focused on following questions for the energy supply: Which short- and long-term effects do occur regarding the analyzed thermal and electrical supply systems? How can knowledge, which evolves through this calculations influence early spatial planning processes and help to endeavor sustainable urban developments?

1.2 STATE OF THE ART

Inward development means an interdisciplinary analysis and the participation of cross-domain expert planners. In turn, this interdisciplinary planning process needs a definite frame. Scholl promotes a planning method called "test planning" which features a flexible framework and forces progress in complex planning processes (cf. Scholl, 2011: 336). A test planning process is structured in multiple levels and offers a practical application for the communication of sketched and refused decisions with various stakeholders (cf. Scholl, 2011: 340ff). Thus it allows to handle and structure the key tasks within a planning process.

Beside structuring planning and decision processes, visual multi-dimensional and quantitative foundations enable feasible support. Especially for cross-domain collaboration, a visual format with spatial pinpointed information outputs allows interdisciplinary overlay for analysis, clarification and verification of calculation models. CAD based software developments (GIS, BIM) for planning and decision support, game engines with CAD model implementations (cf. Forster et al., 2015a) or web based interactive multi-dimensional visualization formats (cf. Forster et al. 2015b) depict a feasible basis for spatial planning purposes and support. Beyond the visual interpretation of information, the mentioned systems interlink different databases and data structures to become simulation tools. To assure efficient progress during planning processes, the visual support must depict dynamic data flows between database, calculation model and spatial interpretation environment. Schleicher describes an operating system representing a flexible work-platform, which structures data and initializes data flows between calculation models and visualization (cf. Schleicher et al., 2016a). Based on this the URBEM Smart City Application (USCA) can be set up and enables holistic calculation flows between domain specific models on various spatial scales (cf. Schleicher et al., 2016b).

1.3 OVERVIEW

Within the interdisciplinary expert team URBEM a holistic application, the USCA (cf. Schleicher et al. 2016) was developed. This embeds domain and scenario specific simulation models and a strategic visualization tool, the 'URBEM-Visualization' (cf. Forster, 2016: 93-114). The URBEM-Visualization depicts an interactive 3D city model and allows interlinking the generated and implemented spatial objects with simulation outcomes from domain models within the USCA. Therefore, the 'URBEM-visualization' allows to geographically pinpoint information, the simulation of planning actions as well as their analysis and validation. This enables decision and planning support for detailed analysis of complex planning problems within an interdisciplinary context.

With this approach, we demonstrate a strategy for analysing energy supply options in early design stages within a cross-domain context. Thereby it targets to exchange linear top-down planning processes towards effective cyclical planning processes. This aspired cyclical planning routine is driven by the interdependency within a problem solving process. Precisely this means, that the development of solutions for a problem in planning is giving birth to new ideas by analyzing their resulting impacts. Simultaneously it means to analyze the root cause of the base problem.

In planning practice a holistic sustainable development in urban regions regarding energy supply and associated climate protection results in the need of interactive data links between domain experts. Analytical data visualization is one possibility to deal with the challenging gaps between these involved agents. Furthermore, it facilitates the explanation of pure numerical information. We assume that data visualization can lead to break linear processes and generates feedback loops dynamically within modern problem solving processes in planning. The UPDR is verifying this assumption.

The paper gives a short insight in two domain specific simulation models for electrical and thermal energy grid infrastructures as well as presents the web based visualization technology developed within the PhD course URBEM. It shows the data flows between these models and a strategic set up for an exemplary test run based on a specific development region with high potential in Vienna. The test run allows to show the necessity of loosening top-down planning processes for the raising challenges of the future energy supply of buildings, which is coherent with ambitious climate protection policies, mostly coming along with infrastructural investments and demand for long-term decisions.

This paper was already published within a chapter of the doctoral thesis “Strategic spatial visualization in the context of the inward development of urban settlements, energy and mobility systems” (cf. Forster, 2016: 115-134).

1.4 CASE STUDY REGION

In Vienna, the sites at the main train stations of the city (North, South and West) and alongside their esodic and near rails have an inherent potential for new urban developments. Due to the renewal of the station building and the infrastructure policy of the Austrian Railway Association (ÖBB), Vienna's western train station “Wien Westbahnhof” and the belonging region has changed since 2014 after Vienna's main train station was developed at the former southern train station areal. Thereby necessary tracks for the movement of travelers and freights as well as many buildings used for infrastructure and administration purposes did become unused at the western train station. Thus, these areas hold new potential for inner developments.

The area is located centrally within the city and is well accessible with public transport. New ‘inward developments’ which target to create sustainable and worth living space are strongly connected to secure supply of thermal and electrical energy. In this area the UPDR simulates prototypic housing designs regarding different approaches for long-term supply of thermal and electrical energy.

2 METHODOLOGY

2.1 METHODOLOGICAL FRAMEWORK

The first methodological step within the UPDR was the analysis of spatial constructional possibilities within the area beside the rails. A master plan for the research area, placed alongside the north and south sides of the rails, has been elaborated (see Figure 1).

The master plan in Figure 1 represents a base for the extrapolation of gross floor spaces and the definition of the utilization of these spaces. Thereby following assumptions (cf. Ziegler, 2016) for thermal and electrical energy demands for the building supply in 2015 are made:

	Residential use	Office use
thermal	47,26 kWh/m ² a	3,67 kWh/m ² a
electrical	33,07 kWh/m ² a	38,84 kWh/m ² a

Table 1: Assumptions for thermal and electrical building energy demand

Beside the underlying definitions for potential building developments and floor space utilizations, the existing supply networks set the main input for the cross-domain simulations.

Figure 1: Elaborated master plan for the research area "Wien Westbahnhof"; Source: own illustration.

Depending on the available grid infrastructures within the focus area, five electrical and thermal supply alternatives (including combinations) have been identified:

	Electrical energy supply	Thermal energy supply
Alternative 1	Electrical energy	Electrical energy
Alternative 2	Electrical energy	District heating
Alternative 3	Electrical energy	Gas
Alternative 4	Electrical energy	Photovoltaic
Alternative 5	Electrical energy	Photovoltaic combined with thermal storage

Table 2: Analyzed building energy supply alternatives within this approach

The cited supply alternatives are simulated for the time period 2015-2045. Therefore, a "business as usual" (BAU) scenario with the assumption of decreasing thermal energy demand (space heating and domestic hot water) is defined with 28% up to 2045 in comparison to the initial year 2015 (cf. Fritz, 2016: 77). This assumption considers impacts of investment decisions on Vienna's building stock (base year 2008) caused by building owners. It includes efficiency actions (thermal renovation / heating system exchange) concerning energy demand as well as the rising population. In terms of electrical energy an assumption of a rising demand of 1,26% up to 2025 in comparison to the base year 2015 has been taken. Additionally the scenario considers additional decentralized power supply (Photovoltaic) by 100 Megawatts up to 2045 in comparison to 2015. This assumption is based on the sustainability strategy (cf. Wiener Stadtwerke, 2016) of the Wiener Stadtwerke Holding, Vienna's biggest energy supplier.

The mentioned scenario assumptions are fundamental elements. They allow long-term effect analysis to verify the supply safety and the evaluation of necessary reinvestments in future. Thereby especially necessary grid upgrades based on rising degrees of capacity utilizations determine additional accruing costs.

In addition and assembling on the housing development assumptions for the focus area, the existing electrical, thermal and gas grid infrastructure needs to be extended. Therefore, realistic new configurations of pipelines and cables are determined. Figure 2 shows a scheme of the necessary new grids, which depict the spatial fundamentals for the thermal and electrical grid simulation models.

Figure 2: Assumptions for the extension of existing energy grid infrastructures; Source: own illustration.

2.2 SYSTEM STRUCTURE AND SETUP

The main setup for the UPDR are the simulation models for the determining capacities within the electrical, thermal and gas grid as well as the visualization environment. These models are embedded in the USCA. The models are the 'processing units' for forecast and visual outcome presentation. They are interlinked which do in turn enable dynamic flows of data for interactive visual requests operated in a planning process by various stakeholders. Figure 3 gives a diagrammatic view of the technical setup and linkage of models to obtain mutual data exchange for the cross-domain simulation outcomes. It illustrates a sub set of implemented simulation models within the whole USCA, which explicitly describe the active components for the treated problem within this approach.

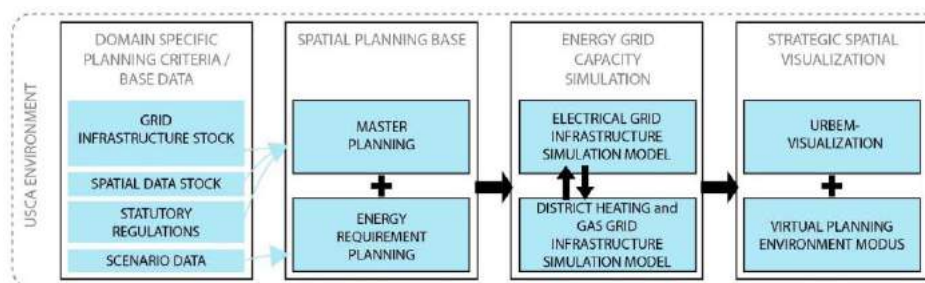

Figure 3: Technical setup of the USCA for energy supply simulation within the test run; Source: own illustration.

2.3 THERMAL ENERGY CALCULATION MODEL

Current developments of the European energy markets are influencing the operation strategy of heat suppliers. Especially providers of district heating systems fed by conventional heat production (i.e. CHP) have to react with appropriate measures to these changes. The integration of thermal storages, decentralization of the heat production, changing heating technologies or adjusting the temperature of district heating networks make it necessary to be able to simulate and analyze existing and future designs of district heating systems. Therefore, a simulating tool for flow networks is developed in Matlab®.

In order to achieve comparable conclusions about operating behavior of district heating systems, it's essential to create a corresponding model including all its main components like pipes, pumps, storages and valves. The basic idea of the created numerical model is the combination of a steady state hydraulic and a transient thermal calculation of the district heating network (see Figure 4). The results of the iterative hydraulic calculation are the pressure and velocity distribution of the pipe network. These pressures and

velocities are serving as Input-parameter of the thermal calculation. To simulate the thermal behavior of the district heating network a discretized one dimensional pipe model is used. The discretization is done by the Finite-Volume-Method and the resulting equation system can be solved explicitly or implicitly. In case of gas networks, only the steady state hydraulic calculation is applied. A common way to define the topology of networks is the usage of a node-edge matrix. This so called incidence matrix is generated automatically from given GIS data.

The result of the combined thermo-hydraulic calculation is the distribution of pressure, velocity and temperature of the flowing water in the entire district heating network. Furthermore it's possible to calculate the heat and pressure losses of each pipe and subsequently doing exergy analysis. The introduced simulation tool serves as basis for analyzing and optimizing different designs of heating networks, which can be used to support economic analysis from a technical point of view.

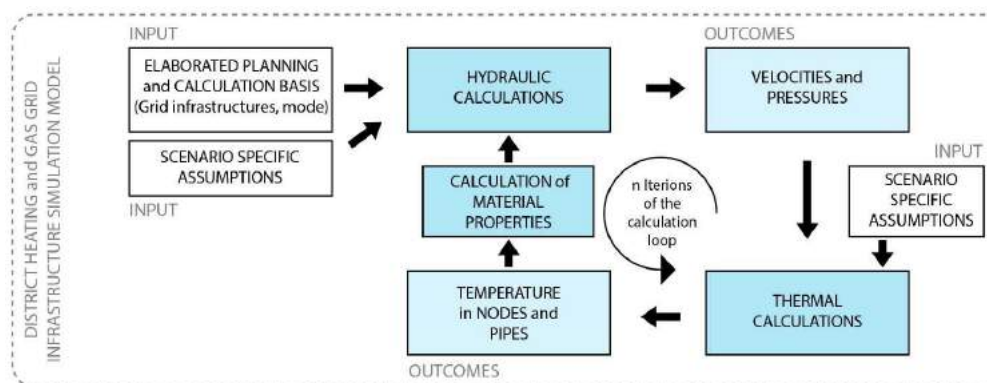

Figure 4: Setup for the district heating and gas infrastructure simulation model; Source: own illustration.

2.4 ELECTRICAL ENERGY CALCULATION MODEL

Power grid models are able to provide statements about reliability, network utilization, and possible overloads considering operational limits within the network. Increasing decentralized generation (e.g., photovoltaic systems), decentralized storage systems and combined energy networks are some of the reasons for defining new operation requirements in future power grids.

In this approach, the model (see Figure 5) describes a medium-voltage power grid with characteristics of an urban area. Short electric line lengths and high load densities are some properties of urban power systems. The input data for the model consist of geographic positions for electric operational equipment used within a specific service area. Handling this large amount of network data needs a powerful data processing platform, in this case Python®. Power flow simulations using the model are implemented in a modified version of the package pypower¹. The Newton-Raphson algorithm used in pypower for power flow calculations is altered by building the Jacobian matrix only for the first iteration. Therefore, simulation time within the model reduces to a minimum compared to other power calculations approaches. The reason for this is the characteristic of an urban power grid where voltage drops or rises can be neglected due to the short electric line lengths combined with the high load density. In addition, optimized network calculations considering results obtained by the simulation model for thermal energy infrastructures are performed to minimize equipment utilizations inside the energy supply network.

The obtained results show future line utilizations comparing base year calculations with scenarios considering increasing integration of renewables, demographic change and changes in cooling and heating demand served by electric energy. Hence, the developed simulation tool allows network utilities to make future investment decision regarding changing requirements within the power grid.

2.5 SPATIAL VISUALIZATION OF THE CALCULATION OUTCOMES

The virtual visualization environment of the USCA depicts a user interface for future developments and for assumed scenarios. It holds the 3D model and triggers the calculation outcomes to gain cross-domain views. Figure 6 shows the web-based spatial visualization environment, the “URBEM –Visualization”, which embeds a planning environment for the elaboration and testing of possible construction works within an urban space.

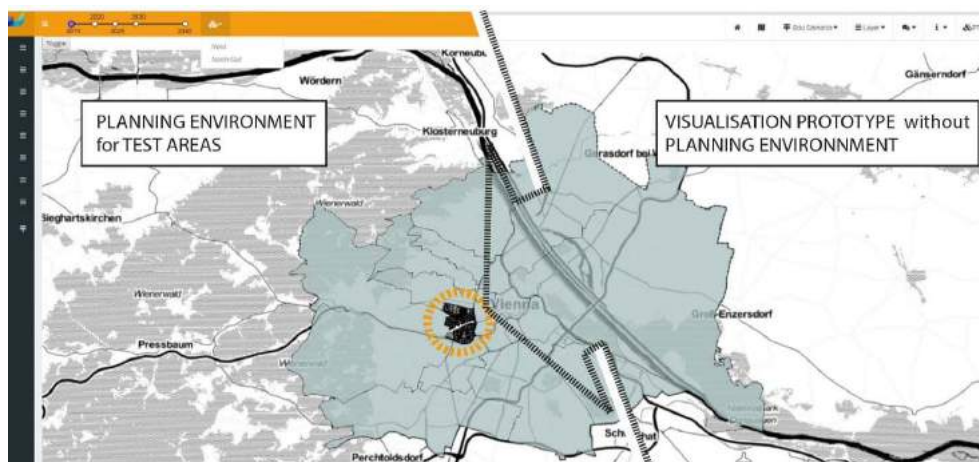

Figure 6: Visual web-based appearance of the interdisciplinary decision and planning support tool, the ‘URBEM-Visualization’; Source: own illustration.

The URBEM-Visualization enables the dynamic generation of multi-dimensional objects and interlinks them with outcomes from domain expert models via identification numbers. Thus, the calculation outcomes are geographically pinpointed and map overviews are designed. These overviews provide the basis for orientation, analysis and communication for input parameters and assist to locate, control and set the ‘regulation screws’ within complex spatial systems. Long-term trends for various frame conditions can become iteratively deliberated.

3 RESULTS

For the determined energy supply alternatives the simulation outcomes are represented in Table 3. Table 3 shows the simulated electrical and thermal supply alternatives to cover the predicted building energy supply within the development area up to 2045. Based on the simulation models for electrical, gas and district heating grid capacities the UPDR shows the need for combined supply technologies to cover electrical and thermal energy supply.

Supply Alternative	2015	2030	2045
Alternative 1	X	X	X
Alternative 2	✓	✓	X
Alternative 3	✓	✓	X
Alternative 4	-	X	X
Alternative 5	-	✓	✓

Table 3: Results for the simulated energy supply alternatives

The calculated numeric outcomes of the grid infrastructure models are processed and visualized within the 'URBEM-Visualization'. Figure 7 - Figure 9 present the visual calculation outcomes. Figure 7 shows an alternative when the predicted building energy demand within the analyzed area is covered only by electrical energy (without the usage of energy storage technologies). Furthermore the figure points out that no area-wide service is available. Due to this fact some transformer stations are colored red which means that the utilization exceeds their limits.

Figure 7: Visualization of capacity loads based on the electrical grid infrastructure simulations for 2030;
Source: own illustration.

The extension of the gas or district heating grid infrastructure in addition to the electrical grid infrastructure provides two more energy supply alternatives. Figure 7 shows the energy supply within the urban development area with electrical energy and district heating. All capacities used therefore are in a valid scope up to 2045. All capacity loads in pipes and knots are lower than 100%. The legend for the electrical grid infrastructure is the same like in Figure 8.

Figure 8: Visualization of capacity loads of the electrical and district heating grid infrastructure based on simulations for 2030; Source: own illustration.

One further valid supply strategy for the building energy supply offers the combination of photovoltaic technologies and thermal storage technologies. This combination causes a pure electrical supply for the development zone. Figure 9 shows this supply alternative.

Figure 9: Visualization of the capacity loads of the electrical grid infrastructure based on simulations including photovoltaic and thermal storage technologies for 2030; Source: own illustration.

Based on the presented holistic knowledge for electrical and thermal long-term area-wide energy supply within the development area 'Wien Westbahnhof' new input is available for the early design stages. The decision of an energy supply technology, especially the decision for the thermal energy supply is an essential parameter besides caused constructional necessities. The commitment about the used energy supply option allows to establish the necessary agents of the planning world as well as to define and include chronological impacts and imperatives. Furthermore it enables the analysis of caused impacts spatially. Thus, it depicts an initialization for further iterative design on larger and smaller scales. The approach shows a method to fit the design of grid infrastructures within early design phases. The dynamic incorporation influences the entire planning process and initiates further iterative feedback loops between both, the planning process phases and the involved stakeholders. Figure 10 presents a showcase for initiated feedback loops involving the infrastructure grid development.

Figure 10: Possible feedback loops within planning process phase sequences; Source: own illustration.

It visualizes a practical multi-phase planning process for multi-scale urban developments. The black arrows show the historical mainstream links and information flows between the individual planning phases. The orange ones present new initiated information feedbacks, which enable impact control and active influence on various planning levels (scales) supporting decisions made by interest representatives.

4 CONCLUSIONS

The interdisciplinary URBEM-Planning and Development Run (UPDR) points out that the URBEM Smart City Application (USCA) concept is a convenient environment and tool to trigger, guide and handle complex planning processes. Thereby the participating agents from the various domains depict the most important parts within the process. The respective domain knowledge is essential for the analysis and interpretation of the implemented information. Furthermore, the explanation and interpretation of the visual outcomes allow setting and testing of new actions. So the URBEM-Visualization within the USCA provides a useful administration environment.

The UPDR shows the need of knowledge about input and outcomes for the decision process to gain and understand interactions within the cross-domain planning purposes. In general, communication is the central topic within the UPDR and the URBEM-Visualization provides a visual base unit concerning this matter.

The survey of energy supply alternatives within the UPDR demonstrate increasing flexibility in planning for future urban developments based on the provision of combined spatial overviews. Thus, new adjusted views provide the finding of comprehensive domains "Hubs", based on the understanding of interdisciplinary connections. These hubs boost more and more importance to gain sustainable strategies of land use and to combine cross-domain possibilities for energy and mobility subsystems as structures for an urban overall system.

In praxis, supply technologies influence architectural arrangements. The predefinition of an energy carrier technology for a development region in early planning phases can become a general condition within architectural competitions. Housing developers and planners have to cogitate about useable storage technologies. This opens new ways for decentralized energy supply in the building sector.

ACKNOWLEDGMENT

The presented test run within this paper would have been impossible without the support of Wiener Stadtwerke Holding AG and their initiative with TU Wien, the PhD course URBEM as well as the FFG funded program SIMULTAN.

ID 1331 | REGIONAL PLANNING RESPONDING TO CLIMATE CHANGE

Dexter Du¹; Richard J. Nunes¹; Jorn van de Wetering¹

¹University of Reading

j.du@pgr.reading.ac.uk

ABSTRACT: Climate change, although defined with global and long-term scales, has currently caused substantial impacts to many local places. Even though wide efforts are being made to ameliorate the future environment, increasingly frequent extreme events due to the changing climate have been rather unbearable to many places and population. The integration of mitigation and adaptation efforts becomes a critical issue, so that improvement is available to both current and future, both local and global conditions. Spatial planning for urban regions demonstrates unique potential of promoting this integration. With the review of existing studies, we lead the mitigation-adaptation integration to the topics of regional planning and policy mobilities, for which regional governance is proposed as the appealing innovation in climate governance.

KEYWORDS: Climate change, Mitigation, Adaptation, Regional planning, Policy mobilities

1 INTRODUCTION

Climate change is essentially defined as the potential long-term increase of the global average temperature, which, along with the many associated issues, has gained prodigious international attention and controversy (IPCC, 2014). The social response to climate change is usually conceptualised as either mitigation or adaptation, which has formed a dichotomy (Biesbroek et al., 2009; Bulkeley, 2013). This dichotomy indicates that the two parallel lines of practice addressing climate change have no need to heed each other. However, the implicit (hard-to-recognise, yet sometimes fundamental) conflicts between these two types of efforts may hint total failures of the overall effort (Laukkonen et al., 2009).

Although the different characteristics of mitigation and adaptation would necessitate a certain degree of division, the integration of them is to ensure the total effect, which is the efficacy of our general response to climate change, because, after all, it is climate change that sits at the core where either mitigation or adaptation is born (McEvoy et al., 2006; Wilbanks and Sathaye, 2007). We propose this integration as a specific point to joint climate change concern with spatial planning which is striving to justify its role in addressing climate change (Campbell, 2006; Davoudi et al., 2009). The finding of researching in the literature on spatial planning narrows down to a scale-sensitive conceptual model which embeds mitigation and adaptation in a cross-scale framework (Howard, 2009). The key potential of integrating mitigation and adaptation is to take into account a full range of spatial scales. This conceptual model suggests a mode of mitigation-oriented adaptation as the most desirable integration of mitigation and adaptation, which would also be the most effective response to climate change. Moreover, compact urban form and green open space are recognised as important elements constituting the spatial planning approach towards mitigation-oriented adaptation, for which we propose further research on regional planning. At last, policy mobilities is briefly reviewed to demonstrate its relevance and competence in searching for effective form of regional planning responding to climate change. The expectant contribution is not only an advocacy of planning in the multi-disciplinary context, but also a proposal of some very effective tactics. The following three sections before conclusion will thus unfold the dichotomy between mitigation and adaptation, a scale-sensitive model integrating mitigation and adaptation, and policy mobilities.

2 THE DICHOTOMY: MITIGATION AND ADAPTATION

The dichotomy between mitigation and adaptation has been observed in policies concerning climate change, which means mitigation and adaptation are traditionally and perhaps still often conceived of as two fundamentally different strategies of responding to climate change (Cohen et al., 1998; Wilbanks and Sathaye, 2007). Mitigation means to prevent or decelerate the increase of global mean temperature, while adaptation means to accept and live with the environmental conditions under the warmer climate. Since climate change is considered largely caused by the human-induced emission of greenhouse gases, mitigation aims at reducing this emission by limiting anthropogenic causes. In contrast, adaptation focuses more on the consequences of climate change than the causes. For example, more frequent extreme precipitation, heat waves and rising sea level (Bulkeley, 2013).

For a long time, mitigation has dominated the political discourse which thus overlooked adaptation (Schipper, 2006; Klein et al., 2007). The quantitative features of mitigation match very well with the evidence-based policy making and international negotiation (Biesbroek et al., 2009). However, mitigation is a long-term strategy whose time lapse between actions and impacts is large (McEvoy et al., 2006). Moreover, the issues of environmental justice and international competition that complicate the global negotiation generate more difficulties in implementing mitigation programmes (Bulkeley, 2013). Even though current mitigation effort successfully proceeds, the extent of the climate change consequences will continue to intensify in the short-term future, which would very likely exceed the response capacity of many countries and cities (e.g. comparing Bangladesh to the Netherlands regarding flooding, and Bangkok to London regarding heat waves). Therefore, adaptation gains budding attention for complementing mitigation to form a more comprehensive response to climate change (Wilson and Piper, 2010). Adaptation is relatively (compared to mitigation) short-term and highly case-specific, because, for instance, major issues facing coastal cities are disparate from those for inland areas (e.g. flooding and drought, both of which prove to be the consequences of climate change, Bulkeley, 2013). These issues fluctuate frequently over time along with different kinds of extreme weather events which affect the cognitive intensity of associated risks (Matthews, 2014). Therefore, adaptation often becomes concrete only at the local scale where particularities are taken into account, which causes great challenges for making adaptation policies concerning wider geographical area. In practice, adaptation strategies tend to match the local scale, while decision-making regarding mitigation often takes place at the national level (Wilbanks and Sathaye, 2007).

The dichotomy between mitigation and adaptation conceptualises the fact that mitigation and adaptation are understood and practiced largely separately (Cohen et al., 1998; Howard, 2009). Because mitigation and adaptation are different in many respects including chief goals, evidence bases, temporal and spatial scales, some policies only consider mitigation while some others only adaptation (Swart and Raes, 2007; Biesbroek et al., 2009). However, mitigation and adaptation are complementary to each other in forming the overall response to climate change (Wilbanks and Sathaye, 2007; Howard, 2009). The dichotomy of them may detract from the efficacy of either, which may further lead to failures of the overall response (Biesbroek et al., 2009). The danger of this dichotomy is firstly the potential of indicating substitution between them. Adaptation maybe used by some parties to avoid taking mitigation responsibilities, since mitigation often means to compromise on economic growth. Similarly, mitigation may be taken as the excuse of making no adapting plans. Secondly, the lack of informative integrating analyses of mitigation and adaptation would foment conflicts between them. One approach could be adaptive at one scale while generating negative impact to mitigation at another scale. For example, in the cities hit by frequent heat waves (e.g. cases from Latin America, Pizarro, 2009), installing air conditioners and increasing distance among buildings would be helpful to decrease the temperature, for which supporting air conditioning and encouraging urban extension could be the adaptive strategies adopted by the local government. However, these adaptive actions will certainly increase emission and eventually increase the heat level at the global and long-term scales, which is undermining to mitigation (also termed mal-adaptation as simply transferring adverse impacts to other time, places or policy sectors, Wilson and Piper, 2010). Therefore, research for synergy is called for to prevent the efforts at one end of the dichotomy from cancelling the efforts at the other.

Studies with an economics perspective offer cost-efficient analysis to integrate mitigation and adaptation (Wilbanks, 2005; Goklany, 2007; Wilbanks et al., 2007). The cost-benefit analysis calculating the cost and benefit of both mitigation and adaptation approaches helps policy-makers to divide fiscal resources between them (Dowlatabadi, 2007; Klein et al., 2007). For example, the adaptation strategy of building

dikes bears the cost of constructing the dikes and generates benefit through the value of the protected land (Tol, 2007). At the same time, the cost spent on mitigation programmes (e.g. energy research) may reduce the cost for adaptation, in this case through lowering the construction cost of building dikes, because the slower rate of sea level rise due to mitigation would require a lower height of the dikes. Concerning the above scenarios, modelling with more sophisticated details would be able to inform policy makers whether a proportion of fiscal resources should be used for mitigation or adaptation, through which decision-making for mitigation and adaptation is integrated (Tol, 2007). Compared to the dichotomist view which suggests the competition between mitigation and adaptation over resources, the cost-benefit integrating model demonstrates why these two could actually share the cost and collectively make better use of the resources. The central merit of this cost-benefit integration of mitigation and adaptation is to make the overall response to climate change the most cost-efficient. However, cost-efficiency may be only one of the desirable scenarios. Moreover, the quantification of mitigation and adaptation may imply that one could be the substitute of the other, which is more about trade-offs than integration (Tol, 2005). Modelling provides calculating tools to measure the integration of mitigation and adaptation, which must be based on an integrating framework that informs the model what factors need to be included. Modelling itself as one way of expressing the integration would require the integration to have been done through an integrating framework beforehand. Such a framework varies greatly across cases among many of which substantial research is still needed before it is ready for quantification. Risk governance is proposed to integrate mitigation and adaptation into the concept of response capacity (Grothmann and Patt, 2005). Mitigation endeavours to reduce the risks of possible adverse impacts, and adaptation builds the capacity with which the impacts would be coped (Jones et al., 2007). For this reason, managing risks and developing capacities would resolve the dichotomy between mitigation and adaptation. Compared to the focus on the inter-relationships between mitigation and adaptation, some alternative proposals argue that trade-offs between investing technological innovation and encouraging social response are more pertinent (Tompkins and Adger, 2005). This suggests policy makers to think about how much to invest technology innovation (e.g. clean energy vehicles) and how much to invest social behaviours (e.g. campaigning for public transiting over driving private cars), rather than how much on mitigation and how much on adaptation. Resilience building proves to be suitable for the current situation which is replete with uncertainties (Saavedra and Budd, 2009). Risk governance transfers the focus on the future (mitigation) into the focus on the current capacity building, the latter of which is more concrete and thus more attractive to local communities (Laukkonen et al., 2009). For policy makers, however, there have been several other dichotomies, for instance, mitigation-adaptation, innovation-behaviour, long and short term, and public-private, one of which could not solve the others. For example, technology innovation could still be divided into mitigation ones (e.g. energy-efficient light bulbs) and adaptation ones (e.g. smart ventilation schemes). The struggle between mitigation and adaptation still exists and may come forward sooner or later.

Sustainable development is taken as another framework to integrate mitigation and adaptation, which warns the discussion between mitigation and adaptation of the potential of overlooking the ultimate goal that both of them are after. For instance, in the cases where air quality is harmed by the emission of polluting gases many of which are also counted as greenhouse gases, a common goal of adaptation (improving air quality) and mitigation (reducing emission) is to protect public health from respiratory disorders (Dowlatabadi, 2007). The focus on the dichotomy between mitigation and adaptation may preclude policy makers from realising that their mitigation policies, which are supposed to aim at sustainability in the long run, actually end up with unsustainable situations (Urwin and Jordan, 2008). The list of the gases harmful for health is different from the list of greenhouse gases, for which policies limiting greenhouse gases emission (e.g. taxing tailpipe emission of cars) may increase the alternative sources that emit less greenhouse gases but more harmful gases (e.g. switching from gasoline cars to diesel cars) (Dowlatabadi, 2007). Therefore, to prevent mitigation policies from disturbing adaptation, or to prevent the enthusiasm for climate change response from harming the quality of environment, the prerequisite is to clearly set sustainable development as the ultimate goal of both mitigation and adaptation (Katarina and Ulrika, 2009). Sustainable development becomes the common criteria to scrutinise mitigation and adaptation policies. The critique to this approach lies in the contentious discussion about sustainability itself. Compared to the author who cherishes the quality of environment at any time (both the future and the current), some author may argue that a certain extent of compromise on the current condition is for the long-term betterment (Dowlatabadi, 2007; Howard, 2009). It is difficult to decide whether a harmful environment now or an even more harmful environment in the future is more unsustainable. In these cases, the integration of mitigation and adaptation still depends on the debatable topic about what integration is considered desirable. In summary of this section, the problematic dichotomy between mitigation and adaptation is difficult to eliminate. The complexity of climate change issues requests

response in various forms and at various levels, which underlies the conceptualisation of mitigation and adaptation that have helped policy makers understand and manage collective actions. However, like a two-edged sword, the separation of mitigation and adaptation efforts may generate redundant cost or significant conflicts. Much research is striving to offer useful frameworks for the integration, although the difficulty of this has not been completely overcome. Therefore, the exploration of the integration of mitigation and adaptation remains a critical research question. The next section will unfold how spatial planning research has prepared for further study on this question.

3 A SPATIAL PERSPECTIVE: REGIONAL PLANNING

Spatial planning policies concern the impact of oft-anthropogenic spatial arrangements as well as the spatial impact resulted from other kinds of natural processes and human activities. For example, planning cities in compact forms may reduce the greenhouse gases emission by limiting the total amount of commuting traffic (McEvoy et al., 2006; Hamin & Gurrán, 2009; Pizarro, 2009). Moreover, transformation of the current form of built environment is urged by the need of spatial adaptation to the risks of sea level rise and increasing extreme precipitation (e.g. programmes about “space for water”) (Davoudi et al., 2009). Furthermore, modern economy continues to encourage population to spatially concentrate at climate-risky locations (e.g. large coastal cities encountering sea level rise) (Bulkeley, 2013). Altogether, planning is interested in the spatial dimension that is seen in many issues and cases, including climate change. Some evidence proves that spatial planning plays a significant role in addressing climate change, for example, compact urban form as mentioned above (Davoudi et al., 2009; Hunt & Watkiss, 2011). However, there also exist doubts about whether spatial planning is thoroughly entitled to deal with climate change, especially considering the predominance of natural science (e.g. meteorology) in climate research (Campbell, 2006). What’s more, there also exists suspicion that climate change is rather a political invention than scientific fact. Against this background, spatial planning policies have to articulate the very contribution of their own in addressing climate change, through which planning approaches solicit political and public support (Wilson, 2006a; 2006b). Spatial planning is keen on managing spatial scales, which are recognised as a key of the integration of mitigation and adaptation (Howard, 2009). The multiplicity of impacts depending on spatial and temporal scales results in the transformation of mitigation and adaptation across scales (i.e. mitigation at one scale simultaneously becomes adaptation at another scale). Therefore, actions should be contemplated in several, instead of single, spatial scales including global, national, regional and local, as well as temporal scales including short, medium and long terms. Conceptual models embedding climate change response into scale-sensitive frameworks provide opportunities for this scale-concerned integration of mitigation and adaptation (Howard, 2009). Howard (2009) offers an integrating conceptualisation whose essential key is the concern on the multiplicity of spatial scales. For example, air conditioning is a local adaptive tactic for the places that are hit by high temperature, but its cost of energy and its emission transform this local adaptation into an action hindering mitigation at the global scale. Another example is urban extension. Encouraging people to live in the suburban areas could be an adaptive strategy that may solve the problems of urban heat island and air pollution in the local city centres, but urban sprawl which would generate more emission from transportation also hinders mitigation at the global level.

Howard (2009) developed the diagram shown in Figure 1 to demonstrate the conceptualisation of the inter-relationships between mitigation and adaptation. The efforts helpful for both mitigation and adaptation fit in the area of A. In the area of D and E, approaches are helpful for one but problematic for the other. Moreover, in the area of B and C, approaches are supportive to one and neutral to the other. The two examples mentioned above (air conditioning and urban extension) belong to the area of E. Planting more trees in the urban regions is an example for the area A, because trees and green parks can absorb emission, function as temporary floodplain, adjust temperature, as well as improve the quality of local environment. Renewable energy research which mainly aims at mitigation with little immediate impact on adaptation could fit in the area B. For the cases where the shortage of water supply is recognised as a climate change issue, harvesting rainwater could be taken as a tactic adapting to the drier micro-climate although it has few impact on the overall climate, which matches the area C. Finally in the area D, compact urban form, as opposed to urban sprawl, could be an example of compromising on the local environment for the purpose of global mitigation. Some of the examples here will be discussed again in more details later.

Figure 1. Conceptualisation of the inter-relationship between mitigation and adaptation (source: Howard, 2009)

So far this conceptual model resembles some other authors' matrices categorising the relationships between mitigation and adaptation (Klein et al., 2007; Wilson and Piper, 2010). These matrices offer four categories including approaches focusing on mitigation while having impact on adaptation, approaches focusing on adaptation while having impact on mitigation, approaches concerning the trade-offs between mitigation and adaptation, and approaches aiming at a win-win situation. Table 1 presents a brief summary of the examples offered by these matrices.

Inter-relationships	Examples
Win-win (Mitigation and adaptation are mutually enhanced.)	Planning for suitable urban form (reducing emission and supporting livelihood) Offshore wind energy farms (providing clean energy with little compromising on other land use, compared to hydro power) Bio-energy crops (providing clean energy and enhancing rural economy) Urban agriculture and local food markets (reducing energy consumption and supporting well-being)
Trade-off (An optimal balance between mitigation and adaptation is to be identified.)	Dikes and surge-barriers (adaptive infrastructure which causes emission and requires energy to operate) Hydro power plants (providing clean energy but may impede emission reduction by permanently inundating large areas of forests) Roads connection to promote rural economy (adaptive infrastructure which causes emission)
Mitigation-centric	Tax on vehicle tailpipe emission Hybrid or complete electric vehicles

Table 1 Categorising inter-relationships between mitigation and adaptation (source: adapted from Klein et al., 2007; Wilson & Pieper, 2010)

Connecting the resource-competing relationship between mitigation and adaptation, any approach of one kind would have at least some cost (negative impact) to the other, since resources being spent on either would mean less resources available for the other. Therefore, it becomes more difficult to evaluate the inter-relationships which would require some exact cost-benefit calculation. Moreover, it becomes thus more difficult to find a truly neutral relationship in which the cost happens to evenly equate the benefit. For this reason, in the qualitative domain, Howard (2009) assumes that adaptive approaches would to a larger or smaller degree hinder mitigation (competing for limited resources), if they have no obviously significant facilitation to mitigation. Furthermore, he considers the mitigation approaches always fundamentally beneficial to adaptation in larger spatial and longer time scales, because any mitigation approach as stabilising changes would make the future situation easier for adaptation. Therefore, back to the diagram in Figure 1, Howard (2009) proposes the trends of approaches in the areas of B and D moving towards A, and those in C moving towards E. The first trend represents the conceptualisation that all the mitigation approaches would ultimately enhance both mitigation and adaptation. The second trend argues against those adaptive tactics which have inadequate concern on mitigation, for which reason short-term passive adaptation mismatches the long-term holistic considerations of climate change response. The essential conclusion of Howard (2009) is two-fold. Firstly, mitigation is a primary form of adaptation. Mitigation is

fundamentally adaptive, in the long run if not immediately, for which mitigation strategies could be treated as adaptation strategies. Secondly, mitigation strategies without significant benefit to adaptation are better than adaptation strategies without significant benefit to mitigation. Any local actions should bear in mind that climate change is essentially a global issue, so avoiding the global responsibility (e.g. free-riding or mal-adaptation) is impeding the long-term progress. Therefore, the integration of mitigation and adaptation in this model is to promote mitigation-oriented adaptation. Even though these mitigation-oriented adaptation tactics might be more expensive, complex or culturally inconvenient than the straightforward approaches, they are worth investment (Howard, 2009).

Among the many examples considered by the integrating conceptualisation, compact urban form (or compact cities) is intensively concerned by spatial planning. Within the planning field, compact city was campaigned for the stabilisation of climate and sustainability, but this strategy has become controversial regarding its two-edged characteristics (Pizarro, 2009). A compact urban form endorses the high concentration of sites, buildings and population, urban fabric with small blocks and many intersections, and the mixed-use of space, so that people have less needs of moving by private cars (Hamin and Gurran, 2009). The high density of population that intensifies mobility needs would support mass-transit system which is at least energy-efficient if not emission-free (Pizarro, 2009). This becomes the most obvious strength of compact cities regarding climate change mitigation, since modern transportation is recognised as one of the most significant sources of emission. Moreover, mixing spatial functions which may encourage social interactions is conceived of positive to social and economic sustainability. However, the very compact forms of many cities also generate problems to climate change. First of all, the compact (i.e. crowded) environment may intensify air pollution and thus public health problems, even if the total amount of emission is reduced (Howard, 2009). Secondly, in the cities with hot-humid summers, a compact form underling the urban heat island effect may encourage air conditioning which then probably cancel the reduction of emission from transportation (Pizarro, 2009). Thirdly, the high density of built environment is likely to sacrifice permeable surfaces, which increases the chance of flooding due to storms (Hamin and Gurran, 2009). Moreover, some case study considers the proximity of sites a risk of exacerbating unfortunate accidents (e.g. explosion and fire, De Roo, 2003).

Bearing the paradoxical issue of urban form in mind, a related planning concern is green open space. More space for planting trees is suggested by many urban planning scholars as a win-win solution contributing to both mitigation and adaptation (Hamin and Gurran, 2009; Howard, 2009). Green space (and ideally forest) can serve as a carbon sink area (Klein et al., 2007; Ravindranath, 2007). Green parks provide natural surfaces to absorb storm water (Stone, 2005). Photosynthesis of plants consume solar heat (Nyong et al., 2007). Open space is helpful for wind circulation which may cool the environment and improve air quality at the same time. In a word, green space seems a key to solve the many problems associated with the compact urban form, but it also seems to add another paradox: planning more green (open) space means a less compact urban form. As a result, Hamin and Gurran (2009) conclude that the most effective form contains a moderate density with adequate green infrastructure. Pizarro (2009) concludes with a multi-angular framework assessing a suitable urban form for a particular case. Moreover, McEvoy et al. (2006) suggest developing regional parks near urban areas as one alternative to increase the proportion of green space in urban regions. The suggestions above about compact cities and green space could be connected to the studies about green infrastructure, eco-cities, and urban ecology, over which what we observe as an overarching issue is the potential advantages of spatial planning at the regional scale. Regional planning has the potential to internalise the paradox between compact urban form and green open space, through which the advantages of both could be delivered. Planning urban regions with the regard to this concern would set up significant spatial foundation of the integration of mitigation and adaptation, and provide fundamental bases for mitigation-oriented adaptive urban societies. While spatial planning is striving to justify its role in addressing climate change, the potential of regional planning in integrating climate change mitigation and adaptation is considered a relevant answer and promising proposal. This section argues about how the call for the integration of mitigation and adaptation leads to the proposal of regional planning. The next section will further introduce policy mobilities as the channel to explore the insights in both practice and research.

4 GOVERNANCE INNOVATION: POLICY MOBILITIES

The integration of climate change mitigation and adaptation becomes a window to deepen the understanding of cross-scale effect, especially between the regional and global. Research on multi-level

governance and supranational networks suggest a way of cross-scale transformation that is beyond the vertical summing-up mode assisted by the hierarchical administrative systems. We consider international policy mobilities one of these channels through which the efforts of climate change mitigation and adaptation are interwoven and transformed through scales. Policy mobilities conceptualises the processes and outcomes associated with the fact that policies for shared issues at various places the world over become increasingly convergent (Temenos and McCann, 2013). The increase of policy mobilities is significantly supported by the extensive flow of information and intensive networks of agents at the current age (McCann and Ward, 2011). Compared to policy mobilities, a highly related concept is policy transfer (Benson and Jordan, 2011; McCann and Ward, 2011; 2013; Marsh and Evans, 2012). Research on policy transfer has focused on transfer-agents and the role of nation states, which matched the situation decades ago when most transfer relations were at the nation scale and the transfer relied heavily on particular agents including both individuals and institutions. At that time, power relation was the backbone issue which was why policy transfer was firstly concerned in political studies. Geographers argued later that geography should be taken into account as time had changed (McCann and Ward, 2013), and researchers in political science also acknowledged that the concept of policy transfer was rather evolving than static (Marsh and Evans, 2012). Both the conceptualisation of transfer and mobilities concern the movement of policies, but the literature about policy mobilities conspicuously intends to bring in new meanings that more accurately match the reality of the current age.

The concern from geography raises the awareness that understanding of policy transfer should go beyond the nation-centred view (Benson and Jordan, 2011; McCann and Ward, 2013). There have been more cases where policy mobilities is inter-urban, and many more actors and venues are involved, which is why some authors deliberately pluralised the word mobility to connote the multiplicity of processes and outcomes involved (Temenos and McCann, 2013; Stone, 2004; Cook and Ward, 2011). Moreover, policy mobilities also has influential impacts on the construction of geographical scales and the assemblage of cities and regions (Allen and Cochrane, 2007; Anderson and McFarlane, 2011). Study on policy mobilities matters not only for the policies and their movement, but also for the physical outcomes of how global geography is drawn and how local places are shaped. Moreover, urban regions are privileged sites of innovation, for which research appeals analyses about the inter-scalar conditioning of governance and policy (Temenos and McCann, 2013). In fact, the popularity of many policy models is based on the popularity of particular cities and the successful implementation of the policy models there (Ward, 2006). Global cities have gained more attention and thus attract more research (McCann, 2004). On the other way, policy mobilities helps cities for their ambition of becoming global. Policy innovation in previous research was conceptualised similarly as policy mobilities (Graham et al., 2013; Berry and Berry, 2007). Policy innovation is distinguished from policy invention while referring to the meaning of „new“ (Berry and Berry, 2007). Policy innovation in literature refers to the adoption of such a government programme which is new to the government adopting it. In contrast, policy invention as the process through which original policy ideas are conceived is much less studied than innovation as adopting policies having existed or implemented somewhere else (Berry and Berry, 2007). Therefore, policy innovation and policy mobilities to a large degree mirror each other. Although a policy may not be entirely new, the adoption of it may be very new to a particular place. Policies are context and geography sensitive, for which adopting a policy from some other context or place can be quite innovative and result in „new“ impacts at the place where it is adopted. Therefore, policy mobilities become the way of innovation by policy-makers who introduce some strategy feels new and may even disrupt the previous condition of a particular place.

5 CONCLUSIONS

The social response to climate change is seen in the dichotomy between mitigation and adaptation, for which there may be conflicts between them impeding the overall efforts of intervening in climate change. The integration of mitigation and adaptation is calling for comprehensive consideration on the multiplicity of scales. Spatial planning approaches can fit in the conceptual model where mitigation and adaptation are well integrated over multiple scales. Compact urban form has the ability to mitigate emission, although it may be unsuitable for adaptation for some geographical areas. Green open space is then suggested to complement the approach of compact cities so as to make progress towards both mitigation and adaptation. The conclusion of this literature study is to propose further research on regional study to demonstrate the role played by spatial planning in dealing with climate change. Moreover, policy mobilities matches the methodological concern on inter-scalar impacts of geography and spatial forms. The transfer

1 THE INCREASE OF FLOOD RISK IN EUROPE

In the last two decades Europe has faced a strong increase of flooding events. Out of 325 flood events recorded from 1980 to 2012, indeed, more than 200 occurred in the 2000s (EEA, 2012). Among all natural hazards, more than 64% of the damages are due to hydro-meteorological events, namely to floods and landslides, with costs higher than 13 billion euros since 2000 (EEA, 2013a). If on the one hand the increase of heavy downpours can be ascribed to climate change, on the other hand the amount of damage has to be imputed to the significant, and sometimes uncontrolled, urbanization processes (EEA, 2017). Therefore, both of these matters have to be addressed in order to prevent future flood disasters.

Climate change, intended as “a statistically significant variation in either the mean state of the climate or in its variability, persisting for an extended period”, is caused by “internal processes” or by “persistent anthropogenic changes in the composition of the atmosphere or in land use” (IPCC, 2001). The subversion of natural patterns has led not only to the increase of the sea level and of the mean temperatures but also to “changes in the frequency and magnitude of heavy precipitations” (EEA, 2017) that are expected to become even more frequent over the 21st century. Meanwhile, the population’s strong migration toward cities has enhanced the growth of urban areas with the consequent processes of land take and soil sealing (EC, 2012). In Europe, since the 1950s, the amount of impervious surfaces has registered an increase equal to 78%, with an increase of only 33% of the population (EC, 2012).

Furthermore, numerous European cities are located close to rivers or along the coast, and are continuing to spread into areas potentially prone to river floods (EEA, 2017), with a consequent increase in the number of inhabitants and assets exposed to fluvial flood risk. The latter, that occurs when the “river run-off volume exceeds local flow capacities” (EEA, 2012b), is only one of the risks connected to heavy downpours.

Extreme rainfalls may put at risk, indeed, also areas located far from water bodies. The increasing levels of land take and soil sealing consequent to the sprawling of urban land uses, often combined with the widespread inadequacy of existing sewage systems, are leading to a significant increase in pluvial flood phenomena that are only optionally considered by the Flood Directive. These phenomena are related to the “excessive superficial run-off and ponding” (EEA, 2016a) that occurs when the rainwater’s load exceeds the city’s sewer system capacity. Furthermore, it is worth noting that pluvial and fluvial flooding risks are strictly connected. As a matter of fact, sewage systems discharge water into the closest water bodies: therefore, their overload due to an excessive amount of impervious surfaces (pluvial flood), may cause the raise of water levels above normal ranges that can culminate with the river’s overflow (fluvial flood).

2 COPING WITH FLOODS: EUROPEAN STRATEGIES

In the face of the significant increase of flooding events throughout Europe, numerous tools and initiatives have been put in place in the last decade. First of all, in 2007, the European Flood Directive has been issued. This document clearly highlights the importance to develop effective flood management plans, outlining both protection and prevention strategies able to “prevent and reduce damage to human health, the environment, cultural heritage and economic activity” (Directive 2007/60/EC). Prevention and protection, as later on explained by the European Commission’s Note “Towards Better Environmental Options for Flood Risk Management” issued in 2011, can also be achieved by implementing environmentally friendly solutions, such as “natural, ecosystem-based water retention measures” (EC, 2011). These solutions, besides requiring less expenses and maintenance compared to the traditional engineering measures, allow to produce numerous indirect benefits, such as promoting tourism, creating

new job opportunities and providing new recreational areas (EC, 2011). Moreover, the increasing awareness that changes in climate conditions are likely to further increase flood risk in Europe and that cities represent not only the major contributors to climate change but also the most vulnerable targets to its impacts, in the April 2014, the European Union launched the Mayors' Adapt Initiative, addressed to support Local Authorities in carrying out comprehensive local adaptation strategies or integrating adaptation issues into relevant existing plans, in order to increase city's resilience in the face of climate impacts.

In order to drive cities towards the development and implementation of effective adaptation strategies in the face of climate impacts, the European Union provided guidelines and platforms aimed at guiding adaptation processes and favouring the sharing of information and best practices. In detail, provided guidelines distinguish adaptation actions into three main categories: grey infrastructure, including physical interventions aimed at improving the capacity of the built environment to withstand extreme events; green infrastructure aimed at using "functions and services provided by the ecosystems to achieve a more cost effective and sometimes more feasible adaptation solution than grey infrastructure" (EEA, 2012b); and soft measures, which include land use planning and control, monitoring and warning systems as well as information campaigns and devoted programs to raise citizens' awareness, to promote adaptive behaviours and to favour stakeholders' engagement. Furthermore, the EEA also underlines how the integration of the two approaches, "soft" and "green", helps achieving better performances. Indeed, the involvement of stakeholders and the growth of awareness among the population strengthen the "inter-connections between natural and social systems" by building up acceptance and accelerating the adaptation process (EEA, 2013b).

In respect to floods, numerous studies (Foster et al. 2011, EEA, 2016a) have recently emphasized how the so far most widespread grey infrastructure, that include retentions or protection structures (e.g. dams, dikes, embankments), show high construction and maintenance costs, create a false sense of safety, pushes further urban developments, and provide a limited flexibility in the face of the uncertainty of long-term climate conditions. Based on these assumptions, current European approach to flood adaptation is progressively shifting from an "engineering-based" perspective, largely based on grey measures, toward an environmental-based perspective, mostly relying on green and soft measures, characterized by lower costs, higher flexibility and multiple benefits. The latter would enable cities to turn climate threat into an opportunity to create a safer urban environment and a better quality of life for citizens. Such a shift is clearly remarked by the French National Strategy for Flood Management, issued in 2014, which consider the creation of new grey infrastructure as the last option, to be put into play only when all other possibilities are insufficient (EEA, 2016a).

Hence, in the last years numerous cities are developing and experiencing "green" adaptation strategies, involving the increase and the enhancement of urban green areas, the integration of Sustainable Drainage Systems (SUDSs) in areas characterized by a predominance of impervious surfaces and the restoration of natural environments such as floodplains. Moreover, an increasing number of cities are promoting community based adaptation processes, in order to improve local awareness as well as to prepare local communities (decision makers and citizens) to make informed decisions about adaptation in a constantly changing scenario (Keys et al., 2016).

Summing up, starting from the second half of the 2000s, European Union has undertaken a path toward the reduction of different typologies of fluvial and pluvial floods that is fully in line with the hints provided, on a global scale, by the Sendai Framework for Disaster Risk Reduction 2015-2030, issued in 2015, that represents a milestone towards more effective risk reduction strategies. The Framework has indeed clearly stressed the linkages among risks, climate change and sustainability, emphasizing the need for strengthening "the sustainable use and management of ecosystems" and implementing "integrated environmental and natural resource management approaches that incorporate disaster risk reduction". Furthermore, the Document has put large emphasis both on the need for "mainstreaming of disaster risk assessments into land-use policy development and implementation, including urban planning" and for promoting "a culture of disaster prevention, resilience and responsible citizenship" by encouraging an active engagement of public and private stakeholders (UN, 2015).

3 CITIES DEALING WITH FLOOD RISK: EUROPEAN BEST PRACTICES

Cities represent the economic, cultural and political core of today's society. In Europe almost 73% of the population lives in cities and this percentage is expected to grow up to 80% before 2050 (EEA, 2015). This high concentration of inhabitants increases on the one hand the exposure to natural disasters and, on the other, the opportunity to spread new prevention strategies.

For this instance, cities represent the best place to encourage the promotion of ecosystem-based strategies. Many have already developed pioneer projects in this line, by adhering to global and/or European initiatives, so that today they can be looked at as best practices. Likewise, cities also offer the opportunity to introduce and successfully employ "soft measures". The latter are conceived to raise awareness and increase citizens' involvement in outlining prevention strategies. This approach, if accurately applied, would not only promote the acceptance of new policies but also positively influence their final outcomes.

Hereunder two European best practices are briefly described: the first one refers to the city of Sheffield that introduced green infrastructures to reduce flood risk; the second one refers to the city of Ghent that successfully promoted citizens' engagement in the implementation of green measures.

The city of Sheffield, located in South Yorkshire (England), rises along two main rivers, the Don and the Sheaf. This city has suffered a devastating flood in 2007 and almost repeated this experience 2012. Thus, in 2015 the "Flood and Water Management Capital Investment Programme" was issued to develop projects able to prevent these events from happening again. Sheffield's flood protection scheme is based on three main goals: "slowing the flow", "containing the flow" and "building resilience" (Sheffield City Council, 2017).

Sheffield aims at achieving the first goal, slowing the flow, by implementing green measures, capable to intercept rainwater preventing it from increasing river's flow. As a matter of fact, the realization of both storage areas and SUDSs would allow capturing rainfall and soaking it before it reaches the river. More precisely, this goal is expected to be achieved by: managing rural land, resorting to "tree planting, moorland restoration and creation of landscape features" to collect rainwater; managing existing reservoirs, that have to be transformed in order to better contribute to flood prevention; creating new storage areas, designed and conceived for storing rainwater; and urban water management, introducing the SUDSs to reduce the superficial run-off. In respect to the second goal, containing the flood, the city aims at improving existing flood defence measures. For instance, by raising the level of existing embankments and reducing possible obstacles along the river. Finally, the third goal, "building resilience", the city aims not only at improving warning systems and emergency policies but also at ensuring a better maintenance of the rivers and at increasing the capability of urban environment to recover after the flood.

In brief, Sheffield integrates green measures into two of its three main flood prevention goals, in "slowing the flow" and in the "building resilience". For both of these purposes green infrastructures are conceived as long-term solutions with multiple benefits, since they would be useful not only for prevention issues, but also to create new recreational areas and improve the overall quality of the urban environment.

The city of Ghent, located in Belgium, rises at the confluence of the Lys and upper Scheldt rivers and therefore has to deal with both pluvial and fluvial floods. However, considering that during heavy downpours fluvial flooding "is more likely to take place in areas intended for flooding or where flooding causes less damage" (Gent Klimaatstad, 2016), the main concern of Local Authorities is to protect inhabitants from pluvial flooding. For this matter, Ghent's strategy addresses the following goals:

- Prevention of more sealed soil due to hardening of surfaces, that involves both the integration of new green areas and the improvement of existing ones;
- 'Greening' the city, to be achieved through a Green Structural Plan, designed both for water retention and for cooling (addressing the heat island effect as well as the flood risk);
- Maximum focus on the green-blue network that calls for major safeguard of the watercourses, by preserving the enclosed areas and greening the banks;
- Creation of space for water, by realizing new floodable areas;
- Maximization of the city's sponge effect that will decrease the water load toward the rivers through "local catchment, retention, reusage, infiltration or buffering and delay" (Gent Klimaatstad, 2016) of rainwater thanks to the introduction of SUDSs;

- Provision of cooling infrastructure, finalized to decrease the heat island effect, by introducing such as trees, water elements and light buildings' coverings.

In brief Ghent, analogously to Sheffield, entrusted green infrastructures to ensure flood protection. Furthermore, this city's prevention strategy deserves credit not only for promoting "green" measures, but also for successfully combining them with "soft" measures. Indeed, in 2015, Ghent launched a crowd-funding platform to ensure the economic feasibility of adaptation actions that are proposed and financed by citizens (EEA, 2016c). This platform, by favouring bottom-up adaptation initiatives, guarantees a large public engagement in improving city's wellbeing. So far, two adaptation projects have been successfully promoted through this platform (EEA, 2016c) and will be soon implemented.

4 RECOVERING FROM AND ADAPTING TO FLOODS: THE BENEVENTO CASE STUDY

Italy, alongside with most of the European countries, is battling with hydro-meteorological events. Floods and landslides caused 1.989 deaths and injured 2.561 inhabitants in the time span 1964-2013 (ISPRA, 2015), becoming a key priority for local and national institutions. One of the most recent flooding events has affected the city of Benevento, located in Southern Italy and characterized by high flood risk levels due to its geographical location. As a matter of fact, this city rises along the banks of the Calore River and more specifically at the confluence of this river with its two main tributaries, Tammaro and Sabato (Figure 1). The confluence with the tributaries, most importantly with the Tammaro River, represents a weak spot due to abrupt shift of the hydrological regime caused by the overload of gravel and sand (Soreca, 2013). This condition has already caused flooding disasters in the past; the most disruptive one dates back to 1949, when the river's overflow wrecked many residences, agricultural and industrial activities leaving hundreds of inhabitant homeless and jobless (Calò, 2015). In response to this event, massive concrete protection walls were erected along the river in correspondence to the most inhabited area (Comune di Benevento, 2015).

The latest floods occurred the nights between the 14th and 15th and the 19th and 20th October 2015, causing damages to public and private buildings, to flood defence measures, to infrastructures, to the primary services network, to the productive activities. Furthermore, the events caused strong inconveniences to the population, leading to the death of two persons (Provincia di Benevento, 2015). Overall, 33 cities of the Province of Benevento were affected by the hazardous events with costs equal to 120 million Euros for the reinstatement of public buildings and infrastructures¹ and further 24 million Euros for the compensation of damages and production losses of the agricultural activities (Giunta Regionale della Campania, 2015).

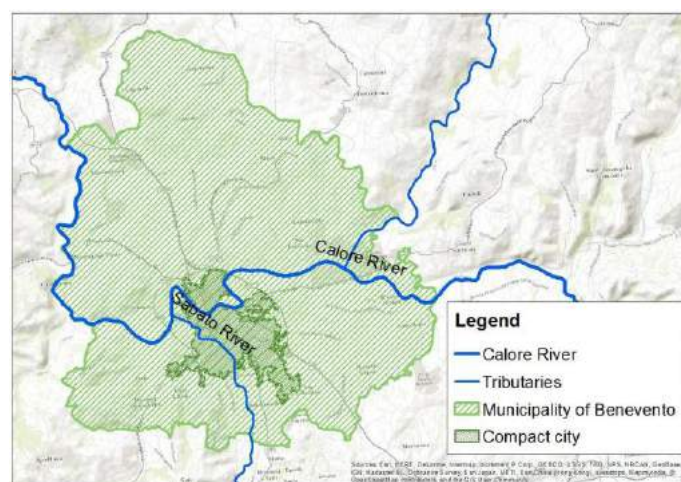

Figure 1: City of Benevento and main Rivers. Source: own elaboration.

¹ Data source: Nota della Regione Capania prot. 0698789 of the 18/10/2015. Available at: <http://provincia.benevento.it/>

Therefore, these events proved not only the inadequacy of the defence system conceived after the 1949 flood, but also the deficiencies of the “Extract Plan for Flood Defence: the Volturno Basin” published in 1999 and still in force in the October 2015. As a matter of fact, the concrete barriers built along the course of the Calore River present many discontinuities, especially in low population density areas (Comune di Benevento, 2015). This condition, combined with the lack of maintenance interventions and the consistent increase of population and of impervious surfaces over the past 60 years, made these barriers obsolete and inadequate to protect the urban area. Furthermore, the flooded areas exceeded the hazardous areas identified by the “Extract Plan for Flood Defence: the Volturno Basin”, highlighting the necessity to review current Plan.

In brief, the event of 2015 highlighted the need for reconsidering and strengthening current strategies against floods in order to guarantee the population’s safety and avoid the likely future flooding events from being disruptive.

4.1 BENEVENTO: ONE YEAR AFTER THE FLOOD

A year after, Benevento is still struggling to recover from the impacts of the 2015 floods. So far, despite most of the implemented measures have been addressed to repair the damage caused by the hazardous events, not all the damages have been repaired; moreover effective risk reduction strategies, aimed at preventing future disasters, are still at a very early stage.

An in depth analysis of the event, its consequences and the measures adopted starting from the immediate aftermath, allows to identify which actions have been implemented and what is still missing. More specifically, the considered actions refer to: the emergency management, the recovery phase, the prevention phase, which is crucial to turn the disaster into an opportunity for enhancing city’s capacities to deal with likely future events.

The flooding events of October 2015 inundated numerous roads and buildings causing many families to be evacuated and many others to be confined on highest floors¹. The management of the emergency phase was entrusted to the “Civil Protection Plan” (Comune di Benevento, 2015). The Municipality adopted the Plan in 2006 and its most recent update, before the 2015 events, dated back to 2010 (Città di Benevento, 2016). The Plan was sized according to the risk scenarios outlined by the “Extract Plan for Flood Defence” issued in 1999 by the Basin Authority of the Liri-Garigliano and Volturno Rivers². Unfortunately, the 2015 events were significantly beyond the expected; hence, in 2016, the new “Civil Protection Plan: Hydrological Risk and Intervention Model” (Comune di Benevento, 2015) has been issued. The Plan includes new detailed cartographic support concerning the most exposed areas of the city, a reviewed list of both the facilities adequate to offer shelter and support in case of emergency and of the human and technological resources to employ in order to manage likely future crises (Città di Benevento, 2016). Furthermore, the plan comes with cartographic attachments representing, the critical points, the fastest escape routes and the areas inundated in the 2015 event.

However, further improvements of the Plan are expected: current risk scenarios should be updated, indeed, according to the on-going revision of the “Extract Plan for Flood Defence: the Volturno Basin”, following the directions provided in December 2015 by the Hydrographic District of the Southern Apennines³ regarding the delimitation and classification of the hazardous and risk areas (Città di Benevento, 2016).

In respect to the recovery phase, it has to be noticed that the Report published in October 2016 and titled “Flood events from the 15th to the 20th October 2016: Interventions implemented by the Province of Benevento” summarizes the actions so far undertaken or still underway to repair physical damages suffered by public facilities and infrastructures (Provincia di Benevento, 2016). The comparison of these data with those listed in the damage reports, released after the event and analysed in-depth by the

¹ <http://www.comune.benevento.it/>

² A detailed description of this Plan is provided in the paragraph 4.1

³ The “Extract Plan for Flood Defence: the Volturno Basin” published by the Basin Authority of the Liri-Garigliano and Volturno Rivers is subordinated to the Hydrographic District of the Southern Apennines. The latter, responsible for all Basin Authorities that fall within its jurisdiction area, provides key criteria and instructions to improve and update the Basin Authorities’ Plans.

Authors in a previous research work (Galderisi and Treccozi, 2017), highlights that many damages involving schools, streets, bridges and flood defence measures for the Tammaro River, haven't been repaired yet. Furthermore, damages involving bike lanes and flood defence measures for the Sabato River haven't been mentioned in any intervention report so far (Figure 2).

Figure 2: Physical Damage to public facilities in the city of Benevento after the October 2015 event (left) and their recovery status in October 2016 (right). Source: own elaboration.

Although the comparison proves that many damages have been repaired, it is important to outline that these interventions were mainly intended to recover the pre-event, and largely inadequate, state (Provincia di Benevento, 2016). Furthermore, even though the biggest challenge is still related to the recovery of the hit industrial and agricultural activities, the provided comparison refers only to physical damages to public buildings, facilities and infrastructures (schools, administrative buildings, bank defence measures, road network, etc.), since no official data and reports regarding the recovery of private buildings and economic activities have been made accessible to the public, impeding to evaluate the progress.

As for the prevention phase, it has to be outlined that the Plan in charge for flood prevention when the 2015 flood occurred was the “Extract Plan for Flood Defence: Volturno Basin”, issued in 1999 by the Basin Authority of the Liri-Garigliano and Volturno Rivers and still in force. Nevertheless, as mentioned above, the surface actually flooded in 2015, revealed itself to be way more extensive than the one portrayed in the Plan. Figure 3 gives a closer look to the difference between the areas actually flooded and the ones expected to be flooded in the confluence area of the Calore with its two main tributaries, in other words in the city's most exposed area. Therefore, on December 2015 the “Management Plan for Flood Risk” was published from the Hydrographic District of the Southern Apennines, acknowledging the need to improve existing flood protection plans for the regions that fall within its jurisdiction area. These modifications had to be started in 2016, and further enhanced in 2019. Hence, starting from 2016, Basin Authorities were required to reconsider the boundaries of hazard and risk areas and their classification, considering historic flood data, such as the ones owed to the 2015 events. The Management Plan for Flood Risk states that in 2019 all flood protection plans have to introduce new prevention, preparation and recovery measures. For the Calore River, the prevention measures should include: the development of a river bank monitoring service, the improvement of ecological corridors along the river and a management policy for the vegetation surrounding the river, the recognition of green areas to drain the river's overflow (Distretto Idrografico dell'Appennino Meridionale, 2015).

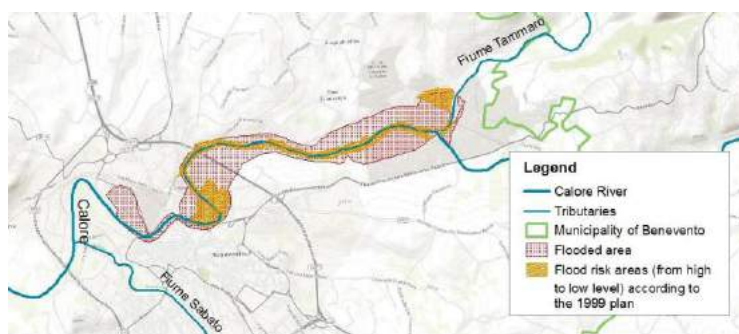

Figure 3: Comparison between the area flooded during the 2015 event and the area considered at flooding risk by the 1999 “Extract Plan for Flood Defence: Volturno Basin”. Source: own elaboration.

Furthermore, the areas along the Calore River, are safeguarded by the “Territorial Plan for Provincial Coordination” approved in 2012, as part of the foreseen provincial ecological network (Provincia di Benevento, 2012). In line with the Territorial Plan for Provincial Coordination, the Municipal Master Plan, approved in 2012, envisaged for the areas included in the provincial ecological network, the creation of naturalistic or thematic parks (Comune di Benevento, 2011b). Although both the mentioned Plans were already in force, none of the planned interventions had been implemented when the 2015 floods occurred. As a matter of fact, only on January 2017, the city has announced that an Agreement between the Municipality and the Liri-Garigliano Basin Authority for the preparation of a work program to implement the City Fluvial/Territorial Park had been signed¹.

Finally, it is worth mentioning that so far Benevento has not adhered to any European initiative aimed to develop adaptation plans.

Summing up, more than one year after the 2015 flooding events, more effective prevention strategies have been only envisaged both at Basin and at the Municipal scale and, although they seem to outline a green strategy for preventing future fluvial floods, they are at a very early stage, hindering an assessment of their effectiveness.

4.2 HINTS TO SHIFT FROM A “COPING” TOWARD A “TRANSFORMATIVE” APPROACH FOR FLOOD ADAPTATION

Learning from the adaptation strategies that numerous cities, within and outside Europe, are developing to face the increased frequency and severity of flood events, in the following we will provide some hints of how to shift from the “coping” approach, that has guided so far the Benevento’ response to flood events, towards a “transformative” approach that, overcoming current sectorial strategies and grounding on a systemic perspective, “seeks to integrate adaptation with other aspects of urban development and turns the challenge into an opportunity, capitalising on many additional, non-climatic benefits” ().

Bearing in mind that current urban vulnerability to flood impacts is ascribable not only to the current urban development patterns but also to the limited awareness among local decision-makers, citizens and economic stakeholders toward climate related challenges, the key pillars for developing an effective local adaptation strategy, capable of turning current challenge into an opportunity for a sustainable urban development by combining green and soft measures, can be synthesized as follows:

- Reducing the river’s load, by reducing superficial run-off through SUDSs;
- Preventing the river’s load from increasing, by controlling the loss of permeable soils in future urban developments;
- Enhancing the river’s capacity, by creating a fluvial park;
- Raising local awareness, by promoting an active engagement of citizens and local business.

The first pillar, reducing the river’s load, entails the control and reduction of the risk of pluvial flood that occurs when large amounts of superficial run-off are produced. This phenomenon is usually due to the prevailing of impervious surfaces that characterize urban areas and to the consequent overload of the sewer system, often inadequate even to the ordinary load, in case of heavy rains. An effective response to this phenomenon can be sought not only in the improvement of the existing sewer system, a measure that has been recently approved by the Municipality of Benevento in 2017², but also in enhancing city’s ability to absorb superficial run off through the widespread implementation of SUDSs.

The most critical area within the Benevento Municipality is represented by the compact historical city that, according to the data provided by the Corine Land Cover programme, is characterized by 88% of artificial surfaces and only 12% of permeable surfaces (Figure 4). In this area the main opportunities to reduce superficial run-off, and consequently the amount of water channelled toward the surrounding water bodies, can be sought through the redesign of public open spaces and namely from the redesign of public streets,

¹ http://www.comune.benevento.it/bn2_pagine/notizie/comunicato.php?id=5775&allComunicati=1

² The intention to improve the sewer system has been notified on Benevento’s website: http://www.comune.benevento.it/bn2_pagine/notizie/comunicato.php?id=5775&allComunicati=1

squares and parking lots through permeable pavements, trapping rainfall underground and directing it to bioswales and rain gardens.

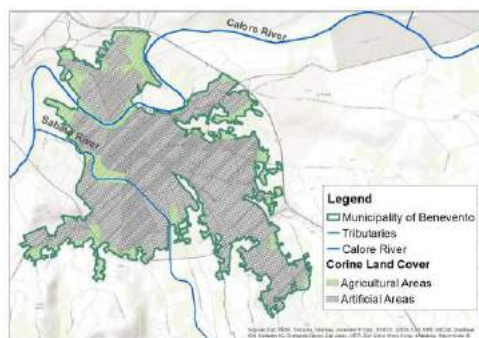

Figure 4: Types of land uses in Benevento's compact city, according to the Corine Land Cover programme.
Source: own elaboration.

The development of SUDSs would allow restricting water flowing into the sewage systems, by enhancing meanwhile the environmental quality of the historical city. The second pillar refers to the need for preventing the river's load from increasing. To this aim the loss of permeable soils in future urban developments should be significantly reduced. Current Masterplan allows new residential development areas within the Municipal area, comprising in the Compact City (Figure 5). As a matter of fact, these areas would further increase the percentage of impervious surfaces. However, the introduction of the principle of "hydraulic invariance" for future urban developments would allow to keep the superficial run off unchanged. This principle – already introduced by the flood management plans in Emilia Romagna in the early 2000s and forcing new urban developments "to preserve peak discharges from urbanized areas to the values corresponding to pre-existing agricultural conditions through adequate flood detention" (Pistocchi et al., 2015) – could be easily adopted by the basin plans, currently under preparation, as well as by current Master Plan.

The third pillar, referred to the enhancement of the river's capacity, could be achieved by realizing a green flood storage area along the Calore River. This solution, which has already been implemented in the Sheffield case-study, would constitute a temporary water storage area in case of heavy rainfall and, during dry periods, an important recreational asset both at Municipal and at wider scale. As mentioned above, both the Territorial Provincial Plan and the Municipal Master Plan envisaged the proposal of a Fluvial Park along the Calore River. Nevertheless, only after the 2015 flood events an Agreement between the Municipality and the Liri-Garigliano Basin Authority had been signed: the Agreement establishes the need for developing a work program addressed to implement the City Fluvial/Territorial Park. However, in order to define such a work programme in a shared and participatory way, the opportunities arising from the development of a River

Contract, intended as a participative management structure capable to bring together multiple different stakeholders and already tested in numerous European countries, should be explored.

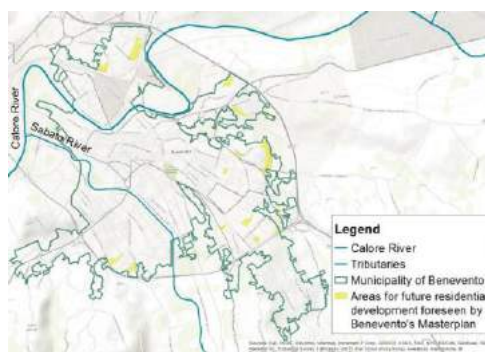

Figure 5: Foreseen new residential developments in the Compact City.
Source: own elaboration based on the Benevento's Master Plan.

The last pillar refers to the need for raising local awareness: according to the Sendai Framework, indeed, effective disaster risk governance requires not only “clear vision, plans, competence, guidance and coordination within and across sectors” but also the effective engagement of all relevant stakeholders to decision-making processes. Thus, the involvement of citizens, local businesses and other stakeholders in developing shared visions for a climate-proof urban development has to be considered as a crucial element to guarantee the effectiveness of a flood adaptation urban strategy. So far, although numerous local news websites handled by activists prove a significant population’s concern for these issues, no effective public initiatives aimed at raising local awareness on occurred flood events or at involving local stakeholders in developing a shared vision for the future, have been undertaken. The introduction of “soft measures”, such as the creation of an open knowledge platform capable to combine and integrate different sources and types of available information (e.g. on historical and recent flood events and related damage, implemented recovery actions and on-going initiatives, current regulations, etc.) as well as to facilitate the interaction among different stakeholders, including civil society, could allow to increase local awareness and address flood risk in a more effective and participatory way. Moreover, the establishment of the Calore River Contract as well as the implementation of a crowdfunding platform, as in the Ghent case study, could allow local stakeholders, including citizens, to be actively engaged in decision-making processes and could stimulate bottom up initiatives capable to complement public action, opposite to the currently prevailing top-down approach to flood management.

5 CONCLUDING REMARKS

Over the past years, in the face of the significant increase of flooding events and their costs, European institutions have largely contributed to raise National and Local Authorities’ awareness and promoted numerous initiatives that are being successfully acknowledged and implemented by most State Members as well as by numerous cities. Up to date more than 600 European cities have undertaken an adaptation process in the frame of European or international initiatives (EEA, 2016b), and many of these chose to rely on green infrastructure, capable to guarantee multiple benefits and proving a successful overall progress toward Europe’s climate-proof goal.

However, some State Members are still straining to implement adaptation strategies and their progress status is delayed. In Italy, for example, very few cities have put into action adaptation strategies – with a predominance of grey measures (technological, infrastructural, etc.) compared to green ones (Giordano et al., 2014) – while most of them haven’t even addressed the issue. Among these, the city of Benevento that, even though it has been struggling with flood risk for decades, is still far from embracing a “transformative” perspective, by starting an adaptation processes effectively integrated into city’s development issues and capable to turn the climate challenge into an opportunity for improving the overall quality of the urban environment. The response of the city to the latest flood events has been, indeed, mainly based on a “coping” approach, by implementing actions aimed to repair and reinstate the pre-event conditions, whereas the potential of green infrastructures to improve Benevento’s resilience against flood has been so far only envisaged.

As a matter of fact, the best practices of Sheffield and Ghent proved how green strategies for flood prevention strategies offer the opportunity to improve not only inhabitants’ safety but also cities’ landscape and availability of recreational facilities, providing cities with numerous environmental, social and economic benefits. Moreover, Ghent’s experience of involving stakeholders and citizens through the implementation of soft measures, suggests a cue to enhance people engagement in public decisions and to strengthen the ownership of the implemented actions.

Therefore, grounding on the experiences so far developed by European cities, Benevento should reverse its current “coping” approach to flood disaster – largely emergency-driven, fragmented and discontinuous – leading the way to a transformative adaptation strategy, based on the discussed pillars and effectively integrated in sectorial and spatial planning processes. Moreover, citizens’ participation and activism emerged in the aftermath of the recent flooding events point out the potential to actively engage local communities in decision-making processes as well as to encourage bottom-up adaptation initiatives complementing institutional ones, which could represent key issues for a successful adaptation process.

ID 1368 | RESILIENCE THROUGH A METHODOLOGY TO PLAN GREEN INFRASTRUCTURES

Isidoro Fasolino¹; Michele Grimaldi¹
¹University of Salerno
i.fasolino@unisa.it ; migrimaldi@unisa.it

OVERVIEW: The increasing use in recent years of the word resilience when considering sustainable development, linking relief to development, adaptation to climate change and the need to give greater priority to addressing vulnerability has been much discussed. It has proved attractive because it appears to offer a way to bring different disciplines and perspectives under a single conceptual umbrella. The impacts of urban sprawl on peri-urban landscapes include, among other things: loss of natural habitats for species; lack of natural water retention areas; negative impacts on water quality; negative impacts on human health, mental/physical wellbeing, recreation, social interaction; impacts in terms of climate adaptation. The climate crisis is hitting a territory in which the hydrogeological instability has made the mountain slopes unstable and fragile and where the lowland areas improperly exploited, particularly in the vicinity of rivers, have become spaces of devastation due to floods and landslides. The territory has suffered profound and disfiguring changes in terms of structure, function and, consequently, of resilience capacity to these extreme events (Fasolino, 2017). Green Infrastructures (GI) can mitigate the effects of climate change and extreme events that they pose, managing, for example, the devastating power of floods or landslides, re-establishing spaces and functions (Austin, 2014; Benedict and McMahon, 2006; Laforzezza et al., 2013). The main elements of GI include parks, private gardens, agricultural fields, hedges, trees, woodland, green roofs, green walls, rivers and ponds. The theme of GI is closely related to Ecosystem Services (ES), which are fundamental to maintaining the resilience of a territory. We propose a methodology for the effective planning of a GI network that will help achieve numerous benefits, including: reducing risks to people and property, improving psychological health & well-being, boosting local economic regeneration and providing a habitat for wildlife. There are currently any tools available and many more emerging. The challenge is to ensure that well planned GI, providing functions which will meet numerous planning objectives, can go beyond the purely scientific and environmental framework and become an integral part of public policies; but this requires thorough planning, design and management. This paper shows how to develop a GI network using existing European data. Most input data for the Geographic Information System (GIS) was taken from published and reclassified sources for analysis purposes. The choices made during the data processing and analysis are based on expert opinions and are open to public control. In conclusion, to achieve the resilience of a territory, it is very important to promote the mainstreaming of risk assessments into land-use policy development and implementation, including into urban planning.

1 FIELD OF INTEREST AND ANALYSIS ABOUT THAT

1.1 EUROPEAN POLICIES ABOUT GREEN INFRASTRUCTURE AND ECOSYSTEM SERVICES

Human-induced climate change, combined with other man-made pressures such as the conversion of soil uses, has altered the functions of ecological systems and has consequently altered the flow of ES in terms of scale, timing and position. Future climate change will probably aggravate these effects.

The European Union (EU) strategy for adapting to climate change aims to make Europe more resilient to climate change by ensuring ecosystem-based approaches. The importance of GI is identified by the European policies in the following documents:

Exploring Nature-based Solution of European Environment Agency (EEA) - EU, which shows the need for GI to mitigate vulnerability to atmospheric agents, climate change and, in particular, landslide risk.

The Seventh Environment Action Programme - 7EAP (Decision No 1386/2013/EU) proposes to increase ecological and climatic resilience, so that the restoration of ecosystems and GI can have important socio-economic benefits, including public health.

The EU Biodiversity Strategy (COM/2011/244 final) requires the restoration of at least 15% of the degraded ecosystems in Europe and aims to expand the use of GI.

The 2013 European Commission Strategy on Green Infrastructure (COM/2013/0249 final) stresses that GI can make a significant contribution to the effective implementation of all policies where some or all of the desired goals can be achieved at least in part through natural solutions.

The Regional Policy 2014-2020 continues to support nature and GI through financial instruments such as the European Regional Development Fund and the Cohesion Fund, which contribute to providing multiple benefits, in particular economic development.

The Water Frame Directive (2000/60/CE), Nitrates Directive (91/676/EEC) and the Floods Directive (COM(2006)15) offer GI related opportunities; for example, supporting actions to improve soil conservation through GI.

The aim of this study is to develop a methodology that allows, from a multi-scalar point of view, to detail the procedure outlined in the European document by highlighting its limits and translating them into actions onto a more detailed scale in the territorial and urban planning.

1.2 LANDSLIDES

Landslides are harmful events that seem to be repeated more frequently and, after earthquakes, are the events that cause the greatest number of victims and damage to inhabited towns, infrastructures, environmental and cultural assets. Eroding soil erosion can cause significant losses in agricultural and forest productivity. Soil erosion depends mainly on precipitation as well as more superficial properties of the soils (Crozier, 2010). Plant cover plays an important role in soil conservation and in the prevention of landslides (Stokes et al., 2013).

According to a study prepared by the EEA, there are many tests that determine how rising landslides are due to climate change. In particular forests, along with other vegetation, are able to reduce the presence of surface landslides. Their global increase is due to the excessive use of natural resources and deforestation, as well as increasing urbanization and uncontrolled land use.

In a recent analysis, we recognize the importance of different types of vegetation to mitigate the risk of landslides. Although a large part of European literature has recognized the link between plant cover and slope stability, the ability of GI to mitigate the risk of landslides is poorly evaluated locally. The potential methods to be applied include the evaluation of the replacement or avoided costs.

Studies show the ability of ecosystems to mitigate the risk of landslides based on the presence of protective forests and the potential danger of landslides. The integration of both maps involves delineating a potential GI network to mitigate vulnerability from landslides.

The regions with good coverage of potential GI elements are areas with dense forests. Overlaying the GI network with settlements and road infrastructure, we can know the application for the GI protection function. The result shows that most settlements and high mountain roads have effective protection from landslides, while the risk increases moderately in hilly areas with a lower percentage of forest protection.

The potential landslide hazard is based on the European Landslide Susceptibility Map (ELSUS1000) by European Soil Data Centre (ESDAC).

1.3 GREEN INFRASTRUCTURE AND ECOSYSTEM SERVICES

Green Infrastructure (GI) consist of a network of natural and semi-natural areas strategically planned with other environmental features, designed and administered to provide a wide range of ES. The importance is

given to the ES provided as well as the use and management of the soil, with the aim of delivering a set of environmental benefits while maintaining and improving the ecological functions (Lennon and Scott, 2014).

Eco-systemic functions are defined as: the ability of processes and natural components to provide goods and services that directly or indirectly meet the needs of man and guarantee the life of all species.

In order to prevent the impacts of uncontrolled urban development and fragmentation, connections are made in ecological networks and green spaces are promoted in the urban context. Potential GI are identified by the combination of an existing hazard in a given region and the presence of ecosystems with ES that mitigate the impact of the hazard.

Ecosystem Services (ES). The ecosystems of a territory, through chemical-physical, biological and more generally ecological processes, provide irreplaceable support to the quality of life of its inhabitants and are the basic factors for sustainable economic development. These processes are recognized as ES, that is, a set of functions naturally provided by ecosystems (Costanza et al., 1997; Burkhard, B. et al., 2010).

Territories able to preserve or restore their natural capital will have greater opportunities for lasting prosperity. If ecosystems are healthy or functional, they will be, for example, more resilient and less vulnerable to extreme natural events (e.g. heavy rains, heat waves) that can absorb atmospheric pollutants (air quality) , to self-purify water (water quality), to replenish the foothills and to regulate the hydrological cycle (water availability), to offer recreational spaces and the possibility of psychological well-being.

The Millennium Ecosystem Assessment (MEA) (2005), the widest and in-depth systematization of the knowledge acquired so far on the status of ecosystems in the world has provided a useful classification by dividing ecosystem functions into four main categories:

- Ecological Integrity (EI) (or Supporting): these functions collect all the services needed to produce all other ESs and contribute to the (in situ) conservation of biological and genetic diversity and evolutionary processes.
- Regulating (SR): In addition to maintaining the health and functioning of ecosystems, regulatory functions collect many other services that have direct and indirect human benefits (such as climate stabilization, waste recycling), which are usually unrecognized until they are lost or degraded;
- Provisioning (SA): These functions collect all those resources supplying services that natural and semi-natural ecosystems produce (oxygen, water, food, etc.).
- Cultural (SC): Natural ecosystems provide an essential consultation function and contribute to the maintenance of human health by providing opportunities for reflection, spiritual enrichment, cognitive development, recreational and aesthetic experiences.

The regulation falls under the protection from the hydrogeological disasters: ecosystems contribute to containing the hydrogeological disaster due to rains and wind. This allows, among other things, to maintain agricultural productivity by reducing the loss of fertile soil.

It has been estimated that over the last 50 years, 60% of ES on the planet have been compromised. Therefore, it has become crucial to integrate the concept of functions and ES into land management and planning decisions so that local administrators can control the pressures that threaten the ecosystem and their functionality, improve their effectiveness and build a model of Governance that is based on tools such as payments for ES.

1.4 EVALUATION OF ECOSYSTEM SERVICES

Since ES have never been fully quantified in monetary terms, they have always had little or no weight in policy decisions.

The potential assessment of the soils to provide ES is considered as an important tool to address the current difficulty of systematically considering ES in land planning.

Several tables found in current literature (Müller et al. 2011; Fisher and Turner, 2008) containing ES, defined by MEA, values for each soil class of Corine Land Cover (CLC) have been compared.

To evaluate the capabilities of the different types of land cover to provide ES, a matrix has been created. The assigned values are based on expert evaluations, both conceptual and derived from different case studies. These values can be seen as research hypotheses that need to be tested in further applications.

The matrix shows the high capacity to provide a wide range of ES for different soil coverings (forests, peat bogs, marshes and moors). The types of soil cover deeply modified by humans, such as urban fabric, industrial or commercial areas, mining and landfill extraction, have a very low capacity.

The different values found in literature for each ES, relative to the four macro-classes, according to the type of soil cover were homogenized by performing an arithmetic average operation. In a single table that follows the same type of assessment of the previous approaches based on the ability of the different types of soil cover to provide individual service: 0 = no capacity, 1 = low capacity, 2 = relevant capacity, 3 = average Capacity, 4 = high capacity, 5 = very high capacity.

1.5 EVALUATION OF HYDROGEOLOGICAL DISRUPTION

Agro-forestry activities, through sustainable management practices, may have a positive impact on the countryside's defences and prevention of disaster, given that much of the countryside is still rural.

The Guidelines for the Evaluation of Hydrogeological Disruption written by Higher Institute for Environmental Protection and Research (ISPRA) propose guidelines and methodologies that, based on the integration of territorial databases of the environment and agriculture sectors, enable the identification of priority areas of intervention throughout the national territory and the most appropriate mitigation measures, both in active and abandoned agri-forest areas.

Agro-silvo-forest interventions are included in the maintenance of the territory.

These interventions can only be used effectively for some types of disruption, such as accelerated erosion and surface landslides, while deafening phenomenon with deeper sliding surface can only be stabilized with traditional engineering interventions such as tunnels and drainage wells, supporting walls, etc.

2 METHODOLOGICAL PROPOSAL AND APPLICATION

2.1 METHODOLOGICAL PROPOSAL

The proposed methodology is based on a spatial analysis implemented in the GIS environment (Foresman, 1998) and consists of three macro-phases: 1) Identification of soil uses that maximize the ecosystemic erosion control (Sr6) service at high and very high danger areas; 2) Construction of networks that maximize ecological integrity and multifunctionality of GI; 3) Identifying strategic priorities.

The macro-phase 1) consists of the following steps:

- assigning value scores associated with each land use according to the CLC classification;
- Identifying the combination of levels of danger with the patches that maximize the Sr6 service.

The macro-phase 2) involves the construction of networks by using cost-distance, using as the resistance values the corresponding scores for soil utilization related to the ES defined ecological integrity (IE), the combination of the latter with SR6 and the combination of Sr6 with the other ES values.

The macro-phase 3), in turn, is articulated in:

- network measurement using network analysis through appropriate indices;
- comparison between the different networks in order to define their maximization;
- definition of strategic priorities.

2.2 TECHNIQUES AND INSTRUMENTS TO SUPPORT THE MODEL

The analysis implemented in the GIS environment, upon which the methodology is based, refer in detail to the following techniques: cost distance, network analysis and map algebra.

Cost-distance analyses were carried out using algorithms (Eastman, 1989) and implemented in the Idrisi 32 (Clark Labs, Clark University) software. Two different algorithms were used for the analyses: for *Sitta europaea*, connectivity was evaluated using an isotropic model (Eastman 1989); In the case of *Triturus carnifex*, an anisotropic model was applied (Eastman 1999).

The network analysis is based on the theory of graphs. Local metrics are important for the Node degree (measures the importance of a node in the network based on node connections), the Betweenness Centrality Index (measures the frequency with which a node appears on the shortest path between nodes of the network) and Proximity (measures the average distance from a given node to all the other nodes in the network).

The algebra map consists of map processes (spatial data layers) as variables in algebraic equations.

The GIS overlay procedure generates a new layer (output level) depending on two or more input layers, the attribute value assigned to each position (such as raster or polygon) on the output layer is a function of the independent values associated with that position on the input levels. There are two commonly used classes for combining overlays in GIS: Boolean overlay (such as AND and OR); Linear Weighted Combination (WLC).

The Graphab software is dedicated to the modelling of ecological networks based on graph theory. It allows for the creation of connections between the same patch types based on the cost-distance, taking into account the type of patches to be crossed or based on the minimum distance between patches, with it being compatible with GIS through which maps can be modelled to create ecological networks.

Once a graph has been created, several reference metrics can be applied.

2.3 APPLYING THE METHODOLOGY TO THE CASE STUDY

Campania has a high lithological and geological-structural variability that makes the territory susceptible to different types of landslides. It is in second place among the Italian regions for the number of victims due to hydrogeological phenomena: almost all of these were due to the rapid castings of loose pyroclastic covered by the carbonate masses of the Campanian Apennine and the stone sequences present in the volcanic areas of the Vesuvius and the Phlegrean Fields.

The distribution of the danger from landslides, identified by the Hydrogeological Basin Authorities falling within the territory of Campania, is highlighted according to the territorialization and use of the soil expressed as the second level of the CLC legend. There are 135,800 hectares with high danger (P3) and 131,500 hectares with very high danger (P4). Regarding the P3 and P4 hazardous areas, the wooded areas constitute the most significant land use type (126,279 hectares), equal to 20,5% of the total landslide areas.

2.4 GREEN INFRASTRUCTURES AND HYDROGEOLOGICAL RISK IN THE CAMPANIA REGION

The Rural Development Program 2014-2020 (PSR) of the Campania Region depicts the regional territory as a territory affected by worrying symptoms of abandonment, partly caused by the decline in agricultural land and demographic impoverishment, with three quarters of it being characterized by mountainous and hilly areas where soil conservation policies with relevant erosive dynamics. Current climate change increases the danger and risk of landslides and floods, the potential risk of erosion and more generally degradation of the soil.

Hydraulic, agricultural and hydraulic-forestry interventions, as well as the persistence of agricultural and forestry activities, particularly in mountainous and/or disadvantaged areas, can significantly prevent and

reduce the issues highlighted. It is therefore necessary to ensure the permanence of agricultural and forestry activities in such areas, by compensating for the disadvantages, encouraging the active management of the forest, promoting, also through training and information actions, farming methods that ensure the maintenance of a protective cover and the recovery of traditional techniques.

Agricultural and forestry interventions cover the maintenance of the territory and contribute to the regional strategy in continuity with the PSR 2007-2013, extending the range of actions to improve soil quality, aimed at reducing soil loss from erosion and hydrogeological disruption in particular in the most at risk and hazardous areas through: the persistence of agricultural and forestry activities in disadvantaged and mountainous areas; hydraulic-agricultural and hydraulic-forestry facilities including maintenance/restoration of agricultural terraces; maintenance/restoration of the surface drainage network in agriculture; crop management systems that mitigate risk (e.g. no and minimum tillage, cover crop); forestation and active management of the forest; protection from forest fires.

It is worth noting the measure 8.2.4.3.9. 4.4.2 Creation and/or restoration and/or expansion of green infrastructure and agri-rural landscape elements and sub-tenure 4.4 - Support for non-productive investments related to the fulfillment of agro-environmental objectives. This measure aims to achieve the sustainable development objective of Campania agro-food business, foreseeing it necessary to improve the environmental conditions of the territory from an agro-climate point of view, pursuing a satisfactory state of conservation of the biodiversity. It should also be pointed out that an environment with a low degree of biological diversity, i.e. less ecologically less diversified, and therefore disorganized, reacts less actively to sudden atmospheric and climatic changes.

Consequently, a specific type of intervention should be provided for the support, restoration and conservation of natural and semi-natural habitats, flora and fauna of EU interest, as well as specific elements of the agrarian landscape through the realization of interventions for the creation and/or restoration and/or expansion of green infrastructures and specific landscape elements in degraded and/or cultivated areas.

Eligible interventions to subsidy are identified in the restoration and/or creation and/or extension of: a) terraces and brickwork; b) buffer bands; c) hedges, rows, groves.

For this purpose, the type of intervention is addressed, in particular, in terms of public utility to areas of the Natura 2000 Network or other areas of great natural value defined by the PSR.

Moreover, the abandonment of agricultural activities also favours the spontaneous dynamics of ecological mosaic evolution, with the loss of ecosystems due to the progressive advancement of the forest of neo-formation. Therefore, the role of farms as a defence has positive effects both on the territory for the economic and productive implications it entails, on the environment in terms of soil protection as well as the protection of complex ecosystems.

In the PSR, the principles guiding the definition of selection criteria include, inter alia, the following rewards: location of the intervention: a) sites of the Natura 2000 Network; b) areas of great natural value defined by the PSR 2014-2020; c) Regional Parks and Regional Nature Reserves; d) vulnerable agricultural zones to nitrates; e) high or very high altitude hazardous areas for terracing and burial operations.

2.5 APPLICATION

With reference to macro-phase 1), we identify the soil uses that maximize the ES erosion control (Sr6) in correspondence of high and very high hazardous areas, the geodatabase is made up of information from the Agricultural Utilization Soil Map (CUAS) of Campania Region, dated 2009.

From the quantification, it has been found that the incidences of the different eco-systemic values in terms of surface are differently distributed. Reference was made to the PSAI for the Central Campania Authority, which has been in force since 2015. From the intersection, the patches that maximize the Sr6 service in combination with the P3 and P4 areas have been identified. Thus, the distribution of land uses in high and very high hazard areas has been reported.

With reference to macro-phase 2), the networks were built to maximize ecological integrity and multifunctionality, and the Graphab software was used to design the networks.

The network that maximizes ES IE was built for the entire regional territory, with it being the one that relates the combination of all ESSs, i.e. IE-SA-SC-Sr6 and finally IE-Sr6. (figure 1)

With reference to macro-phase 3), the software was used to generate the graph and calculate the different metrics at local and global levels. The calculation was made in relation to the insistent area encompassing the territory of the Central Campania Authority.

Then, a comparison was carried out between the different networks in order to define their maximization as well as define the mitigation strategy. (figure 2)

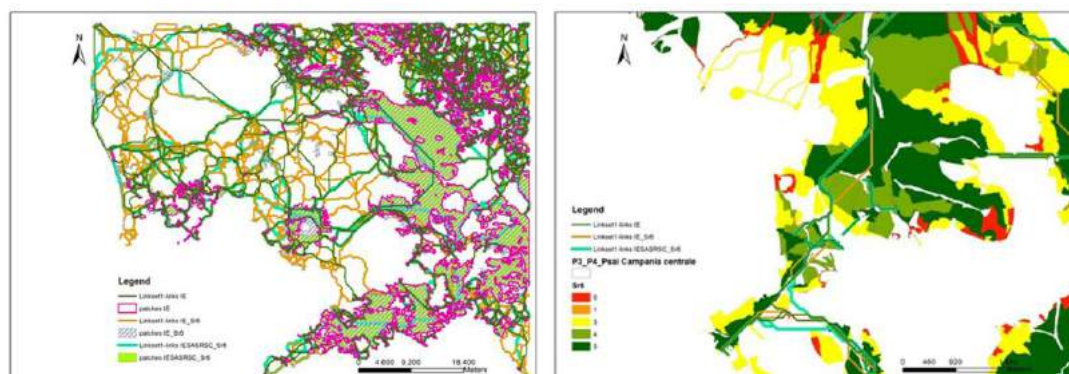

Figure 1 - Overlay network map | Figure 2 - Multifunctional network

3 DISCUSSIONS AND CONCLUSIONS

The application of the methodology to the case of the Campania region, and in particular to the territory included within the Hydrogeological Structure Excerpt Plan (PSAI) of Central Campania Authority, has highlighted how it is possible to identify the contact points between the protection of ecological integrity and the mitigation of landslide risk, in line with EU strategies, thus highlighting the boundaries of the study that should be carefully taken care of.

From the overlay map reading of the Sr6 distribution factor map and the mapping map of the landslide hazard distribution, the concomitant use of high-value Sr6 soil uses with P3 and P4 hazard levels emerges. This information indicates that, on the one hand, the use of the soil performs a protective action, while on the other it alone does not contribute to the resolution of the problem due mainly to geological and geotechnical conditions.

Therefore, the primary consideration is that, as defined in the EU document, the choice of the construction of the ecological network will have to prioritize both strategies in an order of priority: firstly it must be given to the axes that maximize the Sr6 network in order to build ecological network that intersects the high and very high hazard areas; secondarily those in which the IE-Sr6 network is maximized intersecting the P3 and P4 areas. finally, consider the P3 and P4 areas intersecting the IE network.

In these areas, it is possible to implement the actions proposed by the ISPRA Guidelines in order to contribute to the maintenance and hydrogeological protection of the area.

The areas selected in the previously seen order must be subject to appropriate detail analysis in order to determine the use of the soil which maximizes the protective action, possibly subject to the prevision of structural mitigation against landslide hazard.

The present work, however, could be used to provide for pricing mechanisms for areas with high risk of land-sliding and erosion, given the great importance of the resources allocated to the environmental issue.

The methodology therefore provides a new way of drawing the GI, which is generally based on the specific ability to favour biotic and abiotic flows. In this case, we try to optimize this pattern by also maintaining and raising other ES, starting from the regulation of the soil disruption.

ID 1409 | LIVING THE CLIMATE RESILIENT CITY—HANGZHOU'S 'FIVE WATER CO-LEAD' STRATEGY

Dan Liu¹

¹Changsha University of Science & Technology
laudan2004@hotmail.com

1 INTRODUCTION

Climate awareness in urban planning has increased from 2011 due to more frequent occurrences of extreme-weather disturbances in Chinese cities. To deal with climate-related disturbances, the notions of urban resilience and resilient planning have gained increasing attention and interest over recent years in the field of water management and urban planning. A simple definition of resilience is the ability of a city to

absorb disturbance while maintaining its functions and structures (Holling, 1987, 2001; White, 2010). With the challenges of climate change, planners and decision-makers in China realize that it is possible that resilient strategies provide more adaptive and flexible approaches in decision-making. In planning practice, however the concept of resilience features in many policy documents, the implications for planning policy officials remain unclear in the case of Hangzhou, China.

Drawing on information from a review of policy documents supplemented by interviews with policy officials, this paper aims to understand key issues in transitioning to climate resilience in Chinese cities through a study of Hangzhou. The main body of the paper is structured in three parts. The first section presents a review of the notion of resilience and examines its relevance for urban planning and climate change. The second part provided the assessment of planning strategies related to climate change in the city. Specific attention is paid to how planning processes in the city consider or deal with the climate risks that it presents. The third part explored the challenging areas – spatial data infrastructures, climate planning, green infrastructure planning, limiting urban sprawl –as viable facets for sustaining urban transition strategies.

2 RESILIENCE THINKING AS THE BASIS OF A NEW PARADIGM IN PLANNING PRACTICE

The amount of literature on resilience and uncertain disturbances in urban systems has increased greatly over the last decade. Broadly speaking, a resilient system is defined by its two main features: its ability to absorb change and disturbance, and the persistence of systems while retaining its basic functions and structure (Walker et al. 2006); together with the ability to survive, adapt and transform itself (Ludwig et al. 1997).

2.1 REFRAMING THE NOTION OF RESILIENCE

The simple understanding of resilience is the capacity of a system to undergo change and still retain its basic function and structure after facing an external disturbance (Holling, 1973, 1987, 2001; Tasan-Ko and, Stead et al., 2013; White, 2010). Some of the early resilience literature originates from studies of ecological equilibrium in the 1970s (e.g., Holling, 1973). The studies of ecological resilience around this time focused on self-(re)organising ability and the speed of return to a new stable or fully functional state (Ludwig et al., 1978; Pimm, 1991). In the social sciences, the growing interest in the notion of resilience can be seen as a consequence of increasing complexity, uncertainty and insecurity in the search for new approaches for adaptation and transformation (Christopherson and Michie et al., 2010). The notion of social resilience is often associated with the ability to learn, primarily in order to become more robust to change (Newman, 2009; Newman et al., 2009).

The notion of resilience appeared in urban systems and urban planning in the 1990s (Mileti, 1999). In particular, resilience has emerged as an attractive perspective with respect to urban systems, often theorized as highly complex, adaptive systems. Urban resilience refers to the ability of an urban system- and all its constituent socio-ecological and socio-technical networks across temporal and spatial scales- to maintain or rapidly return to desired functions in the face of a disturbance, to adapt to change, and to quickly transform systems that limit current or future adaptive capacity.

The literature on resilience in planning has often put the emphasis on preparation, mitigation and adaptation actions. It is widely acknowledged that spatial planning has an important role in promoting urban resilience. There is widespread recognition that the spatial configuration of cities and towns, and the way in which land is used and developed, has significant implications for both adaptation to the adverse impacts of climate change and the reduction of emissions that cause the change (i.e. mitigation).

2.2 THE ATTRIBUTES OF CLIMATE RESILIENT CITY

Climate change is an increasingly important issue for urban planning. Scholars highlight that, from a resilience perspective, climate change is not only associated with disruptive events (e.g., storms or

heatwaves) but also with gradual trends (e.g. rises in sea level or average global temperatures) that can still give rise to large disturbances if left unchecked (Wardekker and de Jong et al., 2010).

In addition to robustness (or mitigation) and rapidity (or flexibility or adaptation), scholars have also discussed the notion of resilience in terms of characteristics such as redundancy, diversity, efficiency, autonomy, strength, interdependence, adaptability and collaboration (Godschalk, 2003), or attributes of decision-making processes such as fluidity, reflexivity, contingency, connectivity, multiplicity and polyvocality (Davoudi and Strange, 2009).

Some studies of resilience also highlight the importance of Robustness, Social capital, Reflexivity, Contingency, Connectivity, Multiplicity, Learning capacity and so on (Linnenluecke and Griffiths, 2010, Wardekker et al., 2010, Walker and Salt, 2006, Davoudi and Strange, 2009, van den Brink et al., 2011 and Gupta et al., 2010).

Table 1 provides a summary of resilience characteristics from a range of different studies. On the basis of existing studies of resilience attributes, we identify six characteristics of resilience in relation to planning for climate disturbances and flood risks: (i) Recovery; (ii) Connectivity; (iii) Social capital; (iv) Adaptability; (v) Robustness; and (vi) Transformability (Tables 2 and 3).

Literature debates	Characterising the notion of resilience
Linnenluecke and Griffiths, 2010 and Wardekker et al., 2010	<ul style="list-style-type: none"> - Robustness (or strengths, mitigation) - Rapidity (or flexibility)
Walker and Salt, 2006	<ul style="list-style-type: none"> - Diversity - Ecological variability - Modularity - Acknowledging slow variables - Tight feedbacks - Social capital - Innovation - Overlap in governance and ecosystem services
Godschalk, 2003	<ul style="list-style-type: none"> - Redundancy - Diversity - Efficiency - Autonomy - Strength - Interdependence - Adaptability - Collaboration
Davoudi and Strange, 2009	<ul style="list-style-type: none"> - Fluidity - Reflexivity - Contingency - Connectivity - Multiplicity - Polyvocality
van den Brink et al., 2011 and Gupta et al., 2010	<ul style="list-style-type: none"> - Variety - Learning capacity - Room for autonomous change - Leadership - Resources - Fair governance

Table 1 -Summary of studies characterising the notion of resilience.

Resilience characteristics addressed by planning system						
Proposed characteristic in this paper	Recovery	Connectivity	Social capital	Adaptability	Robustness	Transformability

Table 2 - Summary of characteristics describing the notion of resilience.

Characteristic	Description
Recovery	the ability of the system to recover from a disturbance and refers to the ability of a system to respond to an event
Connectivity	the degree to which the nodes of a network are directly linked with each other. In terms of resilience, connectivity embraces more than just the physical dimension, as it includes also the relationships between people and organisations
Social capital	the quality and quantity of a society's social interactions that are shaped by institutions, relationships, and societal norms
Adaptability	the ability of society in a social-ecological system to cope and respond to novel situations and change without losing options for the future
Robustness	the ability to withstand a given level of stress without suffering degradation or loss of function
Transformability	the capacity to learn and create a fundamentally new and different socio-ecological system , one that hopefully would possess the attributes of adaptability and resilience

Table 3 - Six characteristics of urban resilience.

2.3 A FRAMEWORK FOR ASSESSING RESILIENCE

The issue of change is a central dimension of resilience, both in terms of resistance to change and recovery from it. Resilience is therefore related to both preparations to minimize disturbances (or change) and actions to deal with disturbances once they have occurred. As such, resilience represents an on-going process, a time-scale of reshaping, reorganizing and developing new strategies (Lu and Stead, 2013).

The empirical analysis of Hangzhou is based on a review of policy literature from 2010 on-wards (summarized in Table 5 and discussed later in the paper), supplemented by interviews with policy officials from the city of Hangzhou. All the planning policies and documents analyzed in this paper address urban planning and climate change issues.

Resilience characteristics addressed by planning system	Overarching question	Measures/indicators: (the capacity to)
Recovery	Are the policies, programmes, plans and projects promoting capacity in the territory to respond to and recover from disturbance?	A1:Evaluate and maintain the conditions of urban lifeline A2:Establish the system for preventing and reducing flood disasters.
Connectivity	Are the policies, programmes, plans and projects enabling an interrelated territory, in which the nodes of the network are effectively linked?	A3:Develop ecological network A4:Develop soft mobility (pedestrian and bicycle routes) and public transportation networks A5:Coordinate readiness actions
Capital building	Are the policies, programmes, plans and projects under analysis contributing to the build-up of capital (stock), reinforcing in this way the stability and cohesion of the territory?	A6:Collaborate decision-making between different levels of governance A7:Communicate findings (concepts, skills, actions) about water management A8:Raise public awareness and preparation education

Adaptability	Are the policies, programmes, plans and projects enhancing the adaptability of the territory and its capacity to adjust to change in a reactive way?	A9: Identify and assess the probability of risks and disturbances A10: Forecast A11: Promote Low Impact Development technology
Robustness	Are the policies, programmes, plans and projects increasing the robustness of the territory to unforeseen shocks and disturbances?	A12: Evaluate and maintain the conditions of flood-protective facilities
Transformability	Are the policies, programmes, plans and projects contributing to the transformability of the territory and to its ability to innovate and create a new system should the previous become no longer viable?	A13: Setting goals and propose new standards A14: Innovate and propose actions

Table 4 - An assessable framework of resilience in planning decision-making.
Source: based on Eraydin and Tasan-Kok (2013).

3 EMPIRICAL STUDY: RESILIENCE ASSESSMENT OF HANGZHOU

Although water-related spatial strategies for flood risk management have been embedded in the planning system in east China's Zhejiang province throughout history, climate change is a relatively new issue for urban planning. In 2013 two events occurred which affected the city of Hangzhou. Both events led to institutional changes and a reframing of the system of decision-making.

The first event was that some directors of the Municipal Environmental Protection Bureau in Zhejiang province were "invited" to swim in rivers in the beginning of 2013, which showed Public dissatisfaction with water pollution. Then the second event was that Typhoon Fitow triggered heavy rain in Zhejiang province in October, inundating roads and houses, and causing river breaches and power failures. Figs. 1 and 2 indicate the vulnerable position of the city of Hangzhou.

Figure 1 - Water sources in Hang-Jia-Hu Region. Source: Water resources planning for Hang-jia-hu Region (2015).

Figure 2 - Water sources in Hang-Jia-Hu Region. Source: Water resources planning for Hang-jia-hu Region (2015).

The shock of the events prompted heated debates about urban planning, climate change and the traditional water management. Decision-makers proposed new strategies such as 'Sponge city' and 'Five water co-lead'. A 'Sponge city' refers to a city where its urban underground water system operates like a sponge to absorb, store, leak and purify rainwater, and release it for reuse when necessary. 'Five water co-lead' integrate these strategies addressing to polluted water, water-logging, flood, water supply and water saving. Briefly, these planning strategies were established to offer better water environment by changing current river conditions, engineering infrastructure and land-use strategies.

3.1 NEW DEMANDS OF PLANNING TO COPE WITH CLIMATE-RELATED FLOODS

Planning documents in Hangzhou began to demonstrate an awareness of the impacts of climate-related floods from 2010, including the national, regional and local levels. Based on policy reviews and semi-structured interviews with planning officials, the analysis below assesses the use and significance of the notion of resilience in a wide variety of planning documents from the national, regional and local levels (Table 5). The analytical framework presented in Table 3 was used to structure the analysis.

Year	Title	Level of	Focus on	Produced by	In collaboration with
		governance			
2016	Action plan for urban adaptation to climate change	National	Proposing practices for climate change	the National Development and Reform Commission (NDRC)	-Urban-Rural Development of the People's Republic of China
2014	China's National Climate Change Program	National	Establishing a comprehensive framework for climate adaptive strategy-making	The National Development and Reform Commission (NDRC)	-Ministry of Finance of P.R. China; -Ministry of Urban-Rural Development; -Ministry of Transport; -Ministry of Water; -Ministry of Agriculture; -State Forestry Administration -State Meteorological Administration; -State Oceanic Administration
2013	National Strategy of Climate Change Adaptation	National	Proposing strategies for climate change	the National Development and Reform Commission (NDRC)	-Ministry of Finance of the People's Republic of China; -Ministry of Urban-Rural Development; -Ministry of Transport; -Ministry of Water; -Ministry of Agriculture; -State Forestry Administration -State Meteorological Administration; -State Oceanic Administration
2015	Water resources planning for Hang-jia-hu Region	Regional	Spatial plan for the Hang-jia-hu region	The Development and Reform Commission of Zhejiang Province	-Department of Water Resources of Zhejiang Province;
2010	Zhejiang province's programme to address climate change	Regional	Proposing climate-adaptive strategies for the Zhejiang province	Province of Zhejiang	
2016	The master plan for Hangzhou city 2001-2020 (2016)	local		City of Hangzhou	-Hangzhou Planning Bureau
2016	The subject plan of sponge	local	Proposing new strategies for water management	City of Hangzhou	-Hangzhou municipal leading group office for sponge city

Table 5 - List of documents reviewed.

3.2 CHARACTERISTIC 1: RECOVERY

Various planning documents indicate that the ability of recovery has been addressed in planning policies in Hangzhou (A1 and A2 Table 4). At the national level, Action plan for urban adaptation to climate change 2016 and China's National Climate Change Program 2014-2020 both mention new requirements for improve after-disaster reconstruction speed, and reduce the negative influences to the lowest level. Recovery issues in Zhejiang province's programme to address climate change 2010 focus on establish the system for preventing and reducing flood disasters. Attention to the ability of recovery is addressed in local documents like the master plan for Hangzhou city 2001-2020 (2016) and Urban drainage plan for Hangzhou city 2014 at different aspects. For instance, the master plan for Hangzhou city 2001-2020 (2016) focuses on evaluate and maintain the conditions of urban lifeline, while Urban drainage plan for Hangzhou city 2014 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016 emphasises the establishment of the system for preventing and reducing flood disasters.

3.3 CHARACTERISTIC 2: CONNECTIVITY

Three indicators (A3, A4, A5) address the connectivity of ecological network, transportation networks and social network respectively. Regarding the connectivity of ecological network (A3), national, regional and local documents are mainly focused on optimizing ecological network to achieve a better quality of life in the city. Examples are actions for a robust and resilient water system (e.g., Action plan for urban adaptation to climate change 2016, the subject plan of sponge city for Hangzhou 2016, Action plan of 'five water co-lead' for Hangzhou city 2014-2016), water environment and quality (e.g., Water resources planning for Hang-jia-hu Region 2015, Action plan of 'five water co-lead' for Hangzhou city 2014-2016), and water landscapes in the spatial framework (e.g., the master plan for Hangzhou city 2001-2020, Action plan of 'five water co-lead' for Hangzhou city 2014-2016).

In addition, national documents address two different aspects of transportation networks: China's National Climate Change Program 2014-2020 emphasise soft mobility (pedestrian and bicycle routes) and Action plan for urban adaptation to climate change 2016 consider public transportation networks.

Coordinative capacity (A5) is another indicator of the connectivity. In Action plan for urban adaptation to climate change 2016 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016, the importance of inter-sectoral collaboration between politicians and scientists is highlighted.

3.4 CHARACTERISTIC 3: SOCIAL CAPITAL

In regard to the capacity of multi-level collaborative decision-making (A6), national documents in many cases give the directions for provincial and local policies to follow, especially in relation to water (flooding) issues which have been the primary task. Local policies indicate the active attitudes of multi-level collaborations with national policy-making for managing climate disturbances and relevant floods. Zhejiang province's programme to address climate change 2010, Water resources planning for Hang-jia-hu Region 2015, the master plan for Hangzhou city 2001-2020 (2016), Urban drainage plan for Hangzhou city 2014 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016 are all influenced by Action plan for urban adaptation to climate change 2016, China's National Climate Change Program 2014-2020 and National Strategy of Climate Change Adaptation 2013.

The second social capital characteristic relates to the capacity to communicate, build public awareness and educate. Regarding the capacity to communicate findings (concepts, skills, actions) about water management (A7), various national, provincial and local documents (e.g., Action plan for urban adaptation to climate change 2016; Zhejiang province's programme to address climate change 2010; the subject plan of sponge city for Hangzhou 2016; and Action plan of 'five water co-lead' for Hangzhou city 2014-2016) refer to public education about climate risk, Sponge City and five water co-lead Strategy.

Evidence of public awareness and preparation education (A8), can be seen in the online citizens' panel in Action plan of 'five water co-lead' for Hangzhou city 2014-2016, climate-related flood knowledge promotion in Action plan for urban adaptation to climate change 2016.

3.5 CHARACTERISTIC 4: ADAPTABILITY

In relation to the capacity to identify and assess the probability of risk and disturbances (A9), Action plan for urban adaptation to climate change 2016, China's National Climate Change Program 2014-2020, National Strategy of Climate Change Adaptation 2013, Zhejiang province's programme to address climate change 2010, and Urban drainage plan for Hangzhou city 2014 all have relevant strategies to define and assess climate risk probability and potential disturbances. Action plan of 'five water co-lead' for Hangzhou city 2014-2016 proposes practical strategies for rivers (water and flooding issues) which have been implemented since 2014 to ensure enough space for water discharge by 2016.

Regarding the capacity to forecast (A10), national documents like Action plan for urban adaptation to climate change 2016, China's National Climate Change Program 2014-2020, and National Strategy of Climate Change Adaptation 2013 mention strategies for risk forecasting, mainly in relation to flood risks.

Low Impact Development technology (A11) are emphasised in local policies. The subject plan of sponge city for Hangzhou 2016 identify and propose relevant studies that focus on the topic of sponge city, including rain garden, low elevation greenbelt, green roof, permeable pavement and so on.

3.6 CHARACTERISTIC 5: ROBUSTNESS

Regarding the capacity to evaluate and maintain flood-protective facilities (A12), national documents like Action plan for urban adaptation to climate change 2016, China's National Climate Change Program 2014-2020, and National Strategy of Climate Change Adaptation 2013 all implement strategies to maintain and improve flood-protective facilities closely related to the requirements of setting new goals of water safety.

At the provincial and local level, Zhejiang province's programme to address climate change 2010 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016 address the 'integrated' approach of creating a safe environment.

3.7 CHARACTERISTIC 6: TRANSFORMABILITY

The policy documents reviewed indicate a wide range of approaches regarding setting goals and creating new standards (A13). National documents highlight priorities and new standards in terms of resilience capacity and sustainability for comprehensive developments between water safety and quality of life.

Local policies, such as the subject plan of sponge city for Hangzhou 2016 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016 focuses on technical strategies (new required standards) not only for flood risk management (such as water safety, a robust and resilient water system) but also for issues like fresh water supply and water landscapes.

Regarding the capacity to propose and elaborate innovational actions (A14), local documents like the subject plan of sponge city for Hangzhou 2016 and Action plan of 'five water co-lead' for Hangzhou city 2014-2016 propose practical strategies for spatial implementation. Interviews suggest that various innovative proposals for 'five water co-lead' strategy were developed and seen as an opportunity for the city's resilient development.

Overall, the review suggests, firstly, that recent planning initiatives show that the main focus of urban planning has shifted from promoting hard infrastructure to green infrastructure (in terms of sponge city). Secondly, the uncertainty of climate change has increased the importance of scientific studies in planning decision-making. Thirdly, the case study of Hangzhou indicates that the city itself is a key driver in developing an integrated adaptive strategy for climate change and water manage. Planners and decision-makers in the municipality are keen to transform climate threats into opportunities for urban resilient transformation.

4 TRANSITIONING TO CLIMATE RESILIENT CITY

Hangzhou's vulnerability to floods and climate uncertainty has motivated the city to become a pioneer in the fields of urban planning and climate change. Interviews suggest that various challenging areas for transitioning to climate resilient city should be explored, such as spatial data infrastructures, climate planning, green infrastructure planning, limiting urban sprawl.

4.1 SPATIAL DATA INFRASTRUCTURES

The demand to plan for urban resilience presents additional infrastructural and technological requirements, especially spatial data infrastructures. Geographic information systems (GIS) technology, in particular, offers a wide range of analytic tools and methods such as feature, grid and network analyses, as well as change, impact and decision modelling (Nyerges and Jankowski, 2009). These additional functionalities also carry the potential to enhance the visualisation of planning issues and solutions. Interactive GIS-based scenario analysis tools, Geoweb tools and 3D visualizations can present spatial characteristics and help demonstrate consequences of environmental and urban change (Sheppard, 2005). A geospatial database at urban level can both enable e-planning and enhance the planning process. Hangzhou 'five water co-lead' Integrated information management platform is established through the Infrastructure for Spatial Information. Though still in its implementation phase, this development has been motivated by the need to harmonize data for environmental planning and management across Hangzhou Region, and clearly carries some relevance for urban sustainability and resilience.

4.2 CLIMATE PLANNING

Planning for climate resilient cities faces challenges in terms of water management. Adaptation measures may lower the probability of flooding, reduce the potential damage; or transfer risks (Treby and Clark et al., 2006). However, water-related infrastructure measures need to be implemented through urban planning and land use management. These measures involve a different use of space, which is often limited in urban environments. Hence, requirements for flood protection, water storage, green areas or different building strategies are competing, and priorities for the use of space have to be made. To support Climate planning, improved methods for linking urban land use modelling and assessment of urban functions are required.

4.3 GREEN INFRASTRUCTURE PLANNINGCLIMATE PLANNING

Urban green space policy is increasingly being used as a tool to build sponge city in china. Augmenting the economic models, novel field-based research trials and landscape-scale case studies may consolidate an understanding of the potential of green infrastructure. For example, innovation in green roof technology may show that green infrastructure can be designed to maximise the biodiversity, ecosystem services and carbon storage value of green spaces, if designed towards specific goals (Simmons et al., 2008). Next to green roofs, other ways of enhancing green infrastructure in the urban context should be considered such as the role of rain gardens, and urban agriculture and innovative urban landscape design in conserving regionally important biodiversity and providing food security (Collier et al., 2013). Green infrastructure can be optimized by combining new technologies, public and private initiatives in a coherent 'five water co-lead' strategy.

4.4 LIMITING URBAN SPRAWL

The urban dimension of climate challenges faced by Chinese cities is highlighted in the need to promote a smarter, more sustainable and socially inclusive urban development. This call for a new urbanisation, striving for complexity, compactness, functional diversity plurality and social integration, recognizes wide geographical and contextual diversity across Chinese cities and towns, and rejects the application of 'one-size-fits-all' solutions in integrated urban regeneration plans and programmes, but points towards a more resilient urban destiny.

5 CONCLUSIONS

This paper has examined the awareness and understanding of the concept of resilience in the planning policy arena in Hangzhou. Planning strategies address the notion of resilience not only in relation to tackling external changes and shocks but also in responding actively and positively to risks.

Local authorities have been taking measures as preparation for climate change and flood risks since 2010. As one of Hangzhou's areas of expertise, Sponge city and 'five water co-lead' strategies are communicated widely. Local resilience actions are crucial for developing new, more adaptive approaches to coping with the uncertainty of flood risks. In addition, various challenging areas, such as spatial data infrastructures, climate planning, green infrastructure planning, limiting urban sprawl, should be explored for transitioning to climate resilient city.

The study of Hangzhou illustrates that the assessment framework for resilience is applicable for examining planning strategy-making. What is clear is that urban resilience is a broad concept that can easily become blurred and abstracted. From this study it is clear that the notion can be helpful from a planning perspective in the understanding and analysis of contemporary urban systems, defining a new approach and setting new principles (or priorities) in policy-making. It also suggests that the concept of resilience in

Hangzhou is frequently used as a synonym for adaptation, whereas in more water-specific documents it is understood as a soft form of resistance. And for many stakeholders remains quite abstract.

ID 1411 | SOCIAL RESILIENCE AND NATURAL HAZARDS - ANALYZING MULTIPLE SOCIAL LEVELS OF RESILIENCE IN THE CONTEXT OF PLANNING AND RISK GOVERNANCE

Gerard Hutter¹; Daniel Lorenz²

¹Leibniz Institute of Ecological Urban and Regional Development (IOER);

²Disaster Research Unit (DRU), Freie Universität Berlin

g.hutter@ioer.de

ABSTRACT: The paper conceptualizes resilience as a matrix of social levels (intra-organizational, organizational-, and inter-organizational) and social capacities (coping, participative, adaptive, and transformative). The paper reflects on some advantages and limitations of this resilience conceptualization. The concept is, for instance, strong in considering processes of interpretation and social change. However, it has only limited usefulness in simple quantitative attempts to measure and assess resilience in “the real world”. Furthermore, some implications for future research and practice are discussed.

KEYWORDS: Adaptation, capacity, coping, inclusion, organization, participation, transformation

1 INTRODUCTION

The word ‘resilience’ is used in most diverse research areas and policy fields of modern societies. To name only a few examples: psychologists ask under which conditions and through which processes those children that face adverse risk situations may still build and display “normal” development competencies in specific social and/or cultural settings (e.g., Masten 2014). Social psychologists and management scholars like Karl Weick ask through which social processes teams may be able to deal with surprises and sudden dangers in the context of firefighting (e.g., see the seminal paper on the Mann Gulch Disaster by Weick 1993). Organizational scholars are concerned with organizational performance in the face of increasing levels of complexity, uncertainty, and ambiguity (e.g., Kayes 2015). Resilience is especially prominent in research on so-called “socio-ecological systems” (e.g., Boyd & Folke 2012) and on the prospects of understanding, analyzing, and promoting disaster resilience in the context of natural hazards, climate change, and the possibility of cascading disastrous events (e.g., Tierney 2014, Coaffee & Lee 2016). Given this diversity of research streams and policy contexts and communication across streams and contexts, no wonder that there is also a high diversity of definitions, theories, and methods to use “resilience” in planning research and practice (e.g., Davoudi 2012, Deppisch 2017).

Fortunately, there are useful book-length publications that review resilience definitions in various scientific disciplines and related theoretical approaches as well as their methodological and practical implications for planning research and practice (e.g., Comfort et al. 2010, Tierney 2014, Coaffee & Lee 2016). We do not seek, therefore, to provide another overview of social resilience research that discusses the advantages and disadvantages of diverse perspectives. We are more interested in promoting a specific organizational-institutional and sociological perspective on resilience (e.g., Ansell et al. 2017). Based on an extensive review of the resilience literatures¹, we conceptualize social resilience as a matrix of (1) social levels (intra-organizational, organizational, and inter-organizational level) and (2) as a set of capacities (coping and participative capacity as well as adaptive and transformative capacity). The aim of this paper is to outline and justify social resilience as matrix in the context of planning (Allmendinger 2009, Davoudi 2012, Coaffee & Lee 2016) and governance (Hutter 2016, Ansell et al. 2017), especially from the viewpoint of “human agency” (Emirbayer & Mische 1998). Future work will show in more detail how this conceptualization may be used in theoretical as well as empirical planning research.

¹ See Hutter & Lorenz (2017) for a more detailed account of the literature review. The literature review will be published by Cambridge University Press (CUP) at the end of the year 2017 or the first half of the year 2018. We are thankful to the editors of the CUP-book, Sven Fuchs and Thomas Thaler (both of BOKU in Vienna), for helpful comments on the review.

For us, the following wide definition of social resilience (based on Boin et al. 2010, 9) serves as a starting point of our argumentation:

Social resilience is the capacity of a social entity (social order of actions) to proactively adapt to and recover from disturbances that are perceived within the social entity to fall outside the range of “normal” and “expected” disturbances.

This definition of resilience provides an anchor in the expanding “landscape” of resilience research in the natural sciences, civil engineering, and the social sciences. Therefore, some remarks on the definition are in order: Firstly, resilience is understood as a capacity of social entities. Questions of how and why actors address “resilience” in ideological processes are certainly important (e.g., “resilience” as manifestation of the politics of neoliberalism, Coaffee & Lee 2016). However, the following cannot elaborate on this in detail (for a more detailed account see Hutter & Lorenz 2017). Secondly, the definition highlights social entities understood as social order of actions. Without doubt, ecological systems and individual persons influence social action. Though, from our conceptual viewpoint, they are placed in the context of social resilience. Thirdly, the definition may be characterized as a wide definition because efforts to proactively and reactively manage disturbances are addressed (see Weick & Sutcliffe 2015 for an alternative of understanding resilience mainly as the capacity to react to the unexpected). Fourthly, the definition explicitly refers to perceptions and interpretations. In line with principles of qualitative social research (e.g., Strübing 2013), social resilience is seen as a capacity to manage the unusual and unexpected from the viewpoint of the focal social order of actions. We are interested in understanding social action that shapes perceptions, expectations, interpretations and learning processes based on context conditions that are characterized by power relations, networks, and institutions.

The paper is structured as follows: Chapter 2 introduces the aforementioned matrix and explains how resilience may vary with regard to social levels (intra-organizational, organizational, and inter-organizational) and social capacities that make up resilience in relation to unexpected disturbances. Chapter 3 provides the opportunity to reflect on some advantages and limitations of conceptualizing resilience as matrix of social levels and capacities. Chapter 4 concludes our paper and gives a brief outlook.

2 SOCIAL RESILIENCE AS MATRIX OF LEVELS AND CAPACITIES

Planning and risk governance are both evolving context conditions for conceptualizing social resilience (e.g., Allmendinger 2009, Hutter 2016, Lamker 2016). To simplify our argument with regard to context, we adopt the notion of a “planning project in the twenty-first century” as summarized by Patsy Healey:

• An orientation to the future and a belief that action now can shape future potentialities
• An emphasis on liveability and sustainability for the many, not the few
• An emphasis on interdependences and interconnectivities between one phenomenon and another, across time and space
• An emphasis on expanding the knowledgeability of public action, expanding the ‘intelligence’ of a polity
• A commitment to open, transparent government processes, to open processes of reasoning in and about the public realm

Table 1: Attributes of a twenty-first century planning project (Source: Healey 2010, 19)

All five attributes point to the challenge of developing an inclusive approach to public problem solving. There is wide agreement in the resilience literatures that dealing with unexpected disturbances potentially involves and affects actors from various societal spheres and organizational fields. Researchers and practitioners alike often mention public leaders (elected politicians and public officials), market-oriented business organizations, organizations of the “third sector”, and, last but not least, citizens and self-organized community forms (e.g., Tierney 2014). An inclusive perspective on resilience is not surprising, because the call for resilience materializes especially with regard to non-routine events, crisis, disasters, as well as catastrophes. In such situations, the institutions and social differentiation of everyday life are no

longer functioning by definition and the limitations of state-centered approaches like anticipation-based “command and control” or plan-based disaster management are often salient which paves the way for discussions about policy reform and social change (Wildavsky 1988, Clarke 1999, Boin & McDonnell 2007, Weick & Sutcliffe 2015, Coaffee & Lee 2016).

We do agree that social resilience encourages researchers and practitioners to follow an inclusive approach to public problem solving. In line with a pragmatic understanding of “human agency” (Emirbayer & Mische 1998, for resilience and agency see also Hutter & Lorenz 2017) – instead of prevalent focus on social structures in resilience research –, we are somehow optimistic that actors in modern societies are – to some extent – able to proactively adapt to unexpected future disturbances even in the face of barriers to such resilience organizing.

Furthermore, we are interested in understanding people, tools, and tasks as well as organizational goals, technical systems, and relations between organizations, and how all this fits together to organize for resilience in modern society (Comfort et al. 2010). Hence, social resilience in the context of planning and risk governance requires both an inclusive approach and a multi-level approach to distinguish between social levels of organizing that encompass, for instance, collective resilience efforts of teams, organizations, and networks of organizations.

In a first step, the following elaborates on the dimension of social levels of resilience from an organizational-institutional perspective on planning and risk governance (see Ansell et al. 2017). Then, in a second step, we develop a sociologically informed understanding of how the overall notion of resilience can be disaggregated into more specific social capacities to deal with unexpected disturbances. And in a third step, we combine the social levels of resilience and the capacities of resilience in a “matrix” for analyzing social resilience.

2.1 SOCIAL LEVELS OF RESILIENCE

To understand social resilience in modern societies we need to take into account its constituents in terms of different social levels. In the following, we suggest focusing on three different levels, being the intra-organizational, the organizational, and the inter-organizational level, as resilience may emerge in very diverse forms on the levels as our examples will show.

Proactively adapting to future disturbances that fall outside the perceived range of “normal” events requires that people are able to imagine “strange futures” while simultaneously dealing with the demands of an evolving present. In particular, organizational scholars (e.g., March 1991) have long pointed out that organizations have difficulties in maintaining both learning processes termed exploration to deal with possible, distant, and perhaps strange futures and exploitation to reap the benefits from knowledge accumulation based on experience. Organizations tend to prefer exploitation while neglecting to sustain exploration. However, some researchers also show that face-to-face communication between organizational members may facilitate intra-organizational processes of developing formal or informal social groups that are eager to prepare for rare and even “strange” events in the future. Furthermore, resilience at this social level is also characterized by the collective capacity to discuss the specific implications of imagination for how an organization runs right now.

From the viewpoint of the whole organization, results of efforts to imagine possible, but strange disturbances are rather “useless”, if they do not connect to organizational strategy, structure, incentives, and routines. In modern society, organizations responsible for planning and natural hazard management are often to some extent bureaucratic organizations that display a significant degree of formalization (e.g., formalized responsibilities, authority, standardized processes of communication, and routines like “Standard Operating Procedures (SOPs)”). Social resilience at this level may require that people “at the top” of the hierarchy are willing and able to provide resources and intra-organizational arrangements to facilitate and exploit processes of team-based learning for dealing with future imagined disturbances and for handling current emergencies through mindful process management (Weick & Sutcliffe 2015).

Increasingly, there is research that focuses on inter-organizational relations in the context of risk governance and planning (e.g., Comfort et al. 2010, Boyd & Folke 2012, Goldstein 2012, Thaler et al. 2016). With regard to social resilience, we highlight the following points: A wide preliminary definition

requires that actors interested in proactively adapting to future disturbances are eager and able to combine diverse domains and types of knowledge in processes of inter-organizational collaboration that are often resource-demanding and far from risk-free in terms of realizing the intended collaborative advantage (e.g., Huxham & Vangen 2005,

Zimmermann 2010). For instance, the flood disaster in Dresden in August of the year 2002 triggered collaboration of organizations from research and practice at the spatial level of the whole catchment of the river Weisseritz (a tributary of the river Elbe). This inter-organizational collaboration included state authorities, municipalities, and organizations from civil society. Collaborators were able to jointly produce some innovative products for dealing with future flood events (Wirth et al. 2010), but showed only rather limited capacity to facilitate collaborative pro-active adaptation to future disturbances among the participating organizations (Vulturius 2013). Collaboration among organizations from diverse societal realms may be especially difficult when it comes to collective efforts that address future disturbances and even strange events that are difficult to interpret based on the diversity of the existing strategies, structures, and routines of the participating organizations.

2.2 SOCIAL RESILIENCE AS SET OF CAPACITIES

When it comes to disaggregate the overall concept of resilience into components in order to understand how “a social entity [...] proactively adapt[s] to and recover[s] from disturbances that are perceived within the social entity to fall outside the range of ‘normal’ and ‘expected’ disturbances” (Boin et al. 2010, 9), discussions usually focus on separate, though interlinked capacities (e.g., Tierney 2014). As the discourse on resilience is nowadays situated in various scientific disciplines and research streams, not only a high diversity of definitions of social resilience is to be found, but also of the capacities that constitute resilience.

Some authors argue that resilience encompasses coping capacity, adaptive capacity and transformative capacity (e.g., Davies et al. 2013, Keck & Sakdadolrak 2013, Béné et al. 2016). This influential threefold division is useful to understand various degrees of re- and pro-active efforts of resilience. While some authors, for instance, Pelling (2011, 78), distinguish a “conservative” notion of resilience being the “contained” persistence of functions and practices from fundamentally different transformations meaning the “deepest form of adaptation indicated by reform in over-arching political-economy regimes and associated cultural discourses”, successive authors incorporated the idea of transformation into their resilience conceptualization. Hence, the triad of coping capacity, adaptive capacity and transformative capacity reflects the stepwise evolution of the resilience concept starting with the mere “conservative” persistence of a system, over adaptations of systems ending so far with “evolutionary” transformations of systems in the face of global challenges.

In order to fully grasp social resilience and its distinct social features, the following introduces an alternative set of capacities with a broader sociological informed understanding of the underlying social matrix enabling resilience and human agency. The rationale behind this alternative set is not a critique of the aforementioned three capacities, but rather their limited scope, when it comes to the social sphere and its specific characteristics. This alternative set is rather a broadening from a sociological point of view due to the fact that most important social features of social resilience have been neglected (Voss 2008); without their consideration, the specific social aspects of adaptation and recovery as mentioned by Boin et al. (2010) in our preliminary wide definition of social resilience in the introduction cannot be grasped and understood.

By distinguishing coping capacity and participative capacity as well as adaptive and transformative capacity (e.g., Voss 2008, Lorenz 2013) not only the aforementioned aspects of dealings with risks and natural hazards can be understood, but also the specific social aspects of resilience being in particular social processes of perception, interpretation and meaning as well as power relations and ideological processes that influence social resilience and human agency substantially.

Coping capacity: Sociological as well as anthropological studies (e.g., Erikson 1994) teach us that social actors do not just restore a former status quo after extreme and unexpected events, but show a much more complex and interpretative dealing with such events. A symbolic dimension of meaning (Lorenz 2013) and social processes of remembering, perception, interpretation, imagination and expectation building come into play and need to be considered to understand resilience. Taking into account these

notions, coping capacity is understood as the cultural and social “dealing” with collective stress (Voss 2008, Norris et al. 2008). As a result, coping especially comes to bear in the midst of or after a disaster. Especially endowment with meaning, i.e. attribute meaning to otherwise meaningless disasters, proves to be a significant precondition for the overcoming of disastrous occurrences (Norris & Stevens 2007). Looking at the community level, Dittmer et al. (2016), for instance, show how a local rural community coped with the disaster of the Elbe river flood in the year 2013, both in psychological and physical terms. By establishing their own patterns of interpretation and communal narratives about the disaster, the community displayed significant efforts of human agency in terms of organizing themselves for weeks autonomously in the inundated area – while still experiencing the situation as meaningful and a situation of community-building.

Participative capacity: Whether teams, organizations, networks, communities, and societies can actually cope with threats and disasters depends not only on the coping capacities of actors, but quite often to a greater degree also on the societal factors that enable or constrain these actors to do so. Actual social action is the function of complex social context conditions and processes, for instance, power relations, networks of different types and size, as well as institutional conditions. Especially the underlying dimension of power has been neglected in resilience discussions. But more recently, a significant number of scholars (e.g., Voss 2008, Bohle et al. 2009, Lorenz 2013, Voss & Funk 2015) have addressed this aspect of social resilience. The concept of participative capacity enters the discussion of social resilience to acknowledge different ‘radii of agency’ (Lorenz & Dittmer 2016, 36) and to direct attention to the interpretive power and influential prospects of actors regarding those local, regional, and global processes which affect them. “[P]articipative capacity becomes a key category in the circle of disasters: the lower the participative capacity, the lower the resonance for critical developments, the lower the prevention activities, the lower the capacity to respond and to adapt and so on” (Voss 2008, 52). Arguing for an inclusive perspective on ways to organize for resilience, the concept of participative capacity is most relevant across and on all social levels. It is to be found in intra-organizational processes, for instance, team efforts to balance exploration and exploitation as introduced earlier. In the context of “High-Reliability Organizations (HRO)”, rigid structures of power and formal hierarchies are seen as amplifying errors while flat and more participative hierarchies may contribute to stronger collective mindfulness and this is then translated into more social resilience in the context of technological as well as natural hazards (Weick & Sutcliffe 2015).

Adaptive and transformative capacity: Adaptive capacity is not just – as, for instance, in the ecological discourse on resilience (e.g., Folke 2006) – the ability to adjust in the face of natural hazards or unknown future threats. If we take the contribution of sociology seriously, adaptation as well as transformation need to be seen as deeply entangled with the respective social processes of perception, interpretation and meaning (coping capacity) and existing structures of power (participative capacity). Adaptive capacity, therefore, describes the ability to adjust and adapt in the face of natural hazards or other known as well as unknown threats under the conditions of coping capacity and participative capacity. The dependence on and the available resources for adaptive capacity are in most cases not issues of choice, but rather distributed by all those factors that make up participative capacity. In the discussion on adaptive capacity the significance of social capital is discussed at length (Adger 2000, Hagan & Maguire 2007, Tierney 2014). What is often missing and what is brought to the fore by participative capacity is that the distribution of social capital is never natural, but always the result of social actors struggling for more social capital and that there is always a so-called “dark side of social capital” (van Deth & Zmerli 2010, Aldrich 2012) in terms of social exclusion, marginalization etc. Given the often normative actions and goals, esp. of transformation, for instance in terms of “individual welfare” (Keck & Sakdadolrak 2013, 5) or “good governance” (Béné et al. 2015, 10), the entanglement of transformative capacity with socially build expectations, fundamental norms and values, normative judgements, ethical conceptions of the “good life”, but also power structures becomes even more apparent.

2.3 SUMMARY

Table 2 suggests a quasi-formal depiction of our social resilience (SR) conceptualization as matrix of levels and capacities. Table 2 disaggregates the overall wide definition of resilience (see Chapter 1) into 12 types of resilience propositions² in a “matrix” of social levels and a set of capacities as suggested in this paper.

2 A “proposition is a declarative sentence expressing a relationship among some terms.” (Van de Ven 2007, 117). A proposition and a hypothesis differ by levels of abstraction. Propositions “are relationships among theoretical concepts or construct, while hypotheses are relationships among concrete observable variables or events.” (Van de Ven 2007, 118) This understanding of propositions and hypotheses is in line with the philosophy of science called realism (in contrast to, for instance, relativism, Van de Ven 2007).

	Coping capacity	Participative capacity	Adaptive capacity	Transformative capacity
Level 1: intra-organizational	SR _{1c}	SR _{1p}	SR _{1a}	SR _{1t}
Level 2: organizational	SR _{2c}	SR _{2p}	SR _{2a}	SR _{2t}
Level 3: inter-organizational	SR _{3c}	SR _{3p}	SR _{3a}	SR _{3t}

Table 2 – Analyzing levels of social resilience: 12 types of resilience propositions

Some comments may clarify the purpose of this quasi-formal resilience conceptualization. Firstly, resilience statements are arranged primarily with regard to social levels. This reflects our organizational-institutional approach to social resilience with the emphasis on micro- and meso-dynamics for understanding collective action. Level-specific propositions are then differentiated with regard to social capacities. Secondly, we assume that propositions that refer to transformative capacities are – regardless of the level – the most ambitious analytical statements (see the growing literature on processes of transition and transformation in general, in cities and regions in particular, e.g., Egermann & Hutter 2014). Thirdly, as introduced above, issues of coping, participation, adaptation, and transformation may show relations characterized by tensions on multiple temporal as well as spatial scales. Hence, Table 1 does not emphasize 1-to-1 relations of specific propositions with “the real world”. In contrast, Table 1 may be used in research and perhaps also in practice heuristically to conceptualize the questions that need answering to promote social resilience in the context of planning and risk governance. Questions may emerge out of combining multiple resilience statements (e.g., SR1p - SR2c - SR3a, see Hutter & Lorenz 2017 for this example). Chapter 3 elaborates further on the advantages of our resilience conceptualization, but also on limits to its usefulness.

3 REFLECTIONS ON SOCIAL RESILIENCE AS MATRIX OF LEVELS AND CAPACITIES

Chapter 2 conceptualized social resilience as a “matrix” of social levels (intra-organizational, organizational, and inter-organizational) and as a set of capacities (coping and participative capacity as well as adaptive and transformative capacity). We summarized some social resilience research with regard to these levels and capacities. Overall, resilience research in general, social resilience research in particular, seems to be highly dynamic. Furthermore, policy makers in natural hazard and disaster management as well as in collective efforts for spatial planning and sustainable development increasingly use the notion of resilience to suggest ways to improve policies and practices in the face of the manifold pressing problems of our time (e.g., Tierney 2014). For instance, Jon Coaffee and Peter Lee (2016) outline policies and practices to enhance resilience in the context of climate change, security concerns in urban regions, and large-scale disasters.

Given these dynamics of resilience research and the request of policy makers and practitioners for valid as well as user-friendly and context-specific results of scientific analysis, a widely acknowledged research paradigm about resilience could be helpful to facilitate joint qualitative as well as quantitative analysis and to provide standards and research contents for the assessment of resilience with regard to various temporal and spatial scales. However, as it is now, no such unifying resilience paradigm exists in research and practice (e.g., Coaffee & Lee 2016). Quite the contrary, we observe an increasingly diverse “landscape” of research approaches and frameworks for analyzing and assessing resilience.

Conceptualizing social resilience as “matrix” of levels and capacities adds to this diversity through combining an inclusive approach with the analysis of multiple social levels and through reworking the set of resilience capacities. We encourage scholars of resilience to consider this complexity. Chapter 3

clarifies why they should try to do so. We also point to some limitations of understanding social resilience as matrix of levels and capacities.

Overall, this chapter uses two criteria to reflect on social resilience as matrix (Corley & Gioia 2011): (1) the criterion of originality that refers to the question to what extent a research contribution provides new insights into the phenomenon in question; (2) the criterion of usefulness that refers to the question whether researchers as well as practitioners may benefit from using the research contribution in the face of their own complex, dynamic, and uncertain context conditions.

The following argues that the concept of resilience as matrix provides new insights in the context of planning and risk governance. Furthermore, we are confident that the concept may prove useful in empirical resilience research. However, policy makers and planning practitioners who are eager to analyze, measure, and assess resilience with regard to spatial planning as well as cities and regions may ask about the usefulness of the concept in “the real world”.

3.1 WHY CONSIDER RESILIENCE AS MATRIX?

The concept of resilience as matrix does not claim to be comprehensive in relation to the “social world” in its given complexity. But, we see the concept is in line with an organizational-institutional approach to “governance in turbulent times” (Ansell et al. 2017). This has implications for how we answer the question why students (in a broad sense) should use the concept in their own research. The following highlights three reasons:

Seeing resilience through the sociological eye: The expression “sociological eye” is attributed to Everett Hughes (e.g., Whittington 2007). Of course, seeing resilience through the sociological eye may take on many forms, because sociology is characterized by diverse theories and methods (e.g., see Joas & Knöbl 2013 on social theory). However, it seems justified to state that current sociologies have some commonalities. For instance, they enhance at least two abilities of observers in and of the social world: Firstly, they consider the limits of rationality of actors even if these actors try to show a strong sense of human agency. Secondly, they emphasize differences in perception, interpretation, and learning of actors also in the face of similar context conditions. Our resilience as matrix pays especially attention to differences related to formal and informal organization (Scott 2014). Students of resilience that are interested in planning by organizations are encouraged to use the given resilience conceptualization.

Facilitating strategic research decisions: Discussions about processes of social differentiation and integration have a long tradition in sociology and social psychology (e.g., Weick 2001, Joas & Knöbl 2013). Resilience as matrix supports both researchers that are motivated to focus on specific features of a selected level (e.g., resilience of small social groups in the context of wider organizational forces) and researchers that are ambitious to study multiple social levels and their relations (“cross-level analysis”). Resilience as matrix may also help to focus the scope of dealing with disturbances in specific policy fields. Studies that encompass the whole spectrum of capacities may highlight a selected level. Studies that consider multiple levels may place a specific capacity in the foreground of investigation. We hypothesize that empirical studies will often be characterized – more or less explicitly – by a selective focus, because comprehensive studies are difficult to do (e.g., due to resource constraints). Hence, the concept of resilience as matrix may facilitate strategic research decisions: it allows focusing on specific research questions without neglecting other levels or relations.

Understanding interactions, especially tensions, between levels and capacities: Resilience research and particularly quantitative conceptualizations of resilience often suggest that capacities function in an additive manner, but neglect the interactions or interferences of capacities and different social levels. These interferences might be constructive, i.e. amplifying each other and contributing to an overall increase in resilience. But, and this is most important for us, there are also non-additive interferences to be found, which can also lead to diminished resilience, if such tensions, trade-offs and side effects cross levels and capacities are not considered. Studies that focus on multiple capacities of social resilience have the opportunity to consider such tensions inherent in collective efforts of pro- and reactively dealing with unexpected disturbances. Such studies are especially challenging with regard to the interpretation of tensions based on empirical data. For instance, teams with members from multiple organizations and with the task to analyze future unexpected disturbances need to consider the challenge of communicating team

results in the context of how the participating organizations run right now. Issues of coping, adaptation, and transformation tend to show multiple tensions that may be characterized as trade-offs, dilemmas or even paradoxes¹. The choice of interpretation of tensions is important for how team efforts are perceived by the participating organizations. We hypothesize that understanding tensions between capacities is especially fruitful from the viewpoint of research (e.g., see Wiechmann 2008 on tensions in strategy development in cities and regions, Healey 2009 on tensions of strategic spatial planning). However, emphasizing tensions may be risky or at least unfavorable (even though often needed) in the context of policy making and planning practice for resilience which brings us to the task of considering the limitations of resilience as matrix.

3.2 LIMITATIONS OF RESILIENCE AS MATRIX

Conceptualizing social resilience as matrix of levels and capacities has some limitations which should nevertheless be emphasized. This is not surprising, because “true” research, whether engaged or not, always has limitations (e.g., see Van de Ven 2007 on “engaged scholarship”). To clarify the usefulness of our concept of social resilience, it is therefore worthwhile to think about the limits of our argumentation. From a research perspective, the following briefly reflects on limitations in theory and empirical research, the assessment of resilience, and, last but not least, policy and practice (see Hutter & Lorenz 2017 for more details).

Limitations of theorizing and empirical research: In general, theorizing and empirical research on resilience as matrix is challenging and resource-intensive work. Given some strategic decisions about the selective focus of a study and appropriate research design and resource decisions to implement the intended work, we expect that limitations will especially arise due to the challenge of grasping the processual character of social resilience capacities. Researching social capacities as processes implies making some “tough” research decisions (e.g., defining the notion of “process”, Van de Ven 2007). Social capacities are not just there and easily detectable through, for instance, document analysis and qualitative interviews. Social capacities emerge (or vanish) through complex and dynamic processes that may be characterized by high uncertainty and dynamic conflict. How organizational resilience, for instance, emerges out of specific processes has been studied intensively for “High-Reliability Organizations (HRO)” (Weick & Sutcliffe 2015). HRO-inspired research needs careful adoption in the context of planning and risk governance (e.g., Hutter 2016).

Does the concept help to measure and assess resilience? If the reader expects some direct input or blueprint into efforts to analyze and assess social resilience at multiple levels in cities and regions, the tentative answer would be at best “Yes, but...”. Resilience as matrix may help as a simple classification schema to define indicators or sets of indicators for the measurement and assessment of social resilience. The set of 12 resilience propositions could serve as guidelines for defining and operationalizing a specific assessment approach to resilience. However, currently there is no shortage in resilience assessment efforts (for an overview see, again, Coaffee & Lee 2016). Limitations arise out of the high diversity in basic assumptions, in theoretical considerations underlying assessment attempts, and in empirical approaches to measure and assess resilience. Due to this situation there are, as in social science in general, limitations for integrating approaches to measurement and assessment in line with basic principles of qualitative and quantitative research. We assume that resilience as matrix is more in line with qualitative social resilience research. However, we hope that future research efforts will lead not only to comprehensive social resilience studies based on our conceptualization, but also to more integrative qualitative as well as quantitative research (see van de Ven et al. 1999 for an example in innovation research).

Limitations with regard to policy and planning practice: Obviously, this paper is targeted towards a resilience research audience and less so towards policy makers and planning practitioners. Social resilience, at least in our understanding, arises out of the synthesis of diverse capacities at specific levels

¹ Hence, tension on the one hand and trade-off, dilemma, and paradox on the other differ in levels of abstraction. Tension is the more abstract term. In “the real world”, actors may interpret tensions as, for instance, trade-offs, dilemmas, or paradoxes with significant consequences for planning and risk governance (e.g., Wiechmann 2008, Healey 2009).

of social order. Social processes of synthesizing issues of interpretation, power, and participation, as well as issues of learning, adaptation, and transformation cannot be addressed through checklists, recipes that resemble recipes in cookbooks, and simple causal models. Implementing social resilience in practice requires continuous efforts of agents that desire to enhance social resilience and that are able to consider such diverse issues as constructing and communicating meaning as well as playing power games in risky settings. Resilience as matrix summarizes some social resilience research findings that may serve as a springboard to future research activities with high policy impact. It is our hope that the conceptual arguments proposed here may support future research work that gives policy makers and planning practitioners the opportunity to facilitate social processes of resilience making.

4 CONCLUSION AND OUTLOOK

It is now widely acknowledged that discussions about resilience in research and practice have led to an abundance of concepts, theories, methods, empirical findings, assessments and ideas how to improve policy and practice. This abundance may be interpreted as a threat to the usefulness of resilience for research and practice (e.g., Brand & Jax 2007). But this abundance may also be interpreted as sign of the liveliness of debate and of the importance of resilience in an uncertain, complex, and dynamic world. This paper clearly follows the pathway of the latter rather than the former. However, resilience researchers on this pathway face further challenges of strategic choice.

For instance, Pelling describes a “conservative” notion of resilience within an overall framework to analyze climate change adaptation through resilience, transition, and transformation (2011, 51). In contrast, some planning researchers see resilience as the overall guiding concept to analyze policies and practices for more climate change adaptation, security, and better disaster management in urban regions. We follow Coaffee and Lee (2016) in transcending a conservative concept of resilience by taking issues of coping, participation, and adaptation as well as transformation into account.

To avoid inappropriate fuzziness in resilience analysis, we argue to specify the spectrum of relevant research propositions through identifying the social levels of organizing for resilience in urban and rural regions (Hutter & Lorenz 2017). This is in line with recent attempts to promote an organizational-institutional approach to “governance in turbulent times” (Ansell et al. 2017). Therefore, capacities of resilience may vary with regard to specific social dynamics on intra-, organizational, and inter-organizational levels of organizing to deal with unexpected disturbances. And what is even more important: cross-level social dynamics may be crucial for how successful collective efforts of dealing with unexpected disturbances are.

Of course, there are further dimensions and related variations that could be taken into account (e.g., see Van Wijk et al. 2003 on knowledge and networks and Zimmermann 2010 on knowledge and planning). However, we are confident that our conceptualization may serve as one analytical and heuristic concept among others in future theoretical and empirical research on resilience, planning, and governance. Like in the case of innovation and strategy research, we expect significant research progress from medium-sized to large projects that seek to integrate theoretical discussions, empirical work through qualitative as well as quantitative methods, and practical considerations (e.g., Van de Ven et al. 1999, Van de Ven 2007). It is unlikely that discussions about resilience as hype or hope will vanish. However, resilience in planning research may display similar pathways like the ones that can be observed in psychology that has been analyzing resilience now for decades (e.g., Masten 2014).

m.meng@tudelft.nl

ABSTRACT: Spatial planning is supposed to denote innovations in resolving flood risk. However, taking spatial action is never an easy task. This study aims to explicate the reasons for this difficulty by illustrating why the urban flood risk mitigation is struggling to be tackled locally despite the growing flood risk in delta cities. It does so by investigating the recognition of flood risk in the spatial planning system. Specifically, Guangzhou, a city located in the Pearl River Delta and vulnerable to fluvial, pluvial and coastal flooding, is taken as an example in this research. By using the method framing analysis, the paper finds that the road to face the flood risk in Guangzhou is still at an emerging process from informal activities to formal legislation. With a pace changing from a dedicated to an integral issue, there is an appeal for a combination between nature-based options and engineering options. In spite of these progress, there is still a mismatch between this policy intent and real practitioners. Due to the weak sense of identity in flood-proof initiatives among practitioners, the road toward a more resilient city is challenging.

KEYWORDS: Climate change, flood risk, urbanisation, spatial planning, framing analysis, Pearl River Delta, Guangzhou

1 INTRODUCTION

Flood risk, greatly increased by climate change, is remarkably affecting global cities. It poses a considerable threat to the safety and social-economic development by causing considerable losses. Against this background, spatial planning is increasingly recognised as an essential tool and process to mitigate flood risk and raise the cities' ability to face climate change (Gersonius et al. 2008; Roggema 2009, 2014). On one hand, it works through multiple routines by locating suitable types of land use, arranging activities, regulating scales of development and designing physical environment to avoid or decrease the impact of the potential flood (White et al. 2007). By this, many spatial policies, strategies, plans and projects (in this study, they are collectively named as spatial development) are formulated. On the other hand, water sees no boundaries. Flooding is increasingly regarded as a cross-cutting issue which requires the contribution from different professions. Spatial planning, supported by other relevant fields such as water management, is regarded as a decision-making process which provides the opportunities for mutual learning. Thus, the role of spatial planning in enhancing negotiation stands out.

However, incorporating flood risk into spatial planning is still challenging in many delta cities. Even in the pioneer cities, such as Rotterdam in the Netherlands, applying spatial efforts to resolving flood risk is never an easy task. The situation seems worse in new urbanising flood-prone areas equipped with limited experience in dealing with water, for example, Guangzhou city. It is one of the most vulnerable delta cities

around the world, located in the Pearl River Delta (China). In some initial research, it is indicated the local spatial development has not done a good job in mitigating flood risk. This underlying difficulty can be partly attributed by the priority to the economic development in spatial development rather than water issues (Francesch-Huidobro et al. 2016, Meng & Dabrowski 2016).

The other side of this unsuccessful job might closely be related to the weak recognition of flood risk in the spatial planning system. Here, recognition refers to the way how flood is understood, framed and closely linked with spatial planning practice. Weak recognition can happen in the context of the insufficient understanding of the uncertainties and opportunities brought by flooding and climate change among spatial planners, and reflected by the reluctance in changing the traditional planning approaches to face the new natural hazards on account of potential extra efforts and costs (Gersonius et al. 2008; Roggema 2009; Næss et al. 2005).

In order to mark the significance of recognition and clarify its impact on planning practice, we briefly discuss the responses to flood risk in Guangzhou's case. This article examines whether and how the local spatial planning system acknowledge the flood risk, and, in turn, how this acknowledge facilitates or hinder dealing with the flooding hazard. It contributes to the literature on the explanation why promoting urban flood risk mitigation is so difficult despite the growing flood risk in delta cities and the clarify the interaction between discourse and practice. The discussion draws on fieldwork conducted in Guangzhou city following the emerging trend toward a more resilient habitat inspired by the Sponge City Programme. This special programme is launched by the central government in 2014 and highly promoted at 30 pioneer cities during the last two years, which aims to deal with the loss from frequent flooding and scarce water resources (Ministry of Housing and Urban-rural Development 2014). Although Guangzhou has not been appointed as one of the pioneer cities, the local authorities have set their minds to catch up this new trend.

Though frame analysis of planning documents, and a series of semi-structure interviews, this article argues that the current spatial planning system is living through a transition from an informal planning process, with flood risk embedded in flagship projects, to a formal planning process, with flooding compulsory considered in normal activities. This article begins by illustrating the pace of urbanisation related to flood risk in Guangzhou's case, before setting out the methodology and theoretical concepts. Results are explained in the sections spatial policy making and practise before the implications are discussed.

2 URBAN DEVELOPMENT AND FLOOD RISK

Guangzhou, the largest city in Pearl River Delta, is located on the Pearl River. It is one of the best examples of rapid urbanisation process in this delta while increasing number of inhabitants exposed to flooding. As the capital of the Guangdong province, it is close to Hong Kong with 120 km distance at the north-west and 145 km apart to the north of Macau. The old ancient town of Guangzhou was near Baiyun Mountain on the east bank of the Pearl River. It has a diverse topography, ranging from urban centre area with Pear River passing through and flowing into a south floodplain area, to a mainly agricultural and rural area with natural canals and streams in the north and east. The elevation of the prefecture generally increases from south-west to northeast, with mountains forming the backbone of the city and the ocean comprising the front.

Due to the convenient condition for transportation and maritime trade, it developed into the most important port city in southern China, with the exchange of economy and culture. This city sees an explosive economic growth from 365 billion in 1978 to approximately 7400 billion in 2016, after the launch of the reform and open policy. Correspondingly, the population in this period climbs from 3 million to 14 million. Now it becomes the third heavily settled city in mainland China, with a population of 13,501,100, behind Beijing (2nd) and Shanghai (1st).

The increasing population and economic development result in the dramatic transformation of the urban landscape. During the period from 1980's to 2010's, economic rise led to rapid urbanisation and high-density development, which brought about too much paving in the built area and insufficient capacity of water discharging system (Li et al. 2015). This scenario contributes to the increasingly severe pluvial flooding after 2010's. One of the local authorities showed his concerns in the early time (interview 1),

“The location of waterlogging are mainly distributed in the city centre and the number of those is increasing every year. The sad is it is never easy to handle it in a decent way. This situation has been made worse recently, considering frequent rains and thunderstorms caused by the climate change”.

The latest Sponge City Plan launched in 2017 reconfirms this trend (Figure 1-left), in which the city centre area is regarded as the most vulnerable area threatened by pluvial flooding. As Li (2015) put out in his research, the data of the events of pluvial flooding in the city centre from 1980 to 2012 indicates the density of waterlogging is closely correlated with the percentage of the impervious area. The distribution of these pots stretched by the pace of urban sprawl.

Moreover, Guangzhou is facing a new dilemma as well: the threat of coastal flooding. In a series of literature launched recently (Hanson et al. 2011, Hallegatte et al. 2013), Guangzhou is recognised as one of the most vulnerable cities considering the loss from populations and assets exposed to coastal flooding. According to the latest Sponge City Plan, the southern part of Guangzhou is the worst-hit area (Figure 1-right). Two driving forces could intensify the potential loss from coastal flooding. On one hand, the fluctuation of 30cm higher of mean sea-level in the PRD was speculated between 1990 and 2030 with a 5cm increase annually due to climate change, which brings an external pressure to this area (Chinese Academy of Science, 2002). On the other hand, the unstoppable trend of urbanisation and industrialisation might increase the exposure of people and property to potential coastal flooding. Nansha District, a district in southern Guangzhou, was officially acknowledged as a State-approved Special Economic Zone in 2012, competing and cooperating with Shenzhen and Zhuhai. In the near future, the development based on transportation and maritime trade will definitely bring a new trend of urbanisation and land reclaim. Given the uncertainties of climate change and potential urbanisation on coastal areas, the flooding risk stands out.

In contrast to increasing pluvial and coastal flooding, the fluvial flooding is not so dazzling of light in 2000`s (Carmona et al. 2014). Although Guangzhou is also historically threatened by the fluvial flooding, the continuous construction of water infrastructures like dykes, dams and reservoirs from the 1950s` to 1980`s has built the basic safeguard for Guangzhou city. “The related construction pays more attention to the reinforcement of existing engineering infrastructure”. By this, in the research of Guangzhou, we paid our attention to pluvial and coastal flooding.

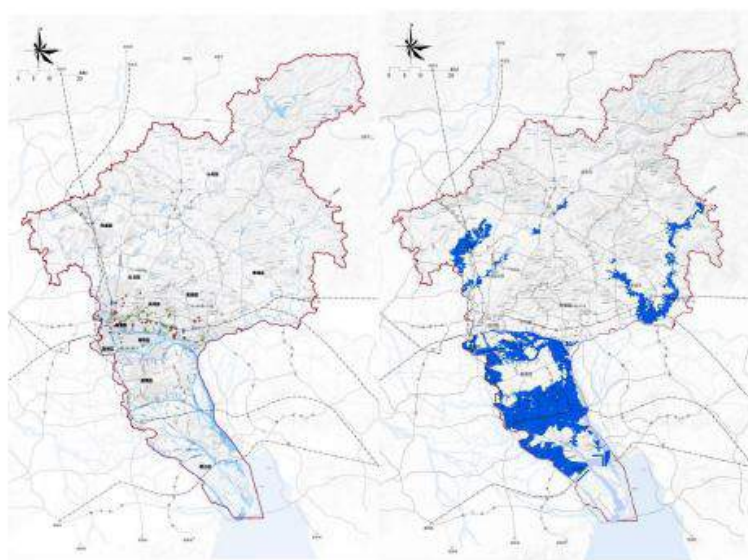

Figure 1 – The spots of frequent waterlogging (left), the vulnerable areas threatened by coastal flooding (right)

3 METHODOLOGY

3.1 FRAMING ANALYSIS

In examining the recognition of flood risk in planning, it is important to address the agreement and disagreement between the claiming of policy discourse such as rules, principles, criteria, and the reflections of policy discourse, such as the activities and choices conducted by institutions and agents. Such controversy can be examined by framing analysis, which is generally used to analyse “the mismatch between administrations’ implementation of legislated policies and policy intent” (Hulst & Yanow 2016 P.92). As proposed by Rein and Schon (1994, 1996), through “frame critical analysis” and “frame-reflective analysis”, the two perspectives of framing analysis, this method helps to explain, such as the sense-making of problems, the evolution of understanding, the gaining of legitimacy and the value reflection of policy designers and practitioners.

Hulst and Yanow (2016) underlines three identities in conducting framing analysis,

1. the substance of policy issue
2. the policy process
3. policy-relevant actors’ identities and relationship

Here, we take use of this outlines of exploration and apply it in the discussion of the agenda setting of flood risk in the spatial planning system. First, the fitting planning policies and plan documents are selected, and the content in relation to flood risk and planning will be sought. Following this, they are analysed to clue the changes of beliefs and standpoints of policy makers and planning practitioners in flood-proof routines. In order to recheck the statement of policy discourse, in reality, we add another discussion to the original framework: the reflection of policy intent.

Based on this, the discussion of this paper are sketched out along four axes:

1. How is flood risk defined in spatial planning documents and brought to the public in policy arena?
2. What routines are set in resolving flood risk in spatial regulations, plans?
3. What are the identities of spatial planners in representing the flood-proof intent in policy?
4. What is the reflection of policy intent in practice?

3.2 POLICY SELECTION AND DATA COLLECTION SOURCES

In order to reflect the new trend towards a resilient city, stimulated by the latest political innovation “Sponge city Programme”, and the transitions in spatial planning during this new trend, this research examine the official documents from 1990’s to present. Two reasons contribute to the time point we selected: the increasing flood risk caused by climate change and urban development. On one hand, it is the time, in 1990, when the climate change started to step into the political arena and had an influence on policy and plan making (Meng & Dabrowski 2016). The recognition of the impact of climate change on urban development was emerging, which sets the premise of this discussion. For the sake of Guangzhou, there is a remarkable increase of waterlogging pots from 2000 to 2012 due to the frequent storms (Li et al. 2015). Thus, flooding hazard caused by climate change is becoming a key factor that affecting residential property and urban development. On the other hand, it is generally recognised 2000 means a lot to China, which opened the door to the period of accelerating urbanisation. This new trend was highly praised in 10th 5 Year Plan (National Social and Economic Development Plan), regardless of the size of cities (Li 2010). During this period, a mass of people immigrated into large cities, for instance, Guangzhou, on account of the advantages in resources, location and employ opportunities (Chen 2013). By this, Guangzhou sees a rapid urbanisation and lots of problems following up.

Here, we choose Guangzhou Master Plan 2000-2010 (MP1), Guangzhou Master Plan 2010-2020 (MP2) and Guangzhou Sponge City Plan (SCP) in the following analysis, which provide the spinal column of the local spatial planning system and play an influential role in ensuring whether flood risk is seriously concerned and in what ways it is handled. Although this policy selection does not cover the full range of flood-related plans and policies, it provides an overview of current local resilient routines in the spatial planning system.

To enrich the insights from framing analysis, 30 experts and professor are invited in a series of semi-structure interviews. Interviewees at the provincial and municipal level were selected to present the principal institutions and reflect on the key viewpoints in the documents review. The interviewees cover administrators in the spatial planning system, administrators of water management system, experts in research institutions and private planning companies and representatives in real estate companies. Three questions concerning recognition and awareness are asked:

- Do you think your profession can contribute to a flood-proof city?
- What obstacles might hinder your contribution?

The survey helps to show the extent of recognition of flood risk among the relevant actors in spatial policy and planning practise. It increases understanding the extent of the correspondence and opposition between the agenda setting in legislation and the following interpretation

4 THEORETICAL CONCEPTS

Four concepts are identified as primary factors in this analysis from the theory of framing analysis derived from Schon and Rein (1994). They are problem-setting, routines for resolving problems and identities of actors in reflecting the policy discourse.

4.1 PROBLEM-SETTING

First, problem-setting, which denotes a sense-making process, is selected. Through this process, the specific uncertain or ambiguous problems are selected, analysed and converted into explicit questions (Schon 2008). Such sense-making work then set the basis for the formulation of rules subsequently and impact on the further implementation. Specifically, the concern of problems setting in this study is derived from the premise that we should not only pay the attention to the external implication from climate change in delta cities. Flood risk is also interwoven with internal pressure from the physical development such as urbanisation, land-use patterns and technical treatment (Meyer 2014). Such “binding together” pattern, if any, not only provide a perspective to view what the troublesome is and what should be fixed but also holds dissimilar patches together in a scrutable and cogent way to motivate and steer actions (Weick 1995; Rein & Schn 1996).

In many delta cities, high-density urban sprawl and uncontrolled development in the flood-prone area may cause the difficult in water discharge and increases the odds of people's exposure to flood hazards, such as Guangzhou in Pearl River Delta and Argentina in the Parana Delta (Bosselmann, Peter 2014; Zagare 2014). In another context, flood risk is correlated to the construction of large dams upstream. The case in Mekong Delta and Nile Delta manifest the concerns that such technical treatment may lead to the lack of sediment disposal and land subsidence (Cornelia & Kantoush. 2014; Marcel et al. 2014). The clarification of this interwoven in policy analysis between flood risk and other elements, thus, contribute to a better understanding of in what ways is flood risk framed and how they shape and impact on the future ambitions and options in spatial development. Consequently, a fundamental reconsideration of the problem setting of flood risk is highly emphasised in this study.

4.2 ROUTINES FOR RESOLVING PROBLEMS

Policy discourse could be regarded as a storytelling process, which naming the problems, defining the features, explaining them to the public what has happened, what is going on, and what should be done at present and in the future (Hulst & Yanow 2016). Through this process, policy discourse bridges the problem setting and real problem solving, and enable a leap from what it is to what needs be done. Here, we pay our attention to the session what needs be done, namely, the routines for resolving problems, through four aspects, goals, philosophy, principles for action and available options.

Since it is easy to understand the meaning of goals, principles for action and available options, we concentrating on the clarification of philosophy. As Wittgenstein (1921; P.25) mentioned, “Philosophy aims at the logical clarification of thoughts”. Similar point of view is also elaborated in Nigel Taylor's study that it

refers to the “activity which is concerned with the clarification, and critical examination, of the basic assumptions underlying our ideas and beliefs (and thus, too, theories) and our actions and intentions (and thus, too, practices)”(1980, P.160). In terms of planning, Taylor argues that philosophical inquiry covers two main aspects: the ethical judgments (e.g. the economic development is promoted even though it might spoil the natural circumstances, or give priorities to the public transportation not the private), and the knowledge of problem (e.g. the causes of traffic jam) (Taylor 1980). In this paper, we build our views of philosophy by emphasising the former one and connecting it with the value judgement. It is, in this way, used to reflect the value orientation of policy, strategy and plans (e.g. a programme is encouraged which brings about long-term economic profits and adds to the living quality in spite of large sum of investment in a short-term). By this, it reflects the collective consciousness, overall tendency or dominating ideology from the decision makers, in most case derived from the government authorities with citizen`s reflection embedded in.

The belief underlying this discussion is that different goals, principles, philosophy and available options could have different impacts on, for instance, the following detailed plan and design process. For the Dutch case in Rotterdam, economic values derived from flood-proof initiatives are remarkable in a series of official documents, for instance, Rotterdam Adaptation Strategy (Rotterdam Climate Initiative 2013). Correspondingly, the cost and benefit analysis is promoted in the following plan and design process, which as a tool consolidates a proposal by comparing the cost of new construction and the loss caused by flooding hazards otherwise. On the contrary, in the Chinese case “Sponge City Programme” in Guangzhou (which will be further explored in paragraph 4 - analysis), the economic benefits is overestimated, which leads to a lack of expenditure comparison and a risk that the programme will not be sustainable. Thus, the role of routines for resolving problems stands out.

4.3 IDENTITIES OF ACTORS IN THE POLICY DISCOURSE

The discussion of identity derives from the concern that planning practice might work as policy discourse claims because of the thoughts of identities of the potential actors. They might detach themselves from the affairs because of the weak sense of responsibility or conflicts out of different political positions (Forester 1999, Forester 2012). Policy discourse contributes to framing this identity through constructing a common ground, appealing mutual recognition, clarifying their power and building relationship between parties within their beliefs (Schon & Rein 1994, Forester 1999, Forester 2012).

4.4 REFLECTION OF POLICY INTENT IN PRACTICE

Although policy might portray a promising future, in reality, the actors will reframe the discourse according to their own understandings and interests, and apply the revised discourse in practice. It means there might be a mismatch between the intent and practise. Here, the discussion focuses on clarifying the real thoughts of actors in spatial policy making and planning practise.

5 SPATIAL PLANS BEFORE THE LAUNCH OF SPONGE CITY PLAN

5.1 PROBLEM SETTING

Both of MP1 (Guangzhou Government 2005) and MP2 (Guangzhou Government 2016) SCP include the discussion of flood risk but the ways of problem definition are different. It indicates flooding risk (too much water) is turning from a detached issue to a connector associated with other urban problems, such as water pollution, water quality, etc.

In MP1 (Guangzhou Government 2005), flooding is concerned under the subtitle flooding prevention and rainfall discharging, a section of the chapter public safety and disaster prevention. Beneath this framework, flooding is recognised as a natural hazard caused by frequent storm and overflows of river and coastal flooding. There is no discussion of the impact of climate and weak description of urban development on flooding. In addition, dealing with flooding is regarded as a detached issue with the construction of engineering infrastructure emphasised.

Although flooding is also framed in the similar framework in MP2 (Guangzhou Government 2016), it sees a slight change. There seems to be a shift in the attitude which tries to clarify the relationship between flooding and urban development. Apart from the description of natural impacts, in this plan, flooding is attributed to the problems brought by the rapid urbanisation, such as the insufficient discharging capacity of drainage and sewer system, the disappearance of waterways and canals system, the decrease of buffer zones for flood discharge and retention due to urban expansion. Correspondingly, traditional flooding mitigation projects are criticised as:

“a series of detached actions, which heavily rely on the engineering facilitates while neglecting their connections with urban development...Flood mitigation projects in the future with the chief objective of safety should be an intriguer which bring profits to a clean water environment and an ecological circumstance for working and living (P.445).”

5.2 WHAT ROUTINES ARE FORMULATED IN RESOLVING FLOOD RISK?

GOALS OF FLOOD-PROOF INITIATIVES

In MP1(Guangzhou Government 2005), water safety is regarded as the primary goal that should be achieved. This goal is explicated in two aspects. On one hand, to protect the city from fluvial and coastal flooding” is highly emphasised through the reinforcement of the existing engineering infrastructure such as dykes, levees, pump station, etc. Beneath this elaboration, the frequency of fluvial flooding in city centre should be “lower than 1 in 100 years in short-term and lower than 1 in 300 years in long-term” (Guangzhou Government 2005, P 47). On the other hand, improvement of the discharging infrastructure and reinforcement of the existing retention infrastructure means a lot in raising the capacity to deal with excessive water though. Based on those infrastructures, “the frequency of pluvial flooding is supposed to be lower than 1 in 10 years in short-term and 1 in 20 years in long-term...”, and “excessive rainfalls should be discharged within 24 hours” (Guangzhou Government 2005, P 48).

Even though the significance of water safety is still re-emphasized in MP2 (Guangzhou Government 2016), the close connection between flood-proof projects with urban development starts to impact on the policy formulation and enriches the goals setting. Apart from the modification of river flood defence standards and water discharging standards, this plan claims that implementing flood mitigation projects could be combined with the measures “improving the quality of water... enhancing the ecological environment... and shaping the culture identity” (Guangzhou Government 2016, P445). Thus, the goals of flood-proof statement start to explore the extensive possibility.

PHILOSOPHY

The philosophy in dealing with flood risk is broadened through the evolutionary development of spatial planning making as time goes by. It is obviously that the concern of safety penetrates in both of two documents. As described in MP1 (Guangzhou Government 2005) and MP2 (Guangzhou Government 2016), the safety is cognizant as their first priority. However, the content of philosophy in MP2 (Guangzhou Government 2016) sees a subtle variation that there is a gradual transition from narrowed focus on water safety to a diverse orientation which adds the value to safety, ecology, environment and cultural identity. The reason why such transition is regarded as a subtle variation is that description of the available options to support this transition is insufficient in spite of these new value judgement in the policy statement. Thus, the extension of philosophy in MP2 seems more like a reframing the irritating flooding risk in a more comprehensive perspective than a radical switch.

PRINCIPLES FOR ACTIONS

The prime principle for Guangzhou`s actions shared by MP1(Guangzhou Government 2005) and MP2 (Guangzhou Government 2016) can be generalised as taking action according to local settings. It can be reflected by two main aspects: the distinctive geographic features of different areas and the status of existing infrastructure. Correspondingly, different options are proposed in terms of potential flooding resources along with the reinforcement the existing infrastructure.

In addition, MP2 (Guangzhou Government 2016) shows a new tendency of joint performance. As mentioned in the philosophy part, this plans calls on an integral choice which combines the flood-proof initiatives with other activities contributing to improving the water quality, living environment and cultural identity (Guangzhou Government 2016, P.445).

AVAILABLE OPTIONS

Divided by the sources of flood risk, In MP1(Guangzhou Government 2005) the options can be into alternatives to deal with the fluvial and coastal flooding, and alternatives for pluvial flooding. The former concentrates on engineering construction. Under its influence, reinforcing flood defence infrastructure, such as embanks, dykes, pumps, water lock; and raising the elevation of ground are emphasised (Guangzhou Government 2005, P.47). The latter focuses on a conservative way by ameliorating of existing water discharging infrastructure and protecting the open canals, waterways and artificial lakes from the negative impacts of excessive urbanisation. Activities such as improving the discharging system; preserving and dredging the canals and waterways; suppressing the erosion to existing waterways out of urbanisation, canals; and preserving the artificial lakes are encouraged (Guangzhou Government 2005, P.48).

The diversity of available options seems to be loosened in MP2 (Guangzhou Government 2016). Options focus their attention on the reinforcement of the dykes, flood walls, pumping facilities, reservoirs, canals and discharging system (Guangzhou Government 2016, P.442-447). Engineering construction appears to be the dominant approaches to face the flood risk.

In spite of those available options, there is a lack of description of areas without any canals and lakes in their site. In fact, lots of areas are located in those positions, where the available options are building underground discharging system and draining the water out of the city as soon as possible. It actually brings a hidden trouble to the city because of the fixed draining capacity of the discharging system. The point is normally it is difficult to change the designed permanent draining volume. However, due to the increasing frequent rainfalls and storms caused by climate change, the draining capacity will finally see its boundary. In that case, the lowland in the city will be submerged. Thus, a more flexible system which can bear the excessive water is needed.

In addition, for the sake of potential fluvial and coastal flooding, suggested options mainly rely on the “barriers”, underpinned by engineering approaches. To face the potential increasing risk caused by climate change, the only solution is to raise the height of dykes, flood walls and building more pumping facilities. Engineering construction is necessary, but the narrow focus on it may lead to troubles. In flood-prone areas, natives will be used to the engineering protection (Solomon 2007)In the case that engineering construction is ill-prepared to resist the floods when water exceeds the capacity of protecting the system, people would encounter a great loss, with little knowledge to handle the unexpected inundation. Thus, some extra protective options are needed.

5.3 IDENTITY ASSIGNED BY POLICY FRAMING

MP1 (Guangzhou Government 2005) and MP2 (Guangzhou Government 2016) share a weak recognition of identity assignment in policy discourse. It seems policy statements in these two files is more likely a technical tool which pays more attention to the problem setting and routines for action, while the discussion about who should be involved and shoulder the responsibility to handle the flood risk is neglected. However, it is still to be emphasised that, in MP2 when flood proof issues are talked about, there is a hint which claims that “water administration institutions will play a significant role in enhancing the water safety, water purification and waterfront environment ” (Guangzhou Government 2016, P 445). Thus, the identities of the relevant actor are vague and uncertain.

5.4 REFLECTION IN PRACTICE

In this session, 30 experts and professor are invited to the interviews, which achieved 25 positive response. They come from the Municipal Urban Planning Department, Water Affair Bureau, Pearl River

Delta Commission, provincial spatial planning and design institute, municipal spatial planning and design institute, research institute, civil engineering institute (working on drainage and sewer system and water supply system), private spatial and landscape planning company and real estate company. Their majors cover spatial planning, sewer discharging, ecology, landscape designer and planning, greening, water resources, sewer discharging water resources, flood defence, administration and management and housing.

Among those are 11 spatial planners, including 6 spatial planners who work on land-use and economic development, 4 spatial planners who work on landscape and ecology (2), and sewer system (2), 1 spatial planning administrator who work on drainage and sewer system.

The investigation established the willingness of participation in the routines towards a resilient city in terms of their past experience. We followed a guideline with two main questions:

- Do you think your profession can contribute to a flood-proof city? The attitudes from different institutions are categorised with five intervals from first priority, strong interest, neutral position, weak interest and no interest.
- What obstacles might hinder your contribution?

RESULT 1:

The results of those interviews show that 7 respondents, nearly 1/3, show strong interested in keeping eyes on flood risk, with 2 spatial planners working on landscape and ecology (1), and sewer system (1) are included.

Nearly half of respondents, 11 out of 25, respondents hold a neutral position in considering flood risk in planning practice. Here, neutral altitude refers to the situation that the respondents are aware of the increasing flood risk in the context of climate change but not reluctant to change their planning tools or measures to face this new challenge. Among them, 4 spatial planners working on land use and economic development, 1 spatial planners working on landscape, 1 spatial planner working on the sewer system and 1 spatial planning administrator working on sewer system are included, showing the neutral position.

3 respondents show weak interested in taking flood risk in their practice related to spatial plans or projects, including 2 spatial planners who work on land use and economic development.

2 respondents, who work on flood defence in the Pear River Delta Commission, put flood risk at their first priority and 2 respondents, who work in the real estate, show no interest in flood-proof initiatives.

Due to the small sample of the interviewees, the result cannot totally reflect the overview of attitudes at local circumstances. However, it still hints some phenomenon indirectly. It seems that not so many interviewees are willing to put flood risk in them agenda. According to the investigation, 16 respondents, nearly 2/3 of the whole sample, hold a neutral, weak or even indifference attitude to the new challenges brought by flood risk. In contrast, 9 respondents, around 1/3 of the interviewee shows a strong interest in flood-proof initiatives or take it seriously.

A similar situation happens among spatial planners. 9 responses show a neutral or weak attitude while only 2 spatial planners show a strong interest.

RESULT 2:

The investigation about the obstacles help our to understand the underlying reasons of such neglect of flood risk in spatial related plans and practise.

According to interviewees, most people attribute their timid attitude to the potential sanitation problems brought by flood- proof initiatives, not the tradition in their fields, no agreement on available options, weak cooperation between different institutions, lack of experts in this new problems and lack of political support.

For spatial planners, the main reasons concentrate on the potential sanitation problems brought by flood-proof initiatives, not the tradition in spatial planning practice, lack of experts in this new problems and lack of political support.

6 A NEW ERA: THE LAUNCH OF SPONGE CITY PLAN

6.1 PROBLEM-SETTING

The definition of flood risk becomes richer in SCP (Guangzhou Government 2017). On one hand, the role of climate change starts to step into the arena and realised by the actors who are involved in the process of plan making. "Due to the climate change, there will be an increase in the events of rainstorm and thunderstorms. By this, the occurrence of waterlogging will be much higher than ever before (Guangzhou Government 2017, P.43). In addition, flood risk is regarded as a hub, closely linked with water pollution, poor ecological environment and weak culture identity. Dealing with flood risk is, thus, packaged in a systematic project, integral with other public issues. By this, decreasing flood risk is regarded an opportunity to resolve the other public problems out of rapid urbanisation.

6.2 WHAT ROUTINES ARE FORMULATED IN RESOLVING FLOOD RISK?

GOALS OF FLOOD-PROOF INITIATIVES

The goals of SCP (Guangzhou Government 2017) are expressed through five main aspects: raising the safety to flood; improving water ecology; purifying water environment; enhancing the usage of water resources and rebuilding the connection between water and citizens. Compared with the suggestions proposed in MP2 (Guangzhou Government 2016) that multi-objectives activities considering the flood risk, quality of water, ecological environment and culture identity are preferred, this time such policy statement is demonstrated clearly in a visionary language and used as a framework to charge the whole file.

PHILOSOPHY

includes clearly value judgement on bringing the benefits to water safety, ecology, environment and cultural identity. Though these clues, it helps to build a more safe, attractive, liveable and resilient city.

PRINCIPLES FOR ACTION

The changes of principles for action highlights the necessity of institutional cooperation and integrated measures in dealing with flood risk. In SCP (Guangzhou Government 2017), it advocates horizontal interactions between the profession of spatial planning, transportation planning, water institution, which provides the legislative foundation for future cooperation in a formal way. Consequently, it may lead to an easy-going circumstance for mutual learning and information exchange in the process of policy and plan making.

Although it is officially claimed that an integral system binding nature-based infrastructure with engineering infrastructure is significant, a greater emphasis on nature-based infrastructure can be perceived. By this, components of nature, such as wetlands, lakes, waterways even the farmland are recognised as a crucial element in water retention and detention. It gets the upper hand uncomplicated in terms of the traditional notion that natural elements are more acting as an ecological habitat for biodiversity. "It is meaningful for the rapid urban sprawl process in Guangzhou." As an interviewee previously put out,

"To get out of the trouble of pluvial flooding is never easy. Because you cannot expect the rainwater discharging system can totally handle it, especially now the frequency and amount of rain can easily surplus our control due to extreme storms surge. However, we can still ameliorate it by relying on the green and blue network in this city. They take

effect by storing the excessive water, slowing down the speed of run-off in transit, and extending the time of flowing into the rainwater discharging system.”

AVAILABLE OPTIONS

In SCP (Guangzhou Government 2017), it calls for new remedies to deal with a series of water problems with flood risk included. In contrast to the conventional methods, new remedies are explicated through as follows:

- Raising of the water safety by the reinforcement of flood defence infrastructure, e.g. dikes, and levees; the construction of pumping; the upgrade of discharging system; the partition of the water basin; the adjustment of ground elevation; the construction of underground drainage tunnel; the building of water retention and detention areas, e.g. wetlands, parks, and green and blue corridors.
- Purifying the polluted water by the improvement of wastewater chain, e.g. the set of sewer treatment plant; the construction of overflows pollution control system; the purification of the contaminated canals and rivers; and the building of eco-purification system, e.g. wetland system
- Improving the ecology environment by softening the channels and canals and the utilisation of green open space in water retention and detention;
- Enhancing the optimisation of the use of water by the diversion of water resources; the improvement of water supplement system; the reuse of treated sewage; and the recycle of rainfalls.
- Reconstructing the connection between water and citizens by facilitating the access to waterfront area; arranging waterfront recreation; and build the image of water-related heritages.

Although the options are categorised into five axes, in real practice, a project might take two or more options. For instance, the softened canals might act as a part of green blue corridors which help to drainage the excessive water and reduce the pressure of underground discharging system out of pluvial flooding and provide an attractive place for recreation. It is obvious that different flood-proof options are related, overlapped, and interacted. Here, engineering based and nature-based options are regarded essential components constitute a comprehensive system.

6.3 IDENTITY ASSIGNMENT BY POLICY FRAMING

The SCP (Guangzhou Government 2017) takes a huge step in clarifying the identities of different actors. This file calls on collaborative efforts from different departments in raising the ability of the city to deal with flood risk, as well as building an attractive, ecological and livable water environment. The roles of key administrator are identified, for instance, the local Development & Reform Commission, Water Affairs Bureau, Housing and Construction Committee, and so on.

In this file, the role of Guangzhou Land Resources and Urban Planning Committee is defined as “the main actor who is responsible for the improvement of sponge city plan, as well as relevant plan and policy, for instance, master plan, detailed plan and greening plan; a coordinator who negotiates the interests from different administrations; a regular who sets the zoning index to guarantee the realization of the notions in sponge city programme; and manager who inspects the final implementation of sponge city projects (Guangzhou Government 2017, P 120) .” By this, spatial planning formally steps into the arena in dealing with flood risk. Although it could be criticised that most descriptions are related to the administrators, those statements are still promising to bring new changes for future spatial planning industry and attract other relevant actors involved in the spatial planning process, such as research institutions and private companies.

6.4 REFLECTION IN PRACTICE

Since the official document of SCP (Guangzhou Government 2017) is such a new plan which has just been launched in 2017, there is no practice operated in the full sense of this special plan. However, we still succeed in interviewing the policy makers of SCP. In this session, 5 experts involved in the plan making

are invited to the interviews, which achieved 3 positive response. It established the willingness of participation in the routines towards a resilient city in terms of their past experience. We followed a guideline with two main questions: Is there any problems arise in the plan making process? And what obstacles might weaken the willingness of relevant actors in participating in the sponge city projects in the coming future?

A spatial planner with the background of ecology and landscape architecture shared her experience on the dilemmas arising in the plan making process and showed the concerns of her role in the future projects:

“The arguments, I mean so many disagreements arose in the planning making process. But the problems concentrated on the seesaw game between nature-based infrastructure and engineering-based infrastructure. On one hand, the experts in the field of water management criticised the unrealistic expectation on the application of nature-based options in the city centre, which is the most vulnerable area while with insufficient space for green space. On the other hand, the experts in the field of landscape planning, with rich experience in low impact development (LID) and green infrastructure (GI), stroke back their opponents using the same cases in city centre by emphasizing the inadequate capacity to drainage rainfalls in the context of climate change even if there existed discharging system... Such conflicts are obvious especially in the initial stage of plan making when the green infrastructure is appointed with a relatively high preference.”

“For me, a representative of spatial planners is a little embarrassed. We didn’t have so much experience in practice concerning technics in water management and LID, which makes us difficulty in voicing our thoughts. Although we are regarded a leader in this planning process, in most cases, we act more likely as a negotiator. This lack of specific knowledge might hinder my future involvement.”

Another spatial planner who majors in water discharging system shared a similar idea on the disagreements between different professions and reframed current dilemmas into two necessities for future work: to raise the awareness of knowledge and to build the platform for mutual understanding and information sharing. In his opinion, resolving flood risk is an issue needed the support from numerous professions. However, the weak awareness of their own contribution and the way of cooperation among potential actors may hinder the collaborative activities in the future.

“It is not a main focus in the traditional spatial planning system. Without sufficient preparation, I mean the knowledge, spatial planners will be reluctant to consider it in following plans and practise. Even the Sponge city plan will be finally launched in the future, it makes no difference because people don’t know how to apply the notions in Sponge City Plan in the real projects. A similar situation might also occur among other potential actors and hinders their involvement in spatial activities.

Currently, it is more significant to build a platform to promote the information sharing and enhance mutual understanding, rather than narrow our eyes on some flagship projects. They are the fundamental ways to solve the unawareness of knowledge.”

An administrator from Water Affairs Bureau proposed another interesting idea on the willingness of participation. In her opinion, the emerging sponge city plan is still like a strategy, with limited enforcement. Only if the different options can be transferred into the specific index and written in zoning plan, then the notions in sponge city could be realised smoothly. As she proposed, “One of the potential work that can be done is to regulate the portion of green space for water retention and detention or the percentage of runoff that can be drained into urban discharge system for every piece of land.” By this, the preference to plan enforcement is more emphasised than the spontaneous willingness of different participants.

7 DISCUSSION AND CONCLUSION

7.1 CURRENT ACHIEVEMENTS

Sponge City Plan (Guangzhou Government 2017) can be regarded as a plan brings flood risk in the arena of spatial planning formally. Compared with the MP1 (Guangzhou Government 2005) and MP2 (Guangzhou Government 2016), it is a big step for local authorities. It builds a new perspective to see this natural hazard, portray a new vision for an attractive, liveable and resilient city, set a more comprehensive routines to resolve problems and calls on the collaborative relationship in planning practice. As a new start, it will bring many changes.

On one hand, it seems the notion of dealing with flood risk is changing from a natural hazard framing to an opportunity framing. In previous experience, building dykes as strong as possible to defend the water and discharging water as soon as possible were highly praised. However, the nature-based infrastructure is now given more attention. Beneath this notion, lots of flagship water retention and detention projects, such as constructing wetlands, lakes, green-blue corridors at the large scale and altering paving into green in the small scale, will be claimed under the umbrella of sponge city programmes in the following years. In contrast to keeping feet dry, Sponge City Plan opens the door living with and bearing the excessive water in a relative safety range.

On the other hand, the combination of risk with other related issues, such as water pollution and waterfront recreation, show a clue in shaping mainstreaming adaptation measures and policies in the near future. It provides the opportunities to incorporate flood risk into existing other water issues and parcel it with other projects, for instance, building a piece of wetland for recreation by using brownfields, meanwhile, creating a micro water purifying and storage system. By this, the developed programs are conducted concerned with both short-term environmental benefits now and long-term climate risks in the future. Thus, flood-proof initiatives are gradually transferred from a separate concern to an integrated and multi-objective process.

7.2 CHALLENGES FOR FUTURE SPATIAL DEVELOPMENT

However, such discourse and intent cannot respond to all the concerns left before. For instance, there is no discussion about the broadcast of disease caused by mosquitos bred by water retention and detention areas. There is also a lack of methods to raise the awareness of specific knowledge and enhance the information sharing. Those missing pieces might leave the weak points which hinder the implementation of the proposed options in the near future.

In addition, there will always be a delay between the launch of a plan statement and the acceptance of this statement, let alone the implementation of the principles, options. Based on that premise, although Sponge City Plan (Guangzhou Government 2017) tries to clarify the responsibility of different actors and build a collaborative circumstance, in the near future, the actors involved in flood-proof initiatives will still be bothered with the difficulty in communicating with different institutions at practice.

1 INTRODUCTION

The loess plateau region in northern Shaanxi province in China is characterized by loess hilly and gully, fragile ecological environment, scarcity of land resources. The delimitation of space growth boundary is critical to the intensive use of land resources and the compact development of space. How to delimit the compact space growth boundary becomes the focus of attention and research.

The urban space growth boundary is one of the earliest urban land management policy tools adopted by the United States under the new urbanism in the West. The concept was presented in 1976 by Salem, Oregon, USA [1]. Its goal is to curb the social, economic and environmental problems brought about by the spread of the city. Urban space growth boundary is not to curb the development of the city, but through the space boundary to limit the development of the city in a clear geographical space. Thus, city's disorder expansion is blocked while meeting the needs of urban development [2]. Once the urban space growth boundary has been put forward, it has become one of the hotspots of urban planning. Many scholars at home and abroad are committed to many aspects of practice and research, such as the concept of its connotation and impact analysis, the formation of mechanism analysis, delineation methods and related management strategies, application in planning [3-7]. In the traditional urban space growth boundary delimitation method, mainly in static analysis, dynamic simulation of two types of methods, the specific technical means, including ecological suitability evaluation, binding CA model, BP neural network, SLEUTH model [8-10]. In the planning practice, planners often use the urban ecological suitability evaluation, and then take the empirical value to delimit the urban space growth boundary. And also some scholars have made a reference to the overall planning of urban construction land to determine the scope, that is, plus 25% of the floating rate on the scale of the construction land in master plan [11]. In general, different demarcation methods have their own strengths. But the association with the goal of urban space growth boundary is weak, which is the intensive use of land. In addition, there is a lack of adaptability research between two elements, regional natural terrain conditions and urban surrounding ecological environment factors, the urban space growth boundary and its urban space development trend adaptability, the urban space growth boundary and urban space development endogenous needs [12]. In this paper, the method of delimiting the boundary space of urban space has made a response to this problem, which is of great significance to the compact growth of urban space.

2 THE TECHNICAL ROUTE OF DELIMITING THE SPACE GROWTH BOUNDARY FROM THE PERSPECTIVE OF COMPACT DEVELOPMENT

In this paper, the technical route is divided into the following steps: boundary development constraint and power interpretation, boundary superposition simulation, boundary comparison and selection, boundary realistic development verification.

Firstly, the paper uses the ecological suitability evaluation to reflect external development constraints, and calculates the construction land area to reflect internal development needs. Secondly, by the superposition analysis of the external development constraints and internal development needs, this paper simulates to generate several possible space growth boundary lines. Thirdly, this paper calculates the fractal dimension to compare the compactness of each possible boundary line, and selects the most compact one as the space growth boundary of Mizhi County. Furthermore, its feasibility and rationality are verified combined with the construction status of Mizhi County to explore the method of delimiting the space growth boundary of Mizhi County. This method which is presented by the technical route effectively improves the compactness of the delineated urban space growth boundary. In the course of the calculation and

comparison of fractal dimension, the coincidence check with the present situation of urban construction is also added, which improves the rationality of the urban space growth boundary.

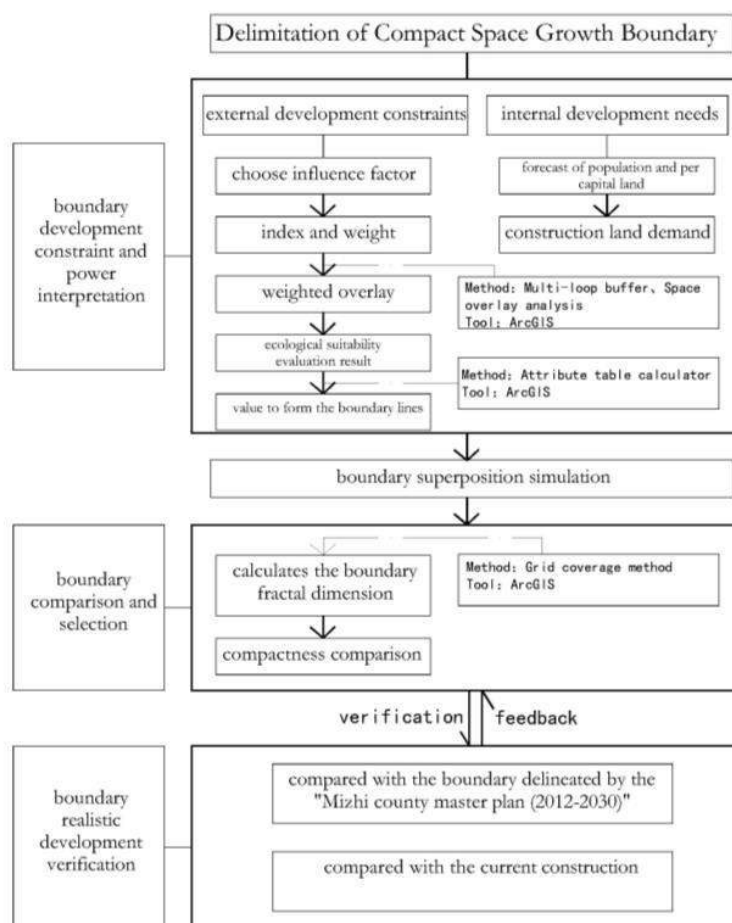

Figure 1 – Technical Route of Compact Space Growth Boundary Delimitation (Source: Author self-painted)

2.1 BOUNDARY DEVELOPMENT CONSTRAINT AND POWER INTERPRETATION

The development of urban boundary includes two aspects: external expansion constraint and internal development needs. The external expansion constraints of urban boundaries are mainly based on the evaluation of ecological suitability. First of all, it begins from the selection of influencing factors, and then carries on an evaluation of each individual factors in order to delineate the score. The more conducive to the compact development of urban space, the higher the score is. By using the ArcGIS software (Geographic Information System platform), the database of influencing factors is established. The multi-loop buffer analysis is carried out according to the evaluation score, and the influence of the single factor is given. Furthermore, by using the yaahp analytic hierarchy process software, the weight of each influencing factor is determined by expert scoring method and analytic hierarchy process (AHP). Finally, the paper uses the Rasterization and Raster Calculator function of the ArcGIS software to superimpose the single factor, and obtain the ecological suitability evaluation result. Based on the ecological suitability evaluation results, taking 0.5 as the intermittent value, the ecological suitability evaluation results are taken on the ArcGIS, and a number of space growth boundary lines can be obtained.

The urban internal development needs are measured by the total amount of land for construction based on the forecast population amount and the per capita construction land size at the end of the master plan.

2.2 BOUNDARY SUPERPOSITION SIMULATION

Through the evaluation of ecological suitability, the urban external expansion constraint is obtained. Also the urban internal development needs are obtained by calculating the total amount of construction land. The two are superimposed and simulated to generate several urban space growth boundary lines.

2.3 BOUNDARY COMPARISON AND SELECTION – CALCULATION AND COMPARISON OF FRACTAL DIMENSION

Boundary comparison and merit is based on fractal theory, and it is compared by measuring the boundary fractal dimension of each urban space growth boundary line.

The fractal dimension of the boundary expresses the complexity of the urban space growth boundary, and also reflects the stability of the patch in the urban built area. In general, the greater the boundary dimension, the more complex the urban space growth boundary is. And it also shows the crushing boundary of urban construction land, the poor stability of built area patch. The expansion of urban form is dominated by external expansion. On the contrary, the smaller the fractal dimension, the more compact the urban construction space is. In this situation, the stability of the built area is relatively good, and the expansion of urban form is mainly by the internal filling or promoting along the area [14]. Therefore, by calculating the boundary fractal dimension of each space growth boundary line, the fractal dimension of each space growth boundary line is compared, and the space growth boundary line corresponding to the minimum value of the boundary fractal dimension is taken as the spatial growth compact boundary.

In this process, the calculation and derivation of the boundary fractal dimension is as follows. Taking “L” for Length, “S” for area, “V” for volume, there is the following relationship:

$$L \propto S^{1/2} \propto V^{1/3} \quad (1-1)$$

In the boundary fractal dimension calculation of urban boundary lines, assuming that the circumference of urban boundary is “C”, the area of urban construction land is “S”, and the boundary dimension of city is “D”, then the following relationship is satisfied:

$$C/D \propto S^{1/2} \quad (1-2)$$

$$\text{That is } C \propto SD^{1/2} \quad (1-3)$$

The above formula is rewritten as a general form:

$$C = \phi S^f(D) \quad (1-4)$$

Where “ ϕ ” is the proportionality constant. If the graph is a square, then constant “ ϕ ” = 4. “ $f(D)$ ” is a function related to the fractal dimension. On both sides with the logarithm, the following formula can be obtained:

$$\ln(C) = \ln(\phi) + f(D)\ln(S) \quad (1-5)$$

Obviously, $f(D) = D/2$, so

$$D = 2(\ln(C) - \ln(\phi)) / \ln(S) \quad (1-6) \quad [15]$$

2.4 BOUNDARY REALISTIC DEVELOPMENT VERIFICATION – VERIFICATION OF SPACE COMPACT BOUNDARY COMPACTNESS

By selecting compact evaluation factors, developing compact factor evaluation criteria, compact fractal comparison, etc., the paper selects a relatively compact urban space growth boundary. The compactness of the border needs to be further validated, including comparisons with the current master plan and current situation of urban land use.

Firstly, the compact space growth boundary is compared with the space growth boundary delineated by the urban master plan. The boundary fractal dimension of the two is measured and compared so as to reflect the compactness of it.

Moreover, the compact space growth boundary is compared with the urban construction land, and the adaptability to the development of urban construction is tested.

3 COMPACT SPACE GROWTH BOUNDARY DELINEATION PRACTICE

3.1 BOUNDARY DEVELOPMENT CONSTRAINT AND POWER INTERPRETATION

3.1.1 EXTERNAL EXPANSION CONSTRAINT – EVALUATION OF ECOLOGICAL SUITABILITY

(1) DETERMINATION OF INFLUENCING FACTORS

The choice of evaluation factors is one of the core problems in the evaluation of ecological suitability of urban land use. The more comprehensive the selected data, the more clear the evaluation target and the more accurate the conclusion is. In view of the difference between the connotation attribute of the urban space growth boundary and the definition of the concept in the traditional planning, the evaluation factor selection process should reflect the combination of the development demand and the ecological suitability, the combination of control and guidance functional properties, and the combination of rigidity and elasticity of the morphological properties [13]. In general, the choice of evaluation factors should reflect the compact characteristics. Evaluation factors should be closely related to land use conditions and ecological environment, and at the same time can have a direct effect on urban development. In the selection of factors should follow the systematic principle, comprehensive principle, dominant principle, operability principle. At the same time, combined with the actual environment and the construction of the city, the ecological environment factors influencing the urban space expansion are analyzed. The evaluation factor intuitively reflects the appropriate construction level of the land, and plays a significant role in the choice of urban land. The influence factors selected in the study can be divided into four categories:

1. Traffic suitability category, including national road, highway, city main road, passenger station, railway;
2. Environmental suitability categories, including rivers, historical units, basic farmland, flood control lines;
3. Urban atmosphere categories, mainly refers to the impact of urban built-up area;
4. Terrain suitability categories, including elevation, slope, slope direction factor.

In this paper, the treatment of these factors is in the construction of the impact factor in the evaluation of the results, excluding the scope of the ban on the construction factors.

In addition, combined with the status of Mizhi county, the single factor for the classification, from high to low were divided into 5,4,3,2,1 five grades. The higher the level, the characterization of the scope of the factors more suitable for the construction are. Taking the grade 5 of the slope factor as an example, it represents the terrain slope in the range of 0-8 degrees. The scope of the land is flat within this area. And it is more suitable for construction relative to other areas (Table 1). In the same way, the paper divides the classification for other factors, including elevation factors, slope factor, river factor, national highway factor, highway factor, urban road primary and secondary factors, passenger station factor, urban built area factor.

Evaluation Factor	Classification	Graded
Slope	0-8 Degree	5
	8-15 Degree	4
	15-25 Degree	3
	25-40 Degree	2
	>40 Degree	1

Table 1 - Slope Factor Evaluation Grading (Source: Author self-painted)

(2) DETERMINATION OF THE WEIGHTS OF THE INFLUENCING FACTORS

Firstly, the paper decomposes each single factor, and scores each factor according to whether it is suitable for urban construction. From the very suitable to unsuitable for construction scores from high to low, that the most suitable for the construction gets 5 points, unsuitable for the construction gets 1 point.

And then the paper puts the results of scoring into the Analytic Hierarchy Process (AHP) to judge the relative importance of each factor, so as to form a matrix to calculate the weight of each single factor. The general steps are as follows.

1. First of all, progressive structure is established according to the attributes of the factors.
2. The paper establishes a judgment matrix, and compares the importance between every two factors. The ecological suitability of urban land use is the criterion C, and the next level of which is dominated by terrain, landform and river system is u_1 , u_2 , u_3 . For criterion C, according to the importance of u_1 , u_2 , it is assigned values of points 1-5. Through this step, it establishes the judgments matrix of every two factors:

$$A = (a_{ij})_{m \times n} \quad (i=1, 2, \dots, m, \quad j=1, 2, \dots, n)$$

Where a_{ij} represents the score represented by the importance of u_i and u_j relative to C.

3. And then the paper uses the root method to calculate the weight of each factor. Let the weights of the factors u_1 , u_2 ... u_n be w_1 , w_2 ... w_n , for the criterion C. The vector of the columns in A is geometrically averaged and then normalized, and the resulting column vector is the weight of its factor [14]. (Table 2)

Factor Classification	Factor Name	Factor Weight
Terrain Suitability	Elevation	0.0487
	Slope	0.2448
	Aspect	0.0445
Environmental Suitability	River	0.0447
Traffic Suitability	State Road	0.1332
	Highway	0.1120
	City Main Road	0.0938
	City Secondary Road	0.0555
	Passenger Station	0.0500
City Atmosphere	Status Quo Built Area	0.1728

Table 2 - Evaluation of the Impact Factor Weights in Evaluation System (Source: Author self-painted)

(3) WEIGHTED SUPERPOSITION OF INFLUENCE FACTORS

In the ArcGIS software, the weight of each factor is substituted into the vectorized base diagram. According to the different scores, the ecological suitability distribution of each factor is obtained. Finally, the weights of the selected factors are all superimposed on the evaluation base map, and the weight of each factor is summed according to the final evaluation of ecological suitability of urban land (Figure 2).

According to the results obtained by weight superposition method, the evaluation criteria and the evaluation values of urban land in different areas obtained by weight superposition method were used to divide the urban construction land according to the evaluation value. The higher the value of urban land, the more suitable for urban construction is. On the contrary, where the evaluation value is lower, it plays a more important role in the city's ecological security and the natural environment protection.

(4) THE FORMATION OF SPACE GROWTH BOUNDARY LINE

In the ArcGIS, taking 0.5 as the interval value, the paper gets seven boundary lines of which the score are 1.0, 1.5, 2.0, 2.5, 3.0, 3.5, 4.0. The two sides of each boundary line show different colors (Figure 3). Among them, the outermost line scores of 1.0 which is the Mizhi county's space growth boundary (UGB). And that is the largest area of construction of the city. On this basis, the paper further seeks the delineation of the compact boundary of Mizhi County. By introducing the fractal theory, the fractal dimension of the boundary line of different scoring land is calculated. The smaller the fractal dimension, the more compact the corresponding boundary line.

Figure 2 - Ecological Suitability Assessment Results
(Source: Author self-painted)

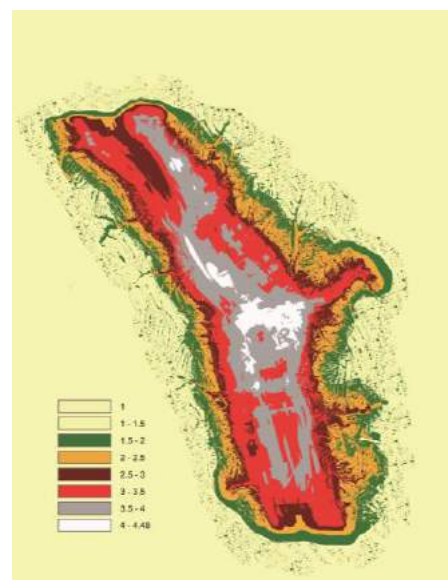

Figure 3 - Spatial Growth Boundary Line
(Source: Author self-painted)

3.1.2 INTERNAL DEVELOPMENT NEEDS – FORECAST OF TOTAL CONSTRUCTION LAND SIZE

In the "Mizhi county master plan (2014-2030)", it has forecasted population size and per capita construction land size at the end of the plan, so as to estimate the total internal development need of the city. The master plan has determined that the population size of Mizhi county in 2030 controls in 10 million, and per capita urban construction land size of 99.4 square meters. Therefore, the construction land should control in 9.94 square kilometers.

3.2 SPACE GROWTH BOUNDARY SIMULATION

Based on the external expansion constraints and internal development needs of Mizhi County, it can be found that the construction area inside the growth boundary line 4.0 and line 3.5 are respectively 0.74km² and 4.99km². The construction area inside these two boundary lines are less than the total forecast of the construction land demand of 9.94km². So it should be excluded (Table 3).

Evaluation of Land Suitability	4.0	3.5	3.0	2.5
Land Area (km ²)	0.74	4.99	10.81	14.18
Evaluation of Land Suitability	2.0	1.5	1.0	
Land Area (km ²)	18.32	22.71	34.33	

Table 3 - Land Area Statistics for Each Land Boundary Line (Source: Author self-painted)

3.3 SPATIAL GROWTH COMPACT BOUNDARY ESTIMATION AND COMPARISON

Firstly, the boundary fractal dimension of the five boundary lines screened left behind is calculated and compared. Then the degree of compactness of each boundary is compared through the boundary fractal dimension. The smaller the fractal dimension, the more compact the land boundary line.

3.3.1 BOUNDARY FRACTAL DIMENSION CALCULATION OF SPACE GROWTH BOUNDARY

For the boundary fractal dimension calculation of each boundary line, it is necessary to establish a square grid with a side length of 50,100,150,200,250,300,350,400,450,500 meters. The boundary line and the square grid are superimposed separately in the ArcGIS software, and counts the number of square grid coinciding with the space growth boundary lines. And then logarithmic operations are carried on the grid side length, the boundary line of the grid number. After that, the two sets of logarithmic values are plotted and fitted in a straight line in Excel. The absolute value of the coefficients of x in the final fitting equation is the boundary fractal dimension value corresponding to the space growth boundary.

In this case, the space growth boundary line with the ecological suitability evaluation value of 2.5 is taken as an example, and the boundary line is superimposed on the square grids (Table 4).

Grid Side Length (n)	0	100	150	200	250	300	350	400	450	500
Number of Grids (m)	1069	441	276	186	151	119	100	80	71	64
ln(n)	3.9120	4.6051	5.0106	5.2983	5.5214	5.7037	5.8579	5.9914	6.1092	6.2146
ln(m)	6.9744	6.0890	5.6204	5.2257	5.0172	4.7791	4.6051	4.3820	4.2626	4.3820

Table 4 - Boundary Dimension Calculation Table for the Boundary Line of the Ecological Suitability Evaluation Value of 2.5 (Source: Author self-painted)

In Excel, the two sets of logarithmic values are plotted (Figure 4), and fitted linearly to produce a linear equation $y = -1.1861x + 11.565$, $R^2 = 0.9926$. It can be seen that $R^2 > 0.9$, indicating that the degree of fitting is high, the boundary line shows fractal characteristics, and the fractal dimension of its boundary corresponds to the absolute value of the x front coefficient, that is 1.1861.

Figure 4 - Boundary Dimension Linear Fitting of Boundary Line with Ecological Suitability Evaluation Value of 2.5 (Source: Author self-painted)

3.3.2 COMPARISON OF BOUNDARY FRACTAL DIMENSION

Similarly, the same method is used to calculate the boundary fractal dimension of the remaining four space growth boundary lines. The final calculation results are obtained in the following table (Table 5).

Ecological Suitability Evaluation Score	3.0	2.5	2.0	1.5	1.0
Boundary Fractal Dimension	1.178	1.186	1.171	1.176	1.183

Table 5 - Fractal Dimension Values of Each Boundary Line (Source: Author self-painted)

The minimal boundary fractal dimension of the five boundary lines can be found to be 1.171, which is correspond to the boundary line with the ecological suitability evaluation score of 2.0. This boundary line is the most compact and intensive of the five boundary lines, which is the compact space growth boundary line of Mizhi county.

3.4 VERIFICATION OF THE COMPACT SPACE GROWTH BOUNDARY

On the basis of the above results, the compact space growth boundary line with the ecological suitability evaluation score of 2.0 is compared with the current construction of Mizhi county. We can find that the current construction is basically included in the compact space growth boundary (Figure 5). It shows that there is a certain realistic feasibility for the compact space growth boundary line of Mizhi county.

Then, the compact space growth boundary and the boundary delineated by the "Mizhi county master plan (2012-2030)" are used to calculate the boundary fractal dimension, so as to discern the compactness of the compact boundary (Table 6). The results show that the boundary fractal dimension curve of the boundary delineated by the "Mizhi county master plan (2012-2030)" is $y = -1.1895x + 10.764$, and the fitting coefficient $R^2 = 0.9988$. So the boundary fractal dimension is 1.1895. It can be found that the fractal dimension of the compact space growth boundary of Mizi county is 1.171, which is minor than 1.1895. This shows that the selected Mizhi County space growth boundary is relatively more compact.

	Mizhi County Compact Space Growth Boundary	Mizhi County Master Plan (2014) Space Growth Boundary
Space Growth Boundary Form		
Linear Fitting Equation	$y = -1.1713x + 11.595$ $R^2 = 0.9959$	$y = -1.1895x + 10.764$ $R^2 = 0.9988$
Fractal Dimension	1.1762	1.1895

Table 6 - Comparison of the Compactness of the Space Growth Margin of the Mizhi County (Source: Author self-painted)

4 CONCLUSION

With the continuous development of the city and the advancement of the urbanization process, delimiting the urban space growth boundary and setting the scope of urban development is an effective means to curb the random expansion of the city and realize the compact development of the city.

Based on the study of the existing urban space growth boundary delimitation method, this paper takes the Mizi county as the research case, and simulates the urban space growth boundary through the ecological suitability evaluation, and calculates the boundary fractal dimension to the space growth boundary lines. At

last, it selects the most compact space growth boundary. At the same time, combined with the status quo of urban construction, the paper verifies its feasibility and rationality.

It is important to emphasize that the ultimate goal of urban space growth boundary delineation is to achieve the sustainable development of the city. The compact development should be based on the necessity of "harmonious relationship between human and nature" idea. The ecological suitability evaluation and the real development check are the responses to it. It still needs to be further studied to join the urban economic and social development considerations in the delimitation of urban space growth boundary.

fmagni@iuav.it

1 CLIMATE CHANGE AND COASTAL AREAS: AN OVERVIEW OF THE MAIN IMPACTS

Coastal areas are commonly the geographical space of transition between land and sea, comprising of the land near the coast and the adjacent territorial waters. These areas include diverse systems such as delta environments, humid areas, lagoons, small islands, low-lying coastal plains, sandy beaches and sedimentary coasts. The borders of a coastal area are often defined arbitrarily and can be divided up among nations. Due to their own nature, these areas are intrinsically dynamic systems characterised by interacting morphological, ecological and socio-economical processes. Some of the characteristics that set them apart from all other systems (IPCC, 2007d, 2013, 2014) can be summed up as:

- high rate of dynamic change in the natural environment;
- high diversity and biological productivity;
- high rate of human population growth and economic development;
- high rate of degradation of natural resources;
- high exposure to extreme events
- strong need of management systems that consider both terrestrial and marine problems.

Thanks to these characteristics, coastal areas provide resources and suitable space for economic activities and human settlements, leading to a high rate of population concentration. It is estimated that, on a global level, 50-70% of the human population currently lives in coastal areas. The international scientific world appears to agree on the fact that coastal areas will be particularly affected by rising sea levels and by temperature and precipitation changes as well as by possible variations in the frequency, distribution and intensity of extreme events such as tornadoes and storms. Climate change will however have different characteristics depending on the region and the impact on the different coastal areas will vary from region to region according to environmental, social, cultural and economic characteristics.

The Mediterranean basin is widely recognised as particularly vulnerable to climate change (Hoozemans et al., 1993; Nicholls et al., 1996, Klein and Nicholls, 1998). Most of the current stressful elements linked to the effect of human pressures will be inevitably exacerbated by climate change. As a general rule, the most serious effects will be felt by the coastal systems already under stress and where human activity diminished the natural capabilities of adaptation. Only a relatively limited number of studies analysed the vulnerability of the Mediterranean basin in light of climate and sea level change. As a consequence, these problems have been rarely considered by coastal planning and management processes. In these contexts, there are in fact no universally applicable methods to assess the impact of future climate change and the relative identification of vulnerabilities (Gorgas, 1999).

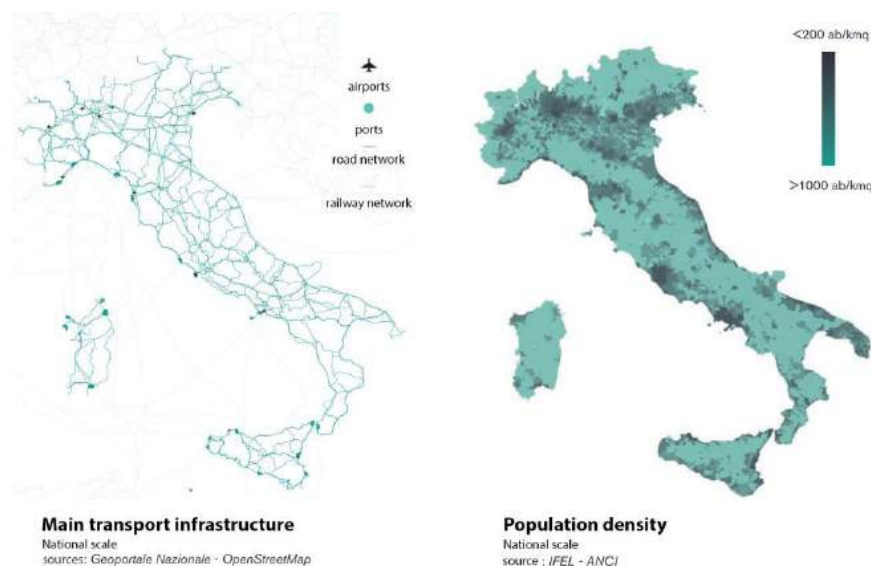

Italy has always been at the centre of the Mediterranean, not only on a geographical level - it has developed a unique coastal complexity that forces those in charge of territorial management and planning to make profound and thorough considerations. Of the 6,477 kilometres of coastline between Ventimiglia and Trieste and of the two largest islands (without therefore considering the numerous smaller islands): 3,291 kilometres have been transformed in an irreversible manner. More specifically, 719.4 kilometres are now occupied by industries, ports and infrastructures and 918,3 have been colonised by urban areas. Another worrying data is the diffusion of low-density settlements, which cover 1,653.3 kilometres, i.e. 25% of the entire coastline. One third of beaches is affected by increasing erosion, the marine habitat is constantly put to the test by pollution, as 25% of city sewage is still unsanitized (40% in some areas) (Zanchini et al. 2016). The Rapporto Ambiente Italia (Italy Environmental Report) paints a picture of these impacts with alarming data and studies that show how to address this situation through a change in policy. The challenge climate change is posing on Mediterranean coastal areas, with significant impact on the

ecosystems, coastline and urban areas, must lead to a new and more incisive vision of the interventions to perform.

2 COAST VULNERABILITY: METHODOLOGY FOR SELECTION OF PILOT AREAS IN THE ITALIAN CONTEXT

The scientific consensus is that even if greenhouse gases were to be eliminated completely today, the air and sea temperatures would continue to rise due to past emissions (greenhouse gases have a lifespan of between 10 and thousands of years). The warming of the air and sea would lead to changes in precipitation, higher sea levels and more extreme weather events. According to Klein and Nicholls (1998) the six more important biogeophysical impacts induced by climate changes on coastal zones are: erosion and sediment deficit, increased flood frequency, inundation of low-lying areas, rising of water tables, saltwater intrusion and consequent biological effects. Due to their significant socio-economic implications, inundation and increased flood frequency will be treated in the socio-economic impacts section, rather than in the biogeophysical impacts one. The enhancement of the desertification process and the related soil degradation is another relevant impact which is already an environmental stress of concern for various Mediterranean regions. These effects, which are already affecting the Italian coastal areas and ecosystems, and the protections to take over the next decades paint a picture of the coastal impact on a national level and enable the identification of intervention areas on which to focus.

For the purposes of this research, we initially collected public data concerning geomorphology, settlements and infrastructures, economy, environment and the climate. Geomorphological data were taken from the Sistemi Informativi Ambientali (ISPRA) database, in particular, a national digital terrain model was used (DEM - 20 metre cells - National Geoportal) to reconstruct the orographic configuration of the Italian national territory. As regards the geological part, we used the geology map for Italy supplied by the Servizio Geologico d'Italia (ISPRA), which reports all geological and lithological characteristics of the Italian soil. This was done to distinguish the areas with alluvial/detrital soil from those with rocky/solid soil. Demographical, infrastructural and economic information was collected from multiple sources to reconstruct a reliable framework. For urban areas (settlements of various kinds, distribution of production macro-areas and population density), we used the database supplied by the IFEL-ANCI organisations. In particular, we took data concerning the localisation of urbanised areas, with specific attention to their population density. Secondly, to identify the economic weight of the settlements, we focused on mapping the economic-productive activities classifying them according to the primary, secondary and tertiary sectors. Transport infrastructures were mapped using two different databases, an open source one and a Ministerial one. The motorway network was taken from the OpenStreetMap database, while the railway network, airports and ports were identified thanks to the database supplied by the National Geoportal.

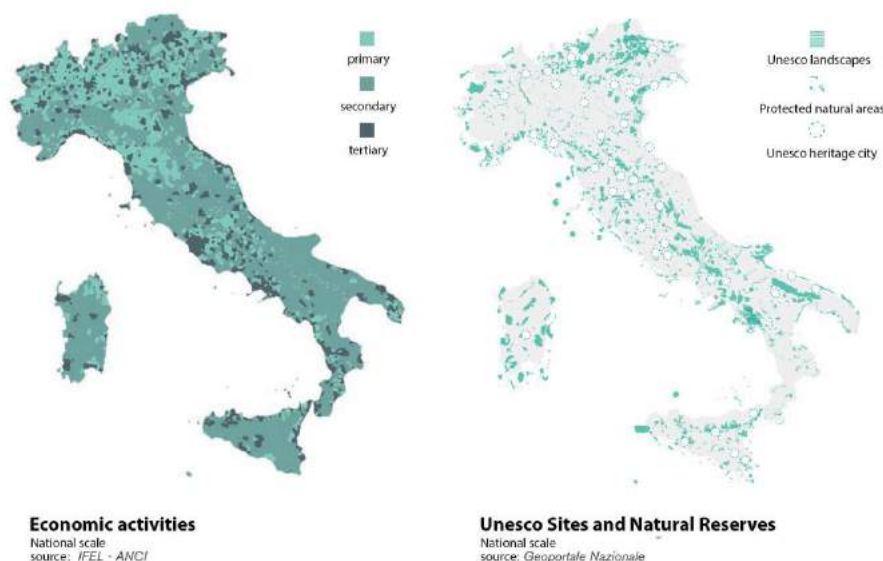

Figure 1 | National map of the main elements exposed to the impacts of climate change.
Processing by Magnabosco G. 2016

The climate question was tackled using multiple data and databases. The first macro-mapping of Italian climate areas was based on the Köppen climate classification scheme, then the factors specific to the Italian climate were analysed in depth: average sunlight (European Commission Joint Research Centre); annual average wind speed (European Commission Joint Research Centre); rainfall (Pluviometria Media Annua - SISEF) and sea currents (Carta delle Correnti Marine - Istituto Idrografico della Marina).

For the topics relating to the variables characterising existing and future problems on a national level, we used various databases and, in some cases, a re-processing of the data presented in said databases. As regards hydrogeological instability, we mapped the data supplied by the National Geoportal. Specifically, for what concerns inundations and flooding, we took into consideration the national data on these phenomena with return periods of 200 years. To these areas, we added the territories subjected to mechanical drainage (considering ENEA projections on the increase of extreme phenomena). As regards landslides, we consulted the Catalogo Frane IFFI (Landslide catalogue - Inventario Fenomeni Franosì Italia supplied by ISPRA) while, for droughts, we referred to the Atlante nazionale delle aree a rischio di desertificazione (National atlas of areas at risk of desertification) supplied by ISPRA and interpolated it with climate shift dynamics, which see the shifting of the interested areas towards higher latitudes.

The data on average sea rise and saltwater intrusion were taken from the Digital Terrain Model. The reports supplied by the IPCC and ENEA, suggesting an average value of +1 metre a.s.l., enabled the identification of the areas which will be affected by rising sea levels. Saltwater intrusion, which is a local dynamic not yet supported by an exhaustive national detection and mapping method, required approximation, calculated using a method similar to the one used for sea level rise. Only the land between 0 and 2 metres above sea level was considered. Finally, coastal erosion was identified using the data supplied by the EUROSION dataset.

2.1 METHOD TO IDENTIFY TARGET AREAS

The identification of target areas on which to focus analyses and governance actions was carried out by recognising and overlapping the drivers mentioned above according to a procedure divided into three steps:

STEP_1

A first selection was carried out by delimiting all the assets and forcings as far as 20 km from the coastline. Then we calculated the quantity of allocated assets (anthropogenic, productive, urban and infrastructural settlements) exposed to weather elements and assigned a number where the allocated asset is exposed

to one of the elements. We then moved on to a recapping of the previous results to identify which areas/networks/soils are affected by most forcings and classified various degrees of exposure.

Starting from this consideration, we proceeded with cataloguing a series of factors to identify the areas with characteristics in common in addition to the exposure factor. The different areas were classified according to their particular geological (soil composition), morphological (sea level and ground roughness), climate (climate classification) and settlement (average population density, forma urbis, transport network distribution) parameters.

Figure 2 | Mapping of the coastal risk in Italy. Processing by Magnabosco G. 2016

STEP_2

Starting from this consideration, we proceeded with cataloguing a series of factors to identify the areas with characteristics in common in addition to the exposure factor. The different areas were classified according to their particular geological (soil composition), morphological (sea level and ground roughness),

climate (climate classification) and settlement (average population density, forma urbis, transport network distribution) parameters.

STEP_3

We then proceeded to identify the areas that shared the conditions which emerged in step_1 and step_2, which enabled their classification according to exposure, anthropization, climate and geo-morphological conditions. 6 TARGET AREAS representative of the entire national coastal territory were categorised.

AREA TARGET 1: VENETO.

SETTLEMENTS:
 - character: diffused
 - density: medium-high
 COASTAL AREA LOW:
 - alluvial soils
 - presence of areas below sea level
 - no relief
 MAIN IMPACTS:
 - floods: settlements / networks - low alluvial soils
 - s.l.r.: Settlements / networks - low alluvial soils
 - i.c.s.: Low alluvial soils

AREA TARGET 2: TUSCANY

SETTLEMENTS:
 - character: concentrated
 - density: medium
 COASTAL AREA LOW + HIGH:
 - alluvial and rocky soils
 - presence of medium relief
 MAIN IMPACTS:
 - floods: settlements / networks - low alluvial soils
 - landslides: settlements / networks - high rocky areas
 - s.l.r.: Settlements / networks - low alluvial areas
 - i.c.s.: Low alluvial soils
 - desertification: low

AREA TARGET 3: LAZIO.

SETTLEMENTS:
 - character: concentrated
 - density: high
 COASTAL AREA LOW:
 - alluvial and rocky soils
 - presence of areas below sea level
 - presence of high relief
 MAIN IMPACTS:
 - floods: settlements / networks - low alluvial soils
 - landslides: settlements / networks - high rocky areas
 - s.l.r.: Settlements / networks - low alluvial areas
 - i.c.s.: Low alluvial soils
 - desertification: medium

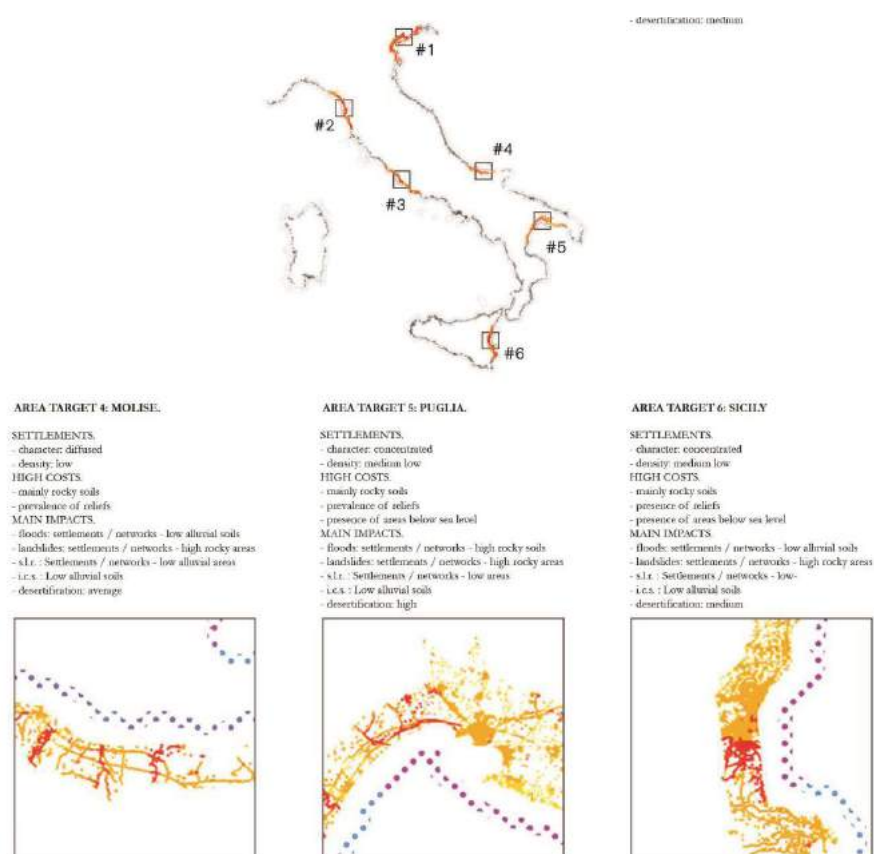

Figure 3 - Selection of target areas. Processing by Magnabosco G. 2016

2.2 2.1 IDENTIFICATION OF SOCIO-ECONOMIC IMPACTS ON TARGET AREAS

Socio-economic implications of sea level rise and climate change on coastal zones are mainly linked to the increase in the risks of flooding of human settlements, goods, infrastructure and services and to the loss of coastal land and habitats due to inundation of low-lying areas (Klein and Nicholls, 1998; Sterr and Klein, 1999). Other socio-economic impacts are those directly affecting important economic activities, such as coastal agriculture, fishery and tourism or those concerning water availability and human health (table 1)

Sector	Biogeophysical Effect					
	Flood Frequency	Erosion	Inundation	Rising Water Tables	Salt Intrusion	Desertification
Water Resources				■	■	■
Agriculture	■		■	■	■	
Human Health	■		■			■
Fisheries	■	■	■		■	■
Tourism	■	■	■			■
Human Settlements	■	■	■	■

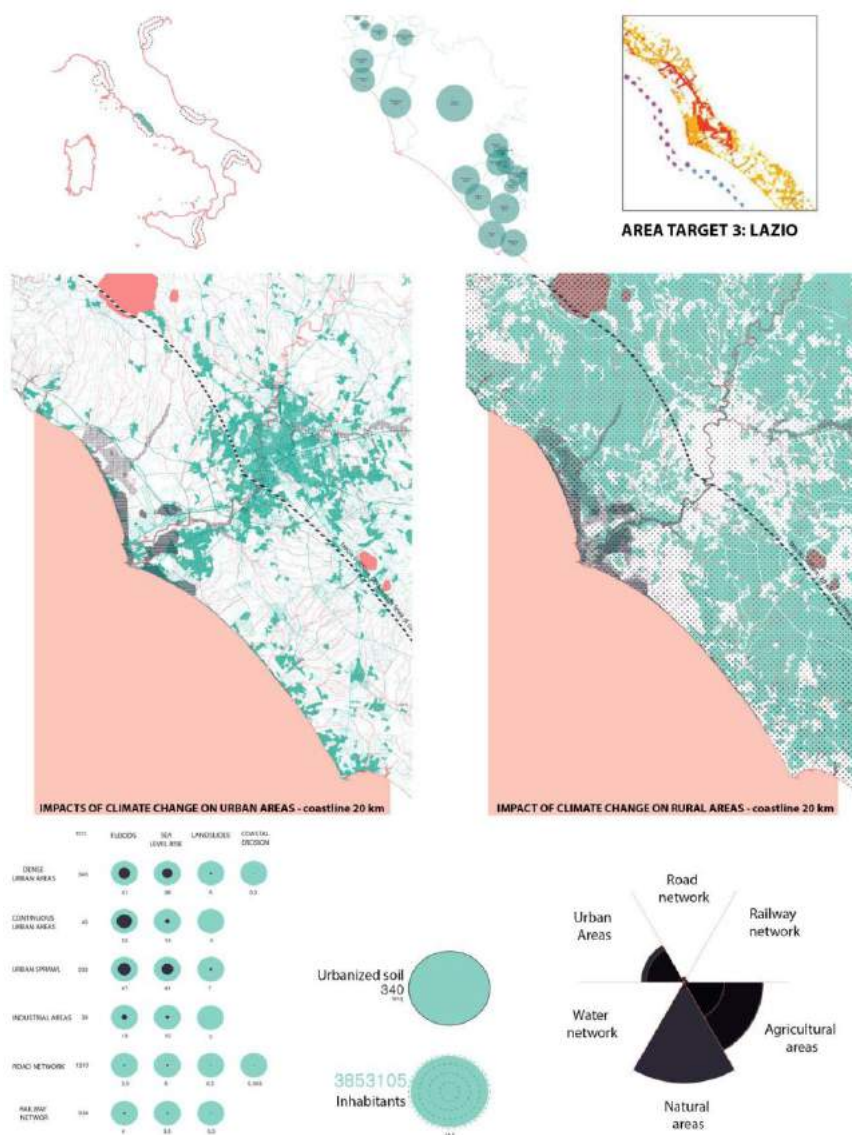

Figure 4 - Example of Climate change impacts on target area 3: Lazio. Processing by Magnabosco G. 2016

3 ADAPTATION AND COASTAL MANAGEMENT

Vulnerability (and related concepts) is specific to a given location, sector or group and depends on its ecological and socio-economic characteristics (Hinkel and Klein, 2007). Moreover, it is dynamic because sensitivity, exposure and adaptation capacity vary over time, stimulate and depend on various political, social, economic, ecological and technological aspects (ETC-ACC, 2010b). In this perspective, vulnerability assessments require different tools for different Space and Time, in different regions and for different purposes (ETC-ACC, 2010b). Considering the complexity of coastal zone dynamics and the long-term implications of climate change, coastal policy and management requires new large-scale integrated assessment and management tools in a wide range of scales: local, national (or regional), National and European. Assessments in each of these scales provide useful information for coastal zone management and if studies are consistent across all scales, they can result in nested results, maximizing their use for policy purposes. A more detailed approach at local and regional level is essential to understanding and managing the complexities of a specific area of study and to identifying more specific vulnerable areas and sectors that could support decision-making in designing appropriate adaptation strategies (Torresan Et al., 2008). Another important aspect to consider is the time scale involved in the processes and dynamics of coastal areas, which may, for example, vary from day to day for stormy waves, from days to years for tide ranges and for decades to decades Millennia in the case of vertical regions regional movements.

Sustainable management of coastal areas in Europe is strongly dependent on the success of an integrated climate adjustment and other changes that take account of and promote the capacity for adaptation of the system. The realistic assessment of adaptation options requires detailed analysis to capture the potential variation of responses within a region for a certain period of time rather than assume a uniform adaptation response (Nicholls and Klein, 2005). The need to adapt to climate change is evident and in coastal areas this need is greater and will continue for centuries considering long-term coastal challenges such as rising sea levels.

Integrated Coastal Zone Management is recognized as the most appropriate process for addressing climate change, sea level rise and other current and long-term coastal challenges (Nicholls et al., 2007; Nicholls and Klein, 2005). Proactive adaptation to climate change aims to reduce the vulnerability of a system by minimizing the risk and / or increasing the resilience of the system. Nicholls and Klein (2005) identified five proactive adaptation objectives for coastal areas: increasing the robustness of infrastructure designs and long-term investments; Increase the flexibility of vulnerable managed systems; Improve adaptability of vulnerable natural systems; Reverse Maladaptive Trends; And improve the company's awareness and preparation. Coastal adaptation is a complex and iterative process and for coastal areas there is another classification of three key adaptation strategies that are often used:

- Protect - to reduce the risk of the event by decreasing the likelihood of its occurrence;
- Accommodate - to increase the company's ability to cope with the effects of the events;
- Retreat - to reduce the risk of the event by limiting its potential effects (Smit et al., 2001; Nicholls and Klein, 2005).

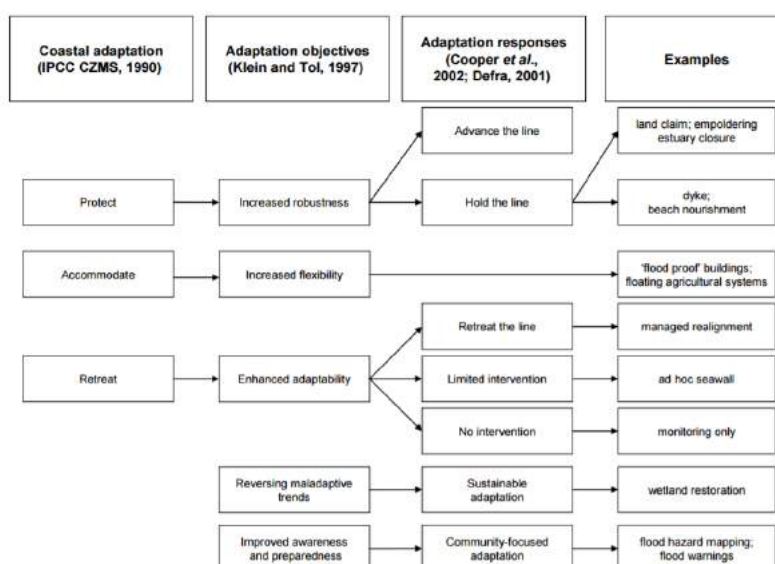

Figure 5 – Evolution of planned adaptation practices in coastal zones. Source: Nicholls et al., 2007

Nicholls et al. (2007) presented a diagram illustrating the links between these approaches and the evolution of thought with respect to adaptation practices in the coastal zone (Figure 5).

The EC White Paper on Adaptation to Climate Change (COM (2009) 147 final) It focuses on four pillars of action; One of these pillars is to integrate adaptation into key EU policies. The EU has a number of relevant instruments and policies for coastal areas that can facilitate sea and coastal adaptation to climate change, including: the Marine Strategy Framework Directive, the Water Framework Directive, the Floods Directive, The Integrated Coastal Zone Management Policy for the European Union, the Birds and Habitats Directives, the Integrated Maritime Policy for the European Union, maritime spatial planning and marine knowledge policy. In addition, EU Member States are developing and implementing national adaptation strategies. The implementation of these strategies has generated hard and soft measures and actions such as the improvement or installation of coastal defenses / floods / drainage, adaptation of ecosystem conservation management and their services, adaptation of agriculture and forestry, Water, climate integration Change in spatial and urban planning, implementation of beach nourishment schemes and institutional and legal measures (ETC-ACC, 2010a).

4 MEASUREMENTS AND TOOLS TO IMPROVE LOCAL PLANNING SYSTEM

It is possible to state that, instead of generating new impacts, climate change will affect Italian and Mediterranean coasts through the growth and intensification of existing problems such as speedy urbanisation, tourist and industrial development, excessive exploitation of marine resources, etc. with a high degree of certainty. These areas of high territorial complexity, where excessive exploitation and a mismanagement of coastal resources has already created vulnerable environments at risk (heat waves, storms, inundations, drought, etc), are precisely where human activity and ecosystems might be worsened by climate change. As it is now widely recognised that a sudden reduction of greenhouse gas emissions on a global level would not completely prevent climate change but would only delay its effects due to the inertia of natural systems against CO₂ concentrations (DETR, 1999), combining our strength to control emissions is of strategic importance to reduce damage to the minimum. International prevention strategies must be combined with the definition and implementation of actions and policies at a regional, sub-regional and mainly local level that can mitigate or, in some cases, even eliminate the negative impact induced by climate change. These win-win strategies will prove useful to respond both to the current climate variability (extreme events such as drought and storms in particular) and to long-term changes characterised not only by weather changes but also by socio-economic factors.

For example, table 2 reports some possible measures that can be implemented in response to the main impacts of climate change for the Mediterranean basin and, in particular, for Italy.

Area	Impact	Possible adaptation measures
Water	<ul style="list-style-type: none"> Water supply variability Longer periods of drought in summer Less water available from superficial aquifers Uncertain water management Increase in the risk of inundation Lower air quality 	<ul style="list-style-type: none"> Increased flexibility in the management of water resources Improvement of the efficiency of the water distribution network Investments to improve the management of rainwater from extreme events Improvement of ducts for the harvesting of rainwater Increase investments to reduce water loss
Coastal areas	<ul style="list-style-type: none"> Increased risk of flooding due to the rise of sea levels (increase in storms) Change in the frequency of flooding return periods Prolonged or permanent inundations with consequent loss of land (coastal habitats, dunes and humid areas in particular) Saltwater intrusion into aquifers Change in superficial water temperature and salinity Lower sediment load in waterways Increased coastal erosion 	<ul style="list-style-type: none"> Drafting and implementation of measures to adapt to climate change within coastal management strategies Improvement of extreme weather events forecast (storms and intense rainfall) Management and planning of moving coastal settlements where density is not too high Creation of coastal monitoring systems and mapping of areas at high risk Upgrading of coastal defence systems Planting of vegetable species suitable to increase coastal resilience Protection and artificial fixing of shorelines Drafting of ICZM plans involving local stakeholders
Ecology	<ul style="list-style-type: none"> Loss or reduction of protected areas Loss of coastal habitats (coastal dunes and lagoons) Change in ecological parameters (temperature, salinity, nutrient availability) Change in the composition and distribution of species Introduction of alien vegetable species Increased risk of fire Degradation of water quality (intensification and eutrophication due to algae) 	<ul style="list-style-type: none"> Review and increase of protected areas through the redefinition of coastal ecosystems Planning of new protected areas and ecological corridors between fragmented habitats

Agriculture	<ul style="list-style-type: none"> Reduced water availability due to the increase in temperature and evapotranspiration, change in precipitations, drought periods and saltwater intrusion. Increased superficial soil erosion Increased variability of harvesting schedules Increased working opportunities due to the availability of new agricultural areas at different latitudes 	<ul style="list-style-type: none"> Introduction of agricultural crops more resilient to intense periods of drought or floods Monitoring of crop response to climate change Implementation of agricultural techniques that limit soil erosion Introduction of physical protection systems of coastal agricultural areas Development of innovative irrigation techniques (combined with the upgrading of existing networks).
Human health	<ul style="list-style-type: none"> Increase of heat islands Worsening of air quality Increased incidence of temperature on disease Increased disease vectors Higher risks connected to extreme events 	<ul style="list-style-type: none"> Strengthening of public health systems Strengthening of vaccination programmes and of the surveillance on the increase of some diseases (e.g. malaria) Training of health personnel specifically for problems connected to climate change Health training to reduce the potential exposure of population at risk Development of alarm systems in case of heat waves

Table 2 - Possible impacts and measures to adapt to climate change. Adapted from WISE, 1999 and Gabrielides, 1998, USAID 1999.

As regards adaptation, the first step is generally represented by the resolution or, at least, the mitigation of existing critical problems. These are often the result of strong human pressures and a stratification of different practices - defined by Burton as “maladaptation” (1996) - along the coast which, over time, limited the flexibility and natural coastal resilience to climate stress. Another important passage for climate-proof coastal planning and management is an assessment of vulnerabilities and the definition of suitable climate change adaptation measures within integrated coastal zone management (ICZM).

ICZM enables the analyses of the effect of pressure and stress factors on coastal systems, including climate change and sea level rise (EC, 1999), and is therefore increasingly recognised as the best tool to tackle current and long-term coastal problems (ECC, 1993). The actuation of the ICZM protocol and the implementation of climate change adaptation measures requires not only a significant change in perspective (long term rather than short term, prevention rather than emergency, integrated approach rather than single interventions) but actually, at least in some national contexts, a radical modification of institutional processes, legal and regulatory aspects and socio-economic development plans. Due to the political, cultural, economic and social differences within the Mediterranean basin, international cooperation and the transfer of technology and know-how are extremely important to construct a more resilient future for the entire region.

In this scenario, the scientific community is important to provide policies and decision makers with suitable support for what concerns the analysis of climate change impact (both on a sub-regional and local level) and for the qualification of said impacts, which requires the modelling of interrelationships on natural and human sub-systems. All efforts should focus on the elaboration of reliable local scenarios that describe how critical parameters will change in the future. However, the reliability of current scenarios is limited by the uncertainty that increases when passing from a global to a sub-regional or local scale. Regional and local studies are also bound by other factors, such as the increased natural variability of climate conditions and the influence on the climate system exerted by variations on local characteristics such as those regarding land use.

It is therefore necessary to elaborate not only sea level rise forecasts, but also a wide range of scenarios that can include possible future variations, as the current local impact of climate change is far from definitive. It is very important that adaptation and mitigation measures are drafted to be flexible and effective for a wide range of possible scenarios. To reach this flexibility, a gradual evolution of vulnerability studies will be necessary. As suggested by Klein (2003, 2007), this must be done first through a screening and then through an evaluation of vulnerabilities to reach a final project assessment. This final assessment, with its relative planning options, should be included in a wider ICZM protocol.

5 OVERCOME BARRIERS TO A PRACTICAL IMPLEMENTATION OF ADAPTATION MEASURES: THE ROLE OF MAINSTREAMING

It is important to recognize that climate change adaptation presents a fundamental challenge to managing the coastal resources and should be “mainstreamed” into coastal management and development at all levels. Mainstreaming means integrating climate concerns and adaptation responses into relevant policies, plans, programs, and projects at the national, sub-national, and local scales.

Mainstreaming recognizes that adaptation measures are seldom undertaken solely in response to climate change (IPCC, 2007b). Considering the scale of the problem and the linkages between climate change and development, coastal adaptation will happen as an overlay to other ongoing initiatives and governance frameworks. Existing institutions should be in the forefront of designing and implementing adaptation measures. This could include the managers of water resources, civil protection, public health and protection of coastal area. Successful mainstreaming requires reinforcing linkages between local and national level adaptation entry points. Together with non-governmental partners, the government must play a fundamental role to facilitate the connections between national, sectoral and local entry points (fig. 3).

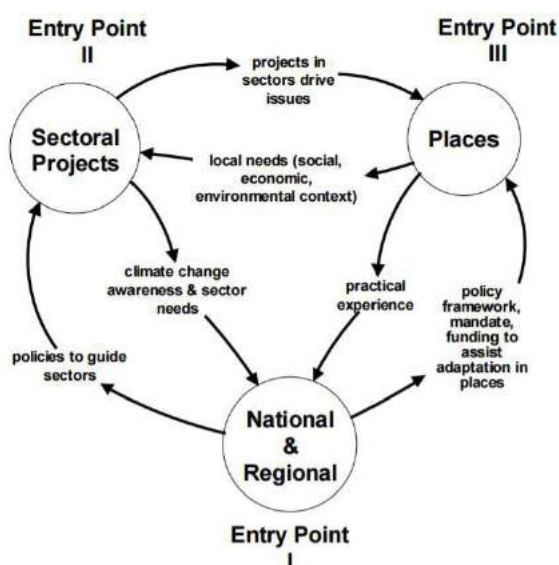

Figure 6 - Points of strength for an effective adaptation mainstreaming process.
Source: USAID Adapting to Coastal Climate Change - A Guidebook for Development Planners (2009)

Some examples include:

Creating enabling policy, finance and legal frameworks. This includes, for example, prioritizing adaptation in national planning and budgeting; harmonizing sectoral policies; creating national coordination committees, chaired by a ministry with power; and providing the financial and technical support necessary for adaptation measures to succeed.

Capturing local experience. Coastal adaptation in a specific place or area builds practical experience and a sense of ownership for those living and working there. This experience can be shared amongst different actors at the national level to build capacity. Linkages between local communities and government strengthen community voice in planning and national policy-making for coastal adaptation to climate change.

Rising public awareness. Awareness raising and education campaigns help convey information about the impacts of climate change and gain consensus on adaptation options. Governments need to engage more actively with the scientific community and provide easily accessible and up-to-date climate change information relevant to the needs of coastal sectors.

In order to be truly effective, mainstreaming requires forging agreements with a broad array of agencies and groups, each with different policies, approaches and objectives. Thus, mainstreaming can be time-consuming and challenging (from a political and economic perspective), especially due to the “normal”

resistance to the introduction of any new policy ideas. In the case of climate change adaptation, this is exacerbated by the cumulative nature and long-term timeframe of climate change impacts. It is also complicated by the fact that different individuals and organizations will have different perceptions of the uncertainties surrounding climate change and its impacts and will have different tolerance levels for risk.

ID 1533 | AN OUTPUT OF PARADIGM-SHIFT IN URBAN PLANNING: "RESILIENT TRANSPORTATION" AND EXAMINATION ON CITY OF ISTANBUL

Seckin Ciris¹

¹Istanbul Technical University
seckin.ciris@gmail.com

ABSTRACT : Throughout the history, urban planning experienced several changes and developments with the light of economic, politic, demographic, social and environmental characteristics of existing time period and effects of these features on society. An example of these developments is the emergence of the idea of seeking a comprehensive and multi-faceted solution to the negative situations of cities in the early 1990s in the context of "sustainable planning". The question of how our cities will react in the face of adverse conditions has become a matter of debate. The focus of this debate lies in the fact that cities and the inhabitants of the city struggle with sudden changes and threats.

Aim of this study is determination of necessities for integrating urban transportation with urban resilience concept and examination of basic approaches for this integration method. One of the most important subject is identification of policies and scenarios in so that resilient transportation concept works with urban transportation system in harmony and reflection of this harmony to city as a whole. In addition to this, the determination of working principles integrated with different disciplines (social sciences, economic sciences, etc.) and the inclusion of macro and micro scales into urban planning are among the topics to be elaborated. Finally, on the Istanbul city, analysing existing potentials and possibilities in the context of urban transportation and making of policies, scenarios and solution alternatives are discussed on the city of Istanbul.

KEYWORDS: Resilient Transportation, Urban Resilience, Disaster Management, Sustainable Development

1 INTRODUCTION

Most of us know that research results which are carried out upon features of our planet are not positive. In recent years, policies and scenarios are being created for this issue and comprehensive solution and planning approaches are being developed. Cities are key point that has to be regarded mostly. More than half of humanity lives in cities according to World Bank data and urban areas are growing day-by day. one of the most important reason behind this issue is urban areas offer much more opportunities than rural areas. Concentration of population leads becoming more vulnerable and diminishing struggle power of cities against possible global threats and sudden changes.

Industrial cities which started to emerge and organize in the first half of 1800s in England can be shown as an example. Rural population fronted towards to urban areas with the changes in means of production and usage of machine power. This situation is accepted as "paradigm-shift" and it caused to accumulation of population in urban areas. As a result of this tendency epidemic disasters, air pollution and irregular urbanization started to emerge in industrial cities.

After this date, urban population has grown rapidly and settlements started to consist both in inner urban areas and periphery. necessity of making important renewals and developments is revived considering negative effects of rapid population growth and global threats (natural disaster, economic crisis, global warming, etc.). Sustainable development emerged in second half of 1900s as a purpose of ensuring balanced development with providing coordination of economic, environmental and social subjects. This new concept is accepted as "paradigm-shift" in urban planning context. Main discussion of sustainable development is progressing in the frame of "space". Environmental carrying capacity, capital of environment have a meaning when they are associated with "space" that has specific culture (Karakurt Tosun,2009). City is a key point for ensuring sustainable development and improvement because it contains many dynamics for ensuring improvement. Evaluation of these dynamics in long term effectively is possible with enabling of resilient urban system. Entire system is named as urban resilience and cities in which these systems are implemented are named as resilient cities.

Definition of resilient city is coordinated and comprehensive struggle system of cities with their dynamics and different actors against all kinds of threats(natural disaster, economic crisis, etc.) in physical, environmental, social and economical framework.

1.1 RESILIENT TRANSPORTATION CONCEPT AND BASIC PRINCIPLES

Resilient Transportation is a concept which emerged as an output of paradigm-shift in urban planning in 1990s. It is defined that comprehensive spatial, physical, economic and social studies in order to create defence mechanism and adopt all kinds of negative conditions and sudden shocks that cities experienced.

Figure 1 – Emergence Process of Resilient Transportation

Basic principles of resilience transportation are examined under 4 fundamental titles:

- Determination of tasks and responsibilities of stakeholders in global platform

Coordination should be ensured in both national and international platform for providing sustainability and resource of investments in regional and urban context, taking precautions for disasters, using all resources beneficially. It is seen that public institutions and local government make preparations for disaster and emergency causes. Moreover, they study to minimize risks in urban areas by using both equity capital and international support resources as World Bank (IPCD,2014)

- Providing integration of strategic and spatial plan of city in macro/micro scale that is prepared in disaster management framework to transportation master plan

Before preparing spatial plan of urban areas; basic decisions, policies and intervention methods has to be determined and strategic development plans should be prepared in macro scale.

Sustainable development which is admitted as an output of paradigm-shift brings sustainable urban concept in the process. Fundamental principles of this concept is resilience thinking and it is started to approve as new and remarkable parameter in planning of urban areas. 3 main elements become significant considering resilience principal.

- Urban structure and usage that has strategically importance
- Open spaces
- Access network

3 elements that are mentioned above have an importance separately, but network has different significance than others. Working in a harmony in a body of urban usages and open spaces has to be provided. Comprehensive access network should be created in order to ensure coordination between two of these. In this condition, a system will be established and 3 elements start to work in together.

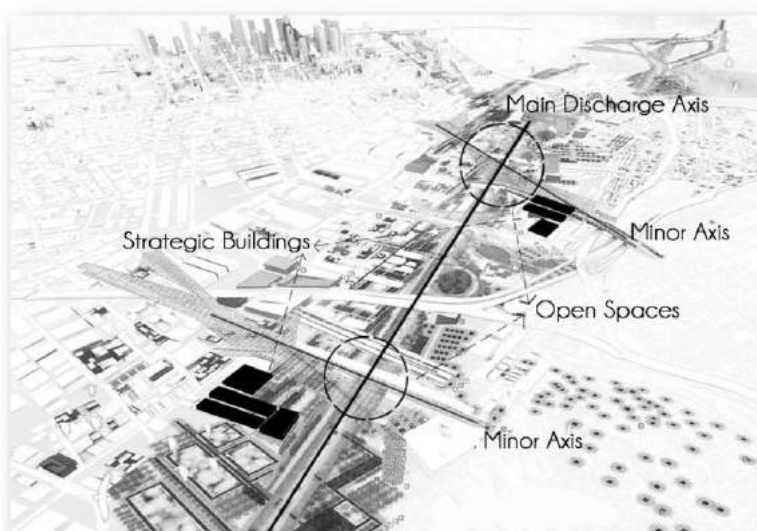

Figure 2 – Urban Elements in Context of Resilient Transportation

Access network should provide discharge people and vehicles easily and safely from assembly areas to less-risky areas such as periphery of cities. In order to do this, important discharge axis has to be determined in both existing and proposed land-use plans. In this point, these axis should be taken into consideration as determinant factor of spine while transportation master plan is being prepared. Determination of these corridors has to be done by experiments and regulations on network pattern which is defined previously. Only if demand based approach and structural characteristics of road are considered, system won't be reliable. Moreover, all axis should be regulated according to a defined hierarchy with each other and be provided continuity of them in entire network. One of the most important point is that main discharge corridors should connect major assembly areas due to having high capacity of

them. Second point is integration of minor network corridors to major axis in specified points. If these points locate in main assembly areas, it brings good solutions.

Determined axis should be designed regarding risk factors in disaster moment. These implementations are exemplified as an increase in setbacks, keeping away of electricity and natural gas line from discharge axis, development in infrastructure of roads that are suitable for vehicle traffic, control of engineering structures which are on these axis. At the same time, creation of powerful access network is important so that vital food and health materials are carried to strategic areas in disaster moment.

- Ensuring inclusiveness, creating awareness of society with providing co-operation in institutional context

Being prepared for disaster does not cover things that should be done only for disaster moment. Society has to be prepared for possible disaster risks before in every aspects. In this point, government and NGO's have crucial role for raising awareness and informing all category of society. This can be ensured with the help of activities and drills that are prepared in public spaces, schools by private and public institutions. This type of activities strengthen organization, coordination and communication between society and NGO's. Thus, institutional capacity will be increased as well as technical capacity. Bringing together of different occupation groups in common point with the approach of creating common idea and action.

- Providing robust, flexible, durable and contemporary physical infrastructure

Methods that are used for ensuring physical infrastructure can show differences according to climate conditions of city, threats which are exposed by city in its history. However, regarding common platform, infrastructure investments that are made in the frame of transportation have to be integrated to existing infrastructure effectively and have to minimize negative effects of possible risks. In this point, using technological and contemporary methods means being more useful in economic aspects and more durable in physical aspect for long-term. Also, beneficial usage of resources is important issue for getting much more benefit in short and mid-term (Cities, 1. R., 2016). Infrastructure practices concentrate on high rainfall ratio, flood risks and increase in sea level scenarios in worldwide (Ebinger; Vandycke, 2015). These scenarios can be exemplified as:

- Healing of regions where illegal housing intensifies by taking care of connector roads, flood risks and security precaution.
- Making embankments for landslide risks, stream improvement in regions where natural precautions are not sufficient (IPCD, 2014).
- Regulating highways and pedestrian ways in selected regions in which are determined as discharge axis
- Increasing capacity of drainage systems in some area where has flood risk.

1.2 EXAMINATION OF ISTANBUL IN RESILIENT TRANSPORTATION FRAMEWORK

Istanbul is the most populated and developed city of Turkey in economic and socio-cultural aspects. It locates in northern-west part of Turkey and it is enclosed by Blacksea from north, Marmara Sea from south. Istanbul contains major fault lines due to its geopolitical location. Risk factors are more than other cities regarding all of these definition such as high population, enclosure by seas, including fault lines. Determining strategies, creating intervention methods, have to be carried out coordinated and comprehensive framework with considering all of these risk factor. This section of research contains integration of resilient transportation concept into the existing system of Istanbul as well as methods and principles.

1.2.1 METHODS AND PRINCIPLES OF RESEARCH

1.2.1.1 DETERMINATION OF RISK FACTORS AND PROBLEMS

Conditions which are cause risk factor have to be defined before determination of risk factors. These conditions:

- Existence of Bosphorus which divide city into two creates necessity of significant transportation projects in order to provide access between Asia and Europe continents.
- Lack of service in urban transportation due to urban sprawl.

Figure 3 – Settlement Areas of Istanbul

- Existence of historical urban pattern especially in city centre causes insufficient infrastructure as well as deficiency in ensuring urban transportation services.

Risk factors can be determined based on these 3 basic conditions. These factors are sorted in the scope of infrastructure as highways railways and metro lines; harbour and piers; viaducts and tube tunnels. Moreover, inadequacy of open spaces that is caused by high population and urbanization, effects of important transportation projects on encouraging private car usage, existence of narrow roads especially in the city centre and as a result of this situation accessibility problem is seen in city centre.

1.2.1.2 DETERMINATION OF POTENTIALS AND DEVELOPMENT PRINCIPLES OF TRANSPORTATION INFRASTRUCTURE

Potentials of Istanbul metropolitan city can be sorted as evaluation of main transportation axis (E-80&D-100 roads) as significant collective axis for disaster moment, prevalence of inner urban marine transportation as an alternative mode, studies that are carried out by chambers, existence of transfer points which enable to interchange among different transportation modes, evaluation of BRT lines as an alternative for discharging people to safe part of city. In addition, existence of grand urban parks, coastal zones and harbours act as major assembly area.

Some infrastructure regulations have to be made in order to utilize all of these potentials that are mentioned above.

- Risk factors which are determined between major and minor axis and they affect emergency case road network have to be demolished. Emergency case road network is a prior network due to providing transportation of emergency medical services, first aid materials to strategically important areas such as hospital, assembly areas (IMM, 2011).
- Traffic flow planning should be done for disaster moment and later. This study covers route planning of ambulance and fire trucks, regulation of connections which are from minor discharge axis to major axis.
- Special strategic plans should be improved for rail lines, harbours and airports so that they can serve after disaster. These areas play significant role on accepting first aid materials from transoceanic countries easily and transporting them to suffered area by disaster. Moreover, these areas are rather useful for storing first aid materials, wrecks and wastes temporarily (IMM, 2011).

1.2.1.3 DETERMINATION OF ROADS THAT ARE AFFECTED BY COLLAPSE NEGATIVELY

The road network must function after the disaster. This situation applies both to public transport vehicles using road infrastructure such as buses and metrobus as well as to private vehicles. In addition, it is necessary to prevent the road network from being shut down for various reasons so that the emergency vehicles can perform their functions at the moment of disaster and afterwards. For this reason, it is desirable to calculate in detail the extent to which the functioning of roads can be taken in emergency situations and to plan for roads and future arrangements for urban areas as a result of the calculation. (JCA; IBB, 2002). First of all, working areas should be identified and the existing road network diagram in these areas is revealed in a stepped manner according to the physical characteristics of the road. Then, the structure of the buildings on these roads and the most important threat elements and the probabilities of destruction should be evaluated. The necessary arrangements should be made primarily in newly

constructed areas and then existing residential areas.

Figure 4 – Road Conditions Before and After Destruction

1.2.1.4 EXAMINATION OF EFFECTS ON BRIDGES & VIADUCTS

City of Istanbul needs several engineering structures because of topographic features and properties of existing transportation infrastructure. Most important engineering structures are bridges and viaducts in the context of disaster resilience and these are significant elements for transportation network. That's why, they links main axis which connect strategic buildings. Main axis have great importance for discharging people and vehicles from disaster area both in disaster moment and after, providing flow of disaster recovery and continuing all kinds of urban activity. Special protection and recovery practices should be made for bridges and viaducts that are significant elements of main axis because impairment possibility is pretty high for them. Even if deterioration of bridge structure is seen as just a point in transportation system it will be resulted in problem of maintaining system performance (JCA; IBB, 2002). Bridges and viaducts that are under risks are classified as major and minor according to disaster prevention report of Istanbul Metropolitan Municipality and Japanese International Cooperation Office. These classification is shown below.

1.2.1.5 CLASSIFICATION OF TRANSPORTATION NETWORK AND ENSURING INTEGRATION WITH OPEN SPACES

Strategies to be developed under this title can cover the entire city as well as appeal to a specific area. The important point is that the potentials determined in the previous phase should be evaluated effectively, the risk factors should be minimized as much as possible, and the problems should be solved. If Istanbul city is considered in particular, the development of strategic structures, increasing the number and quality of open spaces and establishing an effective access network is the starting point for a solution scenario. Because the coordination of these 3 elements both within themselves and among themselves provides an opportunity for the healthier, more effective and more resilient interventions to be carried out in the next phase. For example:

- Regulation of existing main transportation axis (D-100, E-80, Anatolian Highway, etc) and proposed ones which are determined in preparing process of urban transportation master plan as providing access in disaster moment effectively
- Determination of discharging corridors that has the characteristics of minor and collector roads which connect with main transportation axis in specified points.(Barbaros Avenue, Büyükdere Avenue, Şile Highway, Bağdat Street, etc.)

- Preparation of hierarchical system of open spaces, urban parks, university campuses, military zones (ITU Ayazağa Campus, Istanbul Urban Forest, Beşiktaş Square, etc.) in themselves and providing function of these elements with established access network in harmony and effectively
- Making necessary practices in order to strengthen access network inside historical urban pattern (Eminönü, Fatih, Balat, Beyazıt, etc)

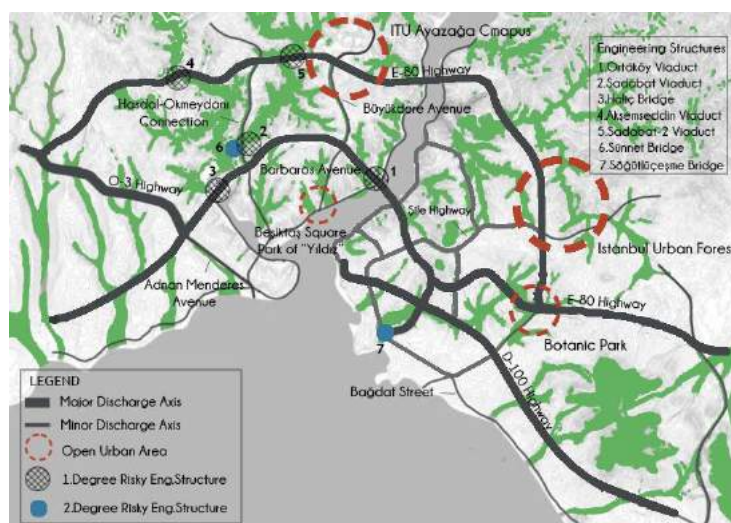

Figure 5 – Transportation Network Classification, Green Areas and Risky Engineering Structures

2 CONCLUSION

Since the past, the cities have been formed by the gathering of the communities of the people that the geography that they are in and ,in time, providing the needs and ownership of people is shaped by social and physical conditions. All of these have developed in the process, within the framework of complementary events and within the framework of causality. This development has continued for centuries, and as a result of these important events, different perspectives have been developed and, in other words, new dimensions, concepts and elements have been added to the urban planning process. Sustainable development that emerged as a product of this process has brought new concepts together. Among these concepts, urban resilience is one of the most interested subject for our cities. Achieving sustainable development is possible with the dynamics that make up the cities. Urban resilience is essential for effective assessment of these dynamics in the long term.

"Resilient transportation" has also emerged at this point as a necessity and an element of urban resilience. This concept is summarized as the evaluation and implementation of resilient city principals in the perspective of urban transportation. Interpretation and regulation of urban transportation policies on the basis of resilience and the fact involving both part of the city and whole city in different scale, including participatory planning approach, and interaction with the dynamics of the city are important characteristics of this concept.

In the past, earthquakes, floods and natural disasters have been exposed to the present and future threats to our country should take important steps to adopt the concept of a resilient city.

In the process from the 1999 earthquake to the day-to-day process, various searches and tests such as the determination of meeting points and area of containers in the structure and area scale within the scope of disaster management were started in city of Istanbul. These searches will have become a whole, not only in the space but also in the transportation, infrastructure, social and administrative areas, with the control and implementation mechanism. For example, it should be ensured that the identified assembly points are integrated with the elements, such as the major and minor discharging axis that are described in the study. In addition to this, informing the citizens about these arrangements will also enable the regulations to function as a whole.

The aim of this article is to present the study that can be done as a proposal in the subject of ensuring coordination among different disciplines which are mentioned above. The most important result to be

drawn when the subject is assessed in the city of Istanbul is the city's significant potential for the establishment of the defence mechanism. However, disaster risks, population surplus, restrictions on possible interventions to be made and great usage of private vehicles make it difficult to use the potentials efficiently and effectively.

ID 1546 | DROUGHT RISK, FARMER COMMUNITIES' PERCEPTIONS AND PLANNING FOR RESILIENCE IN RURAL CRETE, GREECE

Kalliopi Sapountzaki¹; Ioannis Daskalakis¹
¹Department of Geography, Harokopio University
sapountzaki@hua.gr ; i.daskalakis@gmail.com

ABSTRACT: Drought incidents may originate from both, manmade and natural factors and are characterized by uncertainty. The present paper attempts to shed light on the interrelations between exposure, drought perceptions and the adaptive responses opted by agents attempting to cope with drought risk and to provide insights into the planning processes implemented at the levels of the individual agents and the water management authorities. The choice of personal versus collective resilience strategies is largely a function of risk perception and the availability of resilience assets, but it is also a matter of power relations and alliance forging. The farming communities and the local self-government authorities of Messara plain in rural Crete provide the testbed on which the authors have attempted to scrutinize their initial assumptions by using appropriate questionnaires and interviews with key-staff of planning authorities.

1 INTRODUCTION: “DROUGHT”, “DROUGHT RISK PERCEPTION” AND “PLANNING FOR RESILIENCE”: THEORETICAL ASSUMPTIONS AND SCOPE OF THE WORK

Drought is often considered by the general public as the result of changes (more or less permanent) in the local prevailing climatic / meteorological conditions (basically in precipitation). According to the experts however, it is a phenomenon generated and influenced by both natural and manmade factors; even the natural factors may originate from the manmade component of Climate Change (CC). Drought is usually classified into five types or versions interconnected with each other: (a) Meteorological or Climatic; (b) Hydrological; (c) Agricultural; (d) Socio-economic and (e) Ecological. The present work focuses principally on hydrological, agricultural and socioeconomic drought in a rural territory since it is these versions

basically that affect and are affected by local farmer communities' Perceptions and Planning for Local Resilience and Sustainable Development.

Drought events are characterized by uncertainty, it is difficult to be predicted accurately (Keenan and Kranich, 1997). More importantly, the duration (start and end date) of drought incidents and their geographical range are not easily identified and monitored (Olcina-Cantos, 2007).

Agricultural Drought is manifested through insufficient soil moisture hampering crop growth and agricultural production. It is this type of drought that worries people in the grocery and meat business or people in farming communities who depend on agricultural income for their livelihoods. Hydrological Drought is the result of reduced precipitation or human interventions in the surface and groundwater catchments. It is visible in the reduced flow of rivers and lowering of the level of ground water catchments. Urban planners usually mean hydrological drought when they talk about drought, since water supplies and reserves are key components in managing urban growth. Socio-economic Drought is associated with the vulnerability of a community to long-term imbalances between water supply and demand. In this sense, the impacts of socio-economic drought depend on the ability of households, businesses and wider communities to adapt to the varying and deficient water availability (Olcina Cantos 2007). This is indeed why, Resilience to Drought –as the ability of a community to adapt to water shortages- plays a critical role in Drought Risk Reduction.

Resilience is the precondition for effective adaptation. What matters, is not only resilience of the concerned community as a whole but also resilience of individuals and the distinct institutions that make up this community (e.g. households, firms and agricultural holdings, agricultural corporations, water and planning authorities etc.).

Basic assumption of the authors is that both collective and individualized resilience depend on (a) the respective agent's Drought Risk Perception and (b) on the agent's accessibility to the necessary resources (natural, social, economic, political and physical) and consequent ability to engage these resources in appropriate adaptation processes. Davoudi et al. (2012) suggest that exposed and vulnerable agents are not a priori resilient, but instead that they struggle to become resilient. During this process, an agent reaches out for resources that might be available not only nearby and currently, but also at distant spatial and temporal scales, which other agents also appeal to (Sapountzaki, 2007).

The authors assume besides, that the form of adaptation to drought that is opted depends on the agent's initial exposure (real or perceived) and the resilience assets accessed by the agent. For example, the choice of farmers of a rural region to drill shared boreholes depends on their investing capability and their involvement in networks of collaboration with neighboring farmers (i.e. accessibility to economic and social capital). However, should a powerful sub-group of the above farmers achieve accessibility to extra water resources (e.g. to the water of a newly constructed dam and its reservoir) through political lobbying, this group will leave boreholes for a more effective and less costly adaptation to drought. It is evident that accessibility of this subgroup to political capital may deprive others (those who do not manage to connect with the dam's reservoir) from vital water resources. Agents with affluent resilience assets are in an advantageous position; they can select the most convenient for them adaptation solution. On the contrary, those deprived of resilience resources may have no opportunity for adaptation or only at great cost.

In the context of this paper, Planning for Resilience is considered as the process aiming at equitable accessibility to resilience assets. Equitable and just allocation of resilience resources depends however on power relations and is also a matter of Drought Risk Perception on the part of both the exposed agents and the planning and water management authorities. Hence, risk perception is important to planning for resilience at two distinct levels: (a) the level of the individual exposed agent, since it affects the agent's willingness and effort to become resilient and (b) the level of the planning and water management authorities since it affects their views on risk distribution and equitable allocation of the resilience potential. Perceptions matter a lot because (drought) risk does not represent an actual fact in the prevention stage but only an uncertainty about adverse consequences.

The role of perception in people's or social agents' preferences on how to cope with risks has been thoroughly investigated in the past (e.g. Slovic, 1987 and 2000, Tversky and Kahneman, 1974, Kaperson et al., 1988, Douglas and Widalsky, 1982, Renn, 1998).

More importantly, natural hazards are characterized by uncertainty and therefore are hard to perceive and comprehend. Thus, agents are forced to structure their adaptation process based on probabilistic judgements according to the alternatives they are aware of and which are available to them (Slovic, 1987). The social and institutional environment in which the agent operates influences perception of risk. Accordingly, the agent's willingness to adapt depends on the level of risk perception; low risk perception usually translates to no response and no or inadequate preparedness on the agent's behalf.

Individuals and/or institutions however do not perceive all natural hazards in the same way. Fear, new and unknown risks and stigmatized hazards affect perceptions. For instance, flood incidents occur rapidly, last over a short period and usually have a more devastating impact than drought events. It has been argued that the severity of consequences (experienced or imaginable) rather than the actual degree of exposure determines the respondents' perceptions. Risk perceptions are also associated with former experiences (recent or old-dated); agents located in a disaster-prone region but have never suffered any adverse consequences demonstrate lower risk perceptions and are more likely to be less resilient than agents of the same region who have encountered losses in the recent past (Wachinger et al., 2013).

In general, it seems that risk perception is affected by disaster experience, stigmatization of specific hazards, the assumed or imagined consequences and the frequency of occurrence. However, several queries remain open: How do risk perceptions of institutions and social agents interact influencing one another? How risk perceptions of institutions influence their strategies for Resilience Planning? How the latter affect accessibility of individual social agents to resilience assets? How risk perception of distinct social agents determine their option for adaptation and survival? Finally, what is the role of power relations in the allocation of resilience assets and prospects of adaptation? Above queries are at the focus of the present work and rural Crete, in particular the farming communities of Messara plain have been selected as the field of an experimental study to offer tentative answers. More specifically the study will shed light in the interrelations between Drought Risk, Drought Risk Perception and Planning for Resilience of Agricultural Businesses/Holdings to and the local economy Drought.

2 THE EMPIRICAL STUDY IN MESSARA PLAIN, CRETE: METHODOLOGY AND RESULTS

2.1 THE GEOGRAPHICAL AND DEVELOPMENT PROFILE OF MESSARA PLAIN

The Messara Plain is an agricultural region located in the south-western part of the Prefecture of Heraklion, Crete, Greece. Local development and well-being in the area are closely connected with land productivity and water availability. The plain is featured mainly by the Geropotamos River, which springs from the southern foot of Mount Idi (Psiloritis) and runs across the western part of the plain. In broader terms, the Messara Plain is located on an island (Crete) resembling a closed hydrological system with finite water resources.

As regards administrative structure, the plain is divided by the boundaries of two municipalities: the western part lies within the boundaries of the Municipality of Festos, while the central and most of the eastern part is administered by the Municipality of Gortyna. Total population of the Municipalities of Festos and Gortyna is 40,098 people (National Statistical Service of Greece, 2011). The main economic centres in the area are the towns of Moires and Tympaki, which comprise 25% of the total population (approximately 10,000 inhabitants) (Figure 1). About 50% of the area's total economically active population is employed in the primary sector of production and 40% approximately in the tertiary sector (mainly tourism) (National Statistics Service of Greece, Census 2011).

Most of the land in the Messara Plain is used for agricultural purposes. In rural areas, the cultivation of olive trees, citrus fruit trees and vineyards is very common; greenhouse agriculture has also been extensively developed. Near the town of Tympaki in the north-western part of the plain, there is an extensive cluster of greenhouse establishments producing fresh vegetables that are forwarded to domestic and international markets.

Water supply of the housing sector is provided by the respective Municipality, whereas irrigation is provided by the Local Land Reclamation Organizations (LLROs) in collaboration with the Municipality. The

LLROs were formed by the Greek Ministry of Agriculture and are responsible for the abstraction, management and distribution of water intended for irrigation. Today, the municipalities supervise the LLROs that operate within their administrative boundaries. In several cases, municipalities have ceded the operation of municipal boreholes to the LLROs. The Water Directorate of the Decentralised Administration of Crete, in cooperation with the Department of Hydro-Economics of the Region of Crete, is responsible for issuance of permits for drillings. Finally, the construction of large scale infrastructure works on the supply side of the hydrological system are planned and supervised by the Ministry of Agricultural Development and Foods. According to the hydrogeological and water resource management studies that have been carried out in the past (Decentralized Administration of Crete, 2014; Kritsotakis and Tsanis, 2009), approximately 95% of total water abstractions in the Geropotamos River basin is used for irrigation (50 million c.m. annually). Domestic uses account for only 4% approximately (2.7 million c.m. annually). The rest of the land use accounts for less than 1% and includes water consumption for livestock farming and industries (Decentralized Administration of Crete, 2014).

2.1.1 RURAL DEVELOPMENT IN A DROUGHT-PRONE AREA: A RESULT OF OVERDUE AND UNCOORDINATED IRRIGATION AND LAND CONSOLIDATION SCHEMES.

The dynamics of rural development of Messara plain had been identified since the late 1960s. In 1972, the United Nations Food and Agricultural Organization (FAO) carried out extensive research on the potential exploitation of the aquifers of Messara and the introduction of irrigation schemes across the plain (Electro-Watt, 1972, Kritsotakis and Tsanis, 2009). According to this study, water abstracted from the alluvial aquifer located underneath the areas of Tympaki, Moires and Agioi Deka should suffice for the successful implementation of the planned irrigation schemes (Figure 2). Furthermore, the proposed construction of the dams of Faneromeni and Agia Galini would provide additional water supply to meet future demand for irrigation.

The irrigation scheme would be implemented in stages; priority would be given to the areas of Tympaki, Moires and Protoria¹ and would be followed by investments in the area of Gortyna.

Before the onset of the project however, implementation of an extensive land consolidation programme was proposed, in an attempt to boost agricultural productivity and increase the agricultural income. Land consolidation is a tool used by planners worldwide in locations and economies that rely on rural development. It is rather useful in cases where land tenure is fragmented and the net income of agricultural holdings is below par. Such projects aim at consolidating parcels to create enlarged and

¹ The current study focuses on the River Basin of Geropotamos and the Municipalities of Festos and Gortyna. The wider area of Protoria has not been included because it is located in a different river basin and a different Municipality as well.

undivided agricultural units, allowing for better management of water resources, increased productivity and optimal arrangement of drainage infrastructure. Ultimately, land consolidation projects may achieve the renewal of rural societies and a more efficient use of rural space (FAO, 2003).

In the 1970s and 1980s the State of Greece, regulated and implemented a land consolidation scheme in the western part of Messara Plain, aimed at increasing agricultural income, reducing costs per unit of production and reducing water demand per stremma¹. Today, the scheme has been implemented only in the areas that were included in the FAO study. The areas that did not benefit from the process continue to face the same problems as they did before the initiation of the scheme.

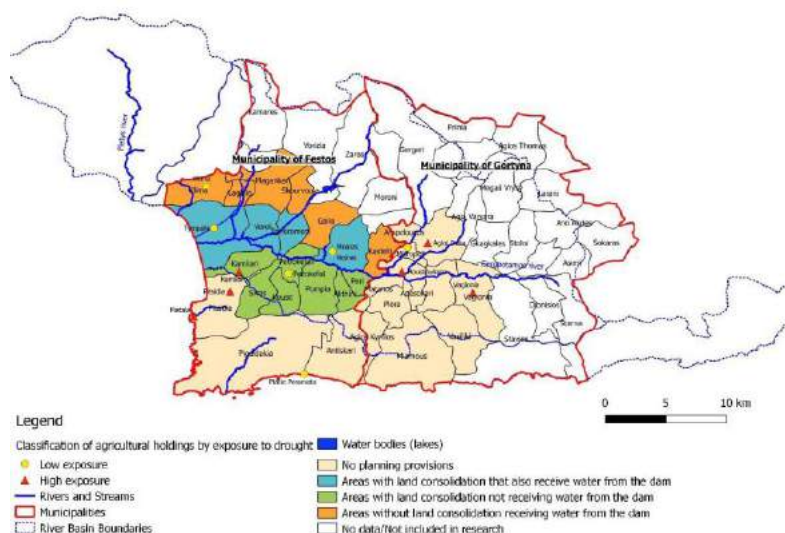

Figure 2: Distribution of land consolidation and water management provisions per local administration unit in Messara plain. Source: Geodata website. Accessed on 15th February 2017. (<http://www.geodata.gov.gr>). Map created by the authors, based on data collected from the questionnaires and the legal documents regarding land consolidation projects in Messara plain.

The plan proposed by the FAO study, considered the construction of the dam of Faneromeni to be an integral part of the irrigation scheme. Significant delays in the initial schedule however, left the farmers' communities exposed to drought. Lack of adequate water resources as well as loose implementation of the legislative framework led numerous farmers to invest in private or shared boreholes in order to mitigate their vulnerability to drought.

It has been estimated that in 2007, more than 1.400 boreholes were used for water abstraction in the entire Messara plain, with the majority being located in the wider area of Moires and Tympaki, (Kritsotakis and Tsanis, 2009). These practices have led to overexploitation of the aquifers, with direct consequences on the quality and quantity of the accessible underground water. Salinization problems have been identified at locations near the coastline, whereas inland areas face the risk of water depletion. The increased risk of hydrological drought is also manifested in the reduced surface runoff of Geropotamos River. Before the implementation of the irrigation and the land consolidation schemes in the mid-1980's, the flow of Geropotamos River and its tributaries was perennial. Since the mid-1980's, water abstraction has increased to such an extent that the rivers dry out entirely during the summer months (Kritsotakis and Tsanis, 2009).

To a certain extent, the prevailing climatic conditions have contributed to this phenomenon. Analyses of rainfall patterns in Messara plain suggest that major meteorological droughts have a return period of 100 years. Nevertheless, droughts of shorter periods (observed as a deviation from the expected precipitation rates) have occurred at least four times during the past 40 years (in 1973-74, 1976-77, 1985-86 and 1999-2000) (Koutroulis et al. 2011). In Eastern Crete, precipitation is significantly less than that of Western Crete, mostly due to the mountainous terrain and the climatic conditions of the Eastern Mediterranean region. Climate Change is likely to affect the existing rainfall patterns, thus increasing the probability of

¹ In Greece, land area is measured by the unit of 'stremma' (plural: 'stremmata'), which is equivalent to 1,000 square metres (<https://en.wikipedia.org/wiki/Hectare#Are>, accessed 10th February 2017).

longer and more severe drought episodes in the future (Koutroulis et al. 2011). Such change might result in reduced potential for irrigation, which in turn will have a negative impact on the local communities and economies that depend on agriculture (Koutroulis et al. 2015).

Since 2013, the dam of Faneromeni and the respective reservoir have been in operation as an alternative method of water supply in the area but only for agricultural purposes because there are no water filtration services in place yet. The dam has been built on a tributary of river Geropotamos. The reservoir of the dam of Faneromeni serves only part of the Messara Plain, i.e. an agricultural land of approximately 40.000 stremmata located in the northern and western part of the Municipality of Festos (Decentralized Administration of Crete, 2014) (Figure 2). Since the full operation of the dam the pressures on the aquifers have been significantly reduced in the areas that are served by the reservoir. However, boreholes and wells are still being used as the sole method of water procurement in the areas that are not served by the dam, thus aggravating the stress on the local aquifers. Additionally, the extensive and occasionally unregulated use of fertilizers has resulted in the pollution of certain aquifers with nitrates.

During the past 20 years, the area of cultivated agricultural land in Messara plain has increased by more than 50%, from approximately 140.000 stremmata in 1991 to 240.000 stremmata in 2010 (National Statistics Service of Greece, 2010). Agricultural production has increased as well. In 2010, the total annual output of the agricultural holdings located in the Municipalities of Festos and Gortyna was approximately 212.000 tons (National Statistics Service of Greece, 2010). It is estimated that more than 20% of this quantity (i.e. approximately 44.000 tons) was produced in the greenhouse cluster located in the northwestern part of Messara plain (Figure 3). This output refers to water intensive cultivations such as cucumbers, tomatoes and eggplants.

The greenhouse hub of Tympaki is the principal employer in Messara plain. It has been estimated more than 2.000 employees work in the cluster, representing approximately 45% of the total agricultural workforce and 25% of the total economically active population of the Municipalities of Festos and Gortyna (National Statistics Service of Greece, Census 2011).

The agricultural holdings of greenhouse farmers range from four to fifteen stremmata. The greenhouse cluster of Messara is the largest cluster in the Prefecture of Heraklion and accounts for the highest share of the local agricultural gross domestic product (GDP). Indeed, most vegetables cultivated in this cluster have a high annual return. According to data from the Greek General Secretariat of Public Income (2014), in 2013, the average income for greenhouse tomatoes was estimated at 1.200 Euros per stremma and 650 Euros per stremma for greenhouse cucumbers and pepper plants. The products of the greenhouse holdings are forwarded directly to European countries (e.g. Germany, Russia, Italy, UK); they are also directed to the main Greek urban centres, principally, Athens.

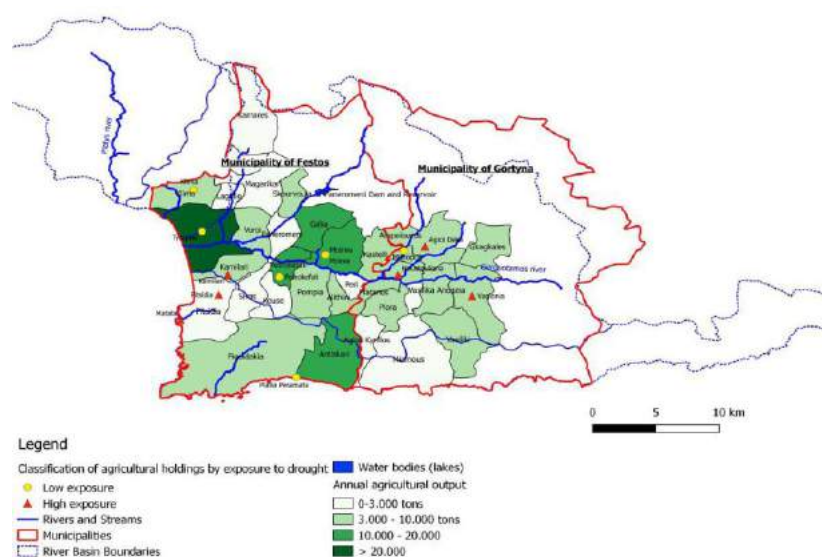

Figure 3: Annual agricultural output per local entity in tons, for the year 2010. Data source: National Statistics Service of Greece. Spatial data: Geodata website. Accessed on 15th February 2017. (<http://www.geodata.gov.gr>). Map created by the authors.

Rural (open-air) farmers mostly grow olive trees, and to a lesser extent, vineyards and citrus fruit trees. These cultivations account for an annual income of approximately 40 to 80 Euros per stremma. Although the total size of their agricultural holdings ranges from 10 to 150 stremmata, many farmers are obliged to cultivate a large number of small and isolated fields of less than two stremmata each, due to fragmentation of land ownership.

2.2 METHODOLOGY, DATA ANALYSIS AND FINDINGS: THE CHALLENGES OF PLANNING FOR RESILIENCE TO DROUGHT IN MESSARA PLAIN

2.2.1. METHODOLOGY AND DATA ANALYSIS

As mentioned the basic objective and scope of the present paper has been to investigate interrelations among (a) exposure to drought of agricultural holdings, (b) perceptions of the leaders of the exposed holdings and of the planning and water management authorities and (c) the planning decisions aimed at resilience and adaptation to drought. The methodology adopted consisted of four successive steps:

1. Selection of a sample of agricultural holdings in Messara Plain

The sample selected represents the various levels of exposure and vulnerability to drought. The basic assumption was that rural (open-air) and greenhouse farming present different degrees of exposure to drought and so do holdings of different size at different locations (enjoying different water provision services). Since the research is still ongoing, the agricultural units included in the sample will grow in number at a later stage. Currently, the authors have investigated a sample of thirty-six farming units, half of which were practicing rural cultivations and the other half, greenhouse farming. Furthermore, in order to 'capture' the repercussions of land use planning and water resource management policies implemented in Messara plain, the holdings were selected from a wide range of locations, eight in the Municipality of Festos and four in the Municipality of Gortyna (Figure 4). So far, the authors have been able to test their initial assumptions and identify some preliminary correlations between exposure, perceptions and resilience to drought. However, the analysis of the full-scale sample is expected to unveil more details regarding the examined interrelations.

2. Submission of a questionnaire to the sample of agricultural holdings

Information on risk perception of the leaders, the resilience potential of the holdings (accessed and contested assets) and the planned or implemented adaptations, were obtained through structured questionnaires that were submitted to the agricultural holdings. More specifically, the respondents were requested to:

- a. Refer to their experience with respect to water shortages
- b. Describe their perceptions about evidences of drought manifestation in their area and anticipated impacts.
- c. Document the natural, social, institutional and financial resources that they sought or had at their disposal during the opted processes of adaptation
- d. Reveal their current and future adaptation preferences
- e. Recognise the actual and perceived impacts of these adaptations, to other holdings and the wider economy and community

3. Interviews with key-staff of planning and water management authorities

In addition to the above, structured interviews with key-staff of planning and water management authorities were carried out, in order to obtain information on drought risk perceptions of these institutions and their rationale regarding distribution of resilience assets and advocacy of certain forms of adaptation. At this stage, the interviewees selected represent the administrative authorities at the local level (i.e. the Municipal authorities and the LLROs) (Figure 6).

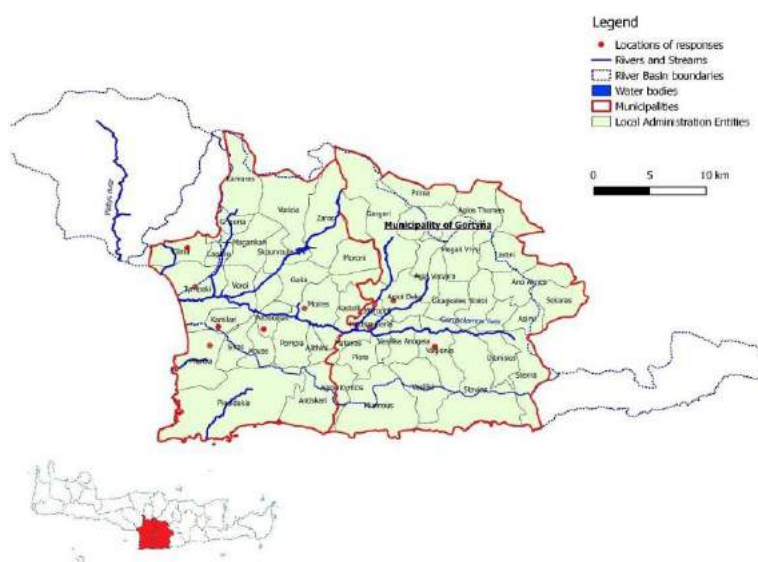

Figure 4: The locations of the responded questionnaires in Messara plain (www.geodata.gov.gr, 2016) (map created by the authors).

Respondent group	Number of responses
Group 1: Leaders of agricultural holdings practicing open-air farming	18
Group 2: Leaders of agricultural holdings practicing greenhouse farming	18
Total sum of responded questionnaires	36

Figure 5: Respondent groups and number of responses received from each category

Administrative authority	Interviewee
a. Municipality of Festos	The Mayor
b. Municipality of Gortyna	The vice-Mayor's assistant
c. LLRO of Typaki	The President
d. LLRO of Moires	The President

Figure 6: Interviewed administrative bodies

4. IDENTIFICATION OF CORRELATIONS

In order to determine the correlations between drought risk perceptions and adaptation options or support of specific adaptive interventions, the authors assumed the factors that were relevant to each of these categories.

- Real exposure to drought is related to current experience of water supply interruptions that besides hamper the productivity of the agricultural units.
- Perception of drought risk is derived from the views on drought as existing threat, causes of drought events and anticipated losses/impacts. Losses include productivity reduction, loss of production, shrinkage of cultivated land, loss of international and domestic markets and loss of income.
- The social, geographical and financial setting as well as political and institutional arrangements determine which resilience assets might be accessible (under certain conditions) to each agent at a given time (now or in the future).

The first step is to classify the sample by their exposure level (high and low), according to their experience of water supply interruptions.

In the next step, the prevailing drought risk perceptions and the preferred choice of adaptation for each exposure group have been estimated by the frequency of positive responses received in the relevant questions in the questionnaires. The objective is to address the impact of exposure on risk perception, of

risk perception on resilience preferences and of exposure on resilience/adaptation options, according to Figure 7.

Finally, in the third step, the responses received from the agricultural holdings were juxtaposed with the responses received by the institutions, in order to identify potential convergence or conflict of the drought perceptions and adaptation options.

Figure 7: Interrelations between exposure, perception and options of resilience and adaptation examined in the current paper

4. A. IDENTIFICATION AND PROFILING OF GROUPS BASED ON THE FARMERS' EXPOSURE TO DROUGHT

The authors classified the agricultural units into two main groups, based on their exposure to drought risk (high and low exposure).

Low exposure group: This group covers the farmers cases who have not experience recently water shortages or interruptions. All members of the group are cases of high water demand and more than 80% of them maintain greenhouse cultivations. Almost 70% of the members are located in areas that are being served by the dam of Faneromeni and have also benefited from the land consolidation

schemes. Additionally, almost 90% of them have further mitigated exposure through boreholes. In most part, this group formulates a spatial cluster (Figure 2).

High exposure group: The group covers farmers who have recently suffered from water interruption. The vast majority of the members of this group are rural farmers maintaining fragmented agricultural holdings; they do not have accessibility to the dam of Faneromeni, have not benefited from land consolidation schemes and do not form a specific cluster.

	High Exposure	Low Exposure	High Exposure (% of total members in the group)	Low Exposure (% of total members in the group)
Total Number of Respondents	19	17		
Number of respondents in group using additional water supply through boreholes	8	15	42%	88%
Number of respondents with high water demand (more than 100 m ³ per stream annually)	4	17	21%	100%
Type of cultivation				
Farmers cultivating in greenhouses only	1	9	5%	53%
Farmers maintaining both, rural and greenhouse cultivations	1	5	5%	29%
Farmers maintaining only rural cultivations	17	3	89%	18%
Agricultural units that receive water supply from the dam of Faneromeni				
	1	11	5%	65%
Agricultural units that have benefited from the land consolidation scheme				
	4	11	21%	65%

Figure 8: Profiling of the high and low exposure groups. Data retrieved from the questionnaires.

4. B. INTERRELATIONS BETWEEN EXPOSURE AND RISK PERCEPTION

Both groups of high and low exposure are featured by high risk perception in the sense that all of them consider their area to be exposed to drought with adverse impacts on their agricultural holdings. This means that current exposure does not affect risk perception.

About 50% of the members of both groups think that drought events result from the combination of natural and manmade factors.

Low exposure group: About 40% of the low exposure group consider exposure to drought as the outcome of exclusively natural causes. This specific subgroup perceives drought as originating from reduced precipitation. A minimal proportion (12%) understand drought as an exclusive issue of insufficient coverage of their own water needs.

High exposure group: No one from the high exposure group believes that exposure to drought is only due to natural causes. It is interesting that half of them attribute exposure to only manmade reasons.

This is consistent also with responses to the query on the meaning of drought; almost 40% of them consider drought as insufficient coverage of their water needs.

Contrary to the former conclusion that recent exposure levels do not affect the perception of drought as an existing and imminent threat in the wider region, it seems that exposure influences the perception of drought causes. All high exposure farmers believe that drought and its impact on their holdings comes at least partly from unwise/discriminating/unfair water management by users and the authorities.

	High exposure group	Low exposure group
Meaning of drought		
<i>Reduced precipitation</i>	16%	41%
<i>Insufficient coverage of water needs</i>	37%	12%
<i>Both</i>	47%	47%
Cause of drought events		
<i>Natural</i>	0%	35%
<i>Manmade</i>	47%	12%
<i>Both</i>	53%	53%

Figure 9: Interrelations between exposure groups and drought risk perceptions.
Data retrieved from the processed questionnaires.

4. C. INTERRELATIONS BETWEEN RISK PERCEPTION GROUPS, MODE OF RESILIENCE AND ADAPTATION RESPONSES

The above analysis reveals three distinct categories of agricultural units regarding risk perception, (a) farmers perceiving drought as reduced precipitation, (b) farmers who consider drought to be a manmade risk and (c) farmers who identify drought to be the result of the combination of both, manmade and natural factors. Each group follows different trajectory as regards the perceived mode of resilience (personal or collective) and the adopted adaptation responses.

Group perceiving drought as reduced precipitation: The majority (70%) of the group that attributes drought to climate change relies on social collaboration options and water policies of the authorities. For this group, individual responses are not sufficient for problem resolution; the only option is trusting water authorities and social collaboration initiatives. However, despite the fact that this group considers collective resilience as the best response to drought, in practice, the majority of the respective farmers aspire to personal options of resilience such as upgrading of cultivation techniques, reduction/rationalization of water consumption and/or drilling new boreholes. Perception comes in contrast with adaptation practices.

Group perceiving drought as a manmade risk: As anticipated, this sub-group considering drought as originating from unwise-discriminating management on the part of the authorities and the other users does not put trust in social collaboration and the water authorities. The farmers of this sub-group prefer relying on their own response initiatives. This finding is supported by the preference that the farmers designate on the personal options of resilience.

Group perceiving drought as being both manmade and natural risk: This sub-group understands drought as the combined outcome of meteorological factors and the socio-economic patterns of water demand.

Contrary to the above sub-groups, the leaders of the agricultural holdings in this group opt for a wide range of adaptation responses involving both, personal and collective options of resilience.

In conclusion, if farmers consider as accountable for drought the water institutions and other farmers who deploy the same water resources, personal resilience becomes then the only option. Reversely, trusting the authorities and neighbouring farmers for collective resilience might be based only on perceiving drought to originate from “exogenous” factors such as climate change. In practice however, it seems that personal resilience is the predominant mode of resilience, regardless of risk perception.

4. D. INTERRELATIONS BETWEEN EXPOSURE GROUPS, MODE OF RESILIENCE AND ADAPTATION RESPONSES

Prevalence of personal resilience options over collective is supported further by the analysis of the interrelations between exposure, perceived mode of resilience and actual adaptation responses.

The high exposure group seeks after water authority activation and social collaboration to address issues of water scarcity, despite the fact that most members of this group consider that the water supply interruptions result from water mismanagement on behalf of the authorities and their fellow counterparts. This indicates that actual and severe exposure to drought may lead farmers to bypass issues of trust and resort to collective resilience options that foster the interaction among farmers or between the farmers and the authorities.

On the other hand, low exposure greenhouse farmers usually afford to proceed with personal resilience investments, particularly private boreholes, to be at the safe side in case of an extreme drought event. Their perceptions favour collective resilience but actions speak louder than words; in practice, they employ personal resilience while lobbying for a water policy favourable for them.

	High exposure group	Low exposure group
Actual adaptation responses	(frequency of responses %)	
Structural and technical resilience reducing demand (personal resilience)	79%	94%
New sources of water abstraction impacting on others (personal resilience)	37%	71%
Struggling for benefits from social and institutional resilience	74%	24%
Opted mode of resilience		
Individualised	37%	24%
Collective	47%	59%
Both	16%	18%

Figure 10: Interrelations between exposure groups, mode of resilience and adaptation responses

4. E. INTERRELATIONS BETWEEN DROUGHT PERCEPTIONS OF AGRICULTURAL UNITS AND INSTITUTIONS

The planning and water management authorities at the local level (i.e. Municipalities and LLRO's) demonstrate different drought risk perceptions.

Municipalities: Since both municipalities include in their jurisdiction areas with recent exposure to drought, both consider drought as a real and existing problem. As the Municipality of Gortyna is faced with more exposed holdings than the Municipality of Festos, the first local authority considers drought as an exclusively manmade issue, while the second attributes the problem to both natural and manmade causes. Perceptions of local authority institutions are on par with the perception of the most representative group of agricultural units in their area.

LLROs: The two LLROs that were investigated also demonstrated different perceptions regarding drought risk. Both LLROs are supervised by the Municipality of Festos, hence it should be expected that these

local institutions would share similar perceptions with their supervising authority. While this stands true in the case of the LLRO of Tympaki, the representatives of the LLRO of Moires believe that the area of Messara is not prone to drought incidents; water availability is sufficient. What considers the LLRO of Moires is the deterioration of water quality due to the extensive use of fertilizers. They thus recognize that any water scarcity issues are clearly due to insufficient management on the users' behalf.

It should be noted that most agricultural units located in the areas of Moires and Tympaki and that are served by the above LLRO's have been included in the low exposure group that perceives drought to be the outcome of reduced precipitation.

While Local Self-Government Authorities share the views of the farmers of their jurisdictional area regarding the origin and cause of drought problems, LLROs are featured by more technical, scientific views, which most probably are far apart from the farmers'. This is unsurprising since the locally elected representatives depend on their electoral clientele.

4. F. INTERRELATIONS BETWEEN ADAPTATION RESPONSES OF AGRICULTURAL UNITS AND INSTITUTIONS

The adaptation options of the institutions range from the provision of information to customers regarding the availability of water resources and advice on water saving techniques, to the enforcement of irrigation by turns, in the case of extreme water scarcity. Furthermore, these institutions use water pricing as the basic mechanism to regulate demand. To their most part however, both the Municipal authorities and the LLROs base their adaptation on accessing new waterbeds and increasing the available supply.

Predominantly, the institutions engage in the effort to increase supply, regardless of their risk perceptions. Although they consider that drought is the result of water mismanagement on behalf of the users, these institutions do not focus on regulating/controlling demand. In high exposure areas the intention is to increase supply; bankruptcy however, impedes the institutions from proceeding with the required investments (e.g. the Municipality of Gortyna). But not only there, water management institutions prioritize increase of water supply (through the dam and municipal boreholes) also in the areas where agricultural holdings are facing low exposure. One can hypothesize that such institutional adaptations aim to enhance water availability in order to reduce private boreholes that besides put the municipal aquifers under intensive pressure. As mentioned, the low exposure group consists mostly of greenhouse farmers producing vegetables of high benefit. This group of farmers is struggling to compete in the international markets; hence, water availability is a precondition to the economic sustainability of their businesses. Consequently, a second and sounder hypothesis is that institutional adaptations serve rather the survivability/economic sustainability of the local greenhouse sector than sustainability of water reserves. This second hypothesis is supported by the fact that prosperity of the local economy of Messara plain relies largely on the profitability of these agricultural units.

		Municipality of Fertos	Municipality of Gortyna	LLRO of Tympaki	LLRO of Moires
Options aimed to increase supply	Drilling of additional boreholes	+		+	+
	Construction and procurement of water from dams and reservoirs	+		+	+
	Purchase/transfer water from neighbouring areas: authority/institution			+	+
Options aimed to regulate demand	Increase in water price	+		+	+
	Informing customers: on water availability and providing motives for water saving	+		+	+
	Enforce irrigation by turns and impose limits on consumption	+		+	+

Figure 11: Adaptation options for each institutional entity.
Data retrieved from the processes questionnaires. The preferred adaptations are highlighted.

The capacity/capability of the institutions to carry out the necessary investments to ensure increased supply as well as the timeframe for the completion of these investments may be crucial factors that determine whether the agricultural units will opt for personal or collective resilience. Unless the agricultural units appreciate the benefits of such investments on their productivity and long term economic

1 INTRODUCTION

Although migration is not new, in recent years Europe has to deal with an entirely unanticipated reality. Since European migration crisis began in 2015, the number of people that have arrived at European Union borders through regular or irregular channels has continually increased. This migration surge rapidly became the largest and most challenging that Europe has faced since the World War II (European Union, 2016a). The term “migrant crisis” is preferred instead of “refugee crisis” explained by analyzing the desegregation of migrants and refugees arrived in Europe by nationality. According to UNHCR (2017a), Syrians constitute the 6.4% of total arrivals in the Mediterranean and 38.5% in Greece. This statistics constitutes an indisputable proof that Europe and Greece, in particular, faces a migration crisis with intense refugee waves.

Since 2015, a large proportion of migration flows has directed to Europe through the countries of the Mediterranean – South (Metcalf-Hough, 2015). Greece is the country of first entry for the vast majority of migrants and refugees arrived in Europe by sea or land because of its geographical location. Greek Islands of the Aegean Sea have greeted more than 70% of arrivals between 2015 and 2016 (UNHCR, 2017a). Thus, throughout this period, the country has been converted into a transit zone for migrants to Central and Northern Europe. Migration/refugee movements formed “corridors” from East to Western Europe; through Turkey and Greece to the mainland EU, which is their final destinations (Frontex, 2016).

This unprecedented phenomenon force European Institutions, which were almost unprepared to deal with an excessive crisis like this, to cooperate and develop a migration policy to immediately respond to the crisis in the Mediterranean and set out longer-term steps to manage migration in all its aspects (European Union, c2017). Asylum policy is the most significant component of EU migration policy. EU objectives are to develop a common policy on asylum, subsidiary protection, and temporary protection, intending to offer an appropriate status to all third-country nationals who need international protection and ensure that the principle of non-refoulement is observed (European Union, c2017). However, the main challenges, as Frontex (2016) noted, consist of effective surveillance measures, rescue operations, gaps to facilitate the accommodation and detection of false records.

Regarding Greek Asylum System as part of a joint European asylum system, it was flawed long before migration crisis bursts. It is indicative the fact that Dublin transfers to Greece from the other Member States have been suspended since 2011 following two judgments of the European Court of Human Rights (ECHR) and the Court of Justice of the European Union (CJEU) which identified systemic deficiencies in the Greek asylum system. The Commission proposed in May 2016 to reform the Dublin system, notably introducing a new fairness mechanism to ensure no Member State remains with a disproportionate pressure on its asylum system (European Union, 2016b). According to UNHCR (2017a), from 1.015.078 migrants arrived in Greece in 2015, only 13.197 applied for asylum. Most of them wanted to get to Germany, Hungary and Sweden. An application for asylum is a time-consuming procedure, though. As a result, Greece, being the gateway to the destination countries for millions of people, turned into an infinite hotspot.

2 ANALYSIS OF SPATIAL TRANSFORMATIONS AND THEIR IMPACTS

Migration dynamics radically altered the urban (and rural incidentally) settings. For the last two years, the intensive migration flows in Greece have affected the urban and rural systems across the country. In this context, through a four-stage research, the types and the consequences of all spatial transformations that have occurred will be determined. The methodology used is the statistics (primarily secondary data) – land

cover map processing, literature review and to a limited extent field observation. However, it should be mentioned that data availability is a limiting factor, but not capable of making the research results invalid.

2.1 1ST STAGE: RECORDING OF MIGRANTS CAMPS

The first stage of the research constitutes a complete record of migrant camps (migrant/refugee structures and gathering places, both formal and informal) all over the country. This process has a primary difficulty; national and international institutions categorize these sites according to different criteria, complicating the record and the data collection as well.

Greek Government set up, in the middle of migration crisis, the Law No. 4375/2016. According to this legal document, refugee structures required for addressing the migration flows categorized into three groups: i) Reception and Identification Centers, located mainly in border areas of Greece, but in inland areas as well, ii) Open Temporary Reception Structures and iii) Open Temporary Accommodation Structures. On the other hand, international organizations such as International Organization for Migration (IOM) has embraced the UNHCR categorization for migration/refugee sites, grouping them into i) Reception and Identification Centers, ii) Emergency Response Sites, iii) Relocation Sites, iv) Collective Shelters.

For the purpose of this research, the UNHCR's categories are adopted. The results of the recording (data retrieved from UNHCR (2017a) Report for May 2017) show that the vast majority of migrant camps are "Emergency Response Sites" (approximately 84%), while "Reception and Identification Centers" are the second most common group (10.71%). "Collective Shelters" (3.57%) and "Relocation Centers" (1.79%) are significantly smaller categories (Diagram 1).

Diagram 1 - Categories of Migrants Camps (%)
Source: (Data retrieved from UNHCR, 2017a), Own Processing

All these categories include formal sites, both in the mainland and the islands (Figure 1), organized and operated by Hellenic Authorities or other Institutions (e.g. United Nations). It is important to note that the geographical distribution of each category is related to the migration flows inside and outside of the country (Frontex, 2015). For Instance, as expected, Reception and Identification Centers are recorded, almost exclusively, in the Dodecanese. This area, where the most overcrowded sites are located, is the entrance gate to Greece and Europe (IOM, 2016). Other types and especially Emergency Response Sites, which host about 1/3 of total migrants waiting for their asylum applications, are scattered across the territory. In some way, the country is divided into two zones; the first one is the inland zone operating as a reception area, while the second one is the mainland as a waiting area.

Another issue concerning these types of camps relates to their capacity. At the first stages of migration crisis, occupancy rates in accommodation facilities had transcended 100% – 46,660 people in total when the average capacity was 34,150 people. The most overcrowded sites recorded mostly in Dodecanese (Chios, Samos, Kos, Rhodes), raising the capacity of sites to 65,682 (including on-hold sites) (UNHCR, 2017a). This situation combined with severe conditions (e.g. food, hygiene) indeed opposites from Dublin's Regulation (Neville et al., 2016). However, the last year this has been improved.

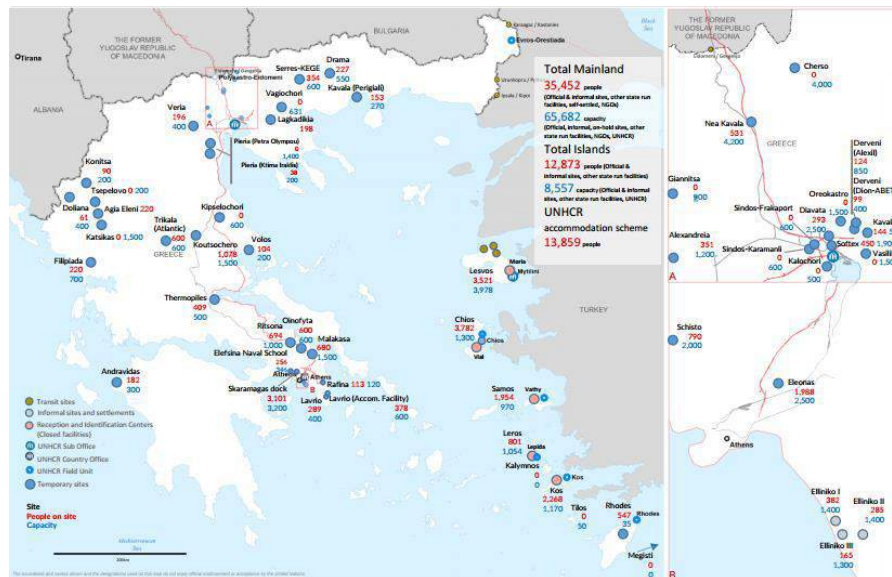

Figure 1 - Daily map indicating capacity and occupancy (as of 14 March 2017)
Source: UNHCR, 2017a

Besides, except for formal sites, there are also informal gathering places as a consequence of the uncontrolled influxes of migrants and refugees, the problems in the Greek asylum system, the lack of information, the detention conditions in several formal camps, etc. These informal migrant sites have been recorded mostly in Athens; Victoria's square and the port of Piraeus are the most representative examples.

Victoria's square located in the center of Athens is a place where migrants set up improvised camps. Although Greek authorities have evacuated the Square since March 2016, they continue gathering there mainly to converse and gain information from other migrants who live in Greece for years. The other informal camp is that in the port of Piraeus. When migrants disembarked from ships, they prefer staying in the harbor, having a potential "freedom," rather than being collected in camps far away from essential services. These two areas, which transformed into informal gathering sites, were not selected randomly. Both are open public spaces in the urban fabric with a high rate of citizen mobility. Consequently, it is easier for migrants/refugees not only to contact with migratory networks and mediators, but also to move to Idomeni. Idomeni is another informal camp. Its peculiarity compared to the above areas lies in the fact that is located away from basic services but very close to FYROM borders making migrants transit to their final north-European destinations much easier. Informal gathering sites are a phenomenon, neither government and media nor locals could overlook.

2.2 2ND STAGE: OVERVIEW OF SPATIAL CONDITIONS

The second stage of the research refers to an overview of spatial conditions of the areas that now host migrant camps. Specifically, in order the spatial transformations occurred to them to be better understood, it is necessary the previous land uses and land covers to be examined. Furthermore, analyzing their geographical location, namely proximity to urban settlements or transport network, is of considerable interest as it provides a clear view of the placement options and their impacts on the spatial structure. Option for accommodating persons of concern appropriate to the context in which displacement is taking place is of utmost importance (UNHCR, 2017b).

As it emerged from the available data, there are many categorizations about these areas. A primary categorization is based on infrastructure existence. The layout, infrastructure and shelter of a camp will have a significant influence on the safety and well-being of its residents (UNHCR, 2017b). Apart from those without any infrastructures, there are migrant camps with infrastructures which vary from buildings with all necessary facilities (e.g. toilets, baths, kitchen, bedrooms, heating, etc.) to rudimentary infrastructures. The latter may not be absolutely appropriate for housing, but to a lesser or greater extent satisfy a temporary need. An indicative example is the fact that during the winter season, the migrants/refugees at camps which have, entirely or partly, any infrastructures were significantly protected

by weather conditions in contrast with those who stayed in tents. Furthermore, their quality is questionable; even in camps that do have the necessary infrastructure, service can be inconsistent and compounded by the state of “permanent temporariness” associated with refugee camps (Cullen Dunnt, 2015 cited by Tomaszewski et al., 2016). The vast majority of migrant camps placed in areas with existing infrastructures, while only 5% of them in areas without existing infrastructures at all, such as urban voids, agricultural land or rural areas (Diagram 2).

Diagram 2 - Categories of camps according to infrastructure existence (%)
Source: (Data retrieved from field observation, local authorities and local press), Own Processing

Another categorization, related to the above, refers to whether these sites and the including buildings were previously used or not. Sites without infrastructures either were used as agricultural land in rural areas or have not been deployed at all (e.g. urban voids in urban settlements). On the other hand, sites with existing infrastructures, which were not used, were abandoned for an extended period or they were seasonally used (such as campsites). The second case, and especially the abandoned infrastructures, is the one that appears most of the time.

2.2.1 LAND USES/COVERS CHANGES

Land use/land cover changes are a basic indicator which reflects the complex spatial transformations and contributes to a more efficient spatial management. Therefore, the previous land uses/covers of the areas that have been transformed, temporarily or in the long term, into migrant camps can define the degree of differentiation they have suffered. The previous land uses/covers of the 56 examined areas vary from military camps to industrial buildings, hospitals and malls. In particular, 17 different land uses/covers have recorded, as shown in the diagram below.

Diagram 3 - Categories of Previous Land Use / Land Covers (%)
Source: (Data retrieved from field observation, local authorities and local press), Own Processing

The preponderance of migrant camps (26.79%) is hosted at former military facilities, either in military camps or less often in military airport bases, while industrial buildings are the second most common “previous land use” (12.50%). Urban voids /agricultural land/ rural areas (they compose a broad category with similar features such as no infrastructure existence), storehouses, hospital and educational facilities (Buildings & Traffic Education Park) constitute the 5.36% of the former uses each. Also, ports, sports facilities, slaughterhouses, shopping malls, orphanages, campsites and hotel facilities (hotels and tourist resorts) represent the 3.57% individually. Other land uses, such as recreation center, student residence and airport are more rarely met (1.79% each) (Diagram 3).

The main reasons why these areas were selected relate to a range of conditions they met. The first and foremost reason is that, due to their acreage, a large number of migrants could be hosted there, combined with the fact that most of these areas had already had infrastructures (e.g. sanitary infrastructures). Camps require significant investments in infrastructure and systems for the delivery of essential services. The running costs of maintaining and operating these dedicated facilities and systems are also considerable and often must be sustained for many years or even decades (UNHCR, 2017b). Therefore, the selected areas, despite the repairs that were made, constituted a fast and cost-effective solution.

2.2.2 GEOGRAPHICAL LOCATION

Geographical location of migrant camps is another aspect of political and social importance. Location options can affect both migrants and host communities and their relations. On the one hand, site selection is a critical factor in the ability to provide a safe and healthy environment for persons of concern (UNHCR, 2017b). It can also define the rights and freedoms of migrants, such as their ability to move freely or easily. On the other hand, security and reducing the economic and social impacts of a migrant presence is the basic priority of the locals. Thus, initial decisions on the location of the camps should involve the Government as well as local authorities and communities. Likewise, they should involve its residents. This approach is necessary to avoid long-term protection issues such as conflict with local communities (UNHCR, 2017b). In the case-study, migrant camps were classified into four groups according to their proximity to urban settlements or transport network: i) Away from Transport Network & Urban Settlement, ii) Near Transport Network, iii) Near Transport Network & Urban Settlement and iv) in Urban Settlement. The first category (approximately 16%) includes camps “Away from Transport Network and Urban Settlements” which imply the alienation of migrants who have difficulty accessing essential services and as a result, they vehemently protest (Diagram 4). However, these sites are accepted more readily from local communities. The option of camps “Near Transport Network” which are the most common category (33.93%) and “Near Transport Network and Urban Settlements”, the second most common category (28.57%), is an “intermediate” solution which cannot remove restrictions of accessibility completely, but it facilitates transit scopes and allows migrants to get access to essential services. Camps located “in Urban Settlements” (21.43%) give migrants the possibility to live with greater dignity, independence and normality as members of the community, either from the beginning of displacement or as soon as possible after that (UNHCR, 2017b). Nonetheless, host communities vehemently oppose this option most of the time causing phenomena of social unrest. In that case, refugees (in urban areas) may be subject to xenophobic attacks and treated with mistrust by host communities (UNHCR, 2017b).

Diagram 4 - Categories of camps according to their geographical location (%)
Source: (Data retrieved from UNHCR, 2017a), Own Processing

2.3 3RD STAGE: CLASSIFICATION OF SPATIAL TRANSFORMATIONS

The classification of transformations occurred in the areas that now host migrant camps is a step required to understand the way previous conditions led to current transitions. Alterations are recorded in different geographical scales, locally and nationally. The first case includes transformations referring to the spatial structure of these areas and the practices through which the changes emerged, while the second is about the new role specific regions obtained because of their geographical location.

At the local level, the spatial structure of areas became migrant sites underwent either form or use changes. Camps located in areas without any infrastructures at all, such as urban voids or agricultural land, provoke both form and use changes; essentially, atypical settlements were developed, changing the form and the use of peri-urban and rural areas. Informal gathering sites (e.g. Victoria's Square) are a commensurable case but in urban areas. By contrast, official camps located in areas with existing infrastructures (abandoned shelters) underwent only use changes. The category of spatial structure changes may also include, in the broad sense, landscape transformations recorded mainly in Greek Islands where a large number of migrants arrive on a daily basis. A pattern according to which islands are reception centers of migrants has replaced the tradition model of cosmopolitan islands full of tourists. These changes are the consequences of two practices i) central command-planning procedures and ii) unauthorized movements of migrants. As noted before, formal sites, organized and supervised by Greek Government (Ministry of National Defense and Ministry of the Interior) and local authorities as well, are selected through a comprehensive planning procedure. On the contrary, informal gathering sites is the result of unauthorized movements of migrants who refused to stay at authorized camps.

At the national level, transformations bears on the role of some regions during the migration crisis. Due to the direction of migrant fluxes and the spatial distribution of migrant camps, specific areas have a dynamic role in addressing this crisis. Analytically, the eastern part of the country operates as a gateway (reception zone) for migrants coming through South-eastern Mediterranean countries. These zone consists of Dodecanese islands. Mainland, as claimed above, operates as "waiting zone". However, the Greek (mainland) territory is divided into two sub-zones where the northern part constitutes the final (interior) destination due to its proximity to the Balkan borders and the metropolitan area of Attica has become a point of transition between the two aforementioned zones.

2.4 4TH STAGE: IMPACTS AND INTERACTIONS

The characteristics of current migration crisis differentiated it from the previous ones. The rate of daily arrivals, the intense diffusion of migration sites, the different socioeconomic and spatial features of the regions where are located, all together, combined with the brute fiscal crisis that has affected Greece entirely, have begotten a complex system of multi-level impacts and interactions.

In the previous stage, spatial transformations at all geographical scales were examined. As shown, areas included in each of the three geographic zones that identified, present similarities regarding the economy, the urban development model and the social structure. This relative homogeneity leads to transformation patterns which are analyzed at this final stage to figure out their impacts and intersections between them and other key issues of urban development.

Dodecanese islands represent the first transformation pattern. This zone faces the strongest pressures of migration flows. The overcrowded camps with dangerous living conditions are considered as polluting sites putting public hygiene at risk. Also, the migrants' presence at tourist hotspots makes these islands an unattractive tourist destination with adverse effects in the local economy which is mainly based on touristic activity. However, migrants and members of international institutions and NGOs working at migrant camps are to some extent a source of income for many local businesses (shops, hotels, etc.). Furthermore, another economic issue is the risk of land values decreasing in areas around migrant camps that are usually intended for vacation houses or tourist resorts. From the social point of view, the local community was unprepared to accept and meet the needs of this sensitive social group. Consequently, social stability and equilibrium are in danger.

The second transformation pattern refers to urban settlements that host migrant camps. This case has some risks similar to the previous ones. The environmental degradation of sites transformed into migrant camps is one of them. Moreover, the wider area around them may suffer from real estate marketing

problems such as land values decreasing or from deterioration in the quality of the built environment. The lack of migration policy in an unprepared community to host such a large number of arrivals, may turn these camps into ghettos and therefore areas of “urban fear”. One basic characteristic of that pattern concerns the changes in cities character which become even more multicultural. This is a two-side issue depending on the policy agenda whether and how it will benefit (economically, socially) the cities.

The last transformation pattern is mostly met in rural areas where migrant camps are located far away from urban settlements and basic services. In that case, camps operate as settlements directly dependent by nearest cities, creating transit fluxes to and from them. However, the most important issue is that a standard of immigrant isolation is reinforced which can affect the relations between the local and migrant community.

3 CONCLUSIONS

As can be seen from the above, Greece faces a complex migration crisis, which has already left its deep social and spatial footprint. During this period, as the country was unprepared to deal with it, many wrong manipulations were made. Thus, it is of great importance to identify the mistakes and develop the best practices, so the “lessons” learned from this situation to constitute an emergency roadmap for other countries and future cases.

Planning is both an indispensable condition and a useful tool for the preparation and response to a migrant/refugee crisis. Site planning, a long-term procedure, which involves hardy political decisions, is among the first of the required steps. The rational spatial distribution of migrant camps is necessary so that the carrying capacity of each area does not exceed. On the one hand, this ensures better living conditions for migrants and consequently avoiding the development of informal gathering sites. On the other hand, it limits local community's protests, fostering better relations between locals and migrants and therefore migrants' social integration to host community. In this context, adopting a 'bottom up' approach to planning, so that decision-making involve national and local governments as well as host and refugee communities is an essential principle. Planning should be based on migrants/refugees needs but also reflect the wishes of the host community as much as possible (UNHCR, 2017b) to address or even prevent potential conflicts between them. A comprehensive immigration policy, which adopts a different, more proactive approach to welcoming newcomers (UNHCR, 2017b) will address such problems. This policy should provide guidelines to other spatial policies and programs in order adaptive urban planning in response to a migrant crisis can be effective.

Focusing on the Greek case, beyond the many problems created, there could be benefits in the long term through making use of migrant human capital. Giving them incentives to stay in Greece, such as housing at abandoned rural settlements or agriculture/farming jobs, can benefit the reconstitution of the agricultural sector or lead to an inversion of desertification of settlements and demographic aging. Apart from policy-making mentioned above, there are also technical aspects that should be fixed. Firstly, there is a need for a database about migrant flows, migrants' profile and migrant camps. Without this information, policy-making is almost impossible.

Finally, the research offers key conclusions that may be exploited so that ways and means to more effectively and integrate urban and regional planning would be addressed in similar situations. Nowadays, it is more necessary than ever to develop best adaptive planning practices capable to manage emerging risks for places of dignity.

ID 1562 | CLIMATE ADAPTATION IN REGIONAL PLANNING IN GERMANY

Hanna Christine Schmitt¹

¹TU Dortmund University, School of Spatial Planning, Institute of Spatial Planning (IRPUD)

hanna.schmitt@tu-dortmund.de

1 INTRODUCTION

The legal basis of the German spatial planning system is the Federal Planning Act (Raumordnungsgesetz des Bundes, ROG), which defines the core task of spatial planning to be the “anticipatory, comprehensive, supra-local and cross-sectoral organisation of the spatial and settlement structure for the medium and long term” (ARL, 2005, p. 965). Within the German planning system, regional planning is the intermediate level of comprehensive planning, bridging the (political) frameworks of the national level, sectoral planning and the (practical) implementation at the local level. It concretises the aims and guiding principles of comprehensive spatial planning of the national and federal-state level for all planning regions and prepares regional plans in accordance with § 8 (1) no. 2 ROG.

Due to regional planning’s comprehensive, supra-local and yet spatially-specific character, it is qualified for addressing impacts of climate change. This becomes especially valuable in the light of absence of a separate sectoral planning division responsible for considering climatic changes (ARL, 2013; BMVBS, 2009; Federal Government, 2008).

In 2008, climate adaptation was given concrete political and legal status through the resolution of the ‘German Strategy for Adaptation to Climate Change’ (Deutsche Anpassungsstrategie an den Klimawandel, DAS) and the amendment of the ROG through the supplementation of the ‘Climate Protection Section’ (Klimaschutzparagraph). The latter states that “the spatial requirements of climate protection must be

taken into account, both by means counteracting climate change and by serving the adaptation to climate change" (§ 2 sect. 2 no. 6 ROG). In addition to the DAS, the 'Adaptation Action Plan' (Aktionsplan Anpassung zur DAS, APA) was published in 2011, representing a national strategy with objectives and measures for climate adaptation (Federal Government, 2008). Additionally, the 'Conference of Ministers on Spatial Planning' (Ministerkonferenz der Raumordnung, MKRO) presented a concept of action regarding the spatial consequences of climate change and possible prevention, mitigation and adaptation strategies in 2009, respectively 2013. The MKRO concept highlights the role of spatial planning in climate change adaptation and mitigation¹ and contains Fields of Action for further elaboration through regional planning.

This paper presents the status quo on the implementation of adaptation-relevant designations in German regional plans, as claimed by DAS, ROG and MKRO. First, an introduction to the methodology of the analysis is given (see subchapter 2). Subsequent, research results of the Germany-wide analysis are presented (see subchapter 3). The overall implementation rate of climate-adaptation related designations for all planning regions and all Fields of Action is presented first, before a more detailed description of the research results follows for the two Fields of Action with the least implementation rate (Coastal Protection and Protection of Mountainous Areas). The two exemplary Fields of Action are described regarding their climatic and spatial-planning relevance and existing approaches and model designations are introduced. Additionally, an in-depth presentation and interpretation of the research results is given. Last, a conclusion on climate adaptation in regional planning and remaining potentials is drawn (see subchapter 4).

2 METHODOLOGY

The formal regional plans serve as the basis for the analysis on climate adaptation in regional planning. As regional plans are both the most important (formal) spatial planning instrument at the regional level (BMVBS and BBSR, 2011) and are available for all planning regions in Germany, comparability of the results is guaranteed (Schmitt, 2014). Although informal instrument are not considered in the analysis, their importance for regional planning processes, e.g. in risk communication, has to be stressed².

The MKRO concept defines seven Fields of Action for climate change adaptation, which are to be implemented at regional and local planning level. For the Germany-wide analysis, these Fields of Action are further concretised into 22 action foci (see Tab. 1). Model designations are derived for each of the 22 action foci (exemplarily see subchapters 3.1.2 and 3.2.2), which are systematically analysed regarding their existence and legal validity in all regional plans.

Field of Action I – Flood Protection in River Areas	
I.i	Preservation of existing flooding areas for retention purposes
I.ii	Retrieval of flooding areas for retention
I.iii	Risk prevention in potential flooding areas
I.iv	Improvement of retention in the river catchment areas
I.v	Preservation of potential sites for flood protection facilities
Field of Action II – Coastal Protection	
II.i	Complementary risk minimisation in storm-surge protected coastal areas
II.ii	Risk minimisation in insufficiently storm-surge protected coastal areas
II.iii	Preservation of buffer zones (building development prohibited) in areas of unprotected coastal erosion
II.iv	Protection of areas for clay and marine sand extraction for coastal protection purposes
II.v	Preservation of areas in embankment foreland and hinterland
Field of Action III – Protection of Mountainous Areas (esp. Alpine Region)	
III.i	Preservation/Restoration of the protective functions of mountain forest
III.ii	Protection from natural (mountain) hazards
III.iii	Protection and development of mountain regions as living, economic and touristic areas
Field of Action IV – Protection from Heat in Settlement Areas	
IV.i	Protection of significant regional climate-effective free spaces and compensation areas
IV.ii	Spatial management of settlement and infrastructure development

¹ While climate mitigation aims to avoid or reduce further anthropogenic influences on the climate (e.g. by reducing greenhouse gas emissions and increasing energy efficiency) climate adaptation aims to adapt to unavoidable impacts of climate change (Birkmann et al., 2013; BMVBS, 2010).

² Informal instruments can support balancing the lack of flexibility of formal instruments, which is one reason why a combination of formal and informal instruments is recommendable in implementing climate adaptation measures.

Field of Action V – Regional Water Scarcity	
V.i	Preservation of water resources
V.ii	Endorsement of preservation and improvement of soil water balance
V.iii	Anticipatory management of highly water-consumptive land-uses
Field of Action VI – Changes in Tourism Behaviour	
VI.i	Determination of new tourism development areas
VI.ii	Protection of sites for tourism-related infrastructure
Field of Action VII – Displacement of Animal and Plant Habitats	
VII.i	Protection of a regional, functionally-connected network of ecologically important free spaces
VII.ii	Minimisation of further fragmentation of the landscape

Table 1 – Fields of Action and action foci for climate adaptation
(own depiction following Bavarian State Government, 2013; MKRO, 2013)

The legal validity of the designations within regional plans is the core element of the analysis, which allows the evaluation of the status quo and further potentials in climate adaptation. The legal validity is differentiated as follows: Aims of comprehensive spatial planning and designations of priority areas (Vorranggebiete) evolve a stronger legal validity as they are directly binding for any subsequent planning (and do not need to become subject to a weighting process). Due to the strong legal validity, aims and priority areas are evaluated with an implementation rate of 100%. Guiding principles of spatial planning and designations of restricted areas (Vorbehaltsgebiete) evolve weaker legal validity as they remain subject to weighting, which is why they are evaluated with an implementation rate of 50%¹. The total implementation rate of a planning region results from the normalisation of the addition of the implementation rates of all action foci relevant for the region². The normalization allows the comparison of planning regions with different number of relevant Fields of Action. Accordingly a planning region achieves an implementation rate of 100% if all action foci are designated as aims or priority areas⁶ (Schmitt, 2014).

The analysis incorporates all German regional plans that were in force on the reporting date 30. June 2014. This also includes regional plans that were temporarily invalid³ as well as segmented plans that were not yet integrated in comprehensive regional plans. However, preparatory regional plans or amendments that were not yet adopted are neglected. Furthermore, special types of planning regions are not taken into account, as comparability cannot be provided. This applies to the city states of Berlin, Bremen and Bremerhaven, Hamburg, the Federal State Saarland, municipalities of Lower Saxony and the city region Ruhr. All in all, the analysis comprises 111 regional plans (Schmitt, 2016).

3 STATUS QUO IN REGIONAL CLIMATE ADAPTATION IN GERMANY

Figure 1 illustrates the strong heterogeneity in the implementation levels of adaptation-relevant designations in Germany's regional plans. Apart from two planning regions in Lower Saxony (temporarily invalid) and the planning regions of Brandenburg (solely segmented plans), all planning regions reveal a status quo of more than 20% in regional climate adaptation. However, only one planning region in Bavaria achieves more than 80%. On average, German regional plans achieve an implementation rate of 52.71% regarding adaptation-relevant designations (reporting date 30. June 2014).

¹ Although the classification of a designation's legal validity is a simplification of the actual effectiveness of aims and guiding principles, the approach allows for quantification and systematisation of the research results. for the regionfor the regionfor the region

² However, an assessment on whether it is appropriate for an individual planning region to solely designate aims and priority areas cannot be provided and lags behind the aim of a Germany-wide analysis.

³ According to the Regional Planning Act of Lower Saxony (Niedersächsisches Landesraumordnungsgesetz, NROG), planning regions are obligated to assess the need for amendment or updating of regional plans according to § 5 (7) NROG. If the regions do not attend this obligation, plans become temporally invalid until updating is completed.

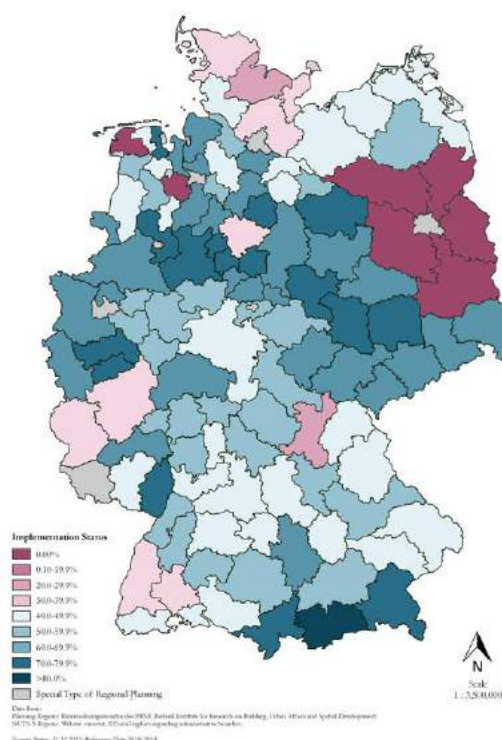

Figure 1 – Status quo of adaptation-relevant implementations in regional plans in Germany (own depiction following Schmitt, 2016)

Table 2 depicts the implementation rate of adaptation-relevant designations for each Field of Action of the MKRO concept. There are large differences between the Fields of Action that range from nearly 90% implementation rate in Fields of Action IV and VII to solely 16.0% in Field of Action III.

	FoA I	FoA II	FoA III	FoA IV	FoA V	FoA VI	FoA VII
	<i>Flood Protection in River Areas</i>	<i>Coastal Protection</i>	<i>Protection of Mountainous Areas (esp. Alpine Region)</i>	<i>Protection from Heat in Settlement Areas</i>	<i>Regional Water Scarcity</i>	<i>Changes in Tourism Behaviour</i>	<i>Displacement of Animal and Plant Habitats</i>
Implementation Rate	43.6%	18.2%	16.0%	88.5%	44.3%	52.5%	89.5%

Table 2 – Implementation rate per Field of Action (own depiction following Schmitt, 2016)

An explanatory approach for the differences between the Fields of Action is that the action foci of Fields of Action IV and VII, which achieve the highest implementation rates, lie within the core task of spatial planning according to § 8 (5) ROG, i.e. settlement development, preservation of free space and infrastructure development (see e.g. IV.ii and VII.i). The high implementation rates in both Fields of Action are achieved mostly indirectly, e.g. through securing regional green corridors rather than by direct addressing climate adaptation. In contrast, the Fields of Action II and III traditionally lie within the responsibilities of sectoral planning and do not yet seem to be addressed in formal regional plans (Schmitt, 2016). In the following, Fields of Action II and III are investigated in more detail.

3.1 FIELD OF ACTION II – COASTAL PROTECTION

Field of Action II – Coastal Protection covers flood protection from storm surges on the one hand and the prevention of coastal degeneration through erosion on the other hand. The contents of this MKRO Field of Action shall supplement the (informal) Integrated Coastal Management as introduced by the European Commission (European Commission, 2016). Germany has an Integrated Coastal Management (Integriertes Küstenzonenmanagement, IKZM) since 2006, which already complements the formal sectoral plans (BMUB, 2006).

3.1.1 CLIMATIC AND SPATIAL-PLANNING RELEVANCE

The most important climate-change related variables in coastal areas are the rise of the sea level, frequency and magnitude of storm surges and swell. As a result of the expected rise of the sea level, a stronger hydrodynamic load as well as an increasing coastal erosion are to be expected. However, the extend of these impacts is highly uncertain (MKRO, 2013). Secondary consequences of the sea level rise may be flooding of insufficiently protected areas, the need for larger (technical) effort for coastal protection measures as well as land-loss due to erosion. Additionally, the increase in extreme precipitation, which leads to larger runoff, the average rise in temperature, which may lead to intensified tourism in coastal areas, as well as the increase of nutrients and pollutants into the coastal sea are results of climatic changes (BMVBS and BBSR, 2013).

The spatial-planning relevance of Field of Action II presents in the fact that the protection from storm surges and erosion are indispensable prerequisites for settlement development in coastal areas, as both reduce the damage potential. Coastal protection is a matter of land preservation and accordingly lies within the responsibilities of spatial planning. Regional planning can contribute to protection from flooding and erosion in particular through active and passive coastal protection measures as well as through the coordination of land-use demands in coastal areas (MKRO, 2013; BMVBS and BBSR, 2013). The most essential regional planning instrument for avoiding damages is the management of land uses through designations in regional plans.

The MKRO identifies five action foci for Field of Action II – Coastal Protection:

- II.i – Complementary risk minimisation in storm-surge protected coastal areas
- II.ii – Risk minimisation in insufficiently storm-surge protected coastal areas
- II.iii – Preservation of buffer zones (building development prohibited) in areas of unprotected coastal erosion
- II.iv – Protection of areas for clay and marine sand extraction for coastal protection purposes
- II.v – Preservation of areas in embankment foreland and hinterland (MKRO, 2013)

3.1.2 EXISTING APPROACHES AND MODEL DESIGNATIONS

The designation of coastal protection measures in regional plans strongly depends on the accuracy of climate change projections and their spatial resolution. Therefore, both an assessment of the current situation (detection of areas endangered by storm surges and erosion) as well as the integration of present and future sensitivities and impacts is necessary. Only then, appropriate measures can be identified and implemented, which are liable with respect to competing land-use demands.

Measures of preventive coastal protection can generally be classified as suitable if they are of flexible and extendable character. Good examples are temporal land-uses as well as temporally compatible, revisable land-uses in buffer zones. The designation of restrictive covenants in especially risky areas (e.g. low-lying areas) can also be an adequate measure. In addition, spatial planning can contribute to the sensitisation and information of population through designation of flood-prone coastal areas and thereby gives incentive for private risk protection (MKRO, 2013; BMVBS and BBSR, 2013). The following designations are suggested by the MKRO and were used for the analysis of regional plans (see Tab. 3)

Action Focus	Model Designations
II.i Complementary risk minimisation in storm-surge protected coastal areas	<p>Complementary risk minimisation in storm-surge protected coastal areas may be carried out using text or designations in maps, e.g. by assumption of risk-prone areas according to flood risk maps of EU FRMD.</p> <ul style="list-style-type: none"> • Designation of risk areas • Rebuilding of roads to higher elevation (dikes) in order to improve accessibility of potential dike damages and for building polders for further protection • Covenants on use for particularly low-lying areas (potential longer and deeper inundation); e.g. through restrictive covenant

II.ii Risk minimisation in insufficiently storm-surge protected coastal areas	<ul style="list-style-type: none"> Designation of restricted areas for development of buildings, infrastructure and other land-uses without additional protection from storm surges
II.iii Preservation of buffer zones (building development prohibited) in areas of unprotected coastal erosion	<ul style="list-style-type: none"> Designation of priority areas for buffer zones (safety distances) in erosive coastal areas Designation of priority or restricted areas for permitted land-uses in erosive coastal areas Designation of land-uses securing free space, e.g. priority and restricted areas for nature and landscape <p>In addition, temporal, compatible and revisable land-uses may be permitted in buffer zones.</p>
II.iv Protection of areas for clay and marine sand extraction for coastal protection purposes	<ul style="list-style-type: none"> Designation of priority and restricted areas for the protection of clay extraction sites in embankment foreland and dike-protected coastal marshland Designation of priority and restricted areas for the protection of clay extraction sites in embankment foreland
II.v Preservation of areas in embankment foreland and hinterland	<ul style="list-style-type: none"> Designation of priority and restricted areas for coastal protection planning in front of and behind coastal protection facilities as well as for the exclusion or restriction of other land-use demands (e.g. settlement, tourism, nature protection)

Table 3 – Model designations for Field of Action II – Coastal Protection
(own depiction following MKRO, 2013; BMVBS and BBSR, 2013)

3.1.3 RESEARCH RESULTS FOR COASTAL PROTECTION

For the analysis of Field of Action II, it was insufficient to solely address planning regions adjacent to the sea, as e.g. coastal protection facilities (action focus II.v) may present in form of a second dike line in the hinterlands. Also, clay extraction points (action focus II.iv) are usually located in the coastal marshes (MKRO, 2013; BGR, 2008). For this reason, flood risk maps according to the EU Flood Risk Management

Directive (FRMD) were used for identifying planning regions for which Field of Action II is of relevance. According to the EU FRMD and the German Federal Water Act (Wasserhaushaltsgesetz, WHG) flood risk maps were to be prepared also for coastal areas by 31. December 2013 and were analysed for the planning regions of the federal states of Mecklenburg-Western Pomerania, Lower Saxony and Schleswig-Holstein¹ (Schmitt, 2014).

The analysis comprises 23 coastal regions. Eight of the 23 regions do not provide any designation regarding coastal protection in their regional plans. On average, only one out of the five action foci is implemented by the coastal regions (see Fig. 2).

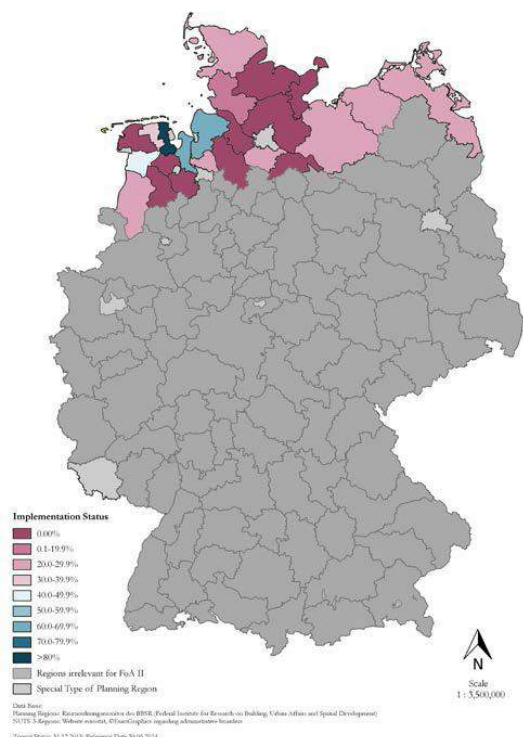

Figure 2 – Status quo of implementations in Field of Action II (own depiction following Schmitt, 2016)

¹ The city states Hamburg and Bremen are also 'coastal areas' but are not considered in the analysis as both are special types of planning regions.

There is great variation among the five action foci of Field of Action II. While action focus II.i (Complementary risk minimisation in storm-surge protected coastal areas) is covered by more than half of the planning regions, mainly as a guiding principle, only one region covers action focus II.ii (Risk minimisation in insufficiently storm-surge protected coastal areas). Designations regarding marine sand extraction for coastal protection purposes, as a part of action focus II.iv, are – so far – non-existent in Germany's regional plans.

A comparison of the federal states shows that Schleswig-Holstein has by far the least designations regarding coastal protection, which is, amongst others, subject to the following critical reflection of the research results. The planning region with the most designations in Field of Action II is Friesland, located in Lower Saxony (see Fig. 2).

3.1.4 REFLECTION AND FURTHER ADAPTATION POTENTIAL

In previous studies, e.g. by the Federal Ministry of Transport, Building and Urban Development (2010), coastal protection was understood to be relevant only for planning regions with a coastline. This analysis uses the EU FRMD flood risk maps as the basis for determining the Field of Actions' relevance for planning regions, i.e. also includes planning regions in the hinterlands. But as all regional plans relevant for Field of Action II entered into force before the deadline for flood risk map implementation, none of the plans uses the advanced definition, which is why especially the hinterland regions achieve poor results in the analysis. Accordingly, the long continuance of regional plans as well as the elaborate perpetuation process seem to be reasons why amendments are not implemented in shorter time. It can be assumed that with the next perpetuation of regional plans, coastal protection (as subject to the EU FRMD) will be integrated also in regional plans of the hinterlands.

Regarding action focus II.iii – Preservation of buffer zones in areas of unprotected coastal erosion, the research results need to be corrected in retrospective, as this action focus is only of relevance for planning regions with coastlines. Accordingly, the analysis results are slightly negatively biased, as II.iii is relevant only for 15 instead of 23 planning regions.

Furthermore, currently sectoral planning seems to cover more adaptation-relevant implementations than comprehensive spatial planning. Mecklenburg-Western Pomerania and Lower Saxony have a 'Coastal and Flood Protection Plan' (Generalplan Küsten- und Hochwasserschutz), which covers all of the action foci of the MKRO concept. Schleswig-Holstein also has a 'Coastal Protection Plan', which contains sectoral development aims that simultaneously serve as aims for comprehensive regional planning (Ministry of the Interior Schleswig-Holstein, 2010). This seems to be the major reason, why the federal state shows the least implementation rate within Field of Action II. However, the 'Coastal Protection Plan' determines that the sectoral aims need to be further concretised in regional plans, e.g. regarding individual coastal protection measures and dike lines, which is currently missing in the regional plans, as the analysis proves.

Further adaptation potential can especially be seen in action focus II.ii – Risk minimisation in insufficiently storm-surge protected coastal areas, as so far this action focus is subject to only one of the regional plans. However, as uncertainties are risk-immanent, the management of risks is a challenging task which deserves to get more attention; not only in Field of Action II – Coastal Protection.

Concluding, the lack of integration of designations in sectoral plans into formal regional plans hints at a lack of cooperation between sectoral and comprehensive planning, which leaves room for further improvement. Additionally, there is a need for revision of coastal protection strategies and measures in order to allow adaptation to climate-change induced impacts (MKRO, 2013). In summary, the results of the analysis remain plausible since the (informal and sectoral) instruments and strategies that exist in coastal protection in Germany have so far been widely disregarded in the regional plans (Schmitt, 2014).

3.2 FIELD OF ACTION III – PROTECTION OF MOUNTAINOUS AREAS

Field of Action III – Protection of Mountainous Areas (especially Alpine Region) addresses the climate-change induced change in hazard potential in mountainous areas as well as the handling of geogenic hazards.

3.2.1 CLIMATIC AND SPATIAL-PLANNING RELEVANCE

Strong climate change impacts are to be expected for mountainous areas in Germany, particularly in the Alpine region. An above-average temperature rise is projected, which is accompanied by an increase in the average annual temperature, an increase in winter half-year temperatures, as well as an increase in days with maximum temperatures above 30°C. Warming is accompanied by a decrease in permanent and partial frost days, a decrease in snow safety for winter sports areas and a significant degeneration of glaciers. In consequence, an upward shift of the vegetation zones and adverse effects on the alpine flora and fauna are to be expected. In addition, an increase in the frequency and magnitude of severe precipitation and thus an increased flood risk is predicted. Severe precipitation can moreover lead to a change in geogenic hazards such as rockfall, mud slides and avalanches (MKRO, 2013; BMVBS and BBSR, 2013). According to the Bavarian Environmental Agency, the following natural hazards are of particular relevance in mountain areas: flood, subsidence (eluviation, leading to sinkholes and subsidence) and karsting, soil deformation (subsidence/uplift) and mass movements (Bavarian Environment State Office, 2014).

These geogenic hazards call for a supra-local and comprehensive management capable of respecting the spatial diversity of mountainous areas, which is why Field of Action III is spatial-planning relevant (BMVBS and BBSR, 2013). Mountain areas are both ecosystems, as well as living, cultural and economic areas. Regional planning can in particular influence the protection of the population against natural hazards. It is also capable of influencing the economic (especially touristic) and settlement-related development possibilities (MKRO, 2013; Federal Government, 2008).

In contrast to the other Fields of Action, the MKRO concept does not contain action foci for Field of Action III, but refers to the contents of the 'Alpine Plan' (Alpenplan), which has been part of the Bavarian Regional Development Programme (Landesentwicklungsprogramm, LEPro) since 1972 and serves as the major instrument for the development of the Alpine region. The following action foci were derived from the 'Alpine Plan' and used to analyse the regional plans in mountainous areas:

- III.i Preservation/Restoration of the protective functions of mountain forest
- III.ii Protection from natural (mountain) hazards
- III.iii Protection and development of mountain areas as living, economic and touristic areas (Bavarian State Government, 2013).

3.2.2 EXISTING APPROACHES AND MODEL DESIGNATIONS

The Federal Geological Service (Staatlicher Geologischer Dienst, SGD), respectively State Offices, can provide hazard maps on geogenic natural hazards for regional planning. Although these maps do not contain statements on the probability of occurrence and the damage potential of natural hazards, they may serve to identify the spatial extent of potential hazards (Bavarian Environment State Office, 2014). Furthermore, sectoral planning divisions can usually provide hazard maps or management plans (e.g. avalanche maps) (MKRO, 2013). Tsectoral planning divisions can usually provide hazard maps or management plans (e.g. avalanche maps) (MKRO, 2013). Tsectoral planning divisions can usually provide hazard maps or management plans (e.g. avalanche maps) (MKRO, 2013). T he following designations are suggested within the 'Alpine Plan' by the Bavarian State Government and were used as criteria for the analysis (see Tab. 4).

Action Focus	Model Designations
III.i Preservation/Restoration of the protective functions of mountain forests	<ul style="list-style-type: none"> Designation of priority and restricted areas for securing mountain forests and their protective functions⁹
III.ii Protection from natural (mountain) hazards	Designations for preservation of areas prone to mountain hazards, e.g. by <ul style="list-style-type: none"> Designation of priority and restricted areas of protective forest (for minimising alpine hazard potentials, especially avalanches, rockfall and mud slides)¹⁰
III.iii Protection and development of mountain areas as living, economic and touristic areas	Designations for securing and development of special functions (settlement, economy, tourism) of mountainous areas

Table 4 – Model designations for Field of Action III – Protection of Mountainous Areas (own depiction following MKRO, 2013; BMVBS and BBSR, 2013)¹²

3.2.3 RESEARCH RESULTS FOR THE PROTECTION OF MOUNTAINOUS AREAS

The identification of planning regions for which Field of Action III – Protection of Mountainous Areas (esp. Alpine Regions) is relevant, is ambiguous. First, the three German alpine regions are considered, as indicated by the title of the Field of Action. However, since all action foci are equally relevant for the German low mountain ranges, all planning regions with an altitude of at least 500 meters are analysed.

Accordingly, Germany has three Alpine regions and 47 low mountain range regions (see Fig. 3). While the regional plans of the three Alpine regions reveal aims and priority areas for (nearly) all action foci, more than half of the remaining mountainous regions currently do not consider any action focus of Field of Action III. In total, 28 of the 50 mountainous regions do not provide any designations in their regional plans concerning Field of Action III.

Figure 3 – Status quo of implementations in Field of Action III (own depiction following Schmitt, 2016)

With 16.0% Field of Action III shows the lowest implementation rate of all MKRO Fields of Action. The comparison of implementation rates of the three action foci within Field of Action III shows, that action focus III.i – Preservation/Restauration of the protective functions of mountain forest is designated most often, while III.ii – Protection from natural (mountain) hazards is designated least often.

3.2.4 REFLECTION AND FURTHER ADAPTATION POTENTIAL

One explanatory approach for the low overall implementation rate in Field of Action III can be seen in the relatively broad definition of mountainous areas (existence of mountains with an altitude of at least 500 metres), which can, nonetheless, be considered appropriate as negative impacts of climate change can also be expected for low mountain ranges (Schmitt, 2014). In the light of increasing climate change-related

¹ Guiding Principle 2.3.2 LEPro Bavaria: "Forests and their protective functions together with the cultivation of the cultural landscape shall be secured in the Alpine regions, in particular through agriculture and forestry."

² Guiding Principle 2.3.3 LEPro Bavaria: "The Alpine region shall be sustainably developed, structured and secured so that a) the diversity, character and beauty of its landscapes as well as the natural diversity of its wild living animal and plant species are preserved by securing and developing their habitats and sustaining their network b) its functions as cross-border areas for living, recreation, economy and transport are secured while respecting its importance as natural and cultural areas of European importance, c) alpine hazards are minimised."

risks, the need for dealing with challenges for mountainous areas in regional plans becomes even more urgent.

A reason why action focus III.i – Preservation/Restoration of the protective functions of mountain forest is designated most often is § 12 of the Federal Forest Act (Bundeswaldgesetz, BWaldG). The BWaldG states that “the designation of protected forest particularly comes into consideration for the protection against adverse environmental effects [...], erosion by water and wind, drying up of soil, harmful surface runoff and avalanches.” (§ 12 sect. 2)

The key challenge in Field of Action III seems to be that currently there are no established formal regional planning instruments. If at all, informal instruments are used for the protection of mountainous areas (e.g. regional management). Generally speaking, the use of informal instruments is an important approach in dealing with mountainous areas in the light of climate change. Regional management initiatives and risk governance processes can e.g. contribute to an increase in risk awareness, better risk communication and the implementation of risk concepts (MKRO, 2013). However, the analysis shows that there is great remaining potential and need for implementation also within formal instruments, especially regarding action focus III.ii – Protection from natural (mountain) hazards.

4 CONCLUSION

The analysis represents the current status quo in implementation of climate adaptation in (formal) regional planning and demonstrates remaining adaptation potentials. It becomes clear that regional planning has a “profound knowledge” (BMVBS, 2010, p. 79) regarding climate adaptation but most often lacks a direct implementation within regional plans. The analysis shows that there are great differences in the implementation rates of the MKRO Fields of Action. Those Fields of Actions, that achieve a high implementation rate, lie mostly within the key responsibilities of spatial planning, as e.g. the management of settlement and infrastructure development. On the other hand, especially in the two Fields of Action with the lowest implementation rates (Coastal Protection and Protection of Mountainous Areas) there are planning regions that do not address relevant action foci within regional plans at all, which hints at a lack of awareness of comprehensive spatial planning for these tasks.

Both examples reveal further adaptation potential: In Fields of Action that currently address climate adaptation rather indirectly, the importance of climate change needs to be stressed so that climate adaptation can soon serve as the justification for regional planning actions. In Fields of Action that are currently barely addressed by regional planning, the cooperation between sectoral and comprehensive planning needs to be strengthened and perpetuation procedures need to be enhanced. Therefore, further adaptation potentials cannot only be seen in raising the implementation rates for each action focus alone but in additionally strengthening the relevance of climate adaptation in regional planning so that it is perceived and handled as an independent action requirement (Schmitt, 2016).

ID 1566 | THE URBAN RISK ASSESSMENT: A METHODOLOGICAL PROPOSAL

Denis Maragno¹; Francesco Musco¹

¹University Iuav of Venice

dmaragno@iuav.it

1 CITY PLANNING AND CLIMATE CHANGE

The risks for cities and natural environment coming from the climate change seems to give back substance to the considerations on urban sustainability, a word rich in promises, but poor in applicative content.

The Global Risks Report 2016 considers all the possible potential impacts on global scale, measured in a Cartesian system. In the diagram, the x-axis defines the probability of occurrence, and the yaxis shows the impact degree on economies, population and environment. The highest position, caused by a high probability and a devastating impact on world scale represents a failure of adaptation and mitigation policies. Then the migration caused by wars and environment disasters follows, and the third position is assigned to water scarcity (both attributable to the climate change consequences).

Today the challenge of climate change represents one of the most complex scientific and political questions of the 21th century. International institutions like IPCC, OCSE, FAO, UNDP, just to mention a few, identify climate externalities like extreme rainfalls, heat and drought waves as scenarios of high environmental impact for the next 100 years. The worst-case scenarios in economic and human life terms will occur above all in the cities (Betsill, Bulkeley, 2005; Biesbroek, Swart, van der Knaap, 2009; Van der Veen, Spaans, Putters, Janssen-Jansen 2010).

The climate change topic enters local political agendas, pushed by the urgency perceived on an international level, though finding difficulties in application.

The climate proof approaches seem to require a substantial modification in the urban planning, both by reducing the climate-change emissions (mitigation), and by making the urban systems more resilient to possible climate changes (adaptation) (Musco, 2015).

These two paradigms, mitigation and alteration, even if both oriented to climate aspects, differ in action scale and application models: the international level deals with mitigation policies (expressed in targets), whereas the local level becomes the place where adaptation challenges will take place, there where the action is oriented to reduce local vulnerabilities (physical, social and economic) in relation to the possible impacts of the climate change (fig. 1).

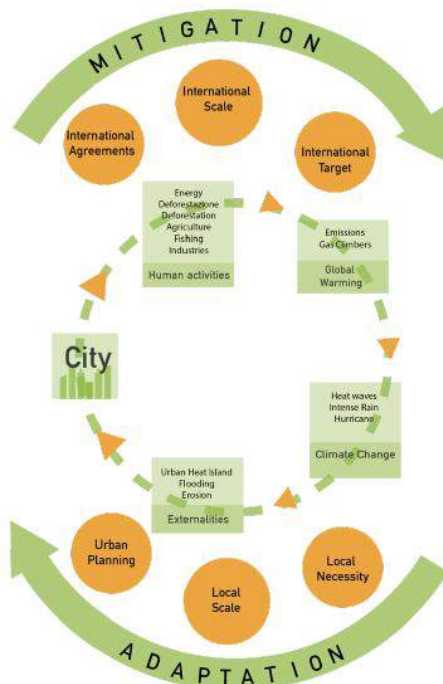

Figure 1 - Diagram of mitigation and adaptation approaches from environmental perspective (personal processing).

Adapting a territory entails mainly the modification of the consolidated fabric, vulnerable to climate impacts. In these terms, to plan a territory transformation, increasing its resilience to climate change, means to generate new rationalities in the territory planning to identify the possible impacts, measure their risk, and evaluate between the various adaptation options.

The analysis scenarios supporting an evaluation of the urban risk of climate change, require not ordinary urban knowledge frameworks (recalling the ordinary knowledge frameworks produced within the present mandatory planning practice). But details and informative types of local institutions prove to be not adequate to vulnerability and risk evaluations.

The implementation of territorial knowledge frameworks and information in general, finds in the new technologies an useful and efficient tool to produce, manage and make use of spatial information. The new technologies (ICT in particular), are more and more active in managing the spatial information. This work originates from this considerations, and investigates the possible modalities to structure an adaptation process on local scale (from analysis to identification of adaptation options), wondering about the role of technological and spatial information setup according to the territorial government activities.

2 ADAPTATION AND NEW TECHNOLOGIES OF INFORMATION

In defined urban contexts, risk perception and management can change in a substantial way. Local administrations try to contribute to mitigation strategies (through the voluntary instrument PAES, Sustainable Energy Action Plan), but above all, in the future, they should try to adapt by integrating multi-scalar policies of risk management into territorial planning and management processes. The new knowledge fostered by the NT allows the arrangement of effective knowledge frameworks as a support in the analysis and assembly phases, and it favours the understanding and the production of risk scenarios of short, medium and long term. The new technologies, if systematically applied in the planning process, can support the different phases, and allow the Plan to be less linear, granting more cyclicity in the work. The cyclicity in planning operations, made possible by the technological implication in the process, releases the planning from the rigidity of the horizontal process (Cecchini A., 1999), and allows continuous reviews and monitoring phases.

The local planning commitment to foreseen adaptation measures today, based on uncertain future scenarios, has to be supported by: a well defined work process, an integrated territorial information system and city planning instruments that take into consideration the possibility of continuous inspections. In this way, even if it means working with uncertainty, the goal of an effective planning is achieved. Therefore the interventions of adaptation will have to be considered through a comparison between the different urban situations, where the risk (or the vulnerability) doesn't refer to the city in general, but to specific urban areas of the city. In this way the risk mapping assumes different values on the territory, by indicating which areas are more vulnerable. They allow to better understand which possible measures can increase the resiliency of the area in relation to the considered expected impact.

The impacts attributable to the climate change considered in this work, which the proposed analysis process is organized on, are: heat waves and urban flooding.

Both the impacts are two of the most common in urban settings, because they both derive from dense urbanization and scarce permeability. These two features make many cities vulnerable, and endanger population, economic activities and infrastructures.

The work goal is therefore to identify an approach able to evaluate the impacts effects in the different urban transepts of the city, with the aim of supporting the planning phases with new investigation instruments, that can return the city as classified for risk and vulnerability. The classifications, besides suggesting the priority areas, are a guide in choosing the possible solution for that kind of city.

3 CONTROL CLIMATE CHANGE IMPACT THROUGH CITY PLANNING

The 5th IPCC report (AR5, 2014), figure 2, defines a new approach to vulnerability evaluation in which it deeply modifies the terminology used in AR4 of 2007, and moves the analysis process close to the one produced by UNISDR for the disaster risk reduction (DRR).

The UNISDR DRR approach is defined as application of policies, strategies and practices to reduce a disaster vulnerability and risk, in the larger context of the sustainable development (UNISDR, 2004). The DRR is rooted in the school of thought founded in 1970 (Torry, 1978, 1979, Hewitt 1983, 2007; Lewis, 1999 et al), that considered the social, economic and environmental aspects as elements strongly exposed to risks. This was in stark contrast with the previous disaster recovery approach that looked at the natural events as inevitable, and the attention was addressed more to post-disaster aspects (Mercer, 2010). We can say that the UNISDR approach in disaster risk reduction anticipated, and perhaps laid the bases to build the paradigm of climate changes adaptation. The DRR recognizes the importance of understanding the different environmental stresses referred to a risk in general, by introducing the evaluation of danger, vulnerability, and adaptation capacity, to identify the best solution to reduce the risk in the most sensitive areas (Wisner et al., 2004). A DRR successful application aims to create a resilient community without limiting its development, or reducing its services (UNISDR, 2004).

The new approach therefore has the merit of further improving the impact evaluation, that beyond vulnerability, also evaluates the environmental risk. The terminological modification entails the necessary reference to one method or the other (2007 or 2004), when factors such as the exposure, for example, are considered.

While in AR4 the term exposure is referred to climate factors, in AR5 the concept of exposure leads back to the possible functions of a specific environment, which can be compromised on the bases of a potential impact.

Figure 2 - Diagram of the aspects considered in the risk evaluation approach proposed in AR5 by IPCC. The new methodology, compared to the previous one of 2007, considers the risk towards a potential impact related to climate change. (source AR5-WG2 IPCC, Chapter 19).

The study defines the hazard (that in 2007 was expressed within the concept of exposure) as the potential possibility of an extreme climatic event to happen, that's able to provoke damages as loss of lives, or damages to infrastructures, services and ecosystems.

In this approach the vulnerability is a variable to calculate the risk (and not anymore a process output), and it is defined as the inclination of a system to be negatively influenced by the hazard. It includes also the concepts of sensitivity and adaptation capacity described in the previous methodology. The exposure, as third variable to determine the risk, is intended as the presence or not of infrastructures, services, species and ecosystems, cultural properties in the considered area, that could be negatively influenced by potential impacts.

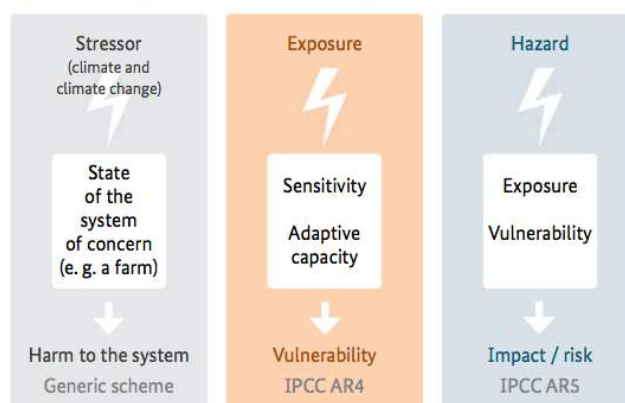

Referring to the aims of the hereby described study, that is the building of a process able to evaluate the vulnerability from the effects of environmental climate change on quarter scale, the developed

methodology finds its roots in the process that is common to all the three evaluation systems described (figure 3). The considered terminology is referred to the IPCC AR5 approach.

The work goal is to return a numerical evaluation of a local scale vulnerability (to arrive to a risk evaluation) for every possible local impact. To reach this goal it's necessary to quantify the sensitivity in every local portion in relation to the supposed impact, and to evaluate the adaptation possibilities. This logical path is the result of considerations emerged after the analysis of all the approaches, characterised by different terminologies.

One of the primary limits of vulnerability (and risk) evaluations, realized to address the urban adaptations processes, is the analysis scale. The adaptation is a set of measures (in structure and governance) linked to a specific local portion, defined in relation to its vulnerability level and risk. To accomplish a vulnerability analysis on urban scale, on the whole town portion, can be useful to know the vulnerability level of a town compared to another. But it suggests very little about where and how territorial government activities could take action. Consequently, it is convenient to clarify that to accomplish a vulnerability (or risk) analysis on local scale, entails having very detailed and homogeneous information about the whole territory. Substantially the fundamental limit, in implementing the analysis processes of urban territory (to adapt them to CC) is the lack of spatial information. This reflection went along with the research in the different applicative experiences. The vulnerability evaluation of the city of Padua, the vulnerability evaluation of some towns of the Metropolitan City of Venice, and the risk analysis of New York City, represented good chances to test the methodology, and to reflect on the employment of new technologies of information as instrument to implement the urban knowledge frameworks.

Figure 6: General logic of the different assessment approaches

Source: adelphi/EURAC 2014.

Figure 3 - Diagram of the different approaches in risk and vulnerability evaluation.
(Fonte Fritzsche K, et al, (GlZ), 2014; rework of Adelphi/ EURAC 2014.)

In all the three areas of work, the first difficulty was related to the lack of territorial information to evaluate the territory uniformly on local scale.

The process here expressed and described, inherited by direct experiences of European Planning, represents a path to adaptation integrated in the local territory government activities.

The fundamental reflection considers that a process of urban adaptation shouldn't weigh on the already numerous tasks of local administrations, but it has to find the way to integrate in the already existing processes, and to be implemented through the compulsory instruments of operational city planning. The significant goal of a local adaptation process is to reduce the vulnerability (related to the risk) of a territorial area in relation to an expected impact, increasing in fact its resiliency. The term resiliency is often linked to the concept of climate change, referring to the capacity of a territory to endure damages caused by an expected event. We can say that the vulnerability is the territorial resiliency unit of measure. The relationship between vulnerability and resiliency is not defined, many researchers underline the complementary nature of the terms (Turner 2010, Gallopin 2006), and often they link the resiliency concept

to the learning ability of a society, and its capacity of responding to negative events. In wider terms, the undeniable relations between the two concepts are in the measurement of climate change effect: by reducing the vulnerability, and increasing the adaptation abilities, the resilience increases.

Following these consideration, the adaptation process for local governances is articulated in 6 steps (figure 4).

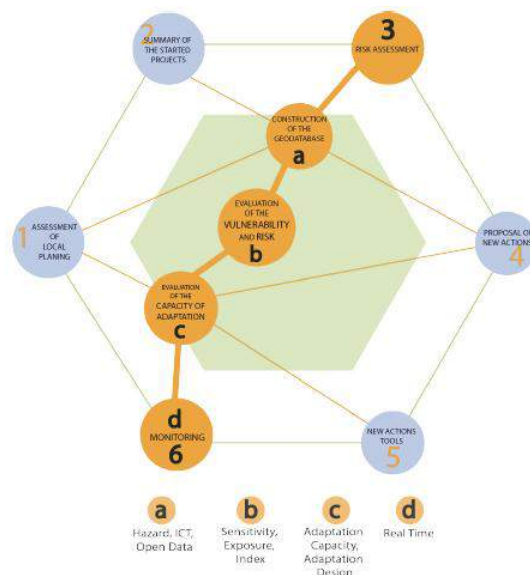

Figure 4 - Simplified diagram of the methodology developed during the work.
Every circle includes different processes designed to support the approach exportability to different cities.

4 VULNERABILITY ASSESSMENT

The backbone that supports the different phases of the assumed adaptation process (a,b,c,d), by producing vulnerability and risk analysis, and fostering the monitoring, is developed with the goal to guarantee the methodology exportation and replicability. The steps sequence, referred to the evaluation of risk and adaptation capacity, was arranged with the goal of guiding the cities towards the elaboration of an adaptation process, by considering the ICT instruments as allied in production, management, sharing of spatial information and territorial knowledge.

The sequence (orange backbone) translates logics and paradigms defined by IPCC in the 5th report (WP II, 2014) and by the UNISDR DDR (Disaster Risk Reduction). As announced, the work goal is to return a quantitative evaluation of urban vulnerability and risk in relation to a potential climate impact. The expected output is a classification of the territory, on local scale, in which every urban portion returns its own inclination to support the impact. To do it, it's necessary to quantify the sensitivity of the local portion in relation to the alleged impact, and finally evaluate the adaptation possibilities (to implement then through planning process) about exposure parameters. To encourage the work replicability, the study produced some tools, built on computer code SQL, to make more ease (and standard) the calculation of indexes of vulnerability and adaptation capacity evaluation on the possible urban impacts caused by heat waves (Urban Heat Island) and urban runoff. The goal is to maximize the support to integrated decision processes, to facilitate the structuring of multifunctional adaptation measures able to reduce the impact of a possible danger, and together improving the quality of the affected area.

The methodology elaboration is represented by flow charts to facilitate its application in other urban contexts (figure 6).

The process starts with the identification of possible impacts deriving from climate change. The probability of every impact in relation to the referred geographic context, will form the list of impacts to analyse. The inherent specificities of every impact will guide then the structuring of the new geo- database (e.g. urban runoff impact requires different information levels than erosion or desertification impacts). The composed knowledge framework has to be put in relation also to vulnerability indexes (respect to the considered

impact). Vulnerability indexes have the function of translating the result of the possible impact on the urban area (in this case the hexagon with side of 60, 80 and 250 meters/side).

At present, the spatial complexity reached by the cities, together with an increasing necessity of analysing and understanding the territory in a even more local scale (that means to aggregate information on population, economy, commercial productions, environmental system etc.), lead to the rediscovery of the hexagonal grid like software GIS spatial analysis model. In the hexagonal grid the angles are reduced to 60°, by drawing the hexagonal shape near a more representative one in the space, that is the circle (picture 5).

Figure 5 - Representation of the distances between focal points of a square and a hexagonal pattern. (Personal processing). Representation of the distances between focal points of a square and a hexagonal pattern. (Personal processing).

At present, the spatial complexity reached by the cities, together with an increasing necessity of analysing and understanding the territory in a even more local scale (that means to aggregate information on population, economy, commercial productions, environmental system etc.), lead to the rediscovery of the hexagonal grid like software GIS spatial analysis model. In the hexagonal grid the angles are reduced to 60°, by drawing the hexagonal shape near a more representative one in the space, that is the circle (picture 5). The added value in employing the spatial hexagonal pattern model in territorial analysis, is the possibility of producing complex calculations in a very fast and automatic way, by using standardised units to develop the mathematical comparison of identical areas. These cells can be compared to the nearby cells or distant ones, so they provide very precise results and maximize the reading of the spatial reports. The hexagonal decomposition of the space, moreover, facilitate the maps communicability.

The database therefore will include only one table (entity), composed by hexagonal grids, in which every feature will include the value (summed up or medium, according to the information type) of information, created by remote sensing (e.g. vegetation, impervious surface etc.), and then intersected with every hexagon area. In this way all the information are included in one table, facilitating its management. But, even more important, the model allows to examine all the aggregated information we have, related to the portion of territory surface contained in every hexagon.

Once organised the database, by aggregating the information into the entity made of hexagonal geometries, we proceed with expressing the chosen index in relation to the considered impact. The operations have been built through SQL programming that formulates mathematical calculations between the fields of the hexagonal table, in which every line represents a georeferenced hexagonal geometry.

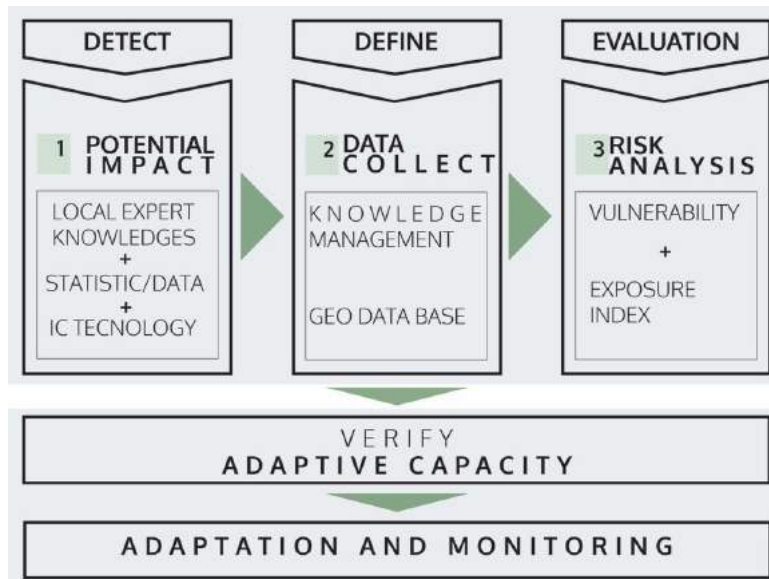

Figure 6 - Simplified diagram of the methodology developed during the Doctorate research. Every point includes different processes aimed to facilitate the approach exportation in different cities (Personal processing).

The operations have been built through SQL programming that formulates mathematical calculations between the fields of the hexagonal table, in which every line represents a georeferenced hexagonal geometry.

The indexes employed for the evaluation of areas subject to accumulate heat (sensitivity), have been identified on the bases of the indexes suggested by A. Mahdavi (2012), (Figure 7).

GEOMETRIC PROPERTIES	SYMBOL	RANGE	DEFINITION
Sky View Factor	Ψ_{sky}	0-1	Mean value of the fraction of sky hemisphere visible from ground level
Built area fraction	$\frac{A_b}{A_{tot}}$ A_b : building plan area $[m^2]$ A_{tot} : total ground area $[m^2]$	0-1	Ratio of building plan area to total ground area; fraction of ground surface with building cover
Impervious surface fraction	A_i	0-1	Ratio of unbuilt impervious plan area (paved, sealed) to total ground area
Built surface fraction 2.0	$\frac{A_w}{A_t}$ A_w : total wall area $[m^2]$	>1	Total wall (vertical horizontal)
	$\frac{A_s}{A_t}$ $A_s = (A_R + A_W)$ A_R : total roof area $[m^2]$ +	~1	Roofs
Street Incoming Solar Radiation	K_{wh}/m^2	>1	Potential solar incoming for street surface
Roofs Incoming Solar Radiation	K_{wh}/m^2		Potential solar incoming for roof surface

Figure 7 - The table summarises the set of indexes employed in the sensitivity analysis of the three pilot areas. For every area have been employed some indexes, according to the available information. A. Mahdavi (2012)

To evaluate the sensitivity, related to the increasing rainfall and possible urban runoff, the methodology considers the employment of the model Soil Conservation Service (USDA, 1972), (figure 8). The model,

based on the mm/rain per exact instant, quantifies the interception and the infiltration from the ecosystem services, and distinguishes the efficient rain or the direct runoff.

The database structure contains information, expressed in square meters, referred to the surface atlas, and the formula calculation for every hexagon.

$$P_e = \frac{(P - I_a)^2}{P - I_a + S}$$

Figure 8 - Formula to calculate the specific volume of saturation based on the curve number. In this way the saturation parameter changes according to the covering type (e.g. grass or asphalt). (Source USDA, 1972).

For experimental purpose, we wanted to proceed with the P_e evaluation in a scenario. It examines the rate of the direct runoff, by supposing a rainfall of 45mm3/m2 in a time frame of one day. The indexes are calculated and added up for every hexagonal portion, and return the vulnerability evaluation for Urban Heat Island and flooding, (Figure 9, 10).

Figure 9 – Map of local Sensitivity to Heat Wave. (Personal processing).

Figure 10 – Map of local Sensitivity to Flooding. (Personal processing).

5 RISK ASSESSMENT

IPCC (2014) defines the risk as “the potential damage, consequent to an impact, in which something valuable can be affected, and the result is uncertain, as the values difference is recognised”. Therefore, to evaluate the risk, after having defined the impact related to the hazard, and classified the territory on the bases of the vulnerability (observing the urban morphology sensitivity to the impact), the research focuses now on the exposure evaluation, by quantifying the urban functions inside every hexagon.

As for the other classifications, the methodology considers:

1. the preparation of necessary informative levels (entity);
2. the phase of information organization into the report database;
3. the phase of migration of all the entities useful for exposure evaluation, into the unique hexagonal entity (by aggregating every information on every intersecting hexagon);

4. the phase of calculation of exposure evaluation indexes (concentration of exposure attributes , e.g. m2 in schools).
5. Creation of an exposure map by summing up the value of every index for every hexagon.

In this way a further urban reading will be created, referred to the functions of the urban fabric on the hexagonal pattern, and every value will be compared with the vulnerability, previously calculated. The risk map is therefore the result of the sum of values expressed in the vulnerability and exposure indexes. In this way a very vulnerable territory, but lacking in relevant functions, has a lower risk value than a territory with the same vulnerability level, but containing many more functions (e.g. schools, commercial activities, demographic density, etc.).

The functions evaluated for every hexagonal cell are:

- population expressed in inhabitants number
- public transport m2
- commercial activities m2
- productive activities m2
- public services m2 (hospitals, schools, public buildings etc...).

The data have been collected from two different sources: the population has been acquired from the Global Human Settlement Layer (GHSL), instead the other functions have been obtained by MapPLUTO 16V2 elaborations.

The risk map (figure 11) is the result of the sum of sensitivity and exposure values.

Figure 11 – Map of local Risk to Heat Waves. (Personal processing).

In this way a further urban reading will be created, referred to the functions of the urban fabric on the hexagonal pattern, and every value will be compared with the vulnerability, previously calculated.

6 THE ADAPTATION CAPACITY AS A PLANNING DRIVER TO URBAN RESILIENCE

In the end, the indexes of adaptation capacity, in the developed methodology, have been developed with the aim of supporting the decisional processes on the actions design (on the bases of the territorial conformation of the investigated sector) to adapt the territory to the evaluated risk. The idea of classifying the urban fabric through morphological parameters comes from a study by Steward and Oke (2009) called “Values of geometric and surface cover properties for local climate zones”. This work considers the employed methodology very interesting, and useful to characterize the urban classification starting from the parameters identified by Steward and Oke.

Therefore the work is proceeded with the identification of the range of values that characterises one area or another for any index. The ranges of chosen values have the bases on the study of Steward and Oke, and identify 7 urban classes. The work final goal, that is to address the transformation of territories built to adapt to CC, considers the “adaptation capacity” variable, the different types of urban space, and the various morphological features of the city.

The final mould of the described process evaluates the city through a series of indexes, able to classify the city territorial morphologies, by returning a series of urban classes with homogeneous physical features (that is for adaptation options). For every homogeneous area, the research provides for flow charts that collect and explain a series of possible technical measures to reduce heat and water impacts, by considering the opportunity of every territorial class (Figure 12).

The inherent difficulty in the attempt to modify the consolidated territory, constrains to think to the transformation project (to facilitate the adaptation) of an area as sum of relevant measures in project opportunities, city planning instruments, and other opportunities (e.g. EU or national funds for urban renewal).

Therefore, to adapt the city doesn't mean to build new resilient areas, but instead to be able to manage a process in continuous transformation. This entails a long term prevision of solutions for uncertain

problems, to find the best possible strategy to apply (in terms of project opportunities, city planning instruments and technique).

To sum up: knowing the morphological and functional situation of an urban district guides the planning towards two important phases: in the analysis phase, it characterizes the risk allowing to trace back the evaluation process in reverse, and identifies distinctive sensitivity and exposure elements; - in the decision process, in which the urban classification, described in the previous chapter, orients the measures selection by considering the adaptation capacity of the contemplated area. The adaptation capacity for every area is the result of the relationship between possibilism (urban spaces, techniques, financing) and opportunities (planning, plan or regulation).

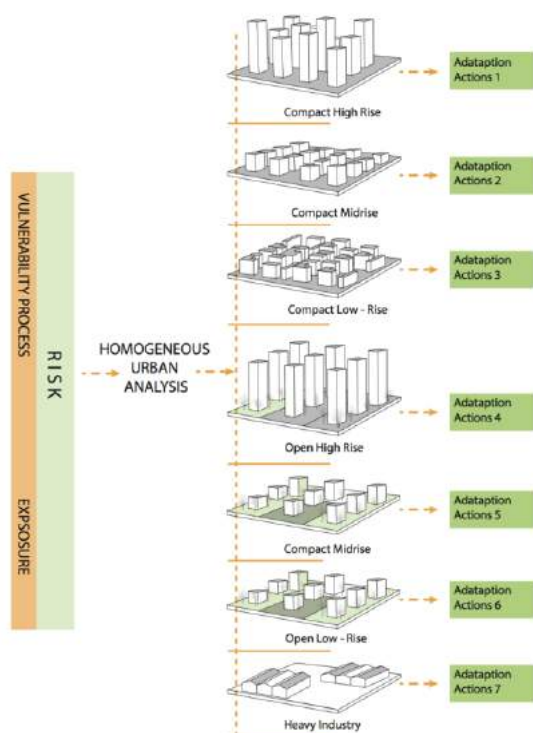

Figure 12 – Logic diagram illustrating the classification of the territory. (Personal processing).

The territorial classification, through the identification of homogeneous morphological parameters, has the aim to support the planning process in the decision phase in planning process. Each of the 7 urban areas considered and classified as examples for the city of Brooklyn, contains some adaptation options that can be applicable, others less applicable.

Every produced profile (figure 13) contains the map that identifies the urban areas that belong to the analysed typology (e.g. Compact Mid-Rise), through the hexagonal pattern. Hexagonal perimeters will be green coloured, orange or red coloured (in the example on vulnerability and risk related to heat waves), representing the risk level.

Therefore every risk map permits to identify the morphologic typology of the endangered area considered.

Figure 13 – Map of classification for "compact mid rise". In red, high-risk cells in urban heat island. (Personal processing).

7 CONCLUSIVE NOTES

The climate, stressed by externalities generated by anthropic systems, produces uncertain and geographically differentiated impacts, involving the cities and the territorial government activities. Urban planning and territorial science, in the next years, will be more and more involved in finding immediate solutions towards unexpected and complex problems created by the interaction between territory and abnormal climate externalities.

Spaces and buildings related to local climate aspects, surfaces materials, ecosystemic services, they are all elements that have to regain centrality in the urbanistic project, and have to be related to long and medium term climate scenarios.

Therefore the adaptation of a reinforced territory will have to compensate for vulnerabilities and climate dangers, through modifications that could reinterpret and enhance the urban landscape features (as result to physical geography, human geography and local culture). In this way, the inevitable city adaptation phase can be a chance to renew the urban areas, an opportunity to inspect the abandoned elements and to create new economies.

The territorial government activities will have to be able to re-elaborate analysis practices and project models, to manage the transformation and support the urban resiliency to climate change, with the aim of guiding the changes of the environments built in relation to the risk level; at the same time they should monitor the transformation efficiency in medium-long term.

To work on uncertain scenarios, and with solutions applicable through a sum of projects covering a period of 10-15 years, needs the structuring of a system to manage the information, that would be able to support the complex analysis phases, and to facilitate a monitoring system. The future knowledge frameworks of the cities will have to be integrated, expressed and shared. In this way they can support the territorial government activities in interpreting “not ordinary” dynamics derived from the climate, with ordinary dynamics. Uncertain scenarios, opposed to action urgency, put the city planning practices more and more in contact with the new technologies of information.

These reflections led to the approach development presented in this work. The work fundamental goal was to support a better reading of urban dynamics, through a territorial analysis process that, not only measures the vulnerability level and the risk of every urban portion, but at the same time it fosters the decision processes in choosing the most effective solution according to the subjectivity of the area, and a “real time” monitor of future implemented solutions. The database structure, built and finalized to contain all the information of the knowledge framework, aggregated in hexagonal areas, functions as matrix for the monitoring process. The measures that step by step are implemented in the territories, modify the numerical values of the attributes in the table, and guarantee a comparison between several years. In this way, the process circularity will guarantee the revision of the informative attributes (e.g. m² of permeability), and it allows to evaluate benefits or possible consequences of the actions that have been implemented up to that moment, and then to rapidly modify them.

The climate variables considered in this work (according to the possible impacts attributable to the rise in temperature and the rainfall intensity), are based on scenarios produced by IPCC, therefore lacking of an accurate local evaluation. The studied analysis process is developed to return vulnerability and risk evaluations starting from the hazard trends (as rise of temperature and rise of rain intensity), and to optimise the evaluations with well defined climate scenarios. This element facilitates the use of methodology, and untangles from the necessity of precise local climate drivers.

The new technologies recently applied in city planning practices, allow to modify analysis, planning and methods of territory organization through the spatial information. The possibility of consistently updating data and project, makes the process planning less rigid and linear, and more inherently temporary (Cecchini A., 1999). As observed, the ICT easily guarantee the acquisition of territorial information, by increasing the options to implement and organise the knowledge frameworks.

The flexibility of innovative knowledge frameworks imposes less rigidity to the plan, as direct consequence, so that it better can accept the alterations resulting from the updates of the dynamic knowledge frameworks.

The hereby described process evaluates the vulnerability and the risk from the result of indexes selected on the bases of data acquirable with the currently available technologies. A predictable technologies innovation can generate new informative typologies which can opt for other indexes, or can improve the existing ones.

The employment of information and communication technologies is essential to start an adaptation process that, working on uncertain and long-term scenarios, needs to be developed in dynamic environments.

It's important to highlight that the technologies, considered in the process, are instruments, options to facilitate the work. While maintaining its independence, it helps to identify, in his dynamic, the best options offered by the technological innovation.

The exposure, that is all the urban functions that risk to be compromised by an assumed impact, is the only variable useful to evaluate the risk, that cannot be considered objective. If the sensitivity and vulnerability evaluation is assumed according to empirical measures, the exposure is influenced by the political will of the territorial government and the local culture. In the proposed work, the exposure evaluation has been carried out by assigning the same importance to every entry (population, public

transport, commercial activities, production activities and public service). But it's possible and desirable that a local governance may diversify the importance of the entries according to the local political agendas. For example, in an area vulnerable to heat, the population (or specific age categories), or the commercial activities, can be more affecting. Choosing one or another modifies the exposure result, and its risk value.

This is one of the reasons for which the adaptation process has to be participative, and able to investigate the risk perception of the inhabitants of urban areas with high vulnerability.

1 INTRODUCTION

Identifying and assessing risk is common across a number of disciplines from health sciences to disaster risk management to critical infrastructure protection. Yet, the climate change adaptation community has preferred a vulnerability-based framework in order to conceptually understand and respond to climate change (Intergovernmental Panel on Climate Change (IPCC), 2012). However, since 2012, the main scientific organisation that leads on climate change, the Intergovernmental Panel on Climate Change (IPCC) has reframed climate change in order to look at risk rather than vulnerability. Such a move intends to harmonise the climate change adaptation community with those working in the allied discipline of disaster risk management (Aven & Renn, 2015). There is a further supposition that the risk-based concept can help to shift the focus from top-down, science-first vulnerability assessments to risk assessments that can better include a range of stakeholders (Meadow et al., 2015). There is, however, scant literature on the means of co-producing risk assessments.

There are also potential difficulties in translating the new risk-based concept into practice, particularly in spatial planning which combines expertise from a range of disciplines. The definition of risk differs across disciplines and sectors (Thywissen, 2006; Wolf, 2011). In addition, existing climate change adaptation projects have used vulnerability-based conceptual frameworks, and there is therefore a question mark over the way that their resultant data can be easily reused.

Our paper explores the move from a vulnerability based framework to a risk based framework. After outlining the underpinning components of vulnerability and risk, we demonstrate the utility of a risk based framework for spatial planning policy and practice. However, the latter half of the paper points to potential issues in the translation of climate change risk to adaptation policy more broadly and spatial planning in particular. We conclude that the concept of risk helps cities to identify adaption options and build resilience to the changing climate by connecting across disaster risk management and climate change adaptation approaches. However, the conceptual mismatches – particularly around the notion of ‘exposure’ - have to be approached cautiously particularly with regard to spatial data.

1.1 THE RESIN PROJECT

The paper draws upon work undertaken for the EU Horizon 2020 funded Climate Resilient Cities and Infrastructure (RESIN) project. RESIN is an interdisciplinary, practice-based research project investigating climate resilience in European cities. Through co-creation and knowledge sharing between cities and researchers, the project develops practical and applicable tools to support cities in designing and implementing climate adaptation strategies for their local contexts. This includes a city typology, which utilises European spatial data in order to build a picture of the hazards, exposure and vulnerability at NUTS3 level.

Before the practical work could commence, it was essential to choose a persuasive and easy to communicate conceptual framework and, within that, definitions. We chose to follow the IPCC’s risk based definition of climate change which represents the state of the art (Carter et al. 2015). RESIN’s conceptual framework is a dynamic risk-based one that highlights two distinct – but potentially interconnected – systems: the urban system and the climate change adaptation system (Figure 1). On the left, the urban system has a number of hazards and drivers of change that lead to climate risk. Awareness of such climate risks may provide the route into the adaptation planning system on the right hand side where city managers can begin a process of assessing risk, identifying and prioritizing adaptation options, and developing an implementation plan. This can then feed back into the urban system in order to build climate

resilience. Of course, we recognise that the synergies between the two systems may not be seamless; some cities may never go on the journey of the adaptation planning process and build resilience in reactive ways. The conceptual framework also shows that risk, and the hazards and drivers of risk, can never be completely eliminated.

2 FROM VULNERABILITY TO RISK

2.1 THE IPCC'S EVOLVING FRAMEWORK

Until recently, the vulnerability assessment of socio-ecological systems (SES) was the main focus of the climate change adaptation literature. Vulnerability, as adopted by the IPCC up to the Fourth Assessment Report (AR4), was defined as: 'The degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude, and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity' (IPCC, 2001, p. 995). This could be expressed as a function: $Vulnerability = f(Exposure, Sensitivity, Adaptive Capacity)$ and is visually outlined in Figure X.

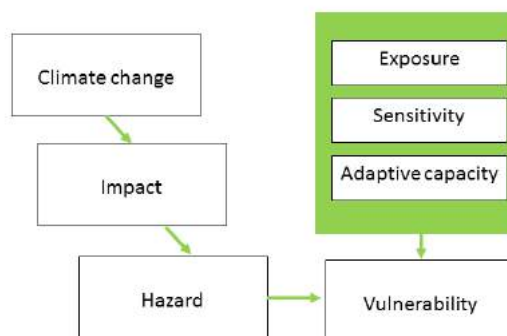

Figure 1: Pre-IPCC AR4 Conceptual Framing of Climate Change Vulnerability

Where:

- Sensitivity: is 'the degree to which a system or species is affected, either adversely or beneficially, by climate variability or change' (IPCC, 2014b);
- Exposure: is 'the nature and degree to which a system is exposed to significant climatic variations' where the exposure unit is 'an activity, group, region, or resource that is subjected to climatic stimuli' (IPCC, 2001);
- Adaptive Capacity: is the 'ability of systems, institutions, humans, and other organisms to adjust to potential damage, to take advantage of opportunities, or to respond to consequences' (IPCC, 2001).

Here, climate change impacts upon a system. The degree to which that system is exposed in terms of the character and magnitude of climate change and the degree to which a given unit of analysis is affected combine to make an impact. Once the adaptive capacity of a system is subtracted, the residual figure would indicate the extent of the system's vulnerability.

Vulnerability-based frameworks developed quickly. Within the climate change literature, the emphasis of early work (so-called 'first-generation') was on biophysical vulnerability which tends to focus on observed and projected changes in climate that may exacerbate exposure and sensitivity (Füssel & Klein, 2006). However, this could be criticized for privileging a 'science first' perspective to the detriment of implementing action. Thus, scholars began to draw attention to the ways in which existing socio-economic circumstances interact with climate change, and led to a distinction between outcome vulnerability and contextual vulnerability (O'BRIEN, ERIKSEN, NYGAARD, & SCHJOLDEN, 2007).

Critics pointed to a number of reasons why the framing climate change in terms of vulnerability could be problematic. Vulnerability can be interpreted negatively and, thus, by labeling people and places as 'vulnerable', a passive attitude may be adopted to climate change. Similarly, the negative framing overlooks the importance of local culture and underlying resilience, particularly in non-western nations (Bankoff, 2001; Giupponi & Biscaro, 2015).

The vulnerability framework also did not fit with other models available in the more present-day oriented disaster risk management literature whereby the concept of risk predominates (e.g. UNISDR 2009). Given that climate change adaptation and disaster risk management have many overlaps, bringing the two disciplines together is desirable from a practical point of view (EEA 2012). Thus, the IPCC has modified their definition of vulnerability in AR5 by moving to a risk-based conceptual framework (IPCC, 2012; 2014a).

Yet, risk is also a term that is difficult to define (e.g. Thywissen 2006; Wolf 2011) even though there is an international standard on risk management. ISO 31000 defines risk as the 'effect of uncertainty on objectives' (ISO/IEC 31000: 2009). An 'effect' is a positive and/or negative deviation from what is expected, whilst 'objectives' may be different aspects or goals. Furthermore, risk is characterised with reference to potential events and consequences, and can be expressed in terms of a combination of the consequences of an event and the associated likelihood of occurrence. Likelihood is the 'chance of something happening' and can be measured qualitatively or quantitatively (ISO/IEC 31000: 2009). In general terms, likelihood can be used interchangeably with probability. That said, probability more precisely refers to a quantifiable measurement where 'measure of the chance of occurrence [can be] expressed as a number between 0 and 1, where 0 is impossibility and 1 is absolute certainty' (ISO/IEC 31000: 2009).

This definition, albeit broad, results in a classic risk calculation whereby risk is a multiplication of the probability of an event with the consequences of an event (1):

$$\text{Risk} = \text{Probability} \times \text{Consequences} \quad (1)$$

However, in the case of natural hazards, the variables are not independent of one another insofar as likelihood of occurrence is affected by the size of the impact (European Commission 2010: 16). That is, it is not the presence of a hazard that indicates the risk, rather, a hazard only becomes a risk when a system is exposed and vulnerable; thus, 'risk is also a function of the underlying environmental and socioeconomic context in which climate change occurs' (Preston & Jones, 2008, p. 278). For these reasons, the notions of vulnerability and exposure can be introduced to capture these nuances – since the probability of an impact occurring may be affected by enacting vulnerability and exposure reduction measures. Therefore, as reflected in the IPCC AR5 approach, there is a functional relationship between the elements of risk, which are broken down to reflect the hazard, exposure, and vulnerability (Figure 2). Exposure and vulnerability combine as the consequences ('the impacts, if these events/trends occur') whilst probability relates to the hazard; or the 'probability of the occurrence of hazardous events/trends' (Birkmann et al., 2014, p. 23)). Ultimately, these concepts lend themselves well to the spatial identification of risk.

$$\text{Risk (R)} = f(\text{Probability of a Hazard (p)}, * \text{Exposure (E)}, * \text{Vulnerability (V)}) \quad (2)$$

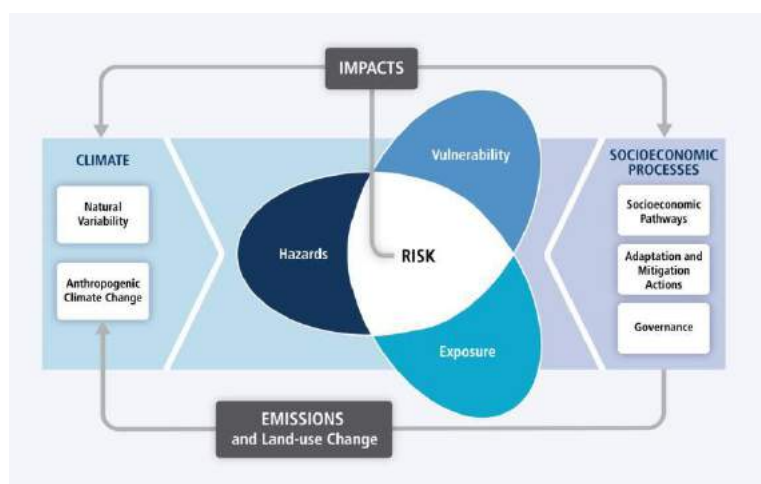

Figure 2 - The IPCC AR5 conceptual framework with risk at the centre. Source: IPCC, 2014

2.2 COMPARING DEFINITIONS

Table 1 compares and contrasts the key concepts between each knowledge area to explore the commonalities and differences. When those working within the pre-IPCC AR5 concepts refer to vulnerability, IPCC AR5 and disaster risk management understands this as risk. Similarly, vulnerability in IPCC AR5 equates to sensitivity and adaptive capacity within climate change studies (pre-IPCC AR5), or, for disaster risk management, simply 'sensitivity' (Kazmierczak and Handley, 2011).

	IPCCAR4	IPCCAR5
Adaptive Capacity	The ability of a system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences (IPCC 2007)	The ability of people, institutions, organizations, and systems, using available skills, values, beliefs, resources, and opportunities, to address, manage, and overcome adverse conditions in the short to medium term (IPCC 2014b).
Exposure	The nature and degree to which a system is exposed to significant climatic variations (IPCC 2001).	The presence of people, livelihoods, species or ecosystems, environmental services and resources, infrastructure, or economic, social, or cultural assets in places that could be adversely affected (IPCC 2014b)
Hazard	No glossary definition	The potential occurrence of a natural or human-induced physical event or trend, or physical impact, that may cause loss of life, injury, or other health impacts, as well as damage and loss to property, infrastructure, livelihoods, service provision, and environmental resources (IPCC 2014).
Risk	No glossary definition	The potential for consequences where something of value is at stake and where the outcome is uncertain, recognizing the diversity of values. Risk is often represented as probability of occurrence of hazardous events or trends multiplied by the impacts if these events or trends occur. Risk results from the interaction of vulnerability, exposure, and hazard.
Sensitivity	The degree to which a system or species is affected, either adversely or beneficially, by climate variability or change.	The degree to which a system or species is affected, either adversely or beneficially, by climate variability or change.
Vulnerability	Vulnerability is a function of the character, magnitude, and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity (IPCC 2007)	The propensity or predisposition to be adversely affected. Vulnerability encompasses a variety of concepts including sensitivity or susceptibility to harm and lack of capacity to cope and adapt.

Table 1 – Comparison of vulnerability related terminology

The most important shift has occurred in the formulation of exposure, a concept has not been well-defined in climate change adaptation studies (Räsänen et al 2016; Jurgelivich et al. 2017). The pre-IPCC AR5 considered the degree of exposure (that is, the degree to which railway tracks or electricity substations come into contact with a hazard as a consequence of the magnitude of climatic variation). IPCC AR5 modifies this to focus more on what is exposed (an electricity substation or railway tracks) (Table 1) It is argued that this makes sense, particularly when thinking about critical infrastructure, because an electricity transmission line, for example, is only exposed to windstorms if it is above ground (McCord et al., 2015, p. 48).

Vulnerability, on the other hand, is now only composed of two components: sensitivity and adaptive capacity which, largely, retain the same definition. Risk, on the other hand, is a newly introduced definition which tries to capture both the language of probability/consequence in addition to the spatial formulation of hazard, exposure and vulnerability. Both definitions are suitably open enough for divergent interpretations.

3 ISSUES IN TRANSLATING CLIMATE CHANGE RISK FOR SPATIAL PLANNERS

Now, why do any of these conceptual changes matter? Quibbling over conceptual differences may seem pedantic in the face of the hard work of trying to increase the resilience of people and places to extreme weather events and climate change. However, the framing of climate change, whether that be through the lens of 'vulnerability', 'risk' or 'resilience', is important because 'frames allow certain questions to be asked while others get silenced' (Fünfgeld & McEvoy, 2011, p. 15). Therefore, the remainder of this paper focuses on why the movement towards risk appears to be a useful concept for spatial planners, but also point to some of the difficulties that the RESIN project has encountered as a result of the changing IPCC terminology.

3.1 WHY IS RISK USEFUL?

3.1.1 DECISION MAKING

There are a number of reasons why the concept of risk, and the undertaking of risk assessments, has advantages over vulnerability driven terminology and related assessments. Conceptually, separating out exposure can be beneficial to spatial planners as it emphasises the worth of exposure reduction measures (e.g. not building in flood risk areas). Conversely, a focus only on probability and consequences tends to privilege the construction of more robust flood defences (Klijn, Kreibich, de Moel, & Penning-Rowsell, 2015). The separation of exposure from vulnerability helps decision makers prioritise actions that can either reduce exposure to a hazard, or else reduce vulnerability through measures that address sensitivity and adaptive capacity. It also moves the climate change adaptation community closer to models that have been used in disaster risk management and, in turn, the insurance industry (Lindley, Handley, Theuray, Peet, & McEvoy, 2006).

An example may illustrate this. In order to understand the risk of flooding to a building, it is necessary to understand whether the building is exposed (spatially) to the flood in the first place. Further accentuating the risk may be particular factors that make a building sensitive to flooding (such as the presence of basement floors). The risk may be less if adaptive capacity is high; the existence of early warning systems is an example here. Given the understanding of the different elements of risk, a decision maker can then prioritise actions based on:

- Reduce greenhouse gas emissions to lessen the frequency and severity of future hazards
- Undertaking adaptation measures that reduce exposure (by relocating the building outside of the potentially flooded area)
- Undertaking adaptation measures that reduce sensitivity (by making sure that vulnerable groups or activities are not housed in that building)
- Undertaking adaptation measures that increasing adaptive capacity (by installing flood mitigation measures for the building; presence of early warning systems).

The resultant data on the IPCC's risk elements (hazard, exposure, vulnerability) can be useful separately; for example, in communicating hazard probabilities and informing measures to reduce vulnerability to hazards. The ability to deconstruct different risk elements offers additional insights to decision makers when planning adaptation responses, by identifying which issues are driving risk in a particular situation. But, it is when these elements are brought together within a risk assessment they become more powerful. This is particularly the case where supporting spatial data is available, as the elements of weather and climate risk vary according to location (Tapia et al. 2015).

Impact and vulnerability assessments remain useful as elements of the risk assessment process in order to advance climate change adaptation and resilience goals. The differences between impact, vulnerability and risk assessments, and the functions that they perform in adaptation and resilience planning, are outlined in Table 2.

It can be seen that impact, vulnerability and risk assessments all have a role to play in adapting and building resilience to climate change. However, neither impact nor vulnerability assessments consider the probability of occurrence of hazards, potential exposure, or the severity of related impacts and vulnerability assessments do not provide the outputs to enable such decisions to be taken as effectively, and could therefore be usefully seen as processes that can contribute to a risk assessment. Risk assessments go beyond impact and vulnerability assessments, and bring together different elements of the adaptation agenda (including impacts and vulnerability) to provide a basis for analysing which weather and climate risks are most pressing.

Risk assessment is, therefore, a process that is focused on supporting decision-making. Brown and Wilby (2012) describe analysing climate risk as a matter of 'due diligence', which can be interpreted as taking a reasonable level of care before taking a decision. This, as Dickson et al. (2012: 23) suggest, ties risk assessment closely to decision making; '... [risk] assessments aim to simplify complicated experiences of risk in order to assist in decision making.'

	Impact Assessment	Vulnerability Assessment	Risk Assessment
Inputs	Impact assessments require details of weather and climate hazards and the natural and human systems with the potential to be affected.	Sensitivity and adaptive capacity data are needed to undertake a vulnerability assessment, based on the IPCC's approach.	The IPCC's risk approach focuses on the interaction between hazard, exposure and vulnerability. Data is required on these themes to complete an assessment.
Outputs	Potential weather and climate impacts to natural and human systems. Cascading impacts, within and between systems, are significant yet can be difficult to establish due to limited data and modelling capacity.	Details of the vulnerability of 'receptors' to weather and climate hazards. Data permitting, vulnerability can be mapped spatially.	Identification of weather and climate risks according to their probability and impact. Data permitting, risk assessment outputs can be mapped spatially.
Issues	Impact assessments generally provide no indication of the probability that impacts may occur. Impact severity, which relates factors including hazard intensity and the vulnerability of the system to the event, is not commonly considered.	Adaptation responses can be developed to reduce vulnerability. However, without details of the probability of, and potential spatial exposure to, hazards, responses to reduce vulnerability cannot be as effectively targeted.	Risk assessments provide a picture of priority risks, in terms of their probability and consequence, enabling available response capacity and resources to be targeted more effectively.

Table 2 Differences between impact, vulnerability, and risk assessments. Source: Authors

The benefits of undertaking a risk assessment can also be observed in the outcomes of decisions informed by a risk-based approach, particularly where spatial risk data is available. Here, developing responses to minimise losses and negative impacts associated with climate change is key. Cities and urban areas face risks from a range of sources, one of which is extreme weather that might occur more often as a result of climate change. Other risks, generated by socio-economic and bio-physical drivers of change, may have a greater or lesser influence on decisions than climate change. This judgement can be made if climate and non-climate risk information is available to be evaluated (Willows and Connell 2003).

King et al (2015: 8) highlight the importance of such an evaluation, noting that; 'The most important decision that any government has to make about climate change is one of priority: how much effort to expend on countering it, relative to the effort that must be spent on other issues.'

3.1.2 ADDRESSING UNCERTAINTY

Risk assessments are particularly good for reducing uncertainty because they focus attention on (i.e. the highest risks), the locations where risks are most prominent, and the relative significance of climate and non-climate related risks. Here, the risk assessment is narrowing or helping to prioritise the range of possible risks to consider, and clarifying the objectives of the adaptation planning process. This can, in turn, help to direct attention to the allocation of available capacity and resources for climate change adaptation and resilience building. Risk assessments also help to fill knowledge gaps by increasing understanding of the probability and consequence of different risks. King et al. (2015: 23) build on this noting that, 'one of the key purposes of risk assessment is to allow decision-makers to weigh choices for action under uncertainty.' Risk assessment can help to illuminate the implications of different decision options when responding to climate risk, which may include a decision not to act and therefore to accept the identified risk(s).

However, risk assessment processes (and therefore outcomes) are affected by uncertainty. For example, uncertainty in climate projections must be recognised within any analysis of the probability of occurrence of hazard events. Here, it is important to be clear as to which dimensions of uncertainty risk assessment can respond to. Addressing this point, Willows and Connell (2003: 48) note that, 'risk assessment deals explicitly with uncertainty in decision-making rather than giving an over-confident view of what is known.' Climate change risk assessments do not reduce uncertainty associated with climate change, but the process can support decision makers in analysing the consequences of an (uncertain) changing climate in order to focus and target strategies and actions in response.

3.2 POTENTIAL PROBLEMS

Having established the utility of a risk assessment, we now turn to some of the problems that may be encountered by the movement from vulnerability to risk in climate change adaptation studies. Many studies undertaken to understand climate change within Europe work within the IPCC's pre-AR5 framework. The EEA's Urban Vulnerability Map (2015) used indicators relating to sensitivity, exposure and response capacity. The ESPON climate vulnerability assessment also utilized the IPCC's AR4 definition where vulnerability is a function of sensitivity, exposure and adaptive capacity (ESPON Climate 2011). The Vulnerability Sourcebook (BMZ 2014), which outlines a detailed process of undertaking vulnerability assessment, also holds to the IPCC's AR4 definition. There is thus a challenge for those who wish to draw on assessments and approaches that have been formulated under the earlier IPCC definition.

Retrofitting extant data may be problematic. For example, the ESPON project produced supporting data on the Territorial Effects of Climate Change on European Cities (ESPON Climate 2011). Underpinning the report was spatial data that resulted in the broad identification of five 'climatic types'. The data is at NUTS 3 level and includes data for climatic conditions and the pre-AR5 components of vulnerability: exposure, sensitivity and adaptive capacity. The data is available for reuse. However, examination of this data entails detailed considerations of how the concepts were developed to ensure that it remains of use today. ESPON's exposure indicators measure change in a hazard (e.g. Changes in annual mean temperature), which corresponds to AR5's 'hazard'. Similarly, ESPON's sensitivity data indicates susceptibility to harm insofar as a receptor is located (AR5's 'exposure') in the presence of an exposure element (AR5's hazard). ESPON Climate (2011) then combine sensitivity and exposure to create an impact which, with the addition of adaptive capacity, gives overall vulnerability scores. The sensitivity indicators are comprised of physical sensitivity, cultural sensitivity, social sensitivity, environmental sensitivity and economic sensitivity. All but the economic sensitivity data are spatial. It is not that the data cannot be reused, but a process of working through the definitions and looking at the indicators is required in order to reframe and repackage them in order to be useful to the AR5 concepts: it is surely a waste of resources to compile new datasets where significant effort has been made to commission and promote the original ones. Exposure indicators may be used as 'Hazard' whilst some, but not all, of the sensitivity indicators can be used to represent 'Exposure'.

4 CONCLUSION

From the perspective of adaptation and resilience, climate change risk assessments can offer decision support in a number of ways, including:

- The provision of valuable insights into context-specific risks associated with the changing climate, which may otherwise not be accessible.
- Risk assessments focus attention on the highest risks, with the highest probability of occurrence and the most severe negative consequences (or impacts). Therefore, a risk assessment can help decision makers to prioritise risks to respond to when aiming to adapt to the changing climate.
- Identifying high risks associated with the changing climate can clarify objectives, help to prioritise adaptation options, and to support the allocation of resources that are available for adaptation and resilience work.

However, in order to make previous climate change adaptation assessments usable for state-of-the-art thinking on climate change, there needs to be a careful translation of the concepts and their allied data: this is particularly acute around the concept of exposure. Vulnerability and risk are commonly employed in everyday usage, thus they are useful to advancing climate change adaptation; however, the focus should be to 'concentrate on assessments instead of detailed theoretical definitions' (Wolf, 2011, p. 1108).

ID 1602 | THE SPATIAL DISTRIBUTION OF URBAN HEAT VULNERABILITY AND COPING STRATEGIES IN BEIJING

Chen Kai¹; Tang Yan¹

¹Tsinghua University

lockepark@126.com

1 INTRODUCTION

Under the influence of global climate change and local urbanization, the heat wave is thought to be more intensified and frequent. So far, the definition of heat wave has not been reached a general agreement all over the world, but severe consequences caused by heat waves on health effects have been demonstrated in many cities. With the constant process of Asia's urbanization, heat wave events will be the uppermost one of extreme weather conditions that Asian cities have to confront in the future (IPCC,2014). Thus, it is emerging objectives for urban planning that how to efficiently reduce the urban vulnerability and prevent public health from the current or potential risk of heat wave events.

Similar to other extreme weather conditions, impact areas of heat wave event are distributed unevenly. Thus, before reducing urban heat vulnerability (UHV) by means of urban planning, to identify the place and people vulnerable to heat waves is the fundamental basis for variant planning strategies. In terms of spatial pattern caused by the heat wave, the intra-urban variation of magnitude and duration during heat waves is significant. Some studies find urban heat island (UHI), a atmospheric phenomena that city area warmer than its countryside, aggravates the intensity of heat wave events within the urban area (Yang and Chen et al., 2015). In turn, higher temperature during heat wave events make UHI effect more significant. With the interaction between heat waves and UHI, urban residents have to be suffered from a higher risk of consistent heat stress. In addition to the variation of geographical range, the difference of heat-related health is another aspect need to be identified. Under the same weather condition, some people may be affected more than others. The research from public health recognizes general characteristics of people that are vulnerable to heat waves by the case study of heat-related mortality and morbidity, which includes age, economic characteristics, pre-existing health condition and thermal environment (Harlan and Brazel et al., 2006). Therefore, mapping UHV, which emphasize not only vulnerable areas, but also susceptible people, is urgently needed.

Through the lens of international experiences, UHV mapping is the key instrument to support technologically the implementation of heat waves prevention and mitigation (Wilhelmi and Purvis et al., 2004). In the cooling actions of eighteen American cities, UHV assessment is widely adopted as a necessary part (GCCA, 2014). For the Birmingham's climate change adaptation action, UHV is utilized in identifying priority areas to improve the resilient capacity (Birmingham city council, 2012). Similarly, based on the map of UHV in Australian capital cities (NCCARF, 2013), Moreland UHI effect action plan identifies five types of priority areas (Moreland city council, 2016). Thus, the first section of this article summarizes the recently progress in UHV assessment, in order to select the comprehensive framework presented for Beijing central city.

2 PROGRESS IN UHV ASSESSMENT

Although UHV assessment is considered as an emerging field in vulnerability studies, the method and index system of UHV is interacted with that of conventional vulnerability research. In view of the different perspective and discipline background, the frameworks (Figure 1) adopted in the assessment of UHV have not been reached a consensus, which are derived from two categories of definition of vulnerability in the context of climate change— biophysical vulnerability and social vulnerability (Brooks,2003). The biophysical vulnerability refers to the influence extent caused by external hazard, which is arisen from the evaluation of natural hazards and their impacts. In the conceptual framework of biophysical vulnerability, a function of hazard, exposure and sensitivity, biophysical conditions have more fundamental impacts on the final result than other indicators. Although this term is seldom used to describe vulnerability recently, similar concepts and frameworks are prevalent in the field of risk assessment. The research of ASCCUE project firstly incorporated the Crichton's Risk Triangle into assessing the heat wave risk within UK's urban areas (Lindley and Handley et al., 2006). However, the vulnerability of the Crichton's Risk Triangle should be referred to as sensitivity of biophysical vulnerability, because there are similar in focusing on the demographic characteristics rather than on the adaptive capacity of people. Following this risk assessment methodology, (Tomlinson and Chapman et al., 2011) considered UHI effect as a nocturnal form of heat wave hazard and made some attempt to evaluate the risk of UHI effect. However, this assessment framework can't present the ability of people in coping with the outcomes and effects of heat waves, which tends to make the result deviating from the original objective.

Compared with the biophysical one, the social vulnerability is described as a state that is rooted within a system before it encounters a hazard event (Allen,2003). In this case, it is thought that vulnerability is determined by the inherent characteristics, such as sensitivity, adaptive capacity of people, rather than any particular type of natural hazard. After the social vulnerability index (SoVI) was developed and presented for all American areas (Cutter and Boruff et al., 2003), this concept was gradually prevalent in different researches. Taking into account the universality of social vulnerability, some studies made some modification to improve its pertinency. (Reid and O'Neill et al., 2009) firstly applied the framework of social vulnerability to the heat waves by means of some specific heat risk factors and developed the heat vulnerability index (HVI). Although some studies followed and validated this conceptual framework, temperature data was utilized to overlay and identify the hot-spot areas, where high heat vulnerability is coincided with high temperature(Wolf and McGregor et al., 2013), or to improve the effectiveness of HVI model in predicting the heat-related mortality (Harlan and Declet-barreto et al., 2013; Maier and Grundstein et al., 2014). A modified HVI (extreme heat vulnerability index, EHVI) which was developed by (Johnson and Stanforth et al., 2012) added three environmental indicators related with health impacts of extreme heat and highlighted the role of exposure to heat. Because the vulnerability which are exclusive of exposure and specific hazard sometimes can't direct proper prevention and mitigation planning, comprehensive concept of vulnerability was presented in the IPCC third assessment report, where vulnerability was defined as "the degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes"(IPCC,2001). From the perspectives of exposure, sensitivity and adaptive capacity, (Wilhelmi and Hayden et al., 2010) developed a specific analysis flow to assess UHV, (NCCARF, 2013) attempted to incorporate the indicator of heat wave hazard into the framework.

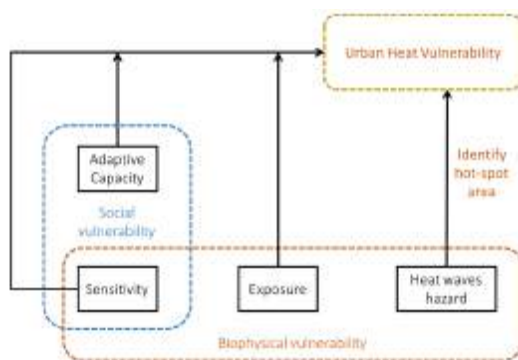

Figure 1 - Conceptual frameworks for UHV assessment.
source: authors' elaboration

Note: The boxes with rounded corner represent the main conceptual frameworks adopted in the related literature. The boxes with black outline represent the important component derived from above conceptual frameworks.

In summary, the assessment of UHV is transformed from unilateral evaluation to comprehensive emphasis, this trend also can be discovered in the field of risk management. Based on the risk assessment framework which is composed of hazard, exposure and vulnerability, (Dong and Liu et al., 2014; Xie and Wang et al., 2015) respectively evaluated the heat wave risk at the city-scale and nation-scale of China. Due to the exposure independent of vulnerability, the contribution made by biophysical indicators is more dominant within the framework. Compared with the progress in UHV assessment abroad, it is an emerging field which has just gained widely attention in China. There are two questions need to be responded in this study: (i) Previous quantitative studies mainly focused on the city-scale in China, how to further implement the assessment methodology into the fine-scale, like sub-district ? Although the assessment at city-scale can help policy-maker directly recognize the overall degree of heat vulnerability, it can't be worked not only as a guideline for distributing the resource of disaster prevention and mitigation, but also as a communication tool for informing people of their high risk state.(ii) As the important part of climate-change risk management and adaptive planning, how to fill the gap between the result of UHV assessment and specific planning methods? If there is no efficient ways that direct the result into implementation, the UHV assessment will be invalid. Therefore, this study utilizes the central city of Beijing as a case study area and puts emphasis on following issues: (1) Setting up the assessment framework of UHV and presenting it for Beijing central city, (2) By overlaying the result of heat vulnerability and heat waves hazard, hot-spot areas will be identified as priority for mitigation strategies and adaptive design, (3) From the perspectives of disaster prevention and mitigation, three specific strategies are presented for priority areas. Thereby, as a spatial decision support tool, this study aims to help policy maker to achieve the more efficient performance of mitigation measures towards the higher vulnerable inhabitants and communities. Meanwhile, for urban inhabitants, the spatial mapping of heat vulnerability can be used for identifying their health conditions during heat waves.

3 STUDY AREA

Beijing, the capital city of China, neighbored by Hebei Province and Tianjin Municipality, is composed of 16 districts, with a total land area of 16,410 km² and a total population of 21.5 million by the end of 2014. The study area is the Beijing central city which consists of six districts, as shown in the Figure 2, Dongcheng and Xicheng districts are classified as urban areas, the rest are classified as near suburban areas including Chaoyang, Haidian, Fengtai and Shijingshan districts.

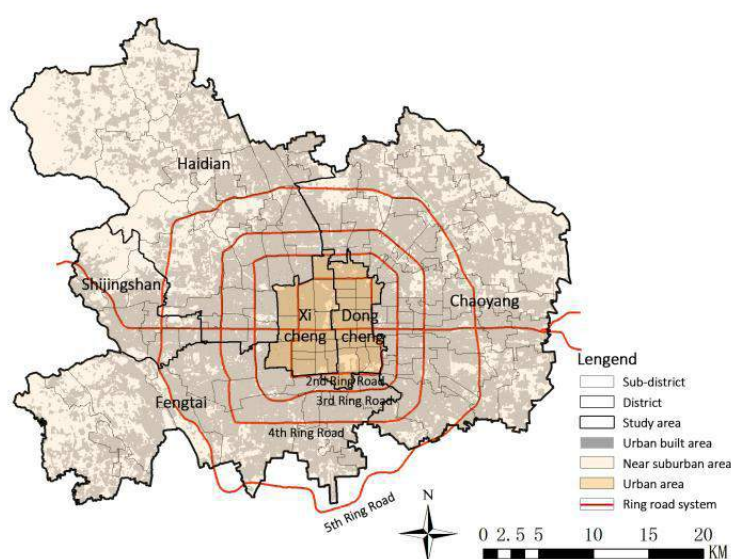

Figure 2 - Sub-districts of study area.
source: authors' elaboration

The central city, with an area of 1084 km², covers 8% of the total administrative area of Beijing with 60% of Beijing's total population. Due to the urban expansion from 2000 to 2010, there are a lot of farmlands outside 4th Ring Road are partly displaced by man-made land, which is also considered as the main reason of consistently aggravating UHI effect in Beijing. As a result, the risk in near suburban areas grows faster than other areas within the city (Dong and Liu et al., 2014). In addition to the high population density, Beijing's aging population is expanding fast, which may also increase the potential risk for heat waves.

For the 1961-2010 period, air temperature in Beijing has risen by average 1.36°C as a result of global warming and UHI effect. Recently the frequency of heat wave is continually increasing. The previous study demonstrated that more extreme high temperature events occurred in the Beijing's urban areas than others (Zheng and Fan et al., 2006). In order to focus on the specific heat wave event, this study adopts the definition of heat waves from China Meteorological Administration(CMA), a period of more than three consecutive days in which daily maximum temperature exceeds 35°C, and selects three heat waves events in the summer of 2009 and 2010 year as research objects. Considering the requirement of similar weather during clear sky condition and quality of temperature data, the research data and weather conditions are shown as Table 1. In addition, the size of assessment unit is important for the final result. As the lowest level of administrative division and smallest unit of census in China, sub-district level plays fundamental role in mitigating the impacts of heat waves. Therefore, this study utilizes 129 sub-districts (not include the Capital Airport sub-district) to identify the spatial pattern of heat vulnerability.

Period of Heat waves event	Research data	Maximum temperature(°C)	Precipitation(mm)	Wind speed(m/s)
23/06/2009-26/06/2009	24/06/2009	40	5.2	2.2
	25/06/2009	36	5.3	2.5
11/08/2009-13/08/2009	11/08/2009	36	4.4	1.7
	12/08/2009	35	4.3	1.9
	13/08/2009	35	4.1	1.7
02/07/2010-06/07/2010	03/07/2010	38	5.9	1.7
	05/07/2010	41	5.9	2.2
	06/07/2010	41	5.9	3.0

Table 1 - Weather condition of selected objects.
source: www.wunderground.com

4 INDEX SYSTEM

For the purpose of this study, UHV is viewed as a function of exposure to heat, sensitivity and adaptive capacity of people. Exposure is defined as the extent to which a system is subject to the geographical range of heat waves hazard; sensitivity is the degree to which a system is affected by heat waves based on the stability within the system; adaptive capacity describes the ability of a system to avoid and reduce the negative outcomes and impacts of heat wave. Thus, high magnitude of vulnerability to heat may results from high exposure, high sensitivity or low adaptive capacity. Based on this framework (Figure 3)and local characteristic of study area, twelve indicators are obtained from census data and remote sensing data. The source of census data includes 2008 Beijing Economic Census Yearbook and 2010 Beijing Population Census, remote sensing data is retrieved from MODIS and contemporaneous Landsat TM satellite images.

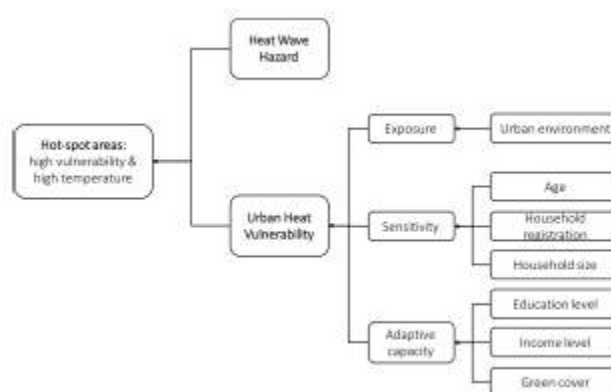

Figure 3 - Detailed flowchart of urban heat vulnerability assessment.
source: authors' elaboration

Within the framework, exposure to heat is affected by both indoor heat and outdoor heat, however there are not specific indicators to describe indoor thermal environment from census data. Thus, this study only focuses on the role of urban environmental characteristic in contributing to outdoor heat. Urban environmental characteristic is represented by the normalized difference building index (NDBI), nocturnal surface UHI effect and population density. The NDBI ($MIR-NIR/MIR+NIR$) is a measure to indicate the abundance of man-made land which is called as impervious surfaces. As shown in some studies, NDBI is used to be alternative indicator of land surface temperature (LST) because of the strong correlation between them. Recently UHI effect has been shown to interact with the high temperature in summer. Therefore, higher risk to heat is often within areas where has a long duration of high temperature all day. To make intra-urban difference in temperature more obvious, UHI effect is represented by nocturnal surface temperature derived from the LST products (MYD11A1) of MODIS satellite image. MYD11A1 product provides per-pixel temperature at 1km spatial resolution and includes daytime and nighttime LST retrieved by the split-window algorithm. Although LST can't be regarded as a direct observation on UHI, it has been demonstrated to be strongly related with air temperature during the clear sky condition. Compared with canopy UHI calculated by interpolation method, the measurement with remote sensing techniques can make the spatial distribution of surface UHI more consecutive. However, the cloud cover within study area can't make all selected objects (Table 1) available. Thus, nighttime LST products during the heat waves in 2010 (03/07/2010, 05/07/2010, 06/07/2010) are selected to present the nocturnal UHI effect. For the third indicator, population density within sub-district is one of indicator to measure urban density. Although the relation between population density and heat-related mortality is ambiguous (Johnson and Stanforth et al., 2012), the role of high population density in aggravating exposure to UHI effect and high temperature is identified among some studies (Tomlinson and Chapman et al., 2011; Romero-Lankao and Qin et al., 2012).

In the case of heat waves, sensitivity of people depends on some indicators that derive from heat-related mortality and socio-economic factors discussed in social vulnerability index (SoVI). Based on the previous studies, age, preexisting health condition and living alone are main contributors that influence the sensitivity to heat. In addition to these general indicators, scholars point that household-registration system, or hukou in Chinese, reinforce the inequalities in public service between immigrants and local inhabitants. Thus, four indicators are selected as representative: the percent of population older than 65 years or younger than 5 years, the percent of immigrants and the percent of population living alone.

Adaptive capacity has a strong influence on the vulnerability to heat. Quantitative and qualitative indicators are both utilized to present the awareness and practices toward the high temperature hazard, however, in this study, it's impossible to investigate this information within the large area. Thus, some alternative indicators are chosen to describe the education level, income level and green cover. The inhabitants with high education level can, to some degree, quickly response towards the current hazard and adopt the exact coping strategies, while some heat-related mortality are mainly attributed to the lack of risk awareness. Thus, low education level is represented by two indicators including the percent of population with education level lower than high school and the percent of illiterate in the population older than 15 years. Income level can indicate not only the economic status, but also the access to public service, thermal environment, dwelling types, the availability of cooling amenities and many characteristics related to that. In the study conducted by (Harlan and Brazel et al., 2006), the concentrated poverty areas are

demonstrated to have higher temperature and less green cover than other communities. Although this phenomenon is not so acute in Beijing, income level plays a crucial role in capacity to adapt to heat waves. Due to no poverty populations or income data within sub-district level, the last three careers are defined as low-income ones based on the 2008 industrial wage ranking from 2009 Beijing statistical yearbook. In view of the employed population of farming, forestry, animal husbandry and fishery is negligible within Beijing's central city, thus corresponding groups engaged in resident service and accommodation & catering are considered to be in the low economic status. With respect to urban green space, it is considered as one of most efficient methods to ameliorate thermal environment. In the studies related cooling effect of urban green space, green coverage is found to have a negative correlation with ambient temperature around the green space. Therefore, this study utilizes green coverage within sub-district as indicator to represent the external resource for mitigating the heat risk. Green coverage is calculated by the dimidiate pixel model based on normalized difference vegetation index (NDVI), which is retrieved from contemporary Landsat TM satellite image.

5 METHODS

5.1 DATA PROCESSING

Due to the difference between the dimension of data, these indicators should be firstly normalized by range standardization method. With respect to the negative or positive correlation (Table 2) between indicator and component, for example, adaptive capacity will decrease when employment population of accommodation & catering increase. Thus, positive standardization equation (II) and negative standardization equation (III) are shown as following. Before indicators are normalized, an $m \times n$ matrix X (I) is composed of individual items x_{ij} .

$X = \begin{bmatrix} x_{11} & \dots & x_{1n} \\ \vdots & & \vdots \\ x_{m1} & \dots & x_{mn} \end{bmatrix}$	(I)
$X_{ij} = \frac{x_{ij} - \min_j\{x_{ij}\}}{\max_j\{x_{ij}\} - \min_j\{x_{ij}\}}$	(II)
$X_{ij} = \frac{\max_j\{x_{ij}\} - x_{ij}}{\max_j\{x_{ij}\} - \min_j\{x_{ij}\}}$	(III)

Where:

x_{ij} refers to the original value at the i th sub-district and j th indicator ($i=1,2,\dots,m$; $j=1,2,\dots,n$);

m refers to the number of sub-districts, n refers to the number of indicators within each component;

X_{ij} refers to the normalized value of x_{ij} ;

$\max\{x_{ij}\}$ refers to the maximum among the original value, $\min_j\{x_{ij}\}$ refers to the minimum among the original value.

5.2 WEIGHTING METHOD

The approach to determine the weight of indicators consists of subjective weighting method and objective weighting method, both of which are widely used in the statistic analysis. As one of the objective weighting methods, entropy weight method is utilized to calculate the weight of indicators within each component in this study. Entropy is originally described as a disordered and chaotic state in the thermodynamics. After Shannon introduced this concept into information theory, entropy represented the uncertainty of information. Because the utility of information is negatively correlated with the uncertainty of information, entropy-weight determines the relative weight among indicators.

$$H_j = -k \sum_{i=1}^m P_{ij} \ln P_{ij} \quad (IV)$$

$$w_j = \frac{1 - H_j}{n - \sum_{j=1}^n H_j} \quad (V)$$

$$C_i = \sum_{j=1}^n X_{ij} w_j \quad (VI)$$

Where:

P_{ij} refers to the proportion of X_{ij} in the sum of all sub-districts' value at j th indicator,
 $P_{ij} = X_{ij} / \sum_{i=1}^m X_{ij}$, when $P_{ij} = 0$, $P_{ij} \ln P_{ij} = 0$;

H_j refers to the entropy of each indicator within the component;

w_j refers to the entropy-weight within each component;

C_i refers to the value of each component.

Component	Indicator	Correlativity to component	Entropy-weight	Data source
Exposure	Nocturnal surface UHI effect	+	0.17	MYD11A1
	NDBI	+	0.24	Landsat TM satellite image
	Population density	+	0.59	2010 Beijing Population Census

5.3 VULNERABILITY SCORING

For the purpose of identifying the intra-urban variation and spatial distribution of UHV, sub-district scores of heat vulnerability (V) are calculated by following assessment equation (VII) where E=exposure to heat, S=sensitivity and A=adaptive capacity.

Although some previous studies adopted statistic method, such as principle component analysis (PCA) or analytic hierarchy process (AHP) to weight among components, the acknowledged relationship between components is still need to demonstrate, meanwhile, in addition to the evaluating scores from experts, the important roles of inhabitants and policy makers in determining the weight need further to be strengthen. Thus, this study utilizes equal weight to integrate these three components.

Because the threshold of heat wave are defined as air temperature, the trasformation from diurnal LST into air temperature need to be calculated by the means of the relation equation (VIII),which R2 is up to 0.797(Li,2013).

$$V = E + S - A \quad (VII)$$

Where:

T refers to the air temperature;

TLS refers to the diurnal land surface temperature during heat wave.

According to the calculation result, the surface temperature is approximately 45.1°C when air temperature reaches 35°C. Because the time that diurnal temperature data of MODIS image collected is belongs to the period of maximum of air temperature one day, the areas that temperature exceeds 45.1°C are thought to be suffering from the impact of heat wave hazard. Thus, this study calculates the average value of LST within each sub-district and then select sub-districts with a surface temperature of 45.1°C and higher to form the heat wave hazard layer.

6 RESULTS

In order to present the intra-urban variant score of sub-districts clearly, five classes are categorized by natural breaks (Jenks) method in ArcGIS 10.3. In this section, results of single component and composite map will be presented and discussed.

According to the spatial pattern of exposure in the study area (Figure 4), sub-districts located in the city center are at high and very high level, as the distance from the city center increased, the score of exposure goes up and then down. In contrast with the highly centralized pattern of exposure score within western cities, there are some sub-districts with low level located in the Beijing's center area. It may be attributed to the presence of large open spaces, including the Forbidden city, Temple of Heaven park and Beihai park, which inhibits the continued increase of exposure to heat. The sub-districts with the very high level, comprising 25 sub-districts, are scattered throughout the city center. These areas are where many communities clustered, including newly-built type with high-volume and old one with high-density.

Figure 4 - Sub-districts scores of exposure.
source: authors' elaboration

Figure 5 - Sub-districts scores of sensitivity.
source: authors' elaboration

According to the distribution of scores of sensitivity (Figure 5), the spatial pattern of sensitivity is utterly different from that of exposure. Sub-districts with high and very high level are located in the near suburban areas rather than city center. The ones with very high level, comprising Wanliu(0.634), Wangsiying(0.620), Cuigezhuang(0.617), Xiangshan(0.571), Jinzhan(0.555), Xibeiwang(0.553) and Shibolidian(0.549), form three high-score clusters. In general, these three clusters highly concentrated sensitive people are all typical areas in urban-rural fringe, which representing both urban and rural features.

Finally, significant concentration in the distribution of human's adaptive capacity is located in the northern part within the study area. The twelve sub-districts with very high level comprise Qinghuayuan(0.846), Yanyuan(0.815), Aoyuncun(0.776), Datun(0.772), Zizhuyuan(0.759), Qinglongqiao(0.758), Xueyuanlu(0.753), Donghu(0.747), Wanliu(0.733), Shangdi(0.730), Haidian(0.719) and Xiangshan(0.715). The concentration of the best education resource and high-skilled employments appeals for many high-class and middle-class residents to live around. Besides, the large parks and natural landscape, owned by Aoyuncun, Xiangshan and Qinglongqiao sub-districts, play a important role in alleviating the thermal environment.

Figure 6 - Sub-districts scores of adaptive capacity.
source: authors' elaboration

Figure 7 - Intra-urban variation of urban heat vulnerability.
source: authors' elaboration

Figure 6 shows that the “very high” vulnerable sub-districts are scattered throughout the city center and the “high” vulnerable sub-districts are located in the southeastern part of study area, where the high exposure is experienced as well as high sensitivity and low adaptive capacity. The histogram (Figure 7) also indicates that the majority of “very high” vulnerable sub-districts are located in the Xicheng and Chaoyang district, while the percent of the “high” vulnerable sub-districts in Chaoyang district is higher than others. The “low” and “very low” vulnerable sub-districts are mainly concentrated in the Haidian district.

Figure 8 - The area percent of each district in the five categories.
source: authors' elaboration

The Pearson correlation coefficient is carried out to determine the relationship between temperature and the UHV. The result shows that the coefficient reaches up to 0.581 ($p < 0.01$). In order to identify the hot-spot areas, where high vulnerability co-occurs with high intensity of heat wave, the “very high”vulnerable

sub-districts, as well as “high”vulnerable sub-districts, are respectively overlaid on the heat wave hazard layer. The hot-spot areas are divided into two categories. The “very high”vulnerable sub-districts with LST higher than 45.1 °C are ranked as the most important hot-spot areas, which comprising Guanganmenwai, Niujie, Youanmen, Dashilan and Chongwenmenwai. Thus, the identified hot-spot areas should be considered as priorities areas for the implementation of adaptive planning.

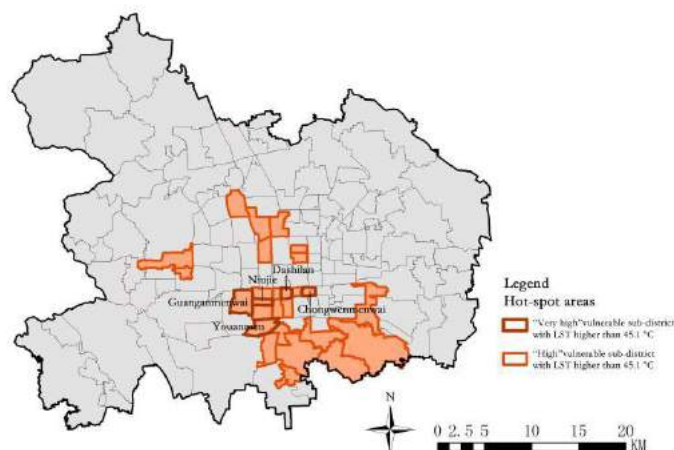

Figure 9 - Hot-spot areas.
source: authors' elaboration

7 PLANNING STRATEGIES FOR HEAT WAVE

In order to cope with uncertainties of climate change by means of urban planning, adaptive strategies should focus both on the pre-disaster prevention and post-disaster mitigation. The hot-spot areas can be utilized to form the priority in implementing adaptive planning. For the specific strategies in the priority area, this study presents the potential ways as following.

Urban design plays the important role in regulating urban micro-climate conditions (Golany,1996). In order to enhance the effect in alleviating the thermal environment, the specific strategies are presented in following three spatial scales. At the city scale, urban design should be integrated with the meteorological data to set up hierarchical ventilation corridors which can facilitate air flow; at the neighborhood scale, the contribution of different physical factors in impacting on air temperature should be identified, then based on the simulation with different combinations of identified factors, the efficient strategy on the cooling effect is presented; at the building scale, the principles of green building and low-carbon building should be implemented in all kinds of buildings as much as possible. Compared with urban and building scale, the cooling effect at the neighborhood scale is easy to perceive and operate. Taking into account the characteristics of physical environment, the planner or policy maker should develop variant plannings at the neighborhood scale, in the sub-district with high proportion of impervious surface and low building density, increasing the area of vegetable cover may be the most efficient way, however, in the sub-district with high building density, the design strategies may be mainly focused on the improvement of cooling effect (Norton and Coutts et al., 2015). Although urban design for prevention can reduce the intensity and frequency of heat wave in some degree, it is impossible to avoid the advent and impacts of heat wave fundamentally. Thus, the seasonable response during the heat wave is equally important. The accessibility to the hospitals and other medical resources within the hot-spot areas should be the first focus of mitigation strategies.

8 CONCLUSION

The study presents a method for quantifying urban heat vulnerability at the sub-district scale in Beijing central city. The result shows that “very high” and “high” vulnerable sub-districts are located in the city center and southeastern part of study area, which means the uneven impacts of heat wave event. By overlaying between heat vulnerability and heat wave hazard, the five sub-districts, which are considered

as the most important hot-spot areas, are identified to be the priority areas in adaptive planning. In terms of the specific implementation of adaptive planning, urban design for prevention and accessibility planning for mitigation are the potential ways. However, before applied into practice, the assessment of urban heat vulnerability and the effect of such strategies are still need to be further tested. This will be the focus of future work.

ACKNOWLEDGMENT

ID 1630 | PARTICIPATORY MODELLING TO SUPPORT GROUP DECISION MAKING PROCESSES IN CLIMATE RESILIENT URBAN DESIGN

Linda Nijland¹
¹Radboud University
l.nijland@fm.ru.nl

1 INTRODUCTION

Interest in climate resilience is growing worldwide among policy makers, urban planners, citizens and scientists. Climate Resilient Urban Design (CRUD) relates to the (re-)design of urban areas in such a way that cities and citizens become less vulnerable to climate change. Weather phenomena like heat stress, droughts and floods impact the lives of city dwellers, villagers, and rural residents all over the globe. The making of policies dealing with climate resilience in urban environments is a process that inevitably involves stakeholders from various disciplines, each with their own interests, constraints and goals.

Group Model Building (GMB) (Vennix, 1999) is known to facilitate the decision making processes by modelling important variables and their causal relations in a Causal Loop Diagram (CLD). This participatory group modelling process creates a shared understanding of the problem, incorporating the views of all stakeholders, and it improves the support for the final decisions taken.

The GRACeFUL (Global systems Rapid Assessment tools through Constraint Functional Languages) project aims at supporting decision making in complex problems by connecting participatory processes (using GMB) to scientific evidence through novel tools. Rapid Assessment Tools typify causal factors and linkages with concrete data from other system layers and produce a set of viable and acceptable alternative solutions to be used in decision making. Simulation tools will simulate the alternative scenarios over time and visualization tools will show the results of the different CRUD solutions on maps. The case study area is a neighbourhood in the city of Dordrecht, the Netherlands. The municipality is planning to redevelop the public space in this neighbourhood taking into account climate resilience and involving different stakeholders, including citizens.

The aim of this paper is to identify important variables, their causal relations and feedback loops which are generally involved in Climate Resilient Urban Design problems. These factors, relations and loops help us to develop the GRACeFUL Rapid Assessment Tools. Student workshops were held in which six groups of Urbanism and Water management students represented different stakeholder roles. Each group created a Causal Loop Diagram (CLD) on the Dordrecht case study neighbourhood and used this participatory modelling process as an exercise to create a better Climate Resilient Urban Design.

This paper is organized as follows. First, the participatory modelling method Group model building will be explained. This is followed by a description of the workshop on climate resilient urban design. Section 4 represents the analyses of the CLDs and the paper ends with a discussion.

2 GROUP MODEL BUILDING

The participatory modelling method Group model building is particularly useful for problem structuring and diagnosis in decision making processes (Vennix, 1999). It is known to include all stakeholders' views, input and explanations and thereby the method guides the participants to an improved and shared understanding of the problem and a stronger support for the final decisions made.

Group model building is a facilitated participatory modelling method which implies that an independent facilitator will guide the group of six up to 15 different stakeholders through the process, often assisted by a modeller/recorder. The participants are generally seated in a semi-circle or U-shape with the facilitator and a whiteboard (or projection screen if the model is created using system dynamics modelling software) in front (Rouwette and Vennix, 2017).

Group model building consists of a divergent as well as a convergent phase. The creative divergent phase is typically covered by using an existing method like brainstorming, in order to elicit as many variables associated with the problem as possible. In the convergent phase those variables will be related to each other, creating a causal diagram or system model. This so-called Causal Loop Diagram (CLD) represents the variables that (in)directly affect or are affected by the problem variable, and the causal relations between the variables. As an illustration, figure 1 shows a picture of a part of the causal loop diagram created by group 2 of the 2017 CRUD workshop. A positive causal relation means that both factors change in the same direction. For instance, according to group 2017_2, an increase in damage caused by floods will lead to an increase in climate awareness. Negative relationships between factors indicate a change in opposite directions (Rouwette and Vennix, 2017). For example, an increase in climate awareness will decrease household consumption (right-hand side of figure 1). Furthermore, feedback loops within the diagram (e.g., between climate awareness and climate policy in figure 1) are important indicators for balancing or escalating behaviour.

Figure 1 - Causal loop diagram made by group 2017_2

Related to the urban planning field, issues regarding specific projects on topics like tourism development in a coastal area (Vugteveen et al., 2015), neighbourhood safety (Rouwette et al., 2016) and coastal flooding were addressed by using Group model building. To the best of our knowledge, this method has not been

applied to climate resilience at the urban design level taking into account pluvial flooding, drought and heat stress.

3 CRUD WORKSHOP

As part of a one-day workshop on Climate Resilient Urban Design (CRUD), in May 2015, 2016 and 2017 two student groups, each consisting of six students, worked on a Causal Loop Diagram (CLD). The remaining five to six groups used other methods/tools in preparation of the design phase. The students were master students Urbanism (Faculty of Architecture and the Built Environment) or Water management (Faculty of Civil Engineering and Geosciences) at Delft University of Technology. Each student was assigned a stakeholder role. The following roles were divided: 1) local residents representative; 2) local businesses representative; 3) city of Dordrecht – spatial planning & development; 4) city of Dordrecht – water; 5) environmentalist; 6) recorder. Their task was to create a climate resilient urban design for the Stadspolder neighbourhood in Dordrecht. As a problem structuring exercise each year two groups of students participated in a Group model building (GMB) session. In these GMB sessions first factors related to Climate Resilient Urban Design were elicited. Subsequently, the students created a CLD by linking the factors that were causally related.

3.1 STADSPOLDER NEIGHBOURHOOD

Stadspolder is a neighbourhood in Dordrecht located in the east part of the city (see Figure 2). The neighbourhood was built in the 1980s and 1990s. Nowadays the public space is in need for reconstruction and therefore the municipality of Dordrecht seized this opportunity to not only renew the streets, sewage system, parking lots and green space, but to redesign the public space and making it more climate resilient. The Stadspolder neighbourhood has a so-called cauliflower structure, which was typically applied to Dutch neighbourhoods designed in the 1970s and 1980s. These cauliflower neighbourhoods are characterised by a maze-like grouping of cul-de-sacs or small courtyards intended to encourage social bonding by facilitating spontaneous encounters among neighbours (Wekker, 2016), to improve intimacy and to reduce through traffic. Main problems in the Stadspolder neighbourhood concern parking (limited parking space, parking in front gardens), dwellings with low doorsteps and accessibility.

Figure 2 - Stadspolder's location in Dordrecht (in red)

4 ANALYSES

This section describes the analyses of the six CLDs constructed by the groups of students at the CRUD workshop. The first thing that catches the eye is that all six models are different even though the Master

students have similar knowledge and the project case is exactly the same. Another observation, which often is noticed when analysing GMB sessions on the same topic, is that the different groups use different words to indicate the same thing. Furthermore, it should be noted that the CLDs are not perfect after only 1.5 - 2 hours of modelling.

The analysis starts with identifying general causal relations to and from 'climate resilience'. This is followed by a specific focus on the climate resilience aspects flooding and heat stress. The respondents did not consider drought to be a problem to the Stadspolder case. Finally, other important themes in the causal diagrams, safety, awareness, liveability and costs, will be evaluated.

4.1 CLIMATE RESILIENCE

The GMB groups worked with 'Climate resilient Stadspolder' as the central variable in the CLD. This implies that 'Climate resilient Stadspolder' was the first factor written in the centre of the empty board and subsequently, the variables elicited in the brainstorming phase which had a causal relation to the factor(s) on the board were added to create the causal diagram. As a consequence, all groups have connected factors to this central variable. Table 1 shows per topic which factors were causally related to it, both ingoing and outgoing arrows, and whether the arrow had a plus or minus sign. When looking at the incoming arrows, the most frequently connected factors to 'climate resilience' deal with flooding and heat stress on the negative side (i.e., the more flooding the less climate resilient), whereas measures, water management factors (like vegetation, green/blue space, drainage/storage capacity, permeable surfaces), sustainability related factors and safety show a positive causal relation. The outgoing arrows from climate resilience head towards living quality, different forms of sustainability and safety holding a plus sign and flooding and heat stress having a negative causal relation.

4.1.1 FLOODING

In the causal diagrams this dimension of climate resilience is indicated by flood risk, floods, flooding and flood events return period. Group 16_2 connects flood risk to floods by an arrow with a positive sign which implies that a higher flood risk leads to more floods. Other factors with a positive link towards flooding concern rainfall (events), impermeable surfaces, groundwater level, maintenance issues, drought dikes risk and run-off. On the other hand, infiltration/permeable surfaces, water drainage, water storage, green space, quality of sewage, quality of water management, (measures and emergency preparedness) are factors which reduce the flood risk when improved. Regarding the outgoing arrows of flooding, variables like damage, hazards and costs, but also measures and awareness are linked with a plus sign (the more flood events, the more damage or the more awareness). Whereas safety, living quality and accessibility are negatively affected by flooding.

4.1.2 HEAT STRESS

Urban heat stress or heat risk was mentioned by four out of six groups. Their causal diagrams show that increasing the space for buildings and roads raises heat stress levels. On the other hand, urban heat stress declines due to an increase in green/blue space, water availability, citizen initiatives and sun reflection. Factors caused by heat stress concern energy cost for cooling and heat stress business opportunity, holding a plus sign (the more heat stress, the higher the costs for cooling) and water quality, safety and native biodiversity are connected with a negative arrow (the more urban heat stress causes poorer water quality).

Table 1 - Factors in CLDs by theme and their causal relations

4.1 OTHER IMPORTANT CRUD THEMES

The six Causal Loop Diagrams show some other topics that are part of a climate resilient urban design system model. Liveability, awareness, safety and costs are often mentioned. Furthermore, 'measures' in general or specific measures are frequently part of the causal diagram. This subsection describes the causal relations regarding those themes.

4.1.1 LIVEABILITY

Liveability is chosen as a blanket term for the factors living quality, quality of local living environment, quality of life, social sustainability and wellbeing residents. This theme appears in five out of the six CRUD system models. Group 16_1 really puts an emphasis on their living quality factor since they identified twelve ingoing arrows, making it the most prominent factor. According to them aesthetics, attractiveness recreational areas, native biodiversity, water quality, climate resilience, urban farming, green mobility, infrastructure and citizen initiatives contribute to a better living quality. On the other hand, flooding, densification and subsidence negatively affect the liveability of the Stadspolder neighbourhood. Group 16_2 adds that interaction with nature positively influences the quality of the local living environment. Furthermore, they indicate that increasing liveability leads to a healthy environment and a growing population. Group 15_1 focusses on quality of life which according to them is affected by more vegetation, safety, environmental quality, measures for climate resilience and a longer return period of flood events. In the case of social sustainability (group 15_2), social cohesion, public awareness and urban farming are positively connected. Finally, the wellbeing of Stadspolder's residents (group 17_1) is influenced by welfare of the residents, vegetation, biodiversity, area for water and water recreation and housing density. The latter factor is in this CLD the only negative causal link (i.e., the higher the housing density the lower the wellbeing).

4.1.2 AWARENESS

Compared to the presentations of groups using other tools/methods at the CRUD workshop, the GMB groups often come up with 'raising awareness' and 'involving local residents' as measures for increasing the climate resilience of the Stadspolder neighbourhood. These are actions which are not directly related to maps (compared to technical measures like bio swales or green roofs). Collective, climate or public awareness turns up in four causal loop diagrams. Regarding the incoming arrows, we see that support for

initiatives, climate policy, education, floods and damage caused by floods are factors raising awareness. Whereas awareness causes more support for initiatives, measures, taxes, acting, climate policy, citizen initiatives and social sustainability. Some direct feedback loops show up here. A decrease in household consumption an effect of increased awareness as well.

4.1.3 SAFETY

Another theme that can be distinguished is safety. This factor is described in half of the CLDs and for this analysis it also includes hazards open water and emergency preparedness. Regarding ingoing arrows, accessibility in crisis, water available for fires and climate resilience show a positive causal relation (the more water for fires the greater the safety), while flood risk, heat risk and health risk negatively affect safety (the higher the risk the lower the safety level). Safety, in its turn, has positive causal effects on quality of life and climate resilience. Hazards open water are increased by more open water availability and more floods, whereas improved water quality decreases the exposure to hazards. Finally, emergency preparedness grows when available funds increase and education on this topic improves. On the other hand, preparedness for emergencies causes a reduced flood risk.

4.1.4 COST

Inevitably costs are involved in restructuring neighbourhoods when applying measures to make them more climate resilient. All of the groups had factors in their CLD that deal with this theme. Costs for business, money/subsidy, maintenance costs, taxes, investments, economic development and economic sustainability were mentioned. With regard to investments, the factors taxes, climate policy and private sector positively affect the number of investments made. 'Investments' is also directly connected to climate resilience (i.e., the more investments the more resilient the neighbourhood is). CRUD measures in general and some specific measures are linked with cost as well. For example, the higher the taxes, the more measures will be adopted, the higher the maintenance costs the lower the number of measures implemented, the more money/subsidy the more green roofs and the more urban farming the more economic sustainability. This economic sustainability is positively influenced by job opportunities, available funds and climate resilience as well.

4.2 DISCUSSION

Six causal loop diagrams were obtained from workshops on climate resilient urban design of the Stadspolder neighbourhood in Dordrecht. Analysis of the causal diagrams shows that all system models seem to be very different even though the case study area is exactly the same and the Master students had a similar background in education. Furthermore, also the wording used to indicate the same factor differs between groups. This is often noticed when evaluating causal diagrams on the same topic. A general explanation is that a causal loop diagram represents how the group thinks about the problem. Other stakeholder groups might create a different model based on the exact same problem.

Another observation is that the CLDs are more focused on flooding than on heat stress or drought. The students might consider pluvial flooding as the main problem, however this could also be caused by an overrepresentation of water management students in the groups (usually five water management students and one urbanism student). This also explains why typical urban design variables, like aesthetics and attractiveness, are not frequently mentioned.

Finally, the group model building sessions in the CRUD workshops were quite short (1.5 – 2 hours) compared the usual GMB process, which covers at least two sessions of 3 to 4 hours with opportunities for reconsideration and improvement. Hence, the final CLDs created by the student groups are not absolutely perfect.

ACKNOWLEDGEMENTS

This research is funded by the EU GRACeFUL (Global systems Rapid Assessment tools through Constraint Functional Languages) project, www.graceful-project.eu, Horizon 2020, grant 640954 EU-GRACeFUL. We thank all students who participated in the CRUD workshops for their valuable contributions.

joanafmdias@tecnico.ulisboa.pt ; mariapartidario@tecnico.ulisboa.pt

ABSTRACT: The world has been facing a continuous increase in the number and size of urban areas. Social dynamics changes are inevitable, calling for the need to examine and monitor urban systems, in particular urban resilience to social problems and to changes in socio-ecological systems. This paper intends to analyze and understand how the municipal policies in Lisbon have been contributing (or not) to the resilience of the urban system, through a social dimension. We have looked at what is that socially drives the urban system, what, why and how social disturbances and changes affect its resilience, and how the municipal policies may contribute to it. A literature review on urban resilience and social innovation was developed to identify a proper methodology to be adopted and to identify the main elements to be addressed in this analysis. The methodology adapted consists of five steps: (i) translation of the social dimension into urban resilience, through social dynamics and social innovation concepts; (ii) definition of the focal scale; (iii) identification of indicators; (iv) development history; (v) interpretation from the perspective of long-term resilience. In applying the methodology to the city of Lisbon, the city governments' policies were analyzed, and the social drivers, social disturbances, and changes affecting the urban system resilience identified and assessed. The results indicate that demography, social vulnerability, mobility and city attractiveness prove to be key drivers to assess the social contribution to urban systems resilience. These key drives can be applied to other cities with the same urban development typology as Lisbon. Research on the Lisbon's system showed that the city has been facing, over the last 50 years, a mix of desirable and undesirable qualities. Desirable qualities seem to facilitate the urban system's transition to a sustainable behavior, building urban long-term resilience; while the undesirable qualities can be seen as an opportunity to reverse the city social disturbances negative trends by changing current city governance policies.

1 INTRODUCTION

The world has been facing a continuous increase in the number and size of urban areas. The United Nations (2014) has already alerted that the world has, currently, a population of 7.2 billion of which over half (54 percent) lives in urban areas.

Cities, as growing drivers of the world's future and engines of economic growth, present several social challenges, as poverty and disease, but at the same time offer opportunities for sustainability. Social dynamics changes are inevitable, calling for the need to examine and monitor urban systems, in particular urban resilience to social problems and to changes in socio-ecological systems.

The present paper intends to analyze and understand how the municipal policies in Lisbon have been contributing (or not) to the resilience of the urban system, through a social dimension.

Thus, a literature review was performed on the concepts of urban resilience and social innovation, in order to identify a proper methodology to be adopted and to identify the main elements to be addressed in this analysis. After, the methodology developed by Kumagai, Gibson, & Fillion (Kumagai et al., 2010) was adapted to the context and purpose of this paper and applied to the city of Lisbon.

A particular focus of this paper is on governance actions. More specifically, on Lisbon municipal policies and plans and their respective strategies, objectives and proposed actions to be developed and implemented.

2 LITERATURE REVIEW

2.1 URBAN RESILIENCE

Urban systems are complex and dynamic systems with ecological and human issues that depend on each other at multiple scales, where ecological functions are altered to accommodate the human activities and structures (Kumagai et al., 2010). Cities, urban systems, as living systems – open, dynamic and connected systems – are continuously evolving through the influence of internal interactions and external factors (Bai, 2003), being considered one of the best examples of a social-ecological system (SES) (Levin, 1999).

Cities may change abruptly and faster than the human capability to understand the influence of certain factors on those changes (Resilience Alliance, 2007), demanding a profound knowledge on cities complexity and development, and capacity to adapt (Batty, Barros, & Alves Junior, 2004). Resilience Alliance (2007) considers that the abrupt changes of cities depend both on temporal and spatial perspectives and that what may appear to be an abrupt change to a certain system might be a gradual or insignificant to another system. For example, the urban gentrification process can take decades, market cycles in housing prices crashes over months and sometimes years, stock markets crashes over days, while urban traffic jams occur over minutes (Batty et al., 2004).

The concept of resilience applied to urban systems can be defined as the "degree to which cities are able to tolerate alteration before reorganizing around a new set of structures and processes" (Alberti et al., 2003), and measured by the way cities balance simultaneously human and ecosystem functions (Resilience

Alliance, 2007). The decrease of resilience increases vulnerability, leading to the urban system exposure to greater risks of the vagaries of surprise and uncertainty (Folke et al., 2002). Generally, the resilience decrease takes progressively smaller shocks to cause crises or chaos on systems. This is a cumulative process that tends to shift a systems towards criticality (Resilience Alliance, 2007).

An earlier approach developed by the Resilience Alliance (Resilience Alliance, 2007), the urban resilience four cores, looks into urban resilience structured in four subject areas:

- Metabolic flows, consider production, supply and consumption chains which do not start or end within the city premises;

- Governance networks, include institutional structures and social organizations and the society capacity to learn, adapt and reorganize to meet urban challenges related to rapid urbanization and its environmental impacts;
- Social dynamics, consider demographics, human capital and inequity, as well as urban individuals and their interactions (groups or communities) with urban landscapes, and the influence of a cultural set of patterns determining a social order;
- Built environment, the urban physical patterns and their spatial relations and interconnections, such as: ecosystem services in urban landscapes, modeled by the process of urbanization, subjected to complex patterns and processes interactions.

Understanding the role of time and how it affects future urban options is a very important part in urban resilience (Resilience Alliance, 2007). These four core subjects allow the study of the urban system resilience (as a whole) and of each of the four subjects of the urban system individually.

Many applications of resilience to urban systems have been dealing with the potential future changes and disturbances that may affect the system, disregarding whether or not the results contribute to a sustainable behaviour. Sustainability includes, as one of its crucial elements, lasting well-being which can be understood as the "decent life for everyone based on integrity of socio-biophysical systems and maintenance of their support functions, while paying attention to intra- and inter-generational equity" (Gibson, 2006; Kumagai et al., 2010). Intra-generational equity requires ensuring that sufficient and effective choices are pursued for all in ways that reduces dangerous gaps in sufficiency and opportunity – and security, health, social recognition, political influence, and so on – between the rich and the poor, while intergenerational equity requires favoring the present options and actions that most likely will preserve or enhance the opportunities and capabilities of future generations to live sustainably (Gibson, 2006).

In order to differentiate from those applications, Kumagai et al. (2010) developed a methodology to assess the resilience of urban systems regarding lasting well-being, the system transition to a sustainable behavior and governance activities through the perspective of long-term resilience. Their methodology consists in understanding what drives the urban system under assessment, what characterizes it, how did the urban system developed/changed through time and in analyzing it through the lens of long-term resilience.

The long-term resilience of an urban system is "the system capacity to respond to change and disturbance and to enhance the conditions for well-being, based on careful attention to the complex interrelationships of all factors and to the specifics of particular contexts through governances combining adaptation with transition" (Kumagai et al., 2010).

Kumagai et al. (2010) identifies as one of the urban resilience study major problems the fact of resilience might be desirable or undesirable. The ecological literature tends to assume resilience – the maintenance or re-establishment of system capacities to maintain structure and function – as positive, but when considering human systems such assumption is more difficult to do and might become considered as regrettable. For example, the resilience of systems that support organized crime and perpetuate racism or high-consumption habits is undesirable because it would not promote lasting well-being of the urban system. It can be assumed that every urban system has a mix of desirable and undesirable qualities and that is not always desirable to have a resilient system (Kumagai et al., 2010).

Building long-term resilience of urban systems requires that the efforts to enhance the resilience of systems delivering desirable services be accompanied by, and integrated with, efforts to facilitate transition to systems that foster and support sustainable behavior (Kumagai et al., 2010).

Building long-term resilience also requires governance structures and practices and can be achieved through five governance activities (Kumagai et al., 2010):

- Recognition (by governance arrangements) of complex system in terms of boundaries, contexts, interdependency, fast and slow variables, modularity, and interactions;
- Anticipation (based on recognition) of future possible disturbances and vulnerabilities;
- Active transition (enabled by anticipation) to act previously to disturbance;
- Adaptability against inevitable surprising disturbances and

- Communication backed by trustworthy networks, willingness to learn and change, and structural flexibility must support and enable the other four activities.

Kumagai et al. (2010) also states that the incapacity to make transition needed to deal with anticipated changes further reduces the potential adaptive capacity of the urban system.

2.2 SOCIAL INNOVATION

The term social innovation (SI) was first addressed, in the academic literature, by Max Weber and Emile Durkheim, who defined SI as “innovations in the organisation of work and of society” (Hubert, Thébault, Schinas, Bonifacio, & Konings, 2010). Max Weber defined a relationship between the concepts of social order – set of social structures, institutions and practices which linkage aims to maintain and apply behavioral and relationship ways – and innovation – improved solutions application to meet new, in-articulated, and/or current market needs (Maranville, 1992) – as the social change impact of certain behaviors considered, in the beginning, as uncommon or unexpected (Hubert et al., 2010).

Afterwards, social innovation re-emerged as a concept and practice to deal with economy restructuring implications, changes introduced by the development on information technology and mass unemployment. Since then, several definitions and considerations on social innovation have been developed in the last years by several authors (Cloutier, 2003; Hämmäläinen & Heiskala, 2007; Hubert et al., 2010; Moore, Westley, Tjornbo, & Holroyd, 2010; Mulgan, Tucker, Ali, & Sanders, 2007; Mulgan, 2006; Nussbaumer & Moulaert, 2007; Phills, Deiglmeier, & Miller, 2008; B. F. Westley, Zimmerman, & Patton, 2006; F. Westley & Antadze, 2010).

F. Westley & Antadze (2010) definition of this concept can be highlighted: “complex process of introducing new products, processes or programs that profoundly change the basic routines, resource and authority flows, or beliefs of the social system in which the innovation occurs” (F. Westley & Antadze, 2010).

The social system may be defined as “any organized assembly of human resources, beliefs, and procedures united and regulated by interaction or interdependence so as to accomplish a set of specific functions” (F. Westley & Antadze, 2010) with its own boundary, culture and political identity, economic structure and social interactions established (F. Westley & Antadze, 2010)(F. Westley & Antadze, 2010). Westley (2008) alerts for the importance of social systems to keep their identity while, at the same time, to be able to adapt to change and novelty.

Christensen et al. (2006) states that a social innovation with a broad or durable impact will be disruptive, catalytic, and will challenge the social system and social institutions as well as will enable some changes in their convictions and governance ideals. In other words, Westley and Antadze (2010) and Westley (2008) refer to a broad or durable impact social innovation as a successful social innovation that must have a wide scope, crossing as many social levels as possible, and reaching different scales.

Huddart (2010) states that social innovation “opens up new approaches to addressing complex problems and covers a lot of ground, but is still taking shape”, and proposes twelve principles to guide strategy around social innovation after developing an analysis of initiatives considering environmental, economic and social spheres. Principle 7 “Commit to social inclusion”, for example, considers that the inclusion of vulnerable populations leads to more wide solutions and enduring results.

Society can be defined as “a myriad of rules, some formal, others informal such as cultural practices that determine how people interact with the ecosystems around them” (Resilience Alliance et al., 2010), and the capacity of a society to generate a steady flow of social innovations is an important contributor to overall social and ecological resilience. In a broad sense, social innovation can be seen as part of the solution for the complex problems regarding SESs in the world (F. Westley & Antadze, 2010; F. Westley, 2008).

Westley and Antadze (2010) and Westley (2008) present the example of vulnerable populations' re-engagement (community reintegration of lonely, homeless, mentally ill and poor people) as a frequently addressed subject in social innovation agenda and as a contributor to resilience increase. Contrarily, the exclusion of some population from primary services, for example, leads to a loss of resilience and also to the exclusion of these population opinions, points of view and diversified experience. Therefore, social

innovation serves and is served by vulnerable populations, and their re-engagement in social systems identity as persons of interest and involved ones is linked to social-ecological resilience (F. Westley & Antadze, 2010; F. Westley, 2008).

3 METHODOLOGY

The methodology adopted in the present paper is based on one existing methodological approach to resilience in urban systems available in the resilience theory literature and developed by Kumagai et al. (2010).

Kumagai et al. (2010) methodology assesses the resilience of urban systems and uses as its focal system the City Region of Tokyo, adopting a long-term perspective, considering people's lasting well-being and governance actions through five steps:

1. Translation of resilience into urban context: defines the elements that characterize and drive the type of urban system in analysis (for example, a city under or already developed or a post-industrialized city), and establishing the framework for performing the resilience assessment;
2. focal scale definition: defines the spatial and temporal boundaries;
3. indicators identification: the focal scale indicators are grounded by the identified elements;
4. development history: analysis of the indicators evolution across time
5. interpretation from the perspective of long-term resilience: assesses the long-term resilience of the focal scale according to the change/evolution of indicators, considering governance activities to build long-term resilience for the lasting well-being of people.

The main purpose of this methodology was to look at how urban system incorporates resilience. In the case of Lisbon, presented in the next sections of the paper, the purpose was to look at how urban resilience can incorporate a social dimension. Therefore an adaptation of the Kumagai et al. (2010) methodology was necessary and developed.

Kumagai et al. (2010) identified four aspects to interpret resilience in the urban context - demography, mobility, tax revenue and resource-efficiency (relevant to relate resilience to the urban redevelopment of post-industrialized cities such as Tokyo City Region). In the case of the city of Lisbon, the objective has been to translate and integrate social resilience into urban resilience context, and four drivers of urban resilience were adopted:

- Demography: understands how and why population has been changing and provides an analysis of the emerging demographic issues that must be considered by governance;
- Social vulnerability: understands people's emerging needs and risks, and provides an analysis of the social state for governance priorities;
- Mobility: provides an analysis of the socio-economic relations between the urban system and its surroundings regarding the population access and use of the transport network;
- City attractiveness: - relates to how attractive the urban system is, what are its strengths and how governance is managing such strengths;

As in the Kumagai et al. (2010) methodology, a particular focus of this paper will be on governance actions. The political and planning measures adopted by the city governments over time, as well as the actions and initiatives developed were analyzed.

The following section shows the application of the adapted methodology to the case of the city of Lisbon. It includes, first, a brief presentation of the city government policies over the years, and after the identification and analysis of the four drivers that will allow the further assessment of the case study's social disturbances through the long-term resilience perspective.

4 CASE STUDY

The present case study is the city of Lisbon, capital of Portugal and one of the Lisbon Metropolitan Area municipalities, as represented in Figure 1. Lisbon is the focal scale in this study.

The city of Lisbon is the most populous one of Portugal, with a population of 506.892 inhabitants within its administrative limits (INE - Instituto Nacional de Estatística, 2014a; PORDATA, 2015), within a surface area of 100 km² (IGP - Instituto Geográfico Português, 2014).

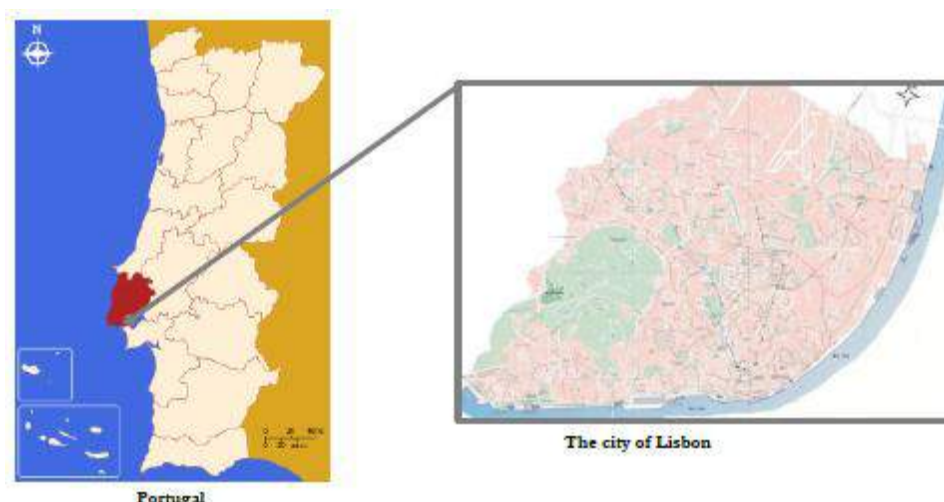

Figure 1: Location of the city of Lisbon in Portugal.

Owner of a characteristic charm and located across Tagus River, Lisbon is considered a global city due to its financial, commercial, artistic, educational and touristic importance, and the country's main economic and urban center. Within its limits, Lisbon has the biggest and busiest airport – Portela Airport – and the oldest underground subway in the country – Lisbon subway.

During the last 80 years, Lisbon urban area has been evolving according to the major directives of development defined in the city master plans. About 80 years ago, the country and the city governments "started" the Lisbon expansion through the construction of roads and new housing neighborhoods, economic housing neighborhoods and housing for poor. The need for a city master plan was recognized, but the urgency for the constructions did not allow it to be done in advance, leading the city government, afterwards, to admit that with the knowledge of a master plan, several problems would have had different solutions than the ones adopted. Thus, in 1938 the city government (under the administration of the Engineer Duarte Pacheco) hired the urban architect Étienne de Gröer to, along with municipal technical services, define the major guidelines of the city expansion and develop the first master plan of Lisbon, which was concluded in 1948, the Lisbon Urban Master Plan of 1948 (LUMP 1948).

After the new legislation for developing Municipal Master Plans (MMP) in 1990, the Lisbon Municipal Master Plan of 1994 (LMMP 1994) established the occupation, use and transformation rules of the municipal territory. However, it did not consider its implementation schedule, being mainly an administrative and supportive document.

In 2001, the city government of Lisbon initiated the process of revising the LMMP 1994 and during the years the LMMP 1994 was under revision, the city government realized several workshops and forums of discussion for stakeholders to participate and assured, afterwards, that their contributions and opinions were considered in the development of the new MMP, Lisbon Municipal Master Plan of 2012 (LMMP 2012).

The LMMP 2012, the MMP currently in force, establishes the major development strategies and the urban policies for the municipal territory. It also defines its implementation schedule, acquiring a strategic character and no longer being just an administrative and supportive document. The LMMP 2012 reflects an integrated vision of the municipal territory and aims to reinforce the city competitiveness, to ensure territorial equity and to support territorial integration and cohesion. Table 1 presents the resume of the main objectives of the three Municipal Plans of Lisbon analyzed, LUMP 1948, LMMP 1994 and LMMP 2012.

LUMP 1948	LMMP 1994	LMMP 2012
Limitation of the urban development	Protect urban life quality	Attract more inhabitants
Regulation of the land use	Harmonize the relation between housing and services construction	Attract more business and jobs
Establishment of the use of high speed paths	Humanize the city and its public spaces	Stimulate urban rehabilitation
Administrative, social and cultural equipping of each neighborhoods and the city	Improve mobility, transports and parking	Qualifying public space
Sanitation and improvement of dwelling and work places	Recovery and rejuvenation of the city resident population	Return the riverfront to the people enjoyment
Conservation and protection of architectonic and natural city wonders	Increase Lisbon potential as a city metropolis	Promoting sustainable mobility
		Increase environmental efficiency

Table 1: Main objectives for the three Municipal analyzed, LUMP 1948, LMMP 1994 and LMMP 2012. Data source: CML - Câmara Municipal de Lisboa (2012, 1994a, 1994b), Groer and CML - Câmara Municipal de Lisboa (1948) and Soares (1994).

The International Society of City and Regional Planners (ISOCARP)¹ assigned, in 2013, an excellence award to the LMMP 2012 for its innovative character regarding the theme: Frontiers of Planning – Evolving and Declining Models of City Planning Practice.

4.1 DRIVERS

As referred before, the analysis of the social dimension was developed according to four drivers: (i) demography; (ii) social vulnerability; (iii) mobility; (iv) city attractiveness. For each driver it was considered a set of available data, allowing the analysis of the drivers.

As for the driver demography, it is possible to state that the evolution of the population living in Lisbon has been decreasing since 1981 as a consequence of the Lisbon Metropolitan Area massive urban development and of the increase of the Lisbon price per m2. As an attempt to revert this situation, the LMMP 1994 defined as one of its major objectives the recovery of the city resident population, which was reinforced in the LMMP 2012 with the definition of the goal: attract more inhabitants. Moreover, the LMMP 2012 intends to: (i) create an affordable housing program through an incentive system directed to the middle class, and of parking for residents, especially in the neighborhoods with an identified need; (ii) approach work and resident places through the previous elaboration of a multifunctional MMP; (iii) protect residential neighborhoods from high levels of noise and bad air quality due to traffic; (iv) construction of new sports equipment and rehabilitation of older ones.

However, this continuous decrease in resident population, mainly due to the exit of the younger population from the city of Lisbon, has been contributing to the population ageing. In fact, in 2001 the ageing population index registered its highest value in Lisbon (203,4%), followed by an apparent stabilization. Nevertheless, local government recognized, in 2008, that this tendency of ageing population had reached a critical point and started developing assisting programs to promote a healthy and active ageing of the city inhabitants. The LMMP 2012 even highlights, as a priority, the intention of constructing day centers, residential housing, nursing homes, university residences and multifunctional spaces for seniors.

The infant mortality and illiteracy rates, both have been decreasing, being nowadays almost eradicated. This decrease is mainly due to the national government reforms on health and education initiated around 1970 (when both indexes were very high) that allowed all population to access education and medical care. Nowadays, the increase access to education and health services continuous to be guaranteed through, for example, the LMMP 2012 action guidelines for these issues: (i) construction of new 1st cycle and pre-schools, rehabilitation of older 1st cycle schools and opening of nursery schools vacancies; (ii) construction of an hospital, of health centers and continuing care units.

¹ ISOCARP is an international association, founded in 1965, that gathers the most recognized and highly qualified urban planners.

The set of data available for the driver social vulnerability presented different evolutions. In one hand, the criminality in Lisbon (number of crimes per thousand inhabitants) has been decreasing, presenting in 2015 its lower value ever.

On the other hand, the unemployment rate of the inhabitants of Lisbon has been increasing, presenting a more pronounced increase since 2010. It can be argued that this pronounced increase is due to the financial and economic crisis in the country since 2009. As an attempt to counterbalance this pronounced increase, the LMMP 2012 has as one of its objectives to attract more jobs, improving the capacity to create more jobs and install more workplaces and increasing the city economic sustainability.

However, the loss of economic power has been contributing to the increase of vulnerability of Lisbon population. The continuous increase of the number people in homeless situation is one of the examples of this increase of vulnerability. This complex issue has been recognized, as critical, by the city government, who has been developing programs to support this vulnerable population in an integrated way.

But, with so many issues contributing to the increase of vulnerability of the city (loss of economic power, increase of unemployment and increase of homelessness population), the need for special attention and for the assistance to the population increase. The Food Bank in Lisbon has been able over the years to increase its assistance to people and institutions, even with a slight decrease in the number of received products.

As for the mobility, the city of Lisbon has registered, over the years, a continuous increase in the number of people entering the city work or study. This is coincident with the major decline in the resident population of Lisbon and consequent continuous growth of the resident population in the other municipalities of the Lisbon Metropolitan Area (population that no longer lives in Lisbon but continues to work there).

Along with this, there is also an increase, although much lower, in the number of people exiting the city to work or study. This might be justified by the exit of some sectors of activity from the city of Lisbon to the periphery (other municipalities of Lisbon Metropolitan Area) due to improvement of the accesses and infrastructures near Lisbon and mostly due to lower rental costs. The need to attract more business and more companies to the city is recognized by the local government in the LMMP 2012, where is declared the intention to: (i) be possible to locate companies in any point of the city; (ii) reserve space for companies in future urbanizations and supply of adequate spaces for companies installation; (iii) use better the existing business areas; (iv) intervene in the market to compete with the business clusters in the border municipalities through MMP new soil programming mechanisms; (v) increase the edificability index and reduce the permissions in urban polarities and business areas; (vi) support initiatives regarding the reuse of abandoned industrial spaces.

The increase of people circulating in the city every day along with the development of accesses and public transportations, led to the increase of collective transports investment, namely to the expansion of Lisbon subway, through the increase on the subway's network length. Also the number of the subway passengers has been increasing through the years. Nowadays, is under discussion the expansion of the subway network to more four areas of the city.

The local government identifies in the LMMP 2012 the need to ensure a sustainable mobility through (i) the promotion and increase of collective transport, (ii) the reversion of traffic congestion, (iii) the daily use of bike paths, (iv) the improvement of sustainable and multi-modal mobility and (v) the qualification of public space. The LMMP 2012 also has several actions identified to be implemented to promote this sustainable mobility, as for example: (a) the increase of bike network, security and comfort in the use of bicycle in urban areas; (b) the creation of a bike sharing service, and of conditions to increase subway network through channels reservation to the network expansion; (c) Reduction of the number of vehicles entering the city through the control of parking supply for those who enter the city to work; (d) Increase the parking supply for residents. Most of these actions are already implement or to be implemented.

At last, the driver city attractiveness. The increase of the real estate valorization, for example, has been leading to the exiting of population from the city of Lisbon to its periphery. As already identified, the LMMP 2012 highlights several actions to attempt to stop this exit.

As for the number of startups operating in the city, despite the financial and economic crisis lived, the innovation persisted, and the number of startups has been increasing over the years. The local government emphasizes the need to keep promoting these business model, promoting, in the LMMP 2012, business incubators through the continuity of the existing start-up model.

The attractiveness of the city to tourists (either foreign or national) has also been increasing, with the overnight stays in Lisbon hotel and similar establishments doubling between 1992 and 2012. The city of Lisbon has even been rewarded for its excellence. In the last 10 years, the city has been distinguished with a total of 29 World Travel Awards, and in the year of 2014 Lisbon received 8 awards including the Europe's Leading Destination. The LMMP 2012 strengthens the need to keep improving the touristic appealing of the city through (i) the creation of more public spaces to overcome the lack of green areas in the city historical center, (ii) the improvement of public space "life" for people and (iii) the qualification of the riverfront for recreation, leisure and tourism. The last two points are being implemented, being still possible to see some of these works in the city under development.

5 DISCUSSION AND CONCLUSION

The urban spatial planning along with the drivers analysis (as presented in the previous section) show that the Lisbon urban system has been facing, over the last 50 years, a mix of undesirable and desirable qualities.

The undesirable qualities correspond to the social disturbances that the urban system has been more difficult to respond to, and which have been the major concern of the current city government in an attempt to revert their negative trends. Thus, it is possible to identify them as the decline in the resident population, mostly the younger and active one, and a consequent ageing demographic trend over the last 30 years, the fast increase of unemployment rate in the last years, the continuous exit of companies from Lisbon to the periphery registered over the last decade and the increasing population leaving in a homelessness situation

All these social disturbances have been recognized by the current government as critical issues that need to be addressed and overcome. For all, were designed strategies and actions, mainly in the LMMP 2012, to be implemented, in an attempt to revert the negative trends, as, for example:

- the creation of affordable housing program through an incentive system directed to the middle class and the approach of work and resident places, to attempt to revert the decline in resident population;
- the construction of day centers, residential housing, nursing homes and spaces for seniors, to promote a healthy and active ageing;
- the improvement of the capacity to create more jobs and install more workplaces, to attempt to revert the increase of unemployment rate;
- the possibility of locating companies in any point of the city, the reservation of space for companies and the intervention in the market to compete with the business clusters in the boarder municipalities, to attempt to revert the exit of companies and
- the development of programs to integrate and support homeless population.

The current MMP not only addresses the undesirable qualities as an attempt to revert them, as it identifies and addresses the desirable ones as a way of promoting lasting well-being.

As for the desirable qualities, these can be identified as those that create capacity for the urban system of Lisbon to respond to disturbances, more specifically, the positive trends previously identified (infant mortality and illiteracy rates almost eradicated, increase of the number of startups, increase of the touristic appealing, decrease in the number of crimes and the increase in the assistance of the Food Bank to people and institutions).

Once again, for all these issues, the current city government identified strategies and actions, mainly in the LMMP 2012, to be implemented, as:

- the construction of new schools and rehabilitation of older ones;

- the construction of an hospital, of health centers and continuing care units;
- the promotion of the business incubators;
- the increase of bike network, security and comfort in the use of bicycle;
- the improvement of sustainable and multi-modal mobility;
- the qualification of public space and
- the requalification of the river front for recreation, leisure and tourism.

Some of these points have already been implemented by the current city government, as the ones regarding sustainable mobility. Others, as the requalification of the river front is being implemented.

As a conclusion, it is possible to state that the municipal policies of the current city government, mainly in the representation of the LMMP 2012, are promoting lasting well-being and contributing to maintain the desirable qualities in that state, as desirable. Moreover, it can be said that these qualities are contributing to the long-term resilience of Lisbon urban system, once they not only promote lasting well-being, as they create capacity for the urban system to respond to disturbances and facilitate the urban system transition to a sustainable behavior. Thus, the municipal policies of Lisbon addressing these desirable qualities are contributing to the urban system resilience.

In terms of the undesirable qualities, it is important to highlight that in previous plans to the LMMP 2012, not all the social disturbances were identified and addressed, which led to a critical point, as being faced nowadays. Even for the case when the social disturbance was addressed, as in the LMMP 1994 attempt to revert the decline of resident population, it appears that the strategy defined to revert the negative trend was not well succeeded, once the trend continued to occur afterwards.

The undesirable qualities represent the social disturbances that the urban system must continue to deal with and that the current city government is attempting to revert, being necessary more time to understand if this attempt will be well succeeded or not.

Thus, municipal policies represent an important contributor for an urban system resilience, as long as they are strategic and, most important, as long as they are flexible to be able to adapt to the changes occurring in the urban system.

ID 1718 | THE PROFILE OF RISK GOVERNANCE (IN MUNICIPAL PLANNING) IN PORTUGAL

Nelson Mileu¹; Margarida Queirós¹

¹Universidade de Lisboa, IGOT / CEG

nmileu@campus.ul.pt ; margaridav@campus.ul.pt

ABSTRACT: This paper aims to define a risk governance profile for hazards with direct intervention in spatial planning, considering the various perspectives involved in Portugal. In risk management, relations between the different levels of the State acquire a successively relevant role, taking into account approaches of cooperation between the national, regional and local actors. Recognizing for the Portuguese case, the weight and influence of the State in the management of risks and the growing diversity of actors and interests involved in land use planning, we question the distribution of responsibilities in risk management among government actors at different geographical levels (local, regional, national) and, beyond the State, which stakeholders and interests. Based on an adaptation of the model proposed by Walker et al. (2013), a risk governance profile was defined for Portugal for hazards/risks with direct intervention in spatial planning, considering the various perspectives involved. In order to support the identification of the governance profile, an online questionnaire was built and an e-mail was sent to the target public, in 2014. Unlike the model advocated by Walker et al. (2013), where a qualitative and non-measurable risk governance profile is chosen, the adaptation of the survey considered an evaluation scale. The identification of the different stakeholders involved in risk management was based on the information obtained from the literature review, analysis of the legislation and discussion with some of the key actors in the field of civil protection. Among other conclusions, the obtained risk governance profile highlight a relevant role of local government actors in the decision-making process, a low culture of multi-stakeholder participation\involvement, and infrequent and limited risk public communication. At the same time, it showed the interest manifested by the technicians of the local administrations focused on the decision on the spatial development, guaranteeing compliance with the legislation. The importance of the risk governance profile derives from the possibility it offers in the identification, evaluation, management and communication of risk, as well as a relevant basis for the development of a spatial decision making support system on the transformation of land uses that integrates the analysis of natural and technological risks.

KEYWORDS: risk governance profile; spatial planning; risk stakeholders.

1 INTRODUCTION

In Portugal, the emergency response continues to be based on Humanitarian Associations / Voluntary Firemen (Amaro, 2009), although Walker et al. (2010) identify a change, in the sense of a greater diversity of actors involved, in the development of new functions, stronger forms of collaboration and partnerships. In risk management, relations between different levels of the State play an increasingly important role, taking into account approaches of cooperation between national, regional and local stakeholders.

Recognizing for the Portuguese case, the current influence of the State in risk management, and the diversity of actors and interests involved in spatial planning (Mileu, 2016), this article searches the way in which responsibility in risk management is distributed among government actors at their different levels (local, regional, national) and which actors and interests are involved? The answers to these questions will allow the identification of stakeholders, their relations and priorities (driving forces) in the land-use transformation and how risks are considered in decision-making.

Based on an adaptation of the framework proposed by Walker et al. (2013), this paper aims to define a risk governance profile in Portugal for hazards / risks with direct intervention in spatial planning. This model is based on several key characteristics identified in the governance literature as well as in specific works on risk governance and that allows in a simple way to determine the variability and dynamism of risk governance practice.

2 METHODOLOGICAL APPROACH FOR PROFILING RISK GOVERNANCE

Based on the risk governance framework proposed by Walker et al. (2013), a model based on the same eight key characteristics was adapted, namely the governance scale and its distribution between national (1), regional (2) and local levels (3), with a spectrum from weak to strong in each case; how much those at risk are expected to be responsible for protecting themselves, compared to how much responsibility rests with government (4); the extent and culture of stakeholder participation in the governance system (5), extending from high to low; the type of insurance provision in place, in terms of how much this is marketized and segmented according to level of risk (6); the extent of communication with the public about risks (7), extending from high to low; and the degree of balance between governance tasks and the availability of resources for such tasks to be carried out (8).

To get a risk governance profile in Portugal for hazards / risks with direct intervention in spatial planning a survey was used. The survey was developed on the online platform www.surveymonkey.com, and was sent to the target audience by e-mail, between January 19 and April 19, 2014 (it was available at <https://en.surveymonkey.com/s/CYYTZ9V>). The dissemination of the survey was carried out using a list of contacts and using the National Association of Portuguese Municipalities as a facilitator near the municipalities.

Unlike the model advocated by Walker et al. (2013), where a qualitative and non-measurable risk governance profile is chosen, the adaptation of the survey consider an evaluation scale between one and four.

3 APPLYING THE FRAMEWORK

3.1 THE STAKEHOLDERS

The identification of the different stakeholders involved in risk management was based on the information obtained from the literature review, analysis of the legislation and discussion with some of the stakeholders. As a result, 156 valid surveys were obtained, with a significant number of responses from the central and local government (59%) and from the general public (17%) (Figure 1).

Figure 1 – Survey answers by stakeholder
Source: Survey

In spite of the interest and involvement of the different stakeholders in the management of risks, assume some volatility and different configurations, a question about the interest associated with spatial planning and/or risk management, was included in the survey. Table 1, adapted from Westen et al. (2011), is a summary of the stakeholder's involvement in risk management and results from the analysis of the responses of the stakeholder's to the different interests manifested in risk management.

Stakeholders	Interests manifested
Civil protection	Ensure adequate measures for disaster response.
Scientist	Develop scientific studies on hazards\risks and disseminate such studies to the community and administration.
Media	Publish information on disasters and their impacts.
Central Government Technician	Ensure compliance with the law.
Local Administration Technician	Support the decision about territory development in compliance with legislation.
NGO\Association	Promote environmental and sustainable development.
General public	Living in the desired location without restrictions.
Politician	Ensure people safety, do not cause controversy and maintain popularity.
Business sector\Industry	Ensure the development of the activity without restrictions.
Insurance Company	Sell insurance policies associated with the real value of risk and make profits.

Table 1 - Interests manifested by different stakeholders in risk management
Source: Survey

3.2 HAZARDS RISKS WITH DIRECT INTERVENTION IN SPATIAL PLANNING AT MUNICIPAL LEVEL

The examples of risk governance profiles presented by Walker et al. (2013) concern a particular natural hazard (floods) or a series of natural hazards (volcanism and earthquakes\landslides and earthquakes). The risk governance profile obtained from the survey concern to a set of hazards that have a common characteristic: their direct intervention in spatial planning. The hazards identified by the stakeholders in their evaluation, allow us to perceive the relevance of the different hazards in Portugal in spatial planning, even if influenced by interests and involvement (Figure 2). Considering the survey results, floods and forest fires assume greater importance, while the subset of other hazards, which included tsunamis or technological hazards, assumed less importance.

Figure 2 – Hazards considered by respondents
Source: Survey

3.3 PORTUGUESE (MUNICIPAL) RISK GOVERNANCE PROFILE

The first three questions in the survey assess how responsibility for risk management is distributed among government stakeholders at different levels (local, regional, national). The first question, addresses the "clear, well-specified and comprehensible national policy framework for risk-related issues", has an average score of 1.95 and can be classified as a weak political framework (Table 2).

1 Weak national policy framework	2	3	4 Strong national policy framework	Average
27,71% 23	49,40% 41	22,89% 19	0,00% 0	1,95

Table 2 – Survey results for risk governance key characteristic 1
Source: Survey

The second question assesses the “role of regional institutions in the implementation of national policies”, and registers an average of 3.0 (Table 3). Although there is no regional administrative level in Portugal (apart the autonomous regions), this assessment reflects the proximity and functions in the risk management and spatial planning by the deconcentrated services of the State, such as the departments of nature conservation and forests, administrations of river basins, regional emergency operations centers or commissions for regional coordination and development.

1	2	3	4	Average
Weak role for regional institutions			Weak role for regional institutions	
4,82%	21,69%	42,17%	31,33%	3,00
4	18	35	26	

Table 3 - Survey results for risk governance key characteristic 2
Source: Survey

Regarding the role of municipalities, the average score of 3.12 indicates the strong role of the municipal level in the response and prevention strategies in major disasters or catastrophes (Table 4). Municipalities in Portugal have strong responsibilities in the emergency response component. They are responsible for civil protection in their territory and in the prevention component, they have a major responsibility in the area of spatial planning.

1	2	3	4	Average
Weak local/municipal role			Strong local/municipal role	
7,23%	16,87%	32,53%	43,37%	3,12
6	14	27	30	

Table 4 - Survey results for risk governance key characteristic 3
Source: Survey

The risk individualization question assesses the responsibility on those at risk to protect themselves. The average of 2.94 reflects the expectation of the involvement of people and/or companies in their self-protection. However, the results show a high variability around the mean, which may reveal the primary role of the Central State and other entities involved in the activities related with emergency response and risk reduction (Table 5).

1	2	3	4	Average
Minor responsibility on those at risk to protect themselves.			Minor responsibility on those at risk to protect themselves.	
8,43%	26,51%	27,71%	37,35%	2,94
7	22	23	31	

Table 5 - Survey results for risk governance key characteristic 4
Source: Survey

The culture of participation\involvement for the different stakeholders in the risk decision-making process presents a high percentage (50%) of responses revealing a low participation culture and a relatively closed decision-making process (Table 6).

1	2	3	4	Average
Weak culture of multi-stakeholder participation			Strong culture of multi-stakeholder participation	
32,53%	50,60%	13,25%	3,61%	1,88
27	42	11	3	

Table 6 - Survey results for risk governance key characteristic 5
Source: Survey

The risk transfer to insurance companies is characterized by having a weak relationship with segmented and risk-oriented insurance. Despite the high level of responses (37%) corresponding to this assessment, it is possible to verify a set of responses in the opposite direction obtained from the insurance companies who participated in the survey (Table 7). The responses justify the high relationship to segmented and risk-oriented insurance related with the seismic risk. The seismic risk is an example of geographic segmentation for the insurance policies values in the national territory.

1 Low reliance on segmented and marketised insurance	2	3	4 High reliance on segmented and marketised insurance	Average
37,35% 31	30,12% 25	27,71% 23	4,82% 4	2,00

Table 7 - Survey results for risk governance key characteristic 6
Source: Survey

The public risk communication, presents an average evaluation of 2.04, denoting a significant communication frequency with the public (Table 8).

1 Very little public risk communication	2	3	4 Extensive public risk communication	Average
28,92% 24	39,76% 33	30,12% 25	1,20% 1	2,04

Table 8 - Survey results for risk governance key characteristic 7
Source: Survey

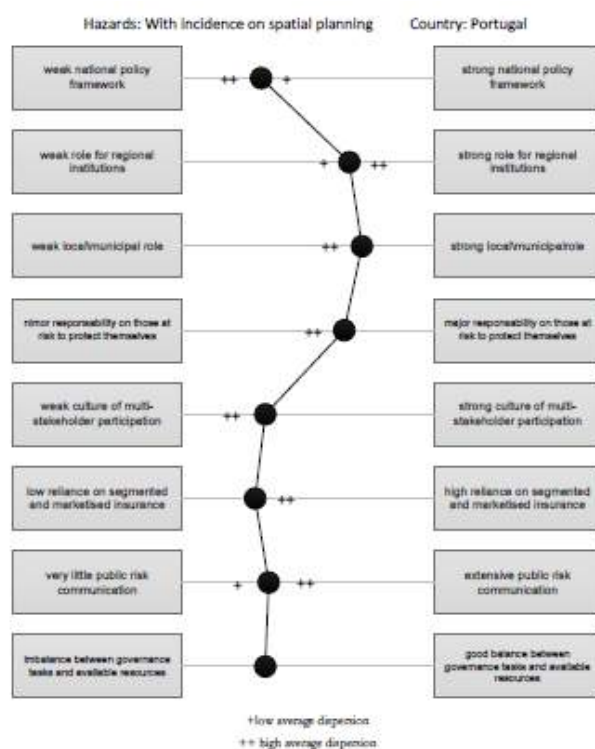

The existence of resources in the entities responsible for risk management in relation to the associated performance presents a high percentage of responses (59%), reflecting an imbalance between the institutions available resources and effectiveness in the development of their competencies (Table 9).

1 Imbalance between governance tasks and available resources	2	3	4 Good balance between governance tasks and available resources	Average
20,48% 17	59,04% 49	20,48% 17	0,00% 0	2,00

Table 9 - Survey results for risk governance key characteristic 8
Source: Survey

4 CONCLUSIONS

Based on the survey results, Figure 3 illustrates the national risk governance profile for hazards with direct

intervention in spatial planning. The result of this profile has a bias, associated with the fact that the sample had a large number of responses from local authorities. This high number of responses is due to the fact that the National Association of Portuguese Municipalities has been requested to collaborate and the questionnaire has been redistributed to all municipalities, and for this reason the analysis must consider this trend.

Figure 3 – Risk governance profile

In this schematic representation of risk governance, it's possible to observe the weak evaluation of the political and legislative framework at the national level, which is explained by the legislative dispersion in the risks domain and in a thematic segmentation of risk management. Regarding this evaluation and the lack of a formal regional administrative level (with the exception of the Autonomous Regions of Madeira and the Azores), the centralizing character of the State is confirmed through the evaluation of the deconcentrated services in the implementation of national policies, since they implement the State's governance approach and thereby segment geographically the state's public policies. The preventive component of risk management has a strong municipal responsibility, while the functions related with the response component are associated to the Central State (eg medical emergency, security, civil protection). Related with risk management, the main functions of the Central State can be summarized in: the provision of scientific information on hazards (eg LNEC, LNEG), monitoring and safety of the main national equipment's and infrastructures (eg REFER, IP, LNEC), providing warnings and alerts (eg IPMA, ANPC), providing response when the municipal level response capacity is exceeded (eg ANPC), development of emergency and spatial plans (eg CCDR, DGT, ANPC) and giving financial support to municipalities and local entities through the state budget and European funds.

The risk preventive component presents a significant importance at municipal level. This importance is related with municipal spatial planning attributions. In the area of civil protection, the Mayor is responsible for the municipal civil protection policy, to trigger, on occurrence of a major accident or catastrophe, the civil protection actions of prevention, assistance and rehabilitation as well as to promote the elaboration of the municipal emergency plan, which defines the guidelines regarding the way the various agencies, services and structures involved in civil protection operations work. Regarding risk individualization, the risk governance profile shows the expectation of involving people and companies in their protection. The multi-stakeholder participation and participatory involvement of the actors involved in risk management is one of the aspects shown by the profile that has a greater consensus due to the weak participation and involvement of the different actors. The risk transfer assessment obtained in the risk governance profile show a weak relation between insurance and risk zoning, although this assessment is not corroborated by insurers, in particular the seismic hazard. The communication of public entities with the population on issues related to hazards/risks is characterized by being infrequent and limited. The last key feature of the governance profile concerns the existence of resources in the entities/agents responsible for risk management, and showed the underfunding of entities and an ineffective performance.

The importance of the risk governance profile for Portugal comes from the possibility of identification, evaluation, management and communication of risk. It can allow in the development of a decision support system (DSS), to identify the different actors, their relationships and priorities in the decision-making component on the transformation of land use, integrating the component of natural and technological risks analysis (Mileu, 2016). In this case, it showed the high interest of the local and central administration as actors in the decision-making process, despite the relationship between the two that can be sometimes classified as ambivalent.

1 INTRODUCTION

The city of Petrópolis, situated in the serrana region of Rio de Janeiro State, is no exception to the rule when it comes to the population growth observed in most cities, and mainly in Brazil, where the urbanization rate today has reached around 80%. The phenomenon of urban growth is set against an absence of improvements in infrastructure that is detrimental to the quality of life of the citizens. Moreover, this has not even been the object of public policies aimed at avoiding the negative impacts on natural resources. On the contrary, these are becoming scarce due to the disorderly nature of the urban expansion on the periphery (Baptista and Calijuri, 2007).

This phenomenon is also present in the city of Amadora, situated in the large metropolitan area of Lisbon. It is the fourth most populated city in Portugal. In the 60s, Amadora changed from being an industrial and residential suburb to a suburban city. As a consequence, the population flow and its concentration in the territory of Amadora – as well as in the surrounding area – have led to high pressure on urban space, the public services, and, of course, the organizations and institutions in charge of administering them. This condition configures a crisis of urban growth (Nunes, 2012).

Although the cities present specificities in their formation and urban layout, the cultures coexist and feel the same socio-environmental impacts attributed to urban densification, aggravated by climate change, which, as a consequence, generate natural catastrophes. In their search for solutions and alternatives, we have adhered to the U.N. international campaign, Constructing Resilient Cities 2010-2015, which addresses issues of local governance and proposes development of assets of good practices that would make all communities more resilient after facing disaster situations.

Both seek to articulate the managerial instruments of prevention with the urban planning, as well as the information programmes, mobilisation and awareness with the aim of reducing disaster risk.

Thus, the objective of this study is to verify possible solutions to minimize the impacts of urban flooding and reflect on the importance of the strengthening of the culture of resilience in the alternative practices of local communities, as well as considering assumption of a philosophical posture towards the common well-being of the world community while acting locally.

At this point, it was considered basic to include a Spiegelberg (1971, p. 522) presentation of a Gabriel Marcel's (195-), the Christian Existentialist, as well as Merleau-Ponty's (1996) expression to describe the relationship subject-world density - "être-au-monde" - which clarifies the inextricable: the man insertion in the world and the world presence on man. In this sense the phenomenological posture demands that relationship also is to be assumed "as a life-style" (Fraga, 2009, p. 114) what is obviously fundamental for the concretization of the proposition presented above.

2 METHODOLOGY

In opting for the case of Amadora as a reference to an analysis of the Brazilian reality, it is prudent and could be productive, due to the cultural proximity to Brazil's cultural origin and the logic of Portuguese language, as, albeit situated on the European continent, Portugal inevitably left undeniable cultural traits (Lima et al., 2016, p. 896).

Upon embarking on this study, a query on the part of Dartigues emerged as an alert regarding its development. He asked: “would it be possible to conceive of dignified humanity without philosophers?” (Dartigues, 1973, p. 89). For the second time, this provocation, stimulating in its reflections about the environmental theme, motivated a second question, one regarding management: would it be sufficient to have a theoretical base for management practice from which philosophical fundamentals were lacking?

In view of the theme's orientation towards the social, fundamental phenomenological philosophy elements at the base of this discussion were considered to be a necessity. This is because Phenomenology, despite making clear its own conception of method – not a path to be followed a priori, but that of the things themselves, in an insertion into the movement of that which happens, distinguishes the traditional justification of the action from its legitimation in the world of the living, implying imbrication between fact and value (Fraga, 2009, p. 44). Besides this,

“The possibility of dialogue between the Philosophy of Experience and Phenomenology is important [...] because it makes the criterion of Relevance appear, which reveals the philosophical meaning of the administrative action. This, as well as being intentional, conscious and essential to the human mind, becomes more comprehensive than mere justification of the results, seeking legitimation only after consideration of the implications of its application to practice, in the real world.” (Fraga, 2009, p. 44).

Therefore, this legitimate self-assertion in the face of the action coexisting authentically in common in resilience, reveals the synthesis aspired by Phenomenology and the Philosophy of Experience: result and consequence taken as universally indissociable in the discourse and practice in the action. This recognisably ambitious proposal, given the fragility of the ethical posture in day-to-day human life, is the aspiration of this study/proposal.

3 FROM THE URBAN SPECIFICITIES TO THE GENERAL NOTION

There are innumerable factors that interfere with the result of construction in city space, such as the configuration of the site, the different interests on the part of the agents and actors, along with the local culture, which directly interfere with the appropriation of the place.

In 1846, the German engineer, Júlio Frederico Koeler presented the project for the Vila Imperial de Petrópolis, which was in a tentacular form, accompanying the courses of the rivers and streams, and divided into a dozen blocks around the centre (Figure 1).

Figure 1 - Plant of Petrópolis (1846)
Source: Souza, 1995

Observing the project and associating it to the decree in the period, an urbanistic plan was contemplated, with clear indications of zoning, roadway hierarchisation, occupation and construction norms, differentiated land division, environmental protection, water supply and sewage disposal. Among the actions of Barão de Mauá, the introduction of railways marked an emblematic historical period. The first railway in Brazil, inaugurated in 1854, linked the port, Estrela on Guanabara Bay to the foot of the Serra de Petrópolis mountain range (Souza, 1995). Furthermore, considering the topography of the place with its geological

and geotechnical peculiarities, the characteristics of the Mata Atlântica forest, and the course, volume, etc. of the rivers involved, we conclude that the plan was perfectly adequate for the natural conditions of the site, and, therefore, devised founded on scientific premises (Souza, 1995).

Regarding the design and use of the centre, the relation between the roadway system with the Serra da Estrela highway, the categories, dimensions and destinations of the periods, indicate there was intentionality in the urban design. The origin of the city of Petrópolis featured a path that did not follow the general urbanistic pattern, resembling a chessboard, not even the colonial Portuguese pattern with an irregular path, with rivers in the background of the plots of land. Originally it was destined to be a work of imperial determination, a scientific idealisation of European construction (Souza, 1995).

With the accelerated urbanisation process as of the 70s, the disobedience of the environmental protection and preservation laws have increased the magnitude of the impacts to extreme levels (Figure 6). The population increase has led to a greater quantity of sewage dumped into water bodies. As the land adjacent to the rivers had already been occupied, concentration of population in the central area of the city and valley bottoms has led to a great occupation of the surrounding region, driven by property speculation that has neglected the non-occupation distances established by law (Baptista and Calijuri, 2007).

The municipality of Amadora (1960-1974), situated in Lisbon's first expansion zone, had the following principal urban growth inducing elements:

“The railway line, the roadway network (in particular the royal highways and, later, the regional network), plus the creation of a vast area adjacent to Lisbon where large manufacturing industries have been established (Venda Nova). Thus, the proximity and easy access to Lisbon, along with the exit of residents from the capital due to the expansion of tertiary activities, are factors that explain the growth in demand for housing and installation of economic activities in Amadora.” (Castro, 2016, p. 13). (Figure 2)

Figure 2 - Map of Amadora, area adjacent to Lisbon
Source: Google Maps, 2016

In this way, Amadora rapidly constituted Lisbon's most important suburb – notably becoming the fifth largest housing nucleus in the country (Salgueiro, 1987, p. 132) in 1960. The case of Amadora is significant in terms of how suburbanisation constituted the most important process of population redistribution in the Lisbon agglomeration in the 50s, 60s and 70s (Nunes, p. 124-125) – akin to the main European cities (Champion, 2001).

The specificity of the Lisbon Metropolitan Area overlapped, among others, phenomena like the suburbanisation and periurbanisation; the successive diversified flows of immigrants; the urbanisation and rehabilitation of the historic districts (Mendes, 2008); the deindustrialization and industrial relocation; the deconcentration of economic activities and litoralisation linked to tourism and leisure by means of notable improvements in accessibility (Castro, 2016).

Among the elements considered in the physical formation of these cities, one may notice that the natural geographical characteristics are not addressed in a consistent manner, and the site becomes the preponderant articulating component between nature and the city. Some scholars of urban form perceive the site as a product of articulation of the parts that form the natural environment, such as water courses,

lakes, oceans, relief and vegetation, but each of these parts is not studied separately. Besides this, both evolve differences of hierarchy and status, and the latter are established as constitutive of the different meanings attributed to the suburban experience.

The site is perceived as the primordial element in the spatial configuration of the urban form. The elements that comprise the space, such as roadways, plots of land, buildings and the possible arrangements among them, give rise to other elements, such as blocks and their layout, which comprise various models and give rise to cities. Moreover, it is possible to identify the ways in which they will be vulnerable, and also develop solutions to minimize the impacts of natural catastrophes.

In parallel, one must also observe that cities present other systems of meanings, other spheres and nuances of social practices. Drawing from philosophical thought, according to Wittgenstein, the discourse of the city has its particular language games that differ in their logic and reach from those manifested at the linguistic level, and within this, in their distinct thematic plans. On the other hand, Victor Hugo homologated the city as a book (Margulis, 2009, p. 89)

For Barthes (1990, p. 260), “the city is a discourse, and this is truly a language: the city speaks to its inhabitants.” The city does not only function, but also communicates. Based on this presupposition, the cities are an immense laboratory of trial and error, success and failure, in terms of construction and urban design. It is in this laboratory that the urban planning should learn, devise and test its theories (Jacobs, 2000). Therefore, more than knowing how to plan, it is important to know how to interpret the lexical polysemy of the city, which houses the old and the contemporary, whose existence is complex and dense.

4 THE URBAN DRAINAGE PLAN: PROBLEM AND SOLUTIONS

A significant part of the impacts caused by natural catastrophes are accentuated in urban areas that present an accelerated, disorderly urbanisation process, without planning and implementation of actions that are conducive to adequate land occupation. In the absence of norms that regulate such occupation, it is inevitable that large areas become impermeable, due to buildings, pavements, paved streets, and the urban densification itself.

Compensatory drainage measures, such as: infiltration trenches, permeable paving, and micro reservoirs for runoff containment, have proven to be good control instruments for surface drainage. Their use has become possible through urban drainage planning that has begun to oblige new constructions to adopt alternative means of urban flood control (Souza and Goldenfum, 2001).

In an attempt to minimize the effects of flooding caused by heavy rain, the cities of Petrópolis and Amadora have identified a need to implement urban drainage plans, as set out below.

Since the natural catastrophes suffered in 2011 and 2013, the city of Petrópolis still awaits release of the Federal and State funds to carry out the works that are required, including those to minimize the impact of heavy rains like those suffered in January this year.

As rightly pointed out by the Mayor, Rubens Bomtempo, “rainfall on this scale is not just a problem for the municipality, but for the whole National Civil Defence System. It is necessary for everyone to play a part, but this is not happening. Throughout 2015, for example, we requested INEA (Instituto Estadual do Ambiente) [State Environment Institute] to dredge our city’s rivers, but nothing has been done till today.” (Prefeitura de Petrópolis, 2016).

In 2013, the Ministério Público [Public Ministry] filed a Public Civil Action so that Petrópolis City Hall, the Rio de Janeiro State Government and INEA would execute works to prevent the Quitandinha and Piabanha rivers from overflowing, contemplating an engineering project and reforestation of the respective riverbanks. Besides this, it requested proposals to solve the problem of unstable mountainsides in the municipality, such as slope containment works and removal of residents from risk areas (Jornal do Brasil, 2013).

The difficulty in abiding by rules, norms and procedures that are not necessarily adequate for the cultural peculiarities, or, as in the case of the Brazilian public administration, considering that the public environment possibly contains traces of patrimonialism, and does not possess adequate material

conditions to execute the scheduled tasks, opens up a path for formalism to arise.” (Lima et al., 2016, p. 896), that is, a certain type of diversion for the purpose of pretending to do.

It is important to mention that there is occupation of a great part of the Quitandinha river basin, the result of the growth experienced in the city over the last few decades. “This expansion has contributed to the aggravation of the drainage conditions in the basin, such as increasing ground impermeability that leads to greater potential for water courses to overflow. These events have become progressively more frequent.” (Amaral et al., 2015, p. 2).

Finally, in accordance with the Municipal Basic Sanitation Plan for the city in question, improvements are necessary in the infrastructure and operational installations of drinking water, sewage, urban cleaning and handling of solid residues, as well as drainage and handling of urban rainwater.

In 2008, the Lisbon City Hall approved a drainage plan that would provide for, among other infrastructure, the construction of a tunnel between Martim Moniz and Santa Apolónia to divert excess river flows that had frequently caused inundation of the squares, Praça da Figueira and Terreiro do Paço (Publico, 2014.)

After approval, “the development of the Plan was concluded, in effect constituting a 20-year planning instrument for the city's drainage network”, covering an area of 10,282 hectares, which, according to the proposal, included the municipality of Lisbon and parts of the Amadora, Oeiras, Odivelas and Loures municipalities. The project would also involve flood control in the Alcântara basin, construction of a reservoir between Benfica and Campolide, and another in Avenidas Novas (Publico, 2014).

Besides this, the Oeiras and Amadora municipal chambers, respectively, by means of Proposta de Deliberação [Proposed Deliberation] no. 109 - CMO, and no. 73 - CMA, both dated 24th February 2016, unanimously decided to ratify the decision of the Conselho de Administração dos Serviços Intermunicipalizados de Água e Saneamento [Administrative Board of the Intermunicipal Water and Sanitation] of the Oeiras and Amadora municipalities, thus commencing the procedure to create a project (Projeto de Regulamento de Drenagem de Águas Residuais dos Serviços Intermunicipalizados de Água e Saneamento dos Municípios de Oeiras e Amadora) to regulate the drainage of residual waters (Câmara Municipal de Amadora, 2016).

Based on the above, it is possible to verify that the application of urban drainage may be as much by means of structural measures as by non-structural ones, taking into account the premise that intervention must begin in the upper reaches of rivers, thereby increasing the effectiveness of the drainage and reducing the possibility of floods in other places downstream.

For the sake of clarification, the non-structural actions seek to discipline territorial occupation, people's consumer behaviour and economic activities. Considering those most adopted, the non-structural measures can be grouped as follows: actions to regulate land use and occupation; environmental education aimed at control of diffuse pollution, erosion and waste; flood insurance; flood forecast and warning systems (Canholi, 2014).

By means of delimitation of areas subject to flooding along with risk assessment, it is possible to establish zoning and respective regulation regarding construction, and also eventual individual protection works (such as installation of panel barriers, watertight doors, and others) to be included in existing constructions.

The viability of the adjustments by means of hydraulic and soil use modelling is a way of mitigating the impact of the urbanization process, at the same time that an attempt is made to, for example, restore the natural hydrological conditions of the rivers. It also requires use of the peak rainfall, not only its diversion. Therefore, in places where such systems are applied, planning must be integrated with the urban growth, that is, with the urban landscape (Gonzalez, 2014).

According to Pompêo (2000), sustainable urban drainage presupposes integration of water in the urban environment, and its synchronisation with the hydrological cycle, taking into consideration the ecological, environmental and landscape aspects along with leisure opportunities.

Such works may not put an end to flooding, but will probably reduce their frequency and minimize their effects. In this sense, it is always valid to seek alternatives for cities and their inhabitants to better resist natural catastrophes and be more resilient.

5 THE CULTURE OF RESILIENCE AND ITS PARTICIPATIVE PRACTICES

As Lefebvre (2001, p. 113) rightly observed, “only groups, classes or fractions of social classes capable of revolutionary initiatives can undertake, and fully carry out, solutions to urban problems; with these social and political forces, city renewal becomes the work.”

The relevance of the human in the results of experience is the meaning sought by philosophical positions, implying engaged self-determination and profound discussions about the issue of the other end of the social. “The relevance is justly the criterion whose level in administrative action, in being more comprehensive, [...] considers the consequences of this action for the human.” (FRAGA, p. 44). This is irrespective of the formal governmental administration or initiatives taken by private organisations, or even of isolated action performed by small neighbourhood groups, since the human being will always be involved.

In Petrópolis, there is an organization called Núcleos Comunitários de Defesa Civil (NUDECS) [Community Civil Defence Nuclei], formed of residents trained by the City Hall to act as volunteers in the prevention of natural catastrophes.

Since 2013, 500 have been trained for the 54 nuclei established. Furthermore, a Comitê de Ações Emergenciais [Emergency Action Committee] has been created, its purpose being to debate what is being done to render Petrópolis safer with regard to the heavy summer rains. Another mobilisation initiative of the local community is Projeto Fortalecendo a Resiliência aos Desastres [Strengthening Resilience to Disasters Project], committees for school safety of formed in schools with the aim of presenting the basic concepts of what constitutes risk (Prefeitura de Petrópolis, 2017).

Faced with delay in the drainage works for the Quitandinha and Piabanha rivers, Petrópolis shopkeepers have developed a culture of resilience in order to prevent floodwater invading their stores. It is observed that increased awareness of risk leads to investment in protection to safeguard against loss due to the rains.

To illustrate the above, we highlight the initiative of two local shop owners. One had always had his shop, situated in Rua Tereza, invaded by water whenever the Quitandinha river overflowed. He used to attach quite a low panel barrier, but, after the 2006 flood event, he decided to increase the height to 1.20m (Figure 3).

Figure 3: Ever higher flood levels demand ever higher barriers. Source: Globo/G1, 2016.

Figure 4: Shop front flood barrier wall 2m high. Source: Globo/G1, 2016.

After 30 years, having suffered six floods, in each incurring a loss estimated at R\$ 50 thousand, another storekeeper built a containment wall almost 2m in height, an investment worth over R\$ 10 thousand (Figure 4).

Based on experience and increased risk awareness, as a response to minimize the problem, shopkeepers and community representatives, in the face of the fragility of public policies, have taken upon themselves the responsibility and the decision-making power, thereby strengthening their culture of resilience.

In 2017, the Petrópolis City Hall approved Projeto Calçada Limpa [Clean Pavement Project], which stimulated the local commerce to place refuse collection bins in front of their premises, including separation of organic waste and recyclables. So as to ensure participation of these businessmen, an information campaign was also conducted.

The local councillor, who presented the bill of law for this project, stresses the following benefits: “As we live in a city with rugged terrain that is detrimental to us, we need to be very careful about our rubbish. So this project will aid conservation of the environment and promote public health, given that it will avoid disease outbreaks, avoid obstruction of street drains that relieve runoff and flooding.” (Diário de Petrópolis, 2017). This responsibility is also attributed to the shopkeepers and other members of the local community. It is worth remembering that these are alternative practices to mitigate the effects of heavy rain, but it is vital that there be greater mobilization and partnership on the part of the public authorities.

Based on the Campanha Construindo Cidades Resilientes [Constructing Resilient Cities Campaign], the city of Amadora, wishing to place emphasis on the local level, launched the so-called Local Campaign, “Sempre em Movimento, Amadora é Resiliente” [Always on the Move, Amadora is Resilient] to run from 2010 to 2015. The Local Campaign team mobilised the diverse stakeholders (municipal services, local agents, civil society groups, universities and specialised organisations, offering them partnerships and local alliances. Several workshops and public sessions were organised to explain the benefits and the commitments necessary to guarantee a more resilient community. This campaign accumulated over 30 stakeholders, and there was intense mobilisation (Carvalho et al., 2013).

Social networks have been remarkable in strengthening the culture of resilience: Amadora Resiliente (Facebook) provides information ranging from how to proceed in case of heavy rain to techno-operational communications from the Instituto de Meteorologia YouTube [YouTube Meteorological Institute] on how to reduce disaster risk on the municipal scale; Canal Amadora Resiliente (YouTube channel) is the audio-visual space of the Making Cities Resilient Campaign – Amadora and the Projeto Amadora Educa [Amadora Educational Project] (Figure 5).

Figure 5: Amadora Educa 2016
Source: MCPC of Amadora, 2016

The relevance of the human in the results of experience is the meaning sought by philosophical positions, implying engaged self-determination and profound discussions about the issue of the other end of the social. Turing back to relevance it is important to emphasize its key to relevance, according to the posture that aggregates the phenomenological essence to the philosophical experience of John Dewey (1979) is the consideration of the consequences of the action as inseparable from the result, at any level or in any situation.

It is perceived, therefore, that the resilient city, in the domain of natural catastrophes, has a greater capacity for preparation, adaptation, anticipation, learning and self-organisation due to external shocks (Santos, 2009).

6 CONSIDERATIONS

Reflecting on Dartigues (1973), perceiving that “the relationship of each person with the world is as singular as each person”, clarifies that there is mutual enrichment among the multiplicities of singularities in the ordinary world. It makes one see that the posture of the agent in the administrative action may strengthen authentic sharing towards participative administration, broadening its possibilities, “[...] not only based on universal abstract principles, but also on resumption of co-humanity with “mutual respect” through “co-responsibility”, concretely among neighbours and public and private administrators in the cities.” (Dartigues, p. 151).

They may be considered alternative multipliers of the good practices implemented, as of the moment that these communication channels and interaction can amplify the number of citizens with knowledge of self-protection measures, besides the awareness and participation of the various community stakeholders in determining strategies to reduce disaster risks with planning and increased awareness.

Finally, it shows the importance of care in its various concretisations, understandable by all and capable of inspiring fundamental values and attitudes that strengthen the culture of resilience, simultaneously contributing to the self-protection of communities in situations of disaster risk, considering the community of the world in authentic co-humanity, regardless of whether a situation experienced is easy to cope with or challenging, accompanied by risk of major disaster.

ID 1747 | INVESTIGATING THE ROLE OF RESILIENCE THEORY IN ASSESSING SUSTAINABILITY OF COASTAL TOURISM DESTINATIONS: THE CASE STUDY OF NEW ZEALAND

Kareem Adel Ismail¹

¹University of Auckland

kism817@aucklanduni.ac.nz

1 INTRODUCTION

The connection between resilience theories and human intervention methods such as coastal management and tourism activities was and remains to be an interest of many researchers in local and international scales. The interest of researchers arises from the growing environmental threats to coastal areas and the importance of tourism in the local and global economies. Their work has focused in two main directions. One direction has focused on measuring ways to decrease the negative effects of tourism on ecological systems. The second direction has been to investigate better ways of incorporating tourism activities within coastal management plans and increasing tourism's contribution to coastal resilience rather than focusing only on reducing its impact on the environment.

Harvey (2006) highlighted that there is a major knowledge gap in the study of the ability of coastal megacities and small communities in the Asia-Pacific region regarding adaptation to changes. He recommends that giving more focus towards developing planning systems, assessment methods, and coastal management techniques could fill such a gap. Pisano (2014) highlighted the need to incorporate the resilience concept when dealing with our vulnerable systems including coastal areas.

Luthe and Wyss (2014) highlighted the knowledge gap in the study of the relationship between tourism governance and resilience and emphasised that resilience has an explanatory power to clarify ways that tourism activities could adapt and even transform under various pressures. Luthe and Wyss (2014) also highlighted how tourism systems could be approached as interrelated Socio-Economic-Ecological Systems (SEES) and that developing resilience in such systems would increase their capacity to deal with stresses while maintaining the stability of a tourism-related economy and at the same time ensuring the diversity needed for innovation and future development. They discussed how current assessments of functional tourism networks complement resilience understanding and how tourism systems could adapt with both slow and prompt change processes. In the New Zealand context, there is a knowledge gap regarding assessing the resilience of coastal tourism destinations. The attention has been given to evaluating the socio-economic and environmental impacts of tourism in coastal destinations in relationship to climate change.

Blackett et al. (2010) have focused on coastal communities' efforts in adapting to climate change effects, using Coromandel Peninsula as a case study of NZ coastal tourism destinations. Other researchers such as Becken et al. (2010) have analysed the activity in itself from an economic viewpoint and through visitor forecasting. In their studies, they investigated the effects of marine farming and fishing on the destinations, as well as using surveys to determine weather and climate effects on tourism, by tourist satisfaction.

Despite these valuable studies and the importance of this topic both in international and national levels, these researchers highlighted the existing knowledge gap and the lack of studies on an integrated assessment and locally developed resilience indicators that assess coastal tourism destinations and their ability to achieve sustainable outcomes, specifically in the New Zealand context. This research goal makes it clear that there is a need for research that makes a connection between resilience theory and multi-dimensional activities such as tourism especially when located in complex systems such as coastal areas.

For the reasons above, this paper investigates the ability of socio-ecological resilience analysis to assess coastal tourism destinations, and how these destinations could achieve sustainable outcomes. This paper is based on the findings from a doctoral research undertook a preliminary assessment using three NZ case studies and uses them to test the proposed mechanism for assessing coastal tourism destinations. Drawing from the research goal, as shown in Figure 1, there is a complex triangular relationship between the three main components of research, coastal tourism activities, socio-ecological resilience, and planning practice within New Zealand as the research case study.

There are three linkages between these research components; one is the linkage between socio-ecological resilience and coastal tourism activities, which is described by the indicators assessing coastal tourism destinations. The second linkage is the connection between tourism activities and the NZ planning practice, which helps in understanding the current situation of tourism activities, measuring their resilience, and perceiving their future trends. The last linkage is coastal management with its different techniques, which represents the intersection area between socio-ecological resilience theory and NZ planning practice. Coastal management techniques help in identifying challenges facing tourism destinations and methods for dealing with these challenges.

Figure 1 – Paper Scope

Therefore, through the course of this paper, these components will be discussed starting with clarifying the relationship between resilience and sustainability followed by explanation of the New Zealand context and responsibilities of different agencies in managing coastal areas.

This is followed by explaining the research methodology that this paper is based on, and then the main discussion of results extracted from the data analysis and fieldwork.

2 SUSTAINABLE DEVELOPMENT (SD) AND RESILIENCE

For a successful assessment of complex systems such as coastal destinations, the relationship between sustainability and resilience and the difference between these two concepts needs to be identified. The resilience concept has a variety of definitions. Some researchers have debated the definition of this concept and its vagueness.

Olsson et al. (2015) were one group of researchers who emphasised the notion of resilience and found connections between the different definitions. Table 1 shows Olsson et al. (2015) understanding of previous resilience definitions by different scholars. They categorised them into definitions with a descriptive attribute indicating a neutrality character of resilience versus other definitions with a prescriptive attribute where resilience is considered as a “good” outcome.

Meanings	Attributes	
	Descriptive— neutral (N)	Prescriptive— good (G)
Bounce back (BB)	BB-N	BB-G
	Holling, (1973) Resilience and stability of ecological systems	Ferrings (1998). Introduction: Resilience and sustainable development
Bounce back and transform (BB-T)	BB-T-N	BB-T-G
	Walker <i>et al.</i> (2006). A handful of heuristics and some propositions for understanding resilience in socio-ecological systems.	Folke <i>et al.</i> (2010). Resilience thinking: integrating resilience, adaptability, and transformability

Table 1 - Typology of resilience definitions in ecology and social-ecological systems from Olsson et al. (2015)

Strunz (2012) and Derissen et al. (2011) attempted to clarify the difference between the concepts of SD and resilience by considering sustainability and SD as a normative target, a goal, and the desired status, while resilience is an analysis concept that deals with change.

Cote and Nightingale (2013) explained the variation between the two concepts by stating that conventional human-environment analyses emphasise the maximisation of sustainable outputs and increase the capacity of institutions to manage “undesired” change and return to an initial stable state. Fath et al. (2015) also maintained that the goal of sustainability is for systems to persist in delivering their function over an infinite time horizon. Based on this definition, resilience is a tool to achieve sustainability; resilience aims to maintain a system’s ability to recover from disturbances and continue delivering its services.

In relation to this research, the complexity in coastal areas is reflected in the relationship between SD and resilience, with examples of overlap in some aspects. For example, environmental sustainability has a direct connection with integrated coastal management, when the coastal area is managed in an integrated framework; this improves the process of managing the area, which will have a positive effect on the environmental sustainability of the area, and could help in enhancing the resilience of socio-ecological systems.

However, some areas do not necessarily relate directly to each other, such as the relationship between the economic sustainability of tourism activities and the resilience of a socio-ecological system. For example, the tourism activity in the area could be economically sustainable with a continuous and rapid increase of tourists while the ecological systems specifically (and coastal resources in general) face continuous degradation that negatively affects resilience. This degradation could be caused by many factors, including excessive use by tourists, the absence of an adaptive management framework, and lack of conservation projects. Whether the factors are generic or case study specific is discussed later in this paper.

Ultimately, there is a difference between resilience and sustainability. For example, a system could be resilient to different changes and adapt without any change in its characteristics. However, this system may not be sustainable on its own. It is evident, therefore, that there is a significant difference between SD as a target, and resilience and transformational change as approaches to explain the system status now and in the future. This difference is significant in this research as it uses indicators and resilience assessment to evaluate the sustainability of an area.

Therefore, according to the discussion in this section, sustainability as a concept as described by (WCED, 1987), Clifton (2010), Cote and Nightingale (2013) and Fath et al. (2015) is a desired status. This status

aims to create a balance between the environmental, social, and economic needs of communities in the present and preserve resources for the future. However, sustainability in itself is not a tool, and it does generate its tools.

In the other hand, resilience as a concept means as described by Walker et al. (2004), Brand and Jax (2007) as the system ability to maintain performing its functions and reorganise itself after any disturbances. Therefore, it is dealing with adaptability to change and dealing with different thresholds and pressures either internal or external. Resilience concept is a practical tool used to assess different complex systems. The resilience assessment process aims towards explaining the status of the systems and their ability to deal with changes with consideration to the potential outcomes.

The above discussion emphasised the need to understand the concept of resilience with its different definitions and its relationship with sustainable development. It critiques the current reformist approach used to deal with development and points out that the challenges faced in achieving sustainable development, along with the increasing complexity of our socio-ecological systems, are all factors that support the need to use other approaches. The transformational approach that is based on the eco-centric paradigm states that social systems are part of nature and there is no separation between social and ecological worlds, and consider the characteristics of both worlds.

This approach aligns with the concept of socio-ecological/ evolutionary resilience where a system tries to avoid disturbance, but if it occurs, the system adapts to it and if necessary transforms to a more desired status. Where socio-ecological resilience under a transformational approach is a way to understand the complexity of socio-ecological systems and facilitate the assessment process of the systems as combined, interconnected entities.

It is dynamic enough to deal with changes that could eventually lead to a sustainable outcome rather than narrowing the understanding of resilience as a return to equilibrium after a shock regardless of whether that equilibrium is desirable.

Therefore, the discussion established the differences between the terms sustainable and resilient. On the one hand, SD is normative, a target which systems should reach. To achieve such a target, organisations/ stakeholders/ planners should define the indicators that measure achievement of such a “desirable” status, as well as the measures needed to manage the complex systems in such a manner that they attain that status. On the other hand, resilience is a tool that allows researchers to achieve the following tasks. Firstly, it leads to an understanding of the complexity of these systems. Secondly, it leads to interaction with a change in a manner that allows innovation and creativity. Thirdly, it identifies the crisis/ disturbances that occur in a system, and the system ability to transform crisis into opportunities for transformation and eventually for the achievement of a more desirable status.

A system could be resilient against shocks/ changes, but that does not mean it is a sustainable system. For example, dictatorships could be resilient systems, but that is not to say that they are sustainable. Systems may survive shocks, but they might not be able to maintain a balance between the current needs of the society and the preservation of resources for future generations’ needs, which is the core of SD. However, the systems do not stand-alone or exist in a vacuum; rather, they are firmly affected by other systems. Therefore, the concept of panarchy was also discussed, where cross-scale relationships between different systems were reviewed and explained, to be used later in this research to explain the changes happening in the case studies. The following section will describe the New Zealand context and its hierarchy.

3 THE NEW ZEALAND CONTEXT

New Zealand as the research case study is a South Pacific country that comprises an archipelago of 33 islands, with two main islands, the North Island or “Te Ika-a-Māui,” and the South Island or “Te Waipounamu,” with a total population of 4,242,048 residents according to the latest statistics (Statistics NZ, 2013). About 85-90% of the urbanised New Zealand communities are located within 10 km of a coastal area (Ministry for the Environment, 2009). Environmentally, New Zealand has New Zealand has around 18, 218 km of coastline, and the world’s sixth largest marine area at 4, 400, 000 km². Due to the importance of the coastal environment, it needs to be clearly defined. However, the NZ legislative system

does not provide a definition of it. The Planning Tribunal stated, “What constitutes the coastal environment will vary from place to place and according to the position from which a place is viewed, where there are hills behind the coast, it will generally extend up to the dominant ridge behind the coast” (Brake and Peart, 2013).

Policy 1 of the NZCPS emphasises on the same perspective, stating that “recognise that the extent and characteristics of the coastal environment vary from region to region and locality to locality; and the issues that arise may have different effects in different localities”(DOC, 2010, P. 11). The same policy also explains the extent and characteristics of the coastal environment, which include the coastal marine area and the islands within it. The explanation extends to areas where coastal processes occur and those at risk from coastal hazards, coastal vegetation, and habitat of indigenous coastal species, and elements of the natural landscape (DOC, 2010, P. 11). The coastal environment also includes the items of historical heritage in the coastal marine area, inter-related coastal marine and terrestrial systems, and factors of infrastructure that have modified the coastal environment (DOC, 2010, P. 11).

The RMA (1991, Part 1) also defined the coastal marine area, as “The foreshore, seabed, and coastal water, and the air space above the water - (a) of which the seaward boundary is the outer limits of the territorial sea, (b) of which the landward boundary is the line of mean high water springs, except that where that line crosses a river” (Section 2).

The importance of reviewing these definitions of coastal environment is that to assess coastal tourism destinations, the boundaries of the coast need to be clarified according to the NZ context along with understanding the NZ legislative system regulating the coastal marine area and any development occurring inside it. The legislative system depends on a hierarchy of statutes covering different levels as shown in Figure 2. This hierarchy starts with the Resource Management Act 1991 as the main statute regulating the use and development of all resources including the coastal areas at the national level.

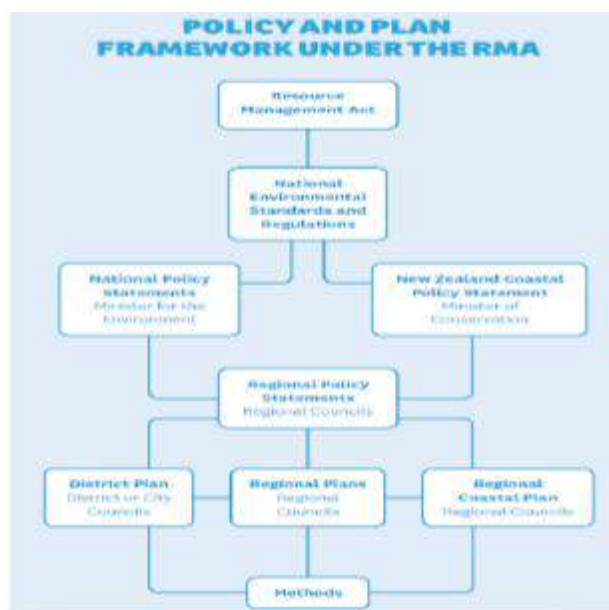

Figure 2: Policies and plans regulating coastal area under RMA. Source: ECAN (2013)

Under the RMA come the national environmental standards and the National Policy Statements including the New Zealand Coastal Policy Statement (NZCPS), which are also statutory documents at the national level. The regional policy statements are the next level of documents at the regional level, and they must achieve the purpose of the RMA as stated in (Part 5, Section 59), and that includes complying with the national policy statements including NZCPS.

Then the hierarchy continues to the next level through regional plans which as stated in the RMA (1991, Part 5, Section 63) should achieve the purpose of the act. The aim of the regional coastal plans as indicated in Section 63 of the RMA is to assist the regional plans in conjunction with the Minister of Conservation. Then comes the district plans that need to give effect to all the higher acts and national

policies and assist territorial authorities to carry out their functions as stated in RMA (1991, Part 5, Section 73).

3.1 AGENCIES' ROLES IN NEW ZEALAND COASTAL MANAGEMENT

After explaining the New Zealand legislative structure, it is important to account for the role of different agencies in managing the coastal areas to clarify an overlap of responsibilities and the power to make decisions regarding preservation of coastal resources or permitting development/ activities. The role of every agency is controlled by its statutory power and responsibilities in the coastal marine area. The responsibility of managing coastal areas spreads between different agencies. Starting with the central government level represented by Minister of Conservation, and the Ministry for the Environment, followed by the regional authorities and then the local/ territorial authorities under the RMA as explained in Figure 3.

In addition, the role of iwi trusts and local community representatives play a role in managing certain parts of the coastal areas, without excluding the Department of Conservation (DOC) role and their responsibilities in their estate land and marine reserves under the RMA and the Conservation Act.

Figure 3: RMA coastal management jurisdictions (DOC, 2013)

The roles and responsibilities of each authority in the New Zealand system is explained through Table 2, as mentioned earlier the roles are defined through the RMA, the Local Government Act, and the Conservation Act.

Authority		Their role in managing the coastal areas
Central Government	Minister of Conservation	Under section 28 of the RMA for preparing and monitoring the implementation and effect of NZCPS, also approving regional coastal plans and regional coastal plan changes.
	Department of Conservation (DOC)	Protecting the environment in Crown land designated as DOC estate land and marine reserves, and maintaining biodiversity, while conserving the local key species generally. DOC works closely with the Minister and carries out a number of tasks under the RMA such as preparing NZCPS, approving regional coastal plans in cooperation with regional authorities (DOC, 2016)
	Ministry For the Environment (MfE)	MfE does not have an actual management power over the coastal marine areas, but it focuses on cooperation with regional and local authorities in the coastal areas. It is responsible for producing national policy statements except NZCPS, national state of the environment reports and national standards using regional and local data that could help the decision makers take actions to solve any emerging problems and help in preventing any potential threats (Brake and Peart, 2013)..

Table 2: The roles and responsibilities of different NZ authorities under the RMA and LGA (Central government level)

Authority		Their role in managing the coastal areas
Regional Scale	Regional councils	Operative side of the government, implementing the RMA and NZCPS, and their role is further explained in the Local Government Act 2002. The regional councils role is set out in section 30 of the RMA, which include among many creating regional policy statements and regional coastal plans and giving directions/ creating cooperation with the local councils regarding issuing resources consents, implementation of these policies and plans in their areas. Also, they possess power over the marine areas, and have the authority to give permits to activities and resource consents to development projects such as within waterways. They should also cooperate with DOC in the case of marine reserves without overlaying powers over DOC estate land or coast (Brake and Peart, 2013, p. 22).
	UNITARY authorities	According to RMA (1991) and LGA (2002), the unitary authority combines both the roles of regional and territorial authorities under one umbrella. As an example the Marlborough District Council (2003) have the Unitary authority power in Marlborough Sound: "Under the Resource Management Act 1991 it therefore has an obligation to prepare a Regional Policy Statement, a Coastal Plan, a District Plan and such other Regional Plans as are necessary" (p. 1-1). This give it the ability to avoid any fragmentation of power between different authorities as in the double tier model in other places in NZ (regional-district).
Local Scale	Territorial authorities (City and district councils)	Their functions are set out in section 31 of the RMA, which include among many preparation of the district plans and monitoring their implementation, working to achieve the RMA objectives, NZCPS goals, and regional plans/ policies regarding the coastal areas (Brake and Peart, 2013, p. 22). Also, they are responsible to give resource consents for activities in the coast and solving coastal issues at a local scale on the land (landward side).
	Local Community representatives	They do not have statutory power to affect decisions, but through the public consultation process granted under the RMA, these representatives can have a say/ express community voice(s) regarding some of the decisions related to coastal development and preserve the environment for the community interest.
	Maori (iwi) organisations	The RMA specified their responsibilities in the management of coastal areas. Their responsibilities among many include prepare iwi management plans addressing coastal issues from their iwi interests, and preserve cultural heritage. However, the RMA does not specify the contents of these plans and gives the councils the option to consider these plans when making decisions regarding the coastal areas. Therefore the plans do not carry statutory power, unless it is a part of a regional coastal plan as a part of a co-governance procedure (Brake and Peart, 2013, P. 23). The iwi organisations may have a joint management agreement with local authorities either under the RMA and the Treaty settlements or in voluntary non-statutory basis. Also, under the Marine and Coastal Area Act 2011, groups that have customary marine titles (access and ownership) can produce planning documents to set out objectives and issues. The decision makers must consider these documents.

Table 3: The roles and responsibilities of different NZ authorities under the RMA and LGA (Regional & Local levels)

4 METHODOLOGY

The research methodology should be based on a clear process. This process as explained by De Vaus (2002) consists of a cycle of steps, which aim to test the existing theory using deductive reasoning. According to De Vaus, the process starts by defining the theory to be tested, leading to deriving a set of conceptual propositions about the theory. These propositions are then converted into testable indicators that determine the appropriate methods of data collection and analysis. This data gathering and analysis leads to the formation of distinct results, which in turn give rise to theory construction using inductive reasoning. The analysis and results are then discussed, leading to the formation of a new theory or the modification of the existing one. Figure 4 displays De Vaus's (2002) steps with the blue boxes illustrating their application in the current study. The steps begin with a definition of resilience theory, followed by the construction of the propositions and a test of whether or not resilience theory can analyse the social and ecological systems in New Zealand coastal tourism destinations. These propositions are then converted into a set of initial indicators derived from the literature, and the data collection methods are determined. Then the relevant data about tourism and socio-ecological resilience in the case study areas are collected to explain the existing situation. Finally, after analysing the data using panarchy and adaptive cycle principles, the results are used either to confirm the usage of resilience theory as an assessment tool for such complex systems or to show the problems of using this theory in the context of New Zealand coastal tourism destinations.

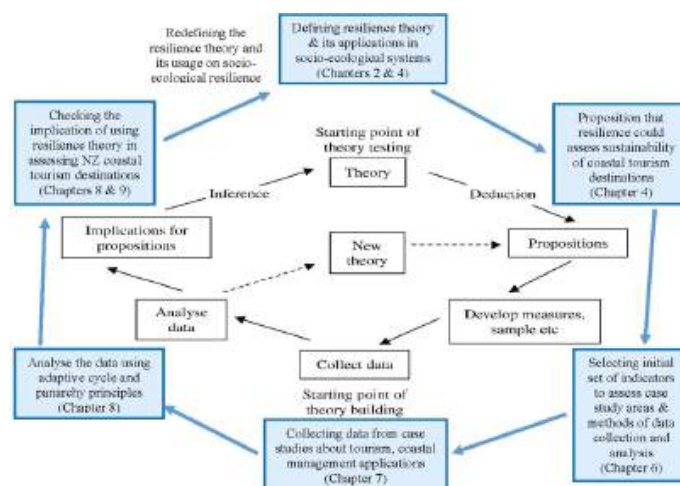

Figure 4: The logic of the research process and its application to the research goal. Adopted from De Vaus (2002)

To reflect the nature of socio-ecological systems in complex structures such as coastal tourism destinations as explained earlier, the methods of data collection and analysis need to be a mix of qualitative and quantitative ones. The underlying definition of mixed method research is triangulation between quantitative and qualitative methods covering the scale of the case study areas. Triangulation, as defined by Creswell and Miller (2000) as “a validity procedure where researchers look for convergence among multiple and different sources of information to form themes or categories in a study” (p. 126). Glenn (2009) stressed the advantage of triangulation as a tool to increase the credibility of results, as it also reduces the potential biases that could exist in a single source or from investigator’s bias.

According to Glenn, the researcher examines data across various sources, as this will reduce any bias either from the researcher or from a data source (e.g., results being influenced by a certain document) and will increase credibility because of the convergence of evidence from different resources. A hypothetical example of this triangulation would be if the intervention process, the opinion of different key players are all subjective and could have some bias to enlarge or critique the role of their organisation in protecting the coastal environment and enriching the tourism activity.

However, the existence of detailed plans produced by governmental authorities to protect the coastal environment and results from indicators about implementation of these plans, give a clear direction about the actual size of human intervention that each of these authorities have in the case study area.

The data collected was analysed in terms of the research questions. The analytical methods were based on the triangulation of qualitative and quantitative methods, as shown in Figure 5. The qualitative methods depended on the content analysis of statutory/ non-statutory documents. The concept and hypothesis coding techniques, were used to analyse interviews, and based on the responses, the status of the case studies was investigated. In addition, the main issues from the point of view of the main personalities managing the coastal areas were identified. For the most part, the coding process was undertaken manually, with some inputs from the Nvivo software package to help with the theoretical coding and to draw relationships between policies stated in the statutory documents and projects in practice.

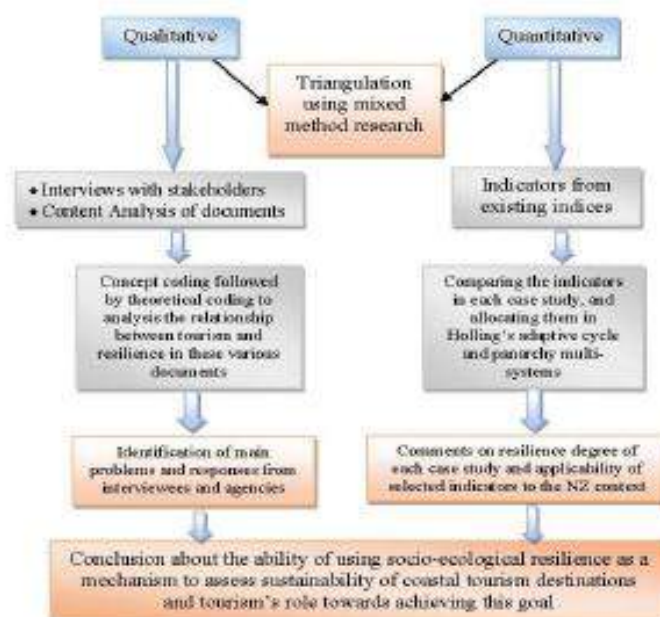

Figure 5: Paper Methodology

In terms of implementation, depending on the indicators that were developed based on the collection of related national and international indices, the preview of the current situation in the selected locations was conducted using observation methods, along with results from indicator assessment supported by conclusions extracted from the interviews and documents analysis.

All formed an integrated database of resilience status of the study areas, which included the existing and potential future coastal tourism activities in New Zealand. All these methods led to an identification of the problems and issues in the case study areas and were used to assess the resilience stage of each case study within the adaptive cycle and through the panarchy concept.

5 DISCUSSION OF RESULTS

This paper goal was to investigate whether and how socio-ecological resilience analysis can be used to assess the sustainability of coastal tourism destinations in the New Zealand context. The answer to this question started with clarifying the relationship between resilience and sustainability as discussed in section 2. Establishing that socio-ecological resilience in coastal areas means “the capacity and potential of a coastal system to absorb disturbance and still maintain its function, structure, and identity and feedback mechanisms.”

Resilience as an analysis tool describes the status of different systems and explains the internal relationship between complex systems through models such as panarchy. It also can monitor different socio-ecological systems over a period by examining changes/thresholds and indicate the future direction of these systems using metaphors such as Holling's adaptive cycle. In contrast, sustainable development is a desired status that complex systems such as coastal tourism destinations aim towards achieving.

Following the course of this paper, it can be concluded that the preferred output is to have socio-ecological systems in the coastal tourism areas that are resilient against thresholds and disturbance. However, the final output should be pushing these systems to reach a sustainable status. Therefore, if there is a reorganisation in these systems after experiencing a disturbance, it should be a change/ opportunity that contributes towards sustainable outcomes for these systems.

The investigation was based on a preliminary assessment model compromising of two parts. One part was based on resilience theory using Holling's adaptive cycle and panarchy model, while the second part was based on tourism models using Butler's life cycle analysis. These metaphors were used to account for the status of the systems and indicate their future direction/scenarios.

This combined assessment model was tested at an empirical level; through three case studies that cover different types of coastal management in tourism destinations within New Zealand. This was followed by resilience assessment of each study area on defining the system components, factors affecting this system and key players and institutions controlling the coastal tourism destinations.

This preliminary resilience assessment finalised by positioning each case study at certain stages within Holling's adaptive cycle and Butler's tourism life cycles using data from initial indicators and other data analysis methods. This positioning of the case studies was accompanied with an explanation about each stage's characteristics and the future scenarios for these case studies based on the study findings.

For example, following the Christchurch earthquakes in 2010 and 2011 an unpredictable change, tourism was negatively affected in Akaroa with a decline in the number of tourists in the township. These changes included the declaration of the Akaroa Harbour Marine Reserve in 2012 and increased coastal protection of the marine reserve through cooperation between ECAN and DOC.

These changes led to the social and ecological systems in Akaroa entering a stage of self-reorganisation as shown in Figure 6 to cope with the outside pressures. Although this means that the socio-ecological system in Akaroa is resilient, it is not to say this delivers a sustainable outcome.

Figure 6 –Results of preliminary assessment of systems in Akaroa shown in panarchy model

Tourism activity in Akaroa has also proved to be resilient by seizing the opportunity to replace Lyttelton as a cruise ship stop, rejuvenating the tourism activity again, and even exploiting the resources. However, these changes have caused pressure on the coastal marine area, which means it could be an unsustainable system in the long term. In Akaroa, the aim is to maximise the economic benefit of the harbour through marine farming and encouraging coastal tourism development and recreational facilities. However, although this proves the resilient character of the socio-ecological system in the area to cope with these changes, it does not ensure that the systems are in or heading towards a sustainable status. The resilience assessment model indicates that the social and ecological systems may be moving into an exploitation phase.

The situation in Whitianga is different, as shown in Figure 7. The increasing tourism activity has resulted in changes in the social system to respond to this growth. However, although the systems appear to be resilient regarding tourism activity, this does not reflect the status of the ecological systems that are neither resilient nor delivering sustainable outcomes.

These results, based on the preliminary resilience investigation, also explain the future direction in which the systems are heading. More exploitation/ growth in tourism activity could cause pressure on the ecological systems and that in itself could initiate a response from the social system to try to adapt to these changes.

Figure 7: Results of preliminary assessment of systems in Whitianga shown in panarchy model

Figure 8: Results of preliminary assessment of systems in Abel Tasman shown in panarchy model

According to the preliminary resilience investigation, the systems in Abel Tasman reflect conservation status in the panarchy model as shown in Figure 8. This status of the system is due to the character of Abel Tasman as a protected area (national park) under strict regulations, with full control of tourism activities and close monitoring from DOC and the unitary authority. However, due to the absence of clear indicators assessing sustainability, it is hard to evaluate the systems' sustainable status.

Also, complicating results is the ambiguity in defining resilience in complex systems, the misuse of resilience theory as a unifying assessment method beyond its potential by many researchers, as well as the complexity and multidimensional nature of tourism.

Furthermore, resilience assessment was limited due to the lack of appropriate definitions of benchmarks, bottom lines, and locally developed indicators to assess these destinations in New Zealand. These factors also showed the absence of empirical measures/ indicators to assess the effects of tourism on the coastal areas in New Zealand. The analysis of the regional plans and regional coastal plans showed the absence of critical resilience thinking in the New Zealand governance process. Overall, policies are moving towards the preservation of the status of the coastal areas and their ecological systems based on an engineering resilience approach, rather than enhancing their quality based on an ecological resilience approach.

Moreover, these plans do not define whether the systems are heading towards a sustainable status. The main focus of these plans is not to improve the outcomes (except some scattered efforts by DOC, and NGOs to improve the status of ecosystems such as in the case of Abel Tasman), but rather to keep the systems functioning in their current status after any disturbance, regardless if this original status is desirable/ sustainable or not. The same situation is evident in the district plans, where the regulations and coastal defence mechanisms are moving towards hard engineering solutions – such as hard concrete sea walls and other precautions – to protect coastal development against natural hazards. The adoption of soft engineering solutions, such as regeneration of wetlands and conserving sand dunes, is still not considered the norm when dealing with coastal issues. Arguably, more sustainable ecological measures could sustain coastal development and enhance the resilience of the socio-ecological system at the same time – as has proved effective in cases such as Abel Tasman National Park and parts of Whitianga.

Also, the district plans currently focus on regulating development with controls on land subdivisions and infrastructure. The plans do not promote the use of innovative ideas that control coastal development while considering socio-economic and environmental factors. Therefore, the plans do not connect future development with activities such as tourism, and there is no clear discussion on tourism's role in enriching the local economy, its effects on the coastal areas, and its ability to enhance the resilience of socio-ecological systems in the case study areas.

Moreover, regarding integration between different organisations and plans to achieve sustainable outcomes in these coastal destinations, the research showed the lack of vertical integration between

governmental agencies responsible for the coastal area, especially in the case of connection between regional and district councils. Furthermore, central government agencies such as MfE, play a weak role in contributing to sustainable coastal development. The lack of horizontal integration in the local coastal communities the local iwi, the private sector, and local NGOs, was evident in the case studies of Akaroa, and Whitianga. However, the integration was better in Abel Tasman National Park as a marine protected area.

6 CONCLUSION

To deal with such complex systems, approaches such as socio-ecological resilience are more applicable than other approaches. Socio-ecological resilience aims to recognise the components of these complex systems, understand their internal relationships, and identify the challenges and opportunities facing these systems. The preliminary resilience assessment revealed that tourism activity could have a positive effect on the sustainability of ecological systems through encouraging environmental protection programs. This effect can be seen in the case of Abel Tasman, where tourism pressures generate more conservation efforts to adapt to these changes. A similar practice happens in Whitianga where the need to retain the level of tourism encourages local authorities to protect the beach from coastal erosion to keep it as a popular tourist destination.

However, one of the main factors that could ensure that the positive impacts of tourism are maximised and its negative impacts are minimised is practising forms of tourism that increase the sustainability of the ecological systems. The results of this study showed that although tourism activity is sustainable in certain locations such as in the Abel Tasman case, there is not enough evidence about the spread of this practice among New Zealand coastal tourism destinations due to the following factors:

Firstly, analysis of tourism practice in the three case studies did not fit the criteria of sustainable tourism. Each area's dependency on tourism activity is increasing, with a growing desire to gain economic revenue from recreational activities. Protection of coastal areas is not happening at the same speed, with some out-of-date plans that need reviewing, such as the Waikato Regional Coastal Plan that includes Whitianga, or limitations in the budget to implement permanent coastal protection measures, as in the case of Akaroa.

Secondly, resilience assessment using indicators and positioning of the case studies in Holling's adaptive cycle and tourism life cycle showed that two case areas – Akaroa and Whitianga – are facing different levels of pressure on their coastal areas. There are signs of mass tourism syndrome affecting the nature of these main destinations.

Thirdly, Abel Tasman National Park is protected and managed under the restricted control of DOC in cooperation with the Unitary Authority of Tasman District Council (TDC). Therefore, it is a special case in that it is one of the national parks in New Zealand – a status that few areas can attain.

Therefore, all these gaps at the theoretical and practical level revealed by evaluation of the case studies require decision makers, managers, and researchers to create a clear definition of what is the desired status and what kind of positive outputs coastal areas should reach. When evaluating resilience in a coastal tourism area, it is important to clarify what kind of resilience is being assessed, what kind of systems are the focus of this measurement, what the stages are, and what the goal of that assessment process is.

T20 | TERRITORIES UNDER PRESSURE: DISRUPTIVE EVENTS, SHATTERED CITIES, COLLECTIVE MEMORIES

CO-CHAIRS: ENRICO GUALINI; ADRIANNA KUPIDURA; SOFIA MORGADO

We live in times of political, socio-economic, and environmental uncertainty in which radical pluralism appears to challenge established socio-spatial orders. In societies of 'liquid modernity', collective belonging is expressed through a variety of processes of territorial identification and spatial appropriation, by which places of collective livelihood, of identity, of memory are constituted. Identification with the cultural heritage and memory of places in the territories of everyday urban life is key to personal, social and cultural identity, and the free expression and coexistence of such forms of identification are essential for a polis which dwells upon diversity.

The impact of current societal changes – multiculturalism, hypermobility, migration – appears however to affect more and more negatively their political perception. Socio-cultural diversity and mobility – once positive connotations of 'multicultural' citizenship – are increasingly perceived as threats as they highlight allegedly irreconcilable contradictions between contrasting spatial claims. This reflects tensions which are deeply inscribed in the spatiality of social relations. While territorial belonging is increasingly relativized as a principle of integration, new spatial practices create new social divides. Tensions and contradictions in social and economic development determine spatial cleavages which challenge the sense of collective belonging: creating new spaces 'at the margin', but also creating margins within the very social fabric of the city.

In the landscape of 'neoliberalized' urban development, effects in terms of accessing health, education and other social services and of benefitting of full citizenship rights are reflected in a sense of spatial non-belonging which becomes a matter of dispute and contestation. Under conditions in which state action and regulation is often incapable of equitably accounting for this diversity of claims, spatial and symbolic orders become openly contested. While contestation bears potentials for improving democratic participation and political integration, hegemonic reactions to urban contestation often result into new forms of inequality. The resulting shifts in political climate may even create less democratic landscapes which are less open towards differences. Thus, all too often, the 'politics of identity' turns into an ideological framework for manipulatory and exclusionary spatial practices, often resulting in the marginalization of social, cultural or ethnic groups. Ideologies of identity, selective austerity practices, and discourses of fear result in restrictions of active citizenship and often produce effects of segregation and/or exclusion which adversely affect the pluralism of urban social life.

Spatial identities, paradoxically, become divisive, and places of memory hard to share. And yet, the capacity to combine these values with recognition of diversity is essential for a progressive and equal city. The track invites to deal consciously with the manifold manifestations of these challenges, and to explore potentials for progressive responses through creative experimentation and social innovation in the practices of spatial planning, urban design and city management.

ID 1389 | STUDY ON THE CONDITIONS OF LAND USE CONVERSION FROM RESIDENTIAL LAND TO FARMING LAND

Tetsuji Uemura¹

¹Nomura Research Institute

t-uemura@nri.co.jp ; tetsujiuemura@alumni.lse.ac.uk

ABSTRACT: The demand for residential land is declining and the number of vacant houses and lots is increasing in depopulated areas in rural areas, suburbs and old city centre in Japan for this a few decades. Recently, afforestation for urban forestry and urban agriculture is being promoted as a countermeasure to the increase in vacant houses and plots in depopulated areas of Detroit in the USA. On the other hand, these countermeasures are rarely found in depopulated areas in Japan because abandoned farmland and derelict forests are also increasing in depopulated areas in Japan due to growing aging population. The Ministry of Agriculture, Forestry and Fishery in Japan gives priority to the reuse of abandoned farmland and derelict forests because of already developed infrastructure, like irrigation systems, rather than focusing on the reuse of vacant residential land. Current scenario of Japan gives rise to a question i.e. “will vacant residential land continue not to be used in the future?” Examples of recycling residential land for farmland are very limited. At present, the only known case of land use conversion in Japan is in the city of Fukugawa where colonization residential lots have been converted to farmland. The aim of this study is to conducts a case study on Fukugawa Land Conversion and investigates the implications of the possibility of land use conversion from vacant residential lots to farmland and of smooth shrinkage of the city area. The colonized residential lots are scattered along the river Ishikari in Hokkaido. In this area, the original colonizers constructed their own accommodation in the centre of their farming land when they settled in the Meiji Period. As a result, the farming landscape became concave. When aged residents of the colonized residential land stopped farming and moved out, this irregular form of farmland prevented transfer of ownership to other farmers because of its low productivity. The main industry of the City of Fukagawa is farming, so the Fukagawa municipal agriculture committee decided to subsidize the demolition of vacant houses, redevelopment of farmland and costs of land use change up to 90%. As a result, some of the colonized residential lands have been transferred and are used as farmland now. At the same time, the lower productivity farmland is being abandoned and derelict farmland in mountainous areas is being left as it is. This case suggests that the economic rationality of improving farming productivity is needed in order to convert land use from residential land to farmland. In an era of population growth and economic growth, the actual demand for secondary and tertiary industries and residential land use increased and consumed farmland, but in a period of population decline, farmland has also shifted and moved from lower productivity areas to higher productivity areas and actual land demand for farming may not be increasing. In other words, the possibility of increased productivity in agriculture and forestry can create the possibility of land use change from residential land to farmland or forest land. This suggests the importance of productivity improvement of regional agriculture and forestry for discussing shrinking city areas.

1 INTRODUCTION

The concerns on the increase in vacant houses and lands are growing significantly in Japan facing due to the problem of population decline. The Ministry of Land, Infrastructure, Transport and Tourism (MLITT), in Japan has already introduced several policies favoring increase in the number of vacant houses. MLITT, for example, is encouraging both promotion of reusing second-hand houses by renovation and conversion from vacant houses to elder care facilities. These are typical examples of reducing the number of vacant houses despite their limited quantitative impact in the reduction of vacant houses. This is because number of total households in Japan will also decline after 2020 and even when the new house construction will become zero, the decline in the number of households leads to increase in the number of vacant houses. Consequently, sooner or later, the reduction of vacant houses and increase in the vacant lots are easily expected to become next social issues.

The vacant lots in the residential areas can be used as the seed lots for expansion of neighbor houses and open space for crowded residential areas. Otherwise, they can be used as green infrastructure to prevent inner-flooding and to conserve bio-diversity. In addition, as can be seen in Detroit in the state of Michigan

and Cleveland in the state of Ohio in the USA, those vacant lots can be used as the land for urban agriculture and urban forestry.

In Detroit, its population decline in the city area, in particular, middle class outmigration from the city areas resulted in food-desert in the city because chain stores like super market withdrew owing to the shrinking its market area. Urban agriculture is proposed as one of countermeasures for this difficult situation. On the other hand, Ministry of Agriculture, Forestry and Fishery (MAFF) in Japan are not positive to convert the vacant residential or commercial land to farming land and forestry land. The ministry considers that the vacant agricultural land (derelict agricultural land) with enough irrigation infrastructures should be revived for the new comer to agricultural sector prior to use those vacant residential land and commercial land needing newly development of irrigation infrastructure. This policy by the ministry has a certain rationality to save the additional investment for land improvement even though the land use conversion to urban agriculture and forestry are the is recent phenomena in the world.

The case introduced in this study is of a city losing its population. It is a rather rare case and completely opposite to the government policy which doesn't prioritize residential lands as the seeds land of farming. As of December, 2016, this case may be the only case of the land conversion from residential land to farming land in Japan. This study, therefore, aims to clarify the rationalities and conditions of land conversion from residential lands to farming land.

The structure of this paper is as follows;

Firstly, the residential land of the case study is very famous as colonized residences. The history and feature of as colonized residence are explained. Secondly, the case history and outline are explained. History of this case includes the background information and the background information becomes the basis of the discussion of the rationality and conditions of the land conversion in this case. Thirdly, the rationalities and conditions of this case are discussed. Fourthly, the implications for land conversion from residence to farming land in depopulated area are extracted from the case. Finally, the discussion is summarized and further research tasks are proposed.

2 METHODOLOGY

2.1 LOCATION OF THE CITY OF FUKAGAWA

The case study area of the city of Fukagawa is located in Hokkaido, Japan. The area is famous for agriculture. There are many rice pads in the city areas.

Figure 1 Location of the city of Fukagawa in Hokkaido, Japan

The city of Fukagawa has been losing its population continuously. Also farming population is also declining significantly in contrast to the stable number of households. The population dropped from 36,579 in January 1975 to 21,500 (estimated) in February 2017. The farming population also dropped from 3531 in February 2000 to 1611 in February 2015. This demographic change means that there are many retired farmers in the city due to ageing and outmigration of the younger generation of farmers' families.

Figure 2 Demographics in the city of Fukagawa

Source: "total population" and "households" are from the statistics of the city of Fukagawa and "agriculture" is from "Agriculture and Forestry census of Japan" by the Ministry of Agriculture, Forestry and Fishery in Japan.

2.2 LITERATURE REVIEW

Only two articles, i.e. Muramoto (2010) and Yamamoto (2012), were published on this. The history and outline of this case were introduced by these articles.

2.3 FIELD INTERVIEW

Due to the lack of information on the case, the field interview was conducted on 7th October, 2016 in Osamunai office of the city of Fukagawa. Three officers of municipality agriculture committee, Mr. Yahitsu (Director), Mr. Miyatani (Deputy director) and Mr. Kubota (Agricultural land promotion chief), were corresponded. Outline of the case, background, response from the citizens, and possibility of application to other areas and prospects of this case were discussed in the interview.

3 RESULTS

3.1 CASE OF LAND CONVERSION FROM RESIDENCE TO AGRICULTURE IN THE CITY OF FUKAGAWA

The city of Fukagawa is located almost at the centre of Hokkaido in Japan. The city was colonized by many colonizers when Hokkaido was colonized in Meiji era. Colonizers constructed their accommodation in the center of pioneered farmland. This accommodation with unique location is called as colonizer's residential lots (屯田宅地). These colonizer's residential lots are typical landscape in the centre of Hokkaido.

Figure 3 Aerial photograph of colonizers' residential lots in the city of Fukagawa Source: Yamamoto (2012)

Figure 4 Residential lots' map in the city of Fukagawa Source: Yamamoto (2012)

The placement of colonizers' residential lots in their farmland was efficient when colonizers cultivated their farmlands on their own or by using cattle horses because of closer distance between their house and farmland. The irregularly shaped narrow farmland surrounding colonizer's residential lot has become inefficient for the cultivation by larger agricultural machines.

Once the trend of farmer's retirement and movement to other areas due to ageing in Fukagawa started like in other agricultural areas of Japan, these irregularly shaped narrow farmlands started facing the difficulty in transfer to the new successors, like neighborhood farmers because of its low efficiency. The case with a vacant house on the land, in particular, creates more difficult situation a vacant house is left even when the surrounded farmlands were transferred.

Fukagawa is famous for its rice production area. Improvement of in the agricultural production efficiency by existing farmers is one of the key issues for sustaining the rice production as major regional industry. The abandoned cultivation lands including colonizer's residential land near existing farmers, in particular, the good agricultural lands, are expected to be liquidized and be transferred to the successor smoothly resulting into the efficiency of farming activity. In addition, this farmland consolidation to existing farmers is also expected from another point of view to keep the area clean. As vacant houses and abandoned cultivation land sometimes causes a nuisance as the weeds on them becomes the sources of pests, deteriorates landscape. Invariably garbage, such as peeled-off tin roof etc. get thrown on the surrounding farmland. The liquidation of vacant houses and colonizer's residential lots was not promoted in spite of these problems like in other regions mainly because of the cost of demolition of vacant houses and land registration changes. Also, permanent vice-minister of MAFF issued the circular of "Shinki Kaiden no Yokusei ni tsuite (新規開田の抑制について) i.e. regulation of new rice /paddy field development" on 10th February, 1969. This regulation does not allow any farmers to increase the area of rice pad freely. This circular also becomes a strong barrier to promote the liquidation of abandoned cultivation land between retired farmers and successors.

In this situation, the central government in the second supplementary budget created a special temporary grant to revitalize the Regions and Life (地域活性化・生活対策臨時交付金). This grant was 100% subsidy to the local government which does not matter regardless of the type of employment. The Fukagawa agricultural committee, therefore, decided to use this grant to liquidize colonizer's residential lots to successors as good farmlands. The agricultural committee created the project of promotion of non-agricultural land reuse (非農用地活用促進事業) and during 2008 and 2009, conducted survey of objective land and re-registration of land use, did soil works to develop agricultural land. This new countermeasure was developed to cope with the above mentioned circular by MAFF. The committee asks the successor to replace the area of rice pad within his/her ownership to satisfy with the circular request. Normally replaced rice pad is converted to the farmland for vegetables and other crops.

In 2009, the upper limit of subsidy set to 90% and 1.35 million JPY. After 2010, the city of Fukagawa developed the same policy and subsidized the cost of land conversion including soil works, survey and re-registration costs by 90% and 0.7 million JPY. As a result, more than 10 applications have been received every year and vacant houses have been demolished.

Figure 5 Results of non-agricultural land utilization promotion programme
Source: interview results to Fukagawa municipality agricultural committee

Figure 6 Budget and total subsidy of non-agricultural land utilization promotion programme
Source: interview results to Fukagawa municipality agricultural committee

Figure 7 Before and After results of removal of vacant houses from farming lands
Source: Yamamoto (2012)

Annually 6.5 million JPY have been allocated in the budget under this policy. In 2012 and 2015, the actual execution amounts were over the original budget, and the supplementary funds were allocated to the deficit. This policy is being demanded by the locals; hence, the officers' in-charge in the committee recommended the policy to continue for the time being.

The results of this policy i.e. before and after are shown in the following pictures. It is obvious from the picture that that the formerly irregular land has been developed to rectangular rice pad.

3.2 EFFECTS AND ISSUES OF THE CASE OF COLONIZER'S RESIDENTIAL LAND CONVERSION

The committee reported the followings as the positive impact of this policy.

- The cases of abandoned farmland with colonizer's residential lots acquisition are increasing and this has resulted in the prevention of increase in the number of absentee land owners.
- Local contractors receive orders of soil works and demolitions. As a result, this policy contributes to local economy development

In addition, the committee also highlighted the following positive impacts in the interview conducted in October, 2016;

- Water distribution in the rice pad has become more efficient and this also makes it easier to demonstrate the performance of agricultural machinery. Accordingly, both the committee and farmers recognize the improvement in the efficiency of farming.
- The committee and farmers understand that the property value of farmland can be sustained by this policy because the farmland can be used as good farmland with rectangular shape.

The committee didn't evaluate the effect of this policy quantitatively, but the demand for this policy is still high and sufficient consensus of the merit of this policy has already been formed. Therefore, it is understood that this policy has sufficient cost-benefits and needs to be continued.

On the other hand, several issues remain unanswered.

- In principal, a land owner of colonizer's residential lot and surrounding farmland has to apply for this policy. Consequently, this policy cannot solve the problem of existing abandoned lands owned by absentee landlord.
- The MASS circular is still effective and this policy cannot be used for the expansion of rice pad area for regional development.
- This policy cannot be applied to residential or commercial lots if they are not situated next to farmland. In the city of Fukagawa, the different policy has been developed for vacant residential or commercial properties.

The first two issues are not the matters of the city of Fukagawa. The countermeasures for this are expected to be developed by the central government.

4 IMPLICATIONS OF THE CASE

Implication in the implementation of the countermeasures to utilize vacant housing lots in the period of population decline is that the land conversion possibility depends on the needs of productivity improvement in adjacent farmlands.

The reason why farmland is eroded by land conversion to housing land during population growth and economic growth period is because of the high demand for housing lands. This land conversion resulted in the net decline in the area of farmland and net increase in the area of housing land.

Based on this research results, even in the period of population decline, as long as the MASS circular is effective, the vacant residential lots will not use for the land conversion seeds of farmland. There will be a decline in the residential lands, but the area of rice pad will not increase when the land conversion from housing land to farmland happens just for the sake of agricultural productivity improvement. This means that, in Japan, based on the current regulatory framework in agriculture, as the reason of land conversion from residential land, the land demand for the expansion of farmland, in particular, rice pad, is not strong enough.

It can be concluded that the land conversion demand for residential lands by agricultural productivity improvement occur in the following process in Figure 8.

Firstly, population decline leads to decline in the number of agricultural workers. This decline will demand for larger agricultural machines and higher performance in order to cultivate the same area of farmlands with fewer workers. Solutions under such circumstances, for improved agricultural productivity and better efficiency are: shaping irregular farmland and expansion of the farmland area. Converting the neighboring residential lands to farmland is the most logical step under those circumstances. This conversion leads to replace active rice pad. Better and closer rice pads are preferred and worse and farther farmlands are

abandoned. At a later date, even if we assume that the MASS circular is abolished, still, worse and farther farmlands, typically, in low uplands are abandoned in case that the work capacity of farmers is limited and low efficient farmland should become inferior. This farmland replacement process can also lead to the improvement of agricultural productivity.

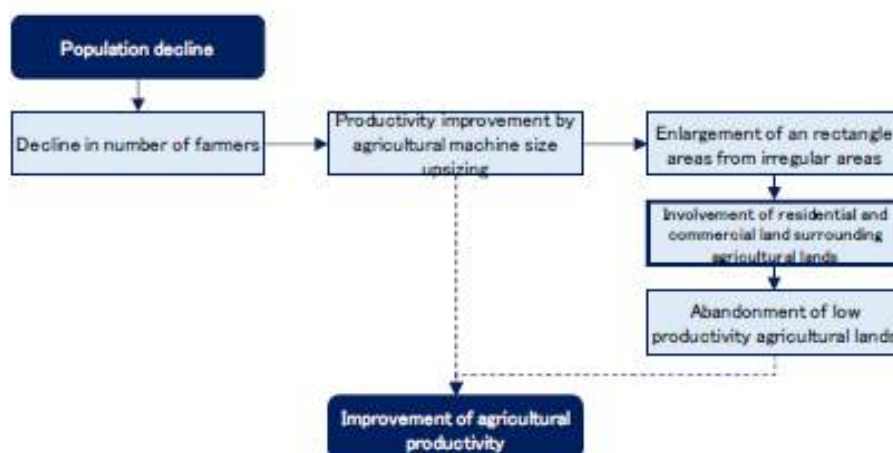

Figure 8 Residential land conversion process in the process of agricultural production productivity improvement caused by population decline

This process suggests that aggressive agricultural policy to improve Japanese agricultural productivity may lead to land conversion from residential land adjacent to farmland. On the other hand, how many areas are converted from residential land to farmland depends on the shape of farmland and how much agricultural productivity is improved there.

Type	Adaptive tractor	Width of work (cm)	Performance (minutes/10a)
HC10 series	11- 18	160-202	13-32
HS20 series	16- 33	183-244	11-28
HR20 series	20- 54	200-310	5-15
HL20 series	45-100	274-391	4-11

Table 1 Pudding performance by types of tractor
Source: Yammer (2016)

For example, in pudding case of rice pad, pudding performance varies depending on the type of tractor. The difference is about three times as shown in Table 1.

Output of tractors in Japan has become gradually higher, but only 14% of tractors of 50 ps output that can attach the high efficient padding equipments are being used. High performance tractor is of course costly, and cost-benefit should be considered carefully. But, from the view point of expansion of per capita cultivation area in the period of population decline, there is a big potential to introduce high performance tractors in Japan. This introduction may lead to shape and expand irregular rice pads and this shaping and expansion may lead to land conversion from vacant residential land.

Figure 9 Composition ratio by based on tractor output
Source: Nichinoko Toukei (each year) by Japan Agricultural Machinery Manufacturers Association

Note: Estimates from shipping statistics on the conditions that durable year Life with the use of tractors is assumed as seven years. What you mean by durable? Is it life?

It is noted that the urban small residential lots adjacent to farmland sometimes has concrete boundary wall as compared to the colonizer's residential land. As can be seen in Figure 10, a colonizer's residential land is very low and there is very little height gap between residential area and farmland. This little gap can reduce the amount of soil movement and save the cost of land conversion. On the other hand, recently developed small residential lands converted from rice pads usually have concrete boundary wall. This means that the demolition works of these small concrete boundary walled residential areas are more costly than that of colonizer's residential area.

Figure 10 Colonizer's residential lands with a vacant house and surrounding farm land

Figure 11 Land conversion work from a colonizer's vacant house to farming land

Ground leveling work in the land conversion can be shown in Figure 11.

Firstly, the embankment for the house is removed. After that, the top soil of rice pad is scraped and collected to move to the area of previous residential area to cover the land there. Finally, the ground leveling work is conducted for smooth supply of water.

The above mentioned discussion is based on the current situation of preventing the new rice pad development and formation by consent of existing landlord on the colonizer's residential land. Once the MASS circular is abolished and much bigger agricultural production corporation is established for expanding its production size on the field, much bigger land conversion from residential land may be happened. Moreover, a new policy for absentee and unknown land owner to liquidate abandoned cultivation, residential and commercial land can be introduced for helping administrative intervention, existing derelict cultivation and more numbers of residential land can be used as active cultivation land.

There are cases of typical abandoned vacant residential lands that are not adjacent to farmland and of big residential complex on the slopes of the hills in the suburb of big cities in Japan that do not have any big farmland area near there. Such cases are difficult and different solutions have to be worked out for such cases.

5 CONCLUDING REMARKS

The countermeasures of vacant houses and vacant land are the usual discussion from supply-side, but Fukagawa case suggests the importance of discussion from demand-side as well. The case suggests that discussions should be held not only from quantitative aspect like demand of areas, but also from qualitative aspect like productivity.

Fukagawa case suggests that the vacant residential land adjacent to farmland may have a possibility to convert to farmland, but it also suggests that “how much of size” depends on “how much of productivity improvement”. It can be found that the expansion of field area, abolishment of the MASS circular on prohibition of new rice pad development and enhancement of agricultural machinery are some of key triggers for potential land conversion. In other words, aggressive agricultural policy reforms are expected to promote land conversion from residential land to farmland.

Fukagawa case can be applied to for only residential lots adjacent to farmland, but there are no good solutions found for the vacant residential lots in the city. We, therefore, have to still look for other solutions for major problems of vacant residential lands. The case study of Fukagawa case suggests that researchers should also take up the perspective of productivity of land use into their research and investigation works.

ID 1457 | TRANSNATIONAL SPACES IN THE CITY, BETWEEN FRACTALIZATION AND DIVERSITY NEW RELATIONS BETWEEN CENTER AND PERIPHERY

Gilles Verpraet¹

¹Sophiapol University Paris Ouest Nanterre
gilles.verpraet@wanadoo.fr

ABSTRACT: Contemporary metropolises are increasing their transnational spaces and relations such as, the CBD, the internet and cluster places directly related to the global and transnational networks. Different migrations are implemented first in areas of Fordist production then in the place of the service economy. These processes challenged the relations between center and periphery (concentration, dispersion, value of urban land). These processes are also challenging the differentiation between internal migrant and the new migrant. The consequences are different on employment access and stability, on residential settlements, on participation to the city. The first question comes for a better description of the transnational metropolis, on the specific process of differentiation, competition so to settle the degree of inequalities : -Transnational areas related to center and periphery; -School policies and migrants access (interior, exterior, new) - Politics of diversity concerning national migrant and external migrants. Two types of discrimination and inequality could be specified : The inequalities and race relations of the subaltern internal migrant, linked with the foundational state; the inequalities of competition and transactional economy for the new migrants. *The second step of analysis intends to develop a better assessment of economic and public policy; Effect of economic redevelopment and conversion policy; Effect of anti discrimination politics concerning the access to market, access to civic rights, access to public service; Effect of diversity policies. The analytical challenge is to compare two metropolises inside their transnational areas concerning key social processes such as the relations between center / periphery, the anti-discriminatory policies.. The comparison will be developed between the two cities of the Paris region (12 millions), Vienne and Bruxelles metropolitan (3/5 million inhabitants). The results concerns the discriminating effects of some policies : The diversity policy manages the competition between migrants, with populist racism .Market policies for equal distribution do not act directly on differential and foundational racism. Public policies are under tension have to combine equality of access, between civic participation and enlarged transnational open networks. The question of metropolitan incorporation and its limits (education, politics, metropolitan economy) comes along with the issues of reinforcement of transnational spaces (multiple relationships, multiple player, polycentrality, dystopia). The metropolitan tensions split between settlement policy and diversity policy, between migrant from the inside and new migrants, between Inequality of access and injustice. The modernization process combining resources, skills, retraining are reframed by these side variables. * Traditional analyzes of transnationalism focus on CBD, their ability to dominate and to reorganize the metropolis by attraction and polarization ‘ Knight and Gappert, Gordon) assuming the risk of subordinating or forgetting the periphery. What has become of the peripheries in this new conjuncture of the transnational economy ?, The images of distribution networks, service society and subordinate flexible employment seem predominating. Our paper consider the double face of transnationalism, in the new regimes of economic interdependence (including neo-liberalism), in the management of populations (numerous migrations, refugees according to the type of incorporation). The regimes of urban interdependence are affected by these two sides of the transnational spaces, hence comes a series of conflict and disruption, which deserve to be specified. Our presentation examines the changing relations between the center and the periphery in popular areas social spaces (peripheral cities and pendulum mobility), in the middle classes (patrimonial city and gentrification, individualized transport). In the centrality of (European) metropolis, the peripheries of the metropolis are driven by the mass consumption, by urban bourgeoisies in their selected access to the center, by cultural tourism. We consider how migrant diversity and possible cosmopolitanism are perceived. New relations between North and South relations write their marks, their inscription and their reference in urban peripheries and in urban centers. The result is a diffracted view of the relations between the center and the periphery which urban analysis must be able to account for. It affects the relationships between urban spaces of diversity and plural identities. *The urban laboratory focus on the diversity of cultures and access to the center (Ledrut, Lefebvre). The migrant question, developed by the Chicago school, involves the reception of migrants and their social rights, and the definition of a common public space (Park, Hughes). Two models are presented; The urban mosaic of communities (Chicago Park) dispatched a plurality of territories in friction

and competition (Kivisto, 2009). It initiates the territorial dialectic of boundaries and identities (Lamont, 1998). Other theses emphasized the conditions and possibilities of gathering identities through iterative processes (Benhabib, 2005), by concrete approaches to gathering closer to bodies and subjectivities (Butler, 2016). Our approach intends to extend the parameters of the urban laboratory, not only on the central occupation, but also on the types of urban exchanges and the trajectories of access to the center. We will present the fieldworks, the communes Bagneux and, Sevran (as laboratory of social differentiation) inside Paris Metropolis. The social dynamic and spatial dynamic organization of Parisian metropolis will be compared with the social and spatial dynamics of the relation center and periphery in Bruxelles and Vienna metropolis.

1 SOCIAL SPACES BETWEEN CENTER AND PERIPHERIES

The periphery can be defined by exclusion, by lackness. It can be defined by its places and its landscapes (cf royal image of the "île de France"). It is also interesting to define the periphery by its relations with center (distance, center, access to places of employment, access to legal decisions and their arbitration), in particular to combat the idea of peripheral and subaltern subjects. So comes the typologies of the middle classes on their access to home ownership, The suburban model of the 1970s (Roux and Bauer, 1976). are dominating the consumption typologies on the purchasing power of these different middle classes, depending on the type of housing and the accession process, depending on access to shops and means of transport, typology of mobility modalities (Damon, 2012). These are typically functional typologies drawn up by specialized management bodies.

It is more difficult to formulate a typology of the places and spaces of the periphery, the modalities of gathering, sedentarisation and residential, social and political cohabitation. The question of social spaces and of political spaces in the periphery disappears between functional, consumer and non-place themes, disqualification and relegation. Suburban subjects and their relation to space remain invisible. They mark a challenge for urban analysis. The question of the different residential peripheries and the complex modalities of cohabitation are quickly covered by the discourses of mediatization. With the fixation of stereotypes, the suburbs are sources of discourse and rejection, such as the rapid image of the ghetto based on the encirclement of minority populations, The suburbs can be presented as places of life style associated with attachment to the neighborhood, residential cosmopolitanism from below. The suburbs are quickly considered as discursive places, with sporting mythologies, supporting a language of the suburbs. Suburbs are proclaimed as places of creation, in search of an authenticity of suburban voices, in the rhetoric of rap (Carpenter and Horvath, 2015).

2 SOCIAL CONTINUITIES WITHIN HETEROGENEOUS URBAN SPACES

The first object of investigation and analysis will be to observe the different contents and social spaces of the periphery, working-class suburbs, residential suburbs, suburbs of middle classes, migratory suburbs. How to observe the different modes of cohabitation between the residential groups and the social groups (belonging and identity), and the corresponding modalities of articulation of the social groups? A related method of approach (linked ecology of connected systems) makes it possible to think both the urban and the collective housing, in a model of social differentiation, including multiple settlements, cohabitation between social groups with different social and cultural contents (Park Burgess, Abbot). It is necessary to characterize the residential spaces, the social and cultural spaces of the periphery, within the new possibilities of the multiple worlds, beyond the classical image of the 1960s / 1970s of the suburban/ rural continuum. Urbanism is modified and diminished in the new post-modern formulas (exotopia and disappearance, dilution of centers in the network society (Soja, 1999)

3 TYPOLOGIES OF URBAN SPACE AND REEVALUATION OF SOCIAL SPACES

Raymond Ledrut analyzes the organization of urban social space. It distributes the typology of social spaces according to the forms of self-organization within the differentiation of the social space and the composition of the social space. The social space characterizes the relations between the center and the

periphery, not only in the distance to the center but also in the access to the public service, their accessibility their decentralization, a certain idea of diffuse republic in front of the central republic .

In his analysis of the neighborhood social space, Bourdieu highlights the weakening of the state as an explanatory variable and the crisis of social reproduction as a consequence (Bourdieu, 1993). The result is a typology of social spaces following the subordinate forms of precariousness and social fragmentation. The result concerns decline and exclusion from the inside (precarious families, young people, migrants). Hence the comes laim for public service to support social reproduction and social integration. Olivier Beaud insists on the crisis of social representation (precarious family, young disqualified) (Beaud 2003). This crisis of durkheimian sociology (representation if integration) introduces the notion of social disqualification.

* The post-modern approach developed by Andrew Merrifield and Ernest Soja (Merrifield, Soja, 1999) describes the fragmentation processes and the polarization of the city (revanchist city) with the demands of justice, spatial justice: environmental justice. The method of marginal alterations (margin / alia), highlights the spatial, social and relational differences that are added in the extension of metropolises. The notion of "exopolis" formulated by Foucault is associated with the reading of the socio-spatial differences. But social space remains fragmented, segmented without political reformulation of civic space. It is a matter of describing the illiberal space. The fragmentary current has been reinforced to the detriment of the reading of social space, the civic reading of space. Michèle Lamont overemphasizes the boundaries and identity of each social group in a process of marking and competition between social groups (Lamont, 2012).

4 EXTREME SOCIAL SPACE.HOW TO COMBINE THE EVENT AND THE STRUCTURE ?

Surveys after the 2005 riots in North of Paris Region focus on the revolts of young people classified as racial riots tried to analyse back the social problems of the periphery (including social housing). Michel Kokoref, Hughes Lagrange and Marco Oberti emphasized the urban segregation and the school problems (Kokoref, 2008, Oberti and Lagrange, 2006). They shared the diagnosis on different groups of young people, forming a unity in the anti-CPE struggles, dividing into urban riots. The questions of culture then come on the socialization significance of the school (Verpraet 2001), the life styles of the families, the possibilities of speech and the conquest of autonomy The urban development of the theme of tradition and modernity can be expanded in access to social housing standards, in the design of residential housing (Stébé, 2016), in the way in which peri-urban housing and small towns assume the conflict between traditions and modernity (Roques, 2009).

5 SOCIAL SPACES AND COEXISTENCE

The central question of urban analysis focus on the qualities and modalies the social space, the different ways of sedentarization and spatialization of social groups. It is a matter of reading the human settlements and the modalities of cohabitation. How to consider and to evaluate the human settlements and the modalities of cohabitation. The approach is to read the relational space and the solidarities that form in the public space and its crisis, ie the disjunctive space.The second objective is to reassess social space in suburban communes, in relation to typical residential spaces, forming communal combinations between social groups.

6 POLITICS OF REQUALIFICATION AND REEVALUATION OF THE RESIDENTIAL SPACE

The requalification policies assessed the notion of residentialization to denote the modes of weak appropriation of the inhabitants (Verpraet, 1991). It is then necessary to specify the modes of social relations within the same space of residence, between relations linked to the locality and external social relations, independent of the locality (Guerin Pacé et al., 2003). The Ined survey (2003, 2009) conducted

with 10 000 inhabitants by questionnaire underlines the diversity of territorial anchorages with regard to migratory paths (Guérin Pacé, 2009). Multifunctional spatial identities are distributed according to the diversity of social relations, especially for young people. Residential attachment and inscriptions take place within a broader set of social relationships. The concept of residential space is important for the anchoring of precarious, The survey finds divergent attachment and identification behaviors between relational and non-mobile young people, rooted ones, difficult paths (migrant precarious adults and the elderly).

The discourse on peri-urban space tends to minorize the suburbs in number and growth, in their capacity for integration and incorporation. The peri-urban pattern overemphasizes integration by the village (social control, between oneself, low density, service chosen) by marking the opposition reported with the mass society in the public housing suburbs (mass housing, Heterogeneous diversity) (Charmes, 2011, Guilly, 2014). This opposition undermines the incorporation of single unit homes inside suburban societies, the coexistence of several models of residence, between several types of mixing in the suburbs of the 1950s / 1970s. It would be more appropriate to envisage and explain an increase in the diversity of cohabitation models.

7 THE REQUALIFICATION OF RELATIONS BETWEEN THE CENTER AND THE PERIPHERY

The notion of center and periphery set up spatial relations (attraction versus rejection) and relations of power (occupy the center versus reject in the periphery). It takes meaning in the deciphering of the different power relations and the different types of subject (Chevallier, 1977). The notion of social space formalizes the balance of relations between social groups. The notion of political space characterizes the balance between political forces and systems of power. Three socio-political models seem to dominate the sociological analysis of the urban periphery.

- a. The civic / national/ republican integration around the city center's shops and communal institutions is the classical model of urban sociology. (Ledrut, 1968). The overflowing of these urban institutions by new populations, rural and provincial migrants, European and non-European migrants) implicates the urban analysis of transition periods, the time to shape some new social actors who will relay to the institutions Public and communal institutions,
- b. In this gap between the center and the periphery, the analysis of margins, of conflict, are developed within the analyzes of self-organization and decentralization, analysis of progressive political acculturation. (Merrifield, Oberti).
- c. The dispersion of the middle classes on the urban periphery combines the processes of urban dispersion and proximity with the nature and the residential, processes of social differentiation and social distinction.

In this framework of plural analysis, it becomes possible to specify the methods of anchoring and associating new populations, especially migrant populations, within these sociopolitical models. To what extent do the distances and the distinction between the middle classes and the urban periphery change the reception of new populations in the periphery? Can we observe and explain the formation of new transnational spaces in the periphery with qualities of sociabilities ?

8 TWO CITIES INSIDE PARIS METROPOLIS

Of the two mixed suburbs, on similar urban types, were formed with different histories between the 1960s and the 1980s, with different rates of migration, different ways of organizing the partition of space, designing Urban and residential mix. The research and analysis approach focuses on the relationship between social space and residential life, - between residential and associative life, on the city management of residential spaces . It is necessary to distant the conflict analysis of the years 2005 (youth revolt) and their polarizing interpretation to better understand the stakes of residential space, the formation of social space and political space; to examine the measured potentialities of polycentrism Bagneux is a city of 59,000 inhabitants, an industrial city converted into a housing estate. It includes 58% of social

housing, but also single unit housing. Industrial restructuring and housing operations have generated the successive strategies of residential occupations. With the factories /firms of the 1930s and 1950s and the HLMs of the 1950s are associated labor class pavilions and small incomes. With the relocations of the 1970s and 1980s (Thompson, Westinghouse), the degradation and precariousness of social housing is compounded.

The years 2001/2010 ensure the development of many city projects under the egide of the anru. Numerous urban redevelopment operations follow one another: a) a one site renovation of mathurins, a former Thompson factory site in 1983, then the DGA until 2014, 16 ha. The urban project concerns the opening up of urban areas, combining housing, public facilities and green spaces, and reserving 25% of social housing (rental and accession) to guarantee a social mix and offer opportunities for residential development.

* We underline the importance of community life in the suburbs cities. Alongside the ecological associations, alongside the republican associations (Movement for Peace, Attac), associations for concrete solidarities (women, nature, africa) are founded, an association of Mali linking different villages, an association of Malian women's associations and ecologists., Community association (Mali, Soninke). The cultural and residential plurality of the municipal life is realized by the associative networks. A cosmopolitanism from below is designed with an associative tone. It is possible to support an anchoring and an opening up of the public space combining republican associations and migrant associations, especially with the presence of migrant women on concrete residential issues (crèche, youth education, response to violent behavior). The strategies of requalification and residentialisation stabilize a diversified associative life. This social and residential ground encourages anti racist actions on the school, carried by the project of the Mouss

*The action of the municipality is coordinated on two registers: The repertoire of neighborhood social development develops as a support to the steps of residentialisation of families and households as a vector of urban socialization anchored in transitional spaces and public spaces concrete. Opening and supporting associative networks for newcomers ensures a relay of municipal policy. The result is the formation of a substantial republican fabric on housing, school and cultural action conceived as vectors of socialization for newcomers.

9 AULNAY / SEVRAN, TWO MODELS OF COHABITATION

Sevrans / Aulnay seem to characterize by two models of social incorporation. Aulnay, a predominantly suburban town has gained its wealth on the incomes of the Peugeot PSA plant. It develops a security model based on the social control of the populations. Sevrans with its numerous public housing dwellings and its diverse populations displays a policy of republican and ecologist integration. The addition of social housing estates in the 1970s and 1980s, oriented towards motorways and industrial zones, creates a disorientation of space following centrifugal logics. Sevrans comprises a population of 50,412 inhabitants, relatively stable since 2004 of which 20% foreign nationality. The policy of republican integration around the republican village and its services seems to be bypassed by the industrial space and its crisis, by the migrating multiplicity and its transnational orientation.

Sevrans is formed of many new urbanizations built after the years 1975 to the north of the city, welcoming populations of recent immigration. They came in addition the republican village and on residential buildings in the suburbs. The first qualification of these peripheral areas are made in terms of poverty, social inequalities and urban relegation. Sevrans Beaudottes, 10 000 inhabitants, groups 33% of the households with the foreign head of household, 23% of the population is unemployed, 1/3 rmi of the city, 80% of the population below the bac, 25% below the resource minimum. between 1960 and 1974, 2000 housing units were built on the Rougemont district. This district is concerned by the "Grand Projet de Ville" (Urban Renewal Operation) devices. The district has 6,634 inhabitants (in 2007).

The economic space around Sevrans is widening between industrial areas Garonor, the Peugeot -Citroen production site decommissioned in 2004, the Villepinte exhibition center, Roissy airport. The Roissy le Bourget territory (IAU 2015) comprises 234,000 jobs for 47,000 companies, organized on very specific functions of the logistics metropolis: 30,000 jobs, airport 92,000 jobs. . Inside the 329,000 active residents in the area, 63,000 do not have a 8% degree. The socio-professional categories are distributed on

qualifications below the regional averages (managers 16%, intermediate occupations 24%, employees 35%, workers 26%).

* The residential life of the city is organized around the village center town; reinforced by many public services, school, cultural center, house of associations, The town hall conducted a policy of "soft security", in opposition to the security policy posted in Aulnay. . The space of the city is marked by a partition according to the type of urbanization and production of the housing, between the residential south, mixed with the majority French and the northern predominantly residential African with poor resources. The social housing units of the 1970s are appropriated by the new migrant populations (Mali, Comoros, Haiti). The African residential area remains poor and relegated distant from the french spaces.

The diversity of the community life presents the diversity of the cultures of the city. But the associations present culture as an affirmation and an exteriority and much less as a residential relational dimension,: Association of the Comores in Sevrans, Association of Friends of Mali, Association of Young People for the Development of Mali, Association of Buddhists Khmers Krom, Association of Sufis of Macedonia in Paris Franco-Guinean Intercultural Association, Haiti dynamic, Cultural Youth Caribbean Heritage, House of Armenian Culture etc ...

10 DEVIANCE, URBANITIES, SECURITY

A recent qualitative analysis of urban conflicts reveals the pervasiveness of insecurity and suspicion, with media focus (Sanchez, 2012). In Sevrans beaudottes (10,000 inhabitants), 38% aged below 20 years, 1/3 rmi of the city, 25% households are below the ceiling of resources. Municipal political life can be exposed on the themes of integration and ecology. It faces the problems of delinquency and insecurity within the partition between the northern and southern districts. Should we talk about urban apartheid and urban separation? The migrant presence in the municipal council includes representatives of migrant european origin 20% migrants of European origin (Portuguese, Romanian) dispute with the migrants of the maghreb, in particular of Morocco. It seems more accurate to analyze the distantiation of the republican village center.

11 DISJUNCTIVE COHABITATION

Integration with a republican and ecologist aim seems to be overwhelmed by new populations, networks and youth. A decentralized transnational space can be formulated with regard to republican integration. A more recent population leads to a weaker residentialization (Guérin Pacé, 2009). As a result, security discourses occupy the public space. The multiple vectors of social support in Sevrans appear divergent and uncoordinated. The economic vectors are dispatched on economic sites. Institutional vectors attempt to converge on the city center and the administrative centers (Bobigny, Paris). But the relational vectors of young people are scattered between community relations and the spaces of mass consumption.

12 COMPARATIVE ANALYSIS : INCLUSIVE INCORPORATION AND CENTRIFUGAL INCORPORATION

Sevrans and Bagneux are two similar mixed suburbs with different histories between the years 1960 and the 1980s, with different rates of migrations, different ways of organizing the partition of space, designing urban and residential mix

- Bagneux - The incorporation of peripheral HLM housing estates is supported by an intense and diversified associative life. The coupling of the municipal institution and the peripheral districts passes through the school and the numerous associative relays (except maghrebins)

Aulnay / Sevrans set up the limits of associative inclusion, for recent populations experiencing the outsourcing/ externalization of employment, Social relays pass through families, social centers and children.

The second thesis deals with a diversity of forms of cohabitation between the suburbs, the neo rural village, the village of executives and their external economic space, the fordist suburbs, the suburbs flexible service, urban mixtures.

The comparison between Bagneux / Sevran highlights the centripetal incorporation (associating the municipal center as village with the requalified periphery of Bagneux) and the centrifugal requalification resulting from a strong partition of the social and urban space (the republican village overflowing). The integration of peripheral populations into the social and political life of the city, costs more effort for the municipality. Some populations are placed outside the republican framework, especially the youngest and more mobile, the most subject to media mass orientations, with possibly pregnancy of religious models.

13 ANCHORING AND MOBILITIES IN THE PERIPHERAL CITY

Transnational population flows are important at the periphery of agglomeration, but they must proceed through the anchoring, association and integration modalities developed by each city, by each commune. Centripetal integration enhance the integration of transnational populations through residential relations and associations, through the support of residential requalification. The centrifugal integration remains marked by the partitions of the space, possibly the political partitions. It excludes certain specific populations (according to a stigma due to the absence of an integration policy). Parallel social spaces are developing, partitions between national and extra territorial, The methods of anchoring and associating peripheral flows remain an important sociological and urban planning question. Diversity politics concerns not only the distributive flows but also the modalities of residential settlements, the type of cohabitation, the community links, the linked ecology of each place and residence. Our fieldwork distinguished between disjunctive cohabitation, converging cohabitation, accomplished cohabitation

14 CONCLUSION : POLYCENTRIC METROPOLIS, POLITICS OF DIVERSITY V POLITICS OF COHABITATION

*The metropolis can be conceived as diffusion and as dispersion, it can also be conceived as an arrangement of residences, cohabitation, mixing and incorporation at the time of the city flow. It is then necessary to distinguish between the different types of social groups, the different types of residentialization and incorporation. The issue moves on the relations between peripheral and metropolitan worlds, between social worlds and the regimes of urban interdependence.

The notion of peri-urban covers a set of landscape and socio-geographical meanings where the definition of space is organized by the distance to the center, according to the relation between oneself and the relation to nature (Charmes, 2011). We must reintroduce the dimensions of lifestyles in order to envision the relations between centralities (consumption, recreation, studies) and peripheries (residential, family, ecological landscapes) (Marchal, 2015). The subject develops a distanced relationship with political institutions.

15 SOCIAL SPACE AND RESIDENTIAL SPACES

The analysis of social spaces and residential areas on two cities, inside suburbs, first and second crown of suburbs, highlights the important articulation between the residential and social areas of the communes. Residential space concerns also the set of social relations developed between families in their daily appropriation, shopping, children, families, associative relations. The requalification operations highlight the constitution of the residential space, its intermediate objects (family game), but also the overall appreciation of the inhabitants on the functioning of the neighborhood; The appreciation of the social space underpinned by residential practices: stay or leave. Guérin Pacé and his team crossed cut the diverse have modes of identification with space and the modalities of belonging. It marks the components of a multiform identity inside spatial relations. (Guérin, Pacé, 2009)

- An attachment to the place of birth for people with little mobility 9%
- A place of anchorage after a difficult life course often 20%

- Geographical inscription, an identity component left behind by decommissioned young people 25%

Attachment and identification behaviors diverge between young people who are more attached to relational practices (24%)and populations that are not mobile, rooted (11%) , difficult paths (20%)(precarious migrant adults and the elderly).

The diversity policy as a flow management, a distributive and non-spatial vision must also recognize and assume the social diversity according to types of association, types of cohabitation and types of rights.

Political space includes cohabitations and bounded alliances between residential and social groups. Municipalities takes an important role to define their support for associative life, in the management of populations as biopower (Esposito2006), inside urban planning decisions, in order to compose and articulate the different modes of production of space (diffuse residential, dense residential, collective housing, residential housing).

16 MULTI-LEVEL METROPOLIS AND URBAN INTERDEPENDENCES:

The social and urban analysis of the current peripheries can be specified by the following substantive and analytical categories

The residential space is framed between the center and the periphery, stressed by the escape of the center, individual autonomy, the new relations between nature and culture.

The social space is stabilized and embedded in the relations between center and periphery (Ledrut 1968). It characterizes the modes of relations between social groups. The central State intends to regulate the relations between social groups, according to civil peace and political space.

The formation of a political space is marked between the center and the periphery. The center ensures centralization, rationalization and regional reforms to delegate problems (Chevallier 1977). The state is formed by these different relations bounded between integration, and dispersion, between revolt and social control. The transnational spaces push the fragile residential political space to form a post-modern state.

Neo-liberalism takes advantage of the regimes of urban interdependence, distribution channels, infrastructure and logistics, resources and shared raw, access to networks. This private appropriation of externalities must access to the political space in order to ensure these captures .

*The hypotheses on the urban continuum-urban-rural perimeter highlight the inflexion and turn points (the preservation of nature, the weight of the residential) that change the pressure of urbanization on diversified urban sequences.

Inside the classical sequence of the 1930s / 1960s the individual pavilions and the rural space are added, to the city center and the dense suburbs of collective dwellings (Bardet), Inside the classical provincial sequence, the natural space and the peri-urban are added inside a diffuse sequence Provincial (Sechi).

The great metropolis, by encouraging the development of transnational spaces, displaces the peri-urban sequences where transnational spaces and peri-urban residences are confronted: between dense suburbs, transnational space, pavilions and rural areas; Between dense suburbs, transnational space, pavilions, natural space, peri-urban areas.

The effects of the transnational flux accelerate the uncertainties and the shortcomings of the centrifugal urbanization between hype place and road for flight. . The social stakes concern the redefinition of political spaces within the relations between center / periphery, between bureaucratization and control, between revolt and autonomy, according to new forms of self-organization (a continuation of socio-political debate). Transnational interdependences tends to distort urban (so-called) interdependencies .

Neo liberalism spaces can develop through different types of incorporation and biopower, the fordist city, the consumer service city with flexible jobs, the knowledge society for high rank professionals. It requires

different types of social space, different labor qualification and stabilization, different bio v institutional powers

17 VIENNA SIEDLUNG, DIVERSITIES AND PERIPHERIES

Vienna (1.7 million inhabitants) is a central city of central Europe which experienced the withdrawal of its empire (in 1920 (Hungary, Czech Republic, Slovakia), but the city welcomes many migrants and refugees of its former Empire. After the war in Yugoslavia in 1993 1995, it hosted refugees from Bosnia, Croatia and Serbia with a large Turkish migration (cf simmering Ottakring district) The important issue of the Syrian refugees in 2015 merely highlights the traditional importance of these transit routes (25% of migrants).

The capital Vienna is an historic passage of the Danube between 'west europe and' east europe (turkey middle east) (Musil). The social space is marked by polarization and social segregations but also characterized by patchworks settlements (Hammadinger). The socio-political relations of the last twenty years also opposed the metropolitan social democratic integration model Vienna (siedlung politics) and a more authoritarian periphery opposite to the migrant presence such as Caranthe. These political formulas have been polarized on the possibilities and limits of incorporation in the case of Syrian refugees 2015.

Diversity policy can take place by enhancing the diversity in social neighborhoods and semi-peripheral neighborhoods (Simering Ottakring). It can also promote the extension and structuring of the metropolitan periphery in a more solidary metropolis. The growth of the service and high-tech sectors has now transformed into office.

The pressure of peripheral urbanization is marked by the organization of the polycentric periphery (Kramar). Urban-Suburban-Management's affirmed policy ("SUM: Stadt-Umland Management", 2006) want to develop an emancipated cooperation between Vienna and suburban municipalities 2006 such as-regional coordination, mediation involving all relevant actors). So results the development of secondary centers in the metropolis, such as Donau city, Erdberger Mais' (5000 habitants), Wienerberg-City

18 BRUXELLES COMMUNITY POLICIES SETTLEMENTS INSIDE FEDERALIST CAPITAL

The metropolis of Brussels is of average size 1, 1million habitants, associating an average administration, a diversified working class and affordable mixed housing. The multipolar city is developing on numerous industrial zones, shopping centers and a few service centers (Lemmert) in relation with residential periphery of middle classes in the Flanders region, forming an alveolar region based on these solidarities of interest (Remy)

The CBD was recently formed around the European affairs district, the Nato and more recently the office centers around the stations were developed according to the 2009-2020 development plan. This development policy was accompanied by the requalification of certain districts and expropriations protest (station du midi (Kesterloot, 1998)

The place of foreign communities in the city is important following the desindustrializations of Liège and Namur. Mixed neighborhoods include Moroccan communities and communities of Turkish origin juxtaposed, Sharbaeck, Mollenbeck and others. These neighborhoods correspond to the poorest district of Brussels (Martiniello). Bruxelles attends 350,000 foreigners so 30% of the resident population. This immigrant presence is an argument of contest for the nationalist parties (Vanlaer). Community policies in a federal state authorize and require the explicit presence of immigrants in the municipal lists associated with the political parties, immigrants present, associated with the PS list, democrat). In terms of cohabitation, we can recognize very mixed neighborhoods, supported by a federal community integration policy with some points of radicalism stemming from the capture of young people radicalized by external networks.

Several interpretations of the periphery may be grasped inside the Bruxelles case. Beside the diffuse city, peripheral urbanization, the alveolar metropolis(J Remy); are rising the Flemish suburbs, highly educated

homogeneous families who opposed the multicultural city center , as a source of community conflicts in Belgian federalism. The interpretations of community treatment tend to diversify between the Flemish communities, the French communities, the multiple migratory communities .

19 METROPOLITAN SOCIETY AND POLYCENTRISM

The geographical and sociological literature set up the diversity of modes of formation of space in the periphery corresponding to the diversity of territorial modalities of social groups by associating sociability and territories, spatial identities, by arranging networks and associations, networks and clubs, for senior managers in urban centers.

* The study of the polycentric metropolis, of the relations between center and periphery inside two communes (first and second crown) frames several models and regimes of polycentrality, as an extension of the relational city, of these connected ecologies. We have exposed some variations inside the existing models :-a/ Diffuse urbanization and centripetal incorporation,

- b/ Diffuse urbanization and centrifugal incorporation, c/ Urbanisation diffuse and transnational networks. Our case studies differentiate between diffuse urbanization, community incorporation and federalism in Brussels, the centripetal and isolation of the metropolis in Vienna, the diffuse polycentrism and the uncertainty of political life (the Paris region). The notion of a diffuse city (extension of urbanization) does not specify the types of association, civic centers, secondary centers, cohabitation policy whoa may connect these expanded urban and social processes

20 PLANNING FACE THE EXPANSION OF THE POLYCENTRIC SPACE

Polycentrism is a subject linked to the planning scheme. A criterion analysis highlights a more complex spatiality formed, between the attraction of the center, the polar network and polycentrism. The challenge concerns the capacity of the center to fix the norms on the various peripheral territories, on the different modes of spatialization, territorialization and socialization. Three solutions appear in the present situation:

In the diffuse polycentrism, the middle classes with status are organized on a residential dispersion, with a social distinction and a social distinction, protected by nature. Some workers' groups follow them in the same patterns on a residential status but within degraded districts of second choice. This urban pattern opposes the middle classes in the center (gentrification), the middle classes in the periphery (residentialization, club society, eco city)

With dense polycentrism, the suburbs recover the city, the suburban areas alongside public housing, shopping centers. Semi-diffuse polycentrism combines high-tech fittings (high-technology research center, technological park ie "cluster") and ecological resources, the "smart city" model completes the model of the residential city peri-urban. It is then possible to specify the identity configurations that are established in the allocation of space (the partition of space), in the qualification of space (according to view and point of view), in citizenship .

21 PLANNING, DIVERSITY OF SOCIAL SPACE AND POLYCENTRICITY

This redefinition of the relations between the center and the peripheries, these plural forms of polycentrism in the urban periphery, makes it necessary to define the role of urban institutions in order to compose the norms of exchange between center and periphery, to articulate centripetal models and centrifugal models of incorporation social..

The assemblage of metropolitan cities (EPCI, commune community) have been able to prove their capacity in urban production, in the organization of sustainable development on an enlarged scale. The questions remain about their responsibilities and their potential in the management of populations, residential flows, cultural exchanges within the periphery, and the social equilibrium between centrifugal

urbanization and centripetal urbanization. It implies the development of new forms of urban citizenship at the periphery.

ID 1511 | GREEN INNOVATION AREAS AS CONTESTED SPACES?

INVESTIGATING POTENTIALS AND RISKS OF REVITALIZATION

SCHEMES IN SHRINKING CITIES

Karina Pallagst¹; José Vargas-Hernandez²; Patricia Hammer¹
¹TU Kaiserslautern; ²University of Guadalajara
karina.pallagst@ru.uni-kl.de

1 INTRODUCTION

All over the world many cities are undergoing structural changes with symptoms of economic crises (Pallagst, et al 2013). In these postindustrial or 'shrinking' cities, the transformation of former brown field areas has left many large urban areas abandoned or vacant. When looking to revitalize these cities, substitute industries often play a major role (Pallagst, 2012; Harkavy and Zuckerman 1999). Previous research by the authors made clear that revitalization efforts often focus on green infrastructure, in particular utilizing vacant properties for commercial uses such as urban gardening, farming, or agriculture (Pallagst, 2013; Pallagst forthcoming). Vice versa vacant or abandoned urban areas offer both, the potential for a sustainable transformation of former polluted sites (Vargas-Hernández 2011), and for creating jobs in new emerging areas thus transforming the identities of places.

The US city of Flint, one of the major cities caught in a long term spiral of economic decline and being governed under conditions of austerity, has brought about the urban planning category 'green innovation areas' in order to implement creative and innovative solutions in existing vacant spaces (Pallagst et al., forthcoming). Potential uses in these much debated areas are not fixed, but should explicitly be experimental and innovative. So far they might range from extensive greenhouse uses to less extensive clover fields, but their potential is not yet fully explored. The implementation of new and innovative modes of production in the urban realm is so far not represented in research for urban areas, in particular when development schemes like bioeconomy are considered. Here, issues and land use conflicts, often raised by civil society, might extend towards nuisance, over-exploitation of space, and rising land prices, leaving many open questions for urban research. This is exacerbated for instance in the Mexican realm, where, traditionally, in many areas public policies have been imported and imposed by external pressure without considering the local conditions, leading to high levels of influence of and power of economic and / or political interests and provoking serious conflicts.

The joint German-Mexican research presented here aims at scrutinizing the use of vacant inner city spaces as green innovation areas – discussing their potentials and detecting possible risks for implementation in shrinking cities.

2 STRATEGIES APPLIED IN THE US CITY OF FLINT AS A STARTING POINT FOR INVESTIGATING GREEN INNOVATION AREAS

2.1 THE GENERAL CONTEXT OF SHRINKING CITIES

Shrinking cities used to be a taboo topic, not fitting into the agenda of local politicians, who wanted their cities to be growing and prosperous, resembling growth machines. According to Oswalt (2006), more than a quarter of the world's metropolises shrank in the 1990s and this will continue to increase, notwithstanding the on-going urbanisation processes. Shrinking cities have been a stigmatised topic in planning for a long time. However, the discourse in planning in Europe, in particular in Germany, actively takes on shrinking cities, and extensive literature has been written on the topic (e.g. Bontje, 2004; Gestring, Glasauer, Hannemann, & Pohlen, 2005; Häußermann & Siebel, 1988; Siedentop & Wiechmann, 2007). In the USA, the academic discussion is catching up as more and more scholars are investigating the trajectories of urban shrinkage (Beauregard, 2003; Hollander, Pallagst, Schwarz, & Popper, 2009; Ryan, 2012). In view of the shrinking cities reality in planning, one has to ask if the one-sided focus on

growth in planning is over. The challenges of shrinking cities seem to have the potential to trigger change in planning cultures and planning styles.

In search of planning strategies to deal with shrinkage, policies, plans, and projects have been initiated with different approaches, such as urban regeneration, urban redevelopment, and urban renewal, and all of these efforts try to tackle shrinkage-related causes to reverse or manage the downward-spiral process. These measures can serve as part of a planning strategy for expansion as well as a strategy for managing decline. The common denominator is their focus on improving the quality of life in the respective area.

Once cities have accepted that they are shrinking, they will most likely plan for decline. Among these strategies are right-sizing and greening, where blighted areas and abandoned quarters are turned into different forms of interim or permanent uses such as wilderness, community gardens, urban agriculture, and parks—thus creating new opportunities for open space and new landscapes while at the same time enhancing the quality of life for residents.

Despite merely dismantling the urban fabric, new opportunities for sustainability and quality of life might arise out of the shrinking cities phenomenon. Among them is ‘applying the green’ as a model for planning and revitalization. The example of Flint can be viewed as an example of how a shrinking city can turn away from an existing growth paradigm.

Greening and green spaces have gained significance in recent years both in growing cities and in shrinking cities, assigning greening the status of a tool with strategic urban development potential (Reimer et al 2015). The term ‘greening’ is used here as a strategic approach that aims to develop green infrastructure along with supporting environmentally and socially acceptable practices at the national, state, regional, and local levels.

How does this relate to the specific situation of shrinking cities? As shrinking cities embed huge conversions of former brownfield sites into green spaces as part of their right-sizing strategies, greening might be of particular and growing importance for shrinking cities. By definition, greening in shrinking cities involves the regeneration of former industrial sites for new parks, community gardens, restored habitats, flood-mitigating measures, water treatment plants, and municipal agricultural land, combined with the integration of existing green spaces (Schilling & Logan, 2008). Furthermore, greening can include the transformation and reorganization of road transport, the expansion of routes for pedestrians and cyclists, design measures to beautify the urban environment, promotion of urban gardens and farms, as well as the deliberate demolition of derelict buildings, which can be replaced through open spaces and sustainable planning policies (Adelaja, 2010).

Greening has the potential to generate benefits throughout all social, economic, and environmental areas. In fact, many of the heavily damaged and devastated areas of urban regions of shrinking cities have great potential for implementing greening measures. Accepting the fact that some areas cannot be considered for further development and instead should be transformed into a network of green spaces, hiking and walking paths, community gardens, and parks is a suitable requirement for the long-term need to deal with shrinkage. In addition, green infrastructure improves the quality of life of local residents, provides recreational opportunities, and increases the property values of neighboring homes (Schilling, 2007). Furthermore, investment in green infrastructure can represent complex economic benefits for the city and thus boost the economic growth of the city and its region.

2.2 THE FLINT CONTEXT OF GREENING

Previous research by one of the authors (Pallagst, 2010) investigated shrinking cities in the USA in order to gather in-depth knowledge about experiences with applying strategies to steer the development of shrinking cities with the example of Flint/Michigan. During the course of the research, greening turned out to be of special importance as a future development path for shrinking cities. Hence, Pallagst further investigated the case of Flint in 2014 with a specific focus on aspects of greening integrated into the new master plan of the city (Pallagst et al, forthcoming). The master plan developed by Flint displays a strong focus on greening embedded in a context of neighborhood stabilization.

The reason for investigating Flint was—among other aspects—the suggestion of the new place type category ‘Green Innovation Area’ in the master plan. The new master plan was developed with a bottom-up collaborative process involving numerous suggestions by the citizens. The plan proposes several aims including citizen-based strategies by encouraging small businesses, developing community assets, and strengthening neighbourhoods. Based on existing vacancy rates, designated development zones were identified throughout the city, including a zone for residential and commercial development, a right-sizing zone, and a zone for residential demolition. The latter were declared as ‘Green Innovation Areas’ (see Figure 1), where formerly residential areas are to be converted to urban agriculture. In particular, green infrastructure is intended to strengthen Flint’s position as an employment centre at the neighbourhood level.

Figure 1: Envisioning the place type ‘Green Innovation Area’
Source: City of Flint (2013): Imagine Flint, Masterplan, p. 33

However, interviews with land bank staff and city officials in 2014 made clear that implementing the new measures is highly dependent on the commitment of stakeholders, in particular the city government and community and neighbourhood groups. Due to the diminishing tax base and high costs for maintaining infrastructure, the city government is in need of new forms of community-based governance and co-production, where community and neighbourhood groups shape the city’s new green spaces step by step. However, due to soaring debts the city of Flint was placed under state management with an appointed emergency manager steering the city’s financial situation, making any type of governance more complicated.

Innovative ideas might have the potential to attract new businesses, and even research and development, but these might at first be rejected by inhabitants in these areas. Residents still residing in the areas find it hard to adjust to the idea that their formerly urban neighbourhood will soon be ‘de-urbanised’ and turned into green space with a use yet to be determined.

3 GREEN INNOVATION AREAS (GIA) AS A DEVELOPMENT PATH FOR MEXICAN AND GERMAN CITIES?

Based on the insights of the Flint case with the yet to be defined category Green Innovation Areas, the authors initiated a joint German - Mexican research project which will be outlined in the paragraphs below.

3.1 THE GIAGEM APPROACH

Following the National Research Strategy “BioEconomy 2030” of the German Federal Ministry of Education and Research, an interdisciplinary approach is considered necessary which ties in with aspects of societal change – involving different stakeholders in a knowledge exchange and by bundling individual research topics. In addition, approaches for regionally- and locally-adapted land management and decentralized

approaches should be tested (German Federal Ministry of Education and Research, 2011; Bundesministerium für Ernährung und Landwirtschaft, 2013). Major challenges lie within in a sustainable

use of natural resources, and in supplying land for bioeconomic uses in a way that minimizes land use conflicts (Bundesministerium für Ernährung und Landwirtschaft 2013). What would that imply for establishing bioeconomy in an urban realm?

Traditionally, public policies of bio economy have been imported and imposed by external pressure on México without considering the local conditions, leading to high levels of influence and power of economic and / or political inmates and provoking serious conflicts. Consequently, it is required to formulate policies, strategies and regulatory frameworks in a country with weak governance.

As mentioned in the introduction, shrinking cities often turn to substitute industries to create a new economic basis. The implementation of new and innovative modes of production attached to a bioeconomic development scheme in the urban realm is so far not represented in research for urban areas. Issues and land use conflicts, often raised by civil society, might extend towards nuisance, over-exploitation of space and rising land prices, leaving many open questions for urban research when it comes to implementing bioeconomic uses in urban areas. Nevertheless, bioeconomic development in urban areas might be a vital source for sustainable development perspectives – in particular in shrinking/ old industrialized cities thus enhancing the quality of life and economic perspectives for citizens.

Already in 2007, Jordan et al called for a more integrated and sustainable approach towards bioeconomic uses: “Financial and policy support should be given to the multi-stakeholder processes of learning, deliberation, negotiation, and experimentation that are needed to establish and evaluate research and demonstration projects” (Jordan et al 2007: 1571). In the same direction goes the discourse of a co-creation of society and biotechnology: First attempts in this respect suggest a quality based agricultural production based on regional/local food chains and a ‘strategy of territoriality’ based on sustainable land uses (Levidow 2008). The concept of a regional bioeconomy has since then taken shape with further research studies, such as where examples of urban gardening in the city of Berlin are showcased as best practices of bioeconomic uses (Ernst & Young 2014). Nevertheless, a discourse on the potentials and strategies regarding bioeconomic uses in postindustrial cities is yet in its infancy – let alone a means of implementing bioeconomy as a land use type in urban planning and development processes and decision making.

As highlighted in part 2 of this paper, the US city of Flint, one of the major cities caught in a long term spiral of economic transformation and decline, has brought about the urban planning category ‘green innovation areas’ in order to implement creative and innovative solutions in existing vacant spaces. The hypotheses underlying the research presented here is that leveraging vacant inner city spaces could offer novel solutions for industries such as bioeconomy, and kick-start urban transformations in a strategic way. As part of a German-Mexican research collaboration, the project GIAGEM (Green innovation areas in Germany and Mexico) aims at enhancing the use of vacant inner city spaces as green innovation areas for bioeconomic uses and their potentials for implementation in German and Mexican cities. It investigates the following research questions:

1. Which key knowledge transfer aspects regarding green innovation areas can be derived from ongoing projects (Germany, Mexico)?
2. What are the legal, administrative, economic, and societal conditions for green innovation areas and for developing areas for bioeconomic uses in Mexican and German cities?
3. In what way can existing approaches such as green innovation areas serve as prototypes for other cities (toolkit)?
4. Which areas for further research can be identified by the partners, setting the frame for coordinated projects?

The main output of this research will be a roadmap defining the different steps in order to prepare cities and local communities as well as SMEs in planning and decision making processes to implement bioeconomic uses in urban areas as an innovative and sustainable urban land use.

3.2 METHODS OF THE GIAGEM RESEARCH

Methods applied in the frame of the project GIAGEM include qualitative and quantitative approaches building on the individual competencies relating scientific and operational practice in urban development

and comparative research and urban transformation processes. A literature review was employed for data acquisition of green innovation areas as potential for bioeconomic uses. In addition, a comparative model for the German and Mexican projects and cases was developed, outlining basic requirements and indicators for GIAGEM. In addition, comparative research methods will be applied for studying the projects in order to identify strengths and weaknesses of previously applied strategies for green innovation areas. These factors will enable a learning process on green innovation areas, and on different strategic approaches on how to deal with this space for bioeconomic uses. One research workshop (in Mexico), offered a platform for discussion of concepts and approaches among researchers an interdisciplinary mode: engaging both fields: shrinking cities/urban development and bioeconomy. The results of the comparative projects and case studies will be evaluated and validated in terms of the analytical frame. On this basis, strategies and policy recommendations will be derived.

3.3 FIRST INSIGHTS IN GIAGEM CASE STUDIES AND RESULTS

One of the first steps in the projects was to define what Green Innovation Areas could or should be. Thus the authors came up with the following definition:

‘Green Innovation Areas (GIAs) are a new kind of land use type with the purpose of revitalizing vacant or abandoned spaces. GIAs are locations for new innovative uses which are not yet specified, yet they are of experimental and innovative character. The range of uses can be attributed to the area of bioeconomy (among others). GIAs address a number of public, private and civil society actors. They aim in particular at connecting the communities’ and the entrepreneurs’ interests by means of long range land use planning and sustainable land use allocations. In doing so they support two aspects: sustainable and land conscious settlement planning, and implementing bioeconomic (or other entrepreneurial) uses in urban revitalization processes.’

In terms of case study research, the project GIAGEM is still work in progress. Both teams, German and Mexican, have identified preliminary cases to be investigated.

Among the German cases currently being examined is ‘Fresh Sea Fish Farm’ located at Völklingen. Increasing demand for fish worldwide led to overfishing. Aquaculture thus offers an alternative to satisfy demand & reduce the ecological footprint. Located on a former coke plant, the area has undergone a tremendous redevelopment process initiated by the city government. But, this process was characterized by a highly contested mix of over-ambitious goals and mismanagement. Despite its innovative approach, the project is still stigmatised by the bad image of its development phase.

Among the Mexican cases being investigated is the ‘Parque Agroecológico Zapopan’, a community based urban farm located in the city of Zapopan/Guadalajara, Mexico. The ‘Parque’ is considered an innovative public space that combines the direct participation of the community within an urban farm project with practices that support the culture of sustainability as well as training workshops on different agroecological themes to generate a unique space in the city open to all citizens. The agro-ecological park seeks to better integrate the relationship between landscape and city in a novel way. With a model of reforestation of the public spaces with the use of species edible, usable and adapted to the habitat. It advocates for educating a new generation of environmental activists. It thus offers a model of community development that includes the formation of citizen leaders committed to their environment.

Both cases show different approaches towards dealing with abandoned spaces – the German case started as a top-down approach, and is now entirely privatized; the Mexican case is based on cooperative sharing. During the course of the research, a stakeholder based analysis will offer more in-depth insight into the opportunities of GIA in urban development and revitalisation efforts.

4 PRELIMINARY CONCLUSIONS

Applying green innovation areas as a revitalization tool for shrinking cities still needs to prove if it is suitable as a model for future development and revitalization in search of a new quality of life. In this regard, Nassauer and Raskin (2014) observe that ‘...the spatial scales and temporal processes of

abandonment and vacancy in the most highly vacant cities may present thresholds representing socio-ecological dynamics that call for novel planning and design approaches' (p. 250).

Research questions which still need to be addressed in terms of green innovation areas are:

- In what way should the new green innovation areas be developed: As grassroots movements? As new employment opportunities for small and medium sized enterprises? As spaces for highly specialized research and development?
- How can social capital be leveraged, potentially in the context of co-production and co-sharing of green innovation areas, and be utilized in shrinking cities?
- In what manner can the development process of the new green innovation areas be governed, and by whom?

ID 1590 | REGIONAL INTEGRATION IN ETHNIC AND RELIGIOUS CONTEXTS: TAKING GERMANY AND CHINA AS EXAMPLES

Zhaoxi Zhang¹
¹Tongji University
xi-527@qq.com

ABSTRACT: Recently, caused by the precarious situation ,a large quantity of refugee are facing a immigrant condition, which is one of the major city development problems in the European region. It also brings social, religious and cultural integration to receiving country, which will be a new challenge in the future urban planning. As we know , the effective regional development strategies to consider different religious and cultural backgrounds will benefit urban stability, harmony and diversification. So this paper will analyze the developmental experience of Germany and China, comparing the referential value of different regional integration strategy under the East and West context. Germany, for example, new status policy protects a large number of refugee camps in most cities, which also makes change to city resource allocation and facilities utilization , as well as urgent need of residential projects and new requirement constructions. Taking Germany as an example, we can see what kind of influence this "top-down" policy will give to city. Compared with China which is another political system, as a multiply nationality country, there is a long history about regional integration in China. Taking Xi'an Huimin Street as an example, to discuss the pros and cons of the "bottom-up" self-built development model.

1 INTRODUCE

Partial precarious situation and intensive regional relationship especially in religious areas arises a critical discussion about regional integration which is one crucial problem in European stability. Regional integration would contribute to territorial cohesion , and both of them are the premises of national cooperation and economic growth, such as Europe 2020 strategy, which explicit the value of territorial cohesion and its meaning in future development. Thus the integration in some regions of ethnic conflicts and religious problems is worthy to getting much more attention.

2 THE PROBLEM REGIONAL INTEGRATION WILL FACE

Involving divergent social group and cultural background, the regional integration is not just a simple planning problem but a serious social problem, the core point of which is about “people”.

For new comers, after enduring different factors like family destroy from war, they have to suit new environment not only living environment , but also social atmosphere. So how to make use of their familiar collective memory and community life to conquer personal psychological barriers and build new life circle becomes a central question. For local people, they will meet more different new out-comer groups which mean social resources like working opportunities, social welfare and education will be distribute again. Obviously, how to make a balance between different groups and culture and benefit form each other in order to build health relationship gets increasing concerns.

No matter for local residents or for the new, it is both a long-time process to coordinate each other and promote themselves' development, which emphasizes especially a powerful instructor and strategic framework to guide and carry out next step 's approaches . In following parts, writers will compare two different developmental examples to explain two kinds of regional integration policies: “bottom-to-up and culture -oriented development approach” and “up-to-bottom and economic -oriented development approach” .

3 EXAMPLE A: URBAN ETHNIC COMMUNITY IN CHINA

Due to the complicate situation of nationality in China formed from thousands of years ago , unity and stability is the theme and aim of each age past. After the establishment of P.R.C, the policy about ethnic minorities have been regarded as the fundamental national policy and been implemented for 68 years (There are 56 ethnic groups , except Han race, another 55 ethnic groups are called ethnic minorities), fully Carrying out the ethnic regional autonomy system. We insist on Opposing oppression and discrimination ,developing ethnic equality and unity, encouraging to establish different ethnic community in scales and types, especially in historical protected areas.

3.1 XI-AN HUI DISTRICT

“ Hui” is the name of Muslim people in China, which is also the third -largest ethnic minority. Due to their distinctive religious culture and eating habit, the majority of Hui people prefer to live in group, so there are many hui settlement areas in northern Chinese city like Beijing, Tianjin and Xi'an. Xi-an Hui district is a typical ethnic community in city and already have been formed for thousands year.

3.1.1 HISTORICAL DEVELOPMENT

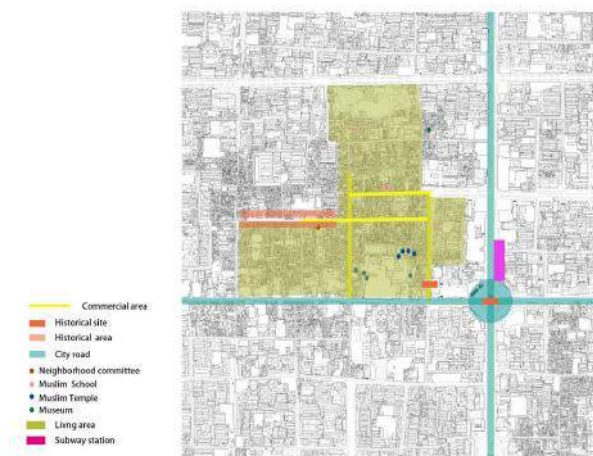

From Han dynasty(around 202 B.C), After ancient silk road formed, Chang' an(ancient name of Xi'an) as the capital city had become the start point of Silk Road, so it attracted a large amount of Muslin came from western Asian and middle Asian countries to do business and settle here who also intermarried with local woman and formed the pioneer Hui group in Xi'an. At the beginning of Song dynasty(around 960 A.C),because of the stop of silk road trade, those ancient Hui group had to build their settlements including Mosque and residential and commercial areas and lead to new Central Plain life. During the war around

Yuan dynasty (around 1271 B.C), a large number of Arabian and Persians came to Central Plain following troops and then settled here. Though thousands years of development of agriculture and economy, Hui group in Xi'an and their habitat had trended to stable situation.

3.1.2 ENVIRONMENTAL SITUATION

Hui district is located in the center area of Xi'an city which is near the historic drum-tower. This district is limited by urban road and separated from another residential areas. So the inner environment of the district is different from outsider. There is the only one entrance connecting this district and city.

The structure of Hui district is like a small village in the city, including commercial street also is main street , residential area , several mosque , school and neighborhood committee. These facilities and services can basically satisfy local people's living request.

Commercial street: The main street is the commercial area not only in this district, also famous around Xi'an city and attracts city residents and tourists increasingly. Various restaurants and booths along the street which is almost operated by Hui people also have along family business history.

Residential area and buildings: Living area is behind the street , using traditional building layout like “street-shop-yard-building-yard-street”, each unit 's inner space organized by the count yard is the family living and working space. But after many years of modern development , increasing population and numerous external population have made local people start to build additional construction on the original buildings in order to get more rent.

Mosque and religious life : The mosque usually located in the joint point of road . Some of them were built in Ming dynasty, regarded as the sacred symbol. Grand mosque is the largest and most well -known one among them. Hui people 's daily religious activities and festival events usually happens in such places.

School and neighborhood committee: The whole Hui district is managed by local committee and be regarded as a community. Local committee will in charge of social work like social insurance , demographic census and social health care insurance.

Traffic situation: Because of old urban district morphology just considering walking as the main commuting way at the beginning , after motor transportation age coming, the street space becomes crowded and chaotic. Lacking of strict traffic policies and traffic plannings , cars ,good vans and electric mobiles also threatens pedestrians' safety .

Recreation Environment: In the main road, Crowded situation and increasing number of tourists does not help to build appreciate environment due to lack necessary facilities like duty water and garbage processing stations and advanced public infrastructure. Numerous public areas around residential areas are also used in commercial way like roadside markets .

3.2 THE RELATIONSHIP BETWEEN XI-AN HUI DISTRICT AND XI'AN CITY

City context and city development strategy are essential to the vision of district as we known. Especially Xi'an, having experience 13 dynasties ' capital , is the symbolized city of "Han "nationality culture. In such urban background, respecting the diversity of culture is fully meaningful to regional prosperity because of favorable social environment and stable economic foundation.

The inclusive attitude given by city to Hui district provides them with more chances to develop local culture and economic. Such as cuisine culture, the main industry in this area is catering services, and restaurants are the main operational business, which are regarded as the most busy catering commercial street in the whole city . Apart from hui people's smart brain and expert business skill, its popularity also depend on government 's support. Even in official assertion, this district is regarded as a recommended place to experience Xi'an various historical culture, which also be beneficial to increase local people's income and provide more job opportunities.

More attention also brings more opportunities and then new development. In recent 20 years , due to mountaining torists flock in Xi'an city, Hui district has become the most attractive point, so local government also give more support to distirct development such like beautifying the street environment , improve the facility, import more financial support.And now, because of "the Blet and the Road" national policy , The position of Xi'an and Hui nationality street also be highlighted.

Nowadays, the Hui district have already become a necessary part in the city, they shared tourist resources and benefit image between each other, also bring a well-being culture and social environment for local people no matter nationality.

3.3 BOTTOM-TO-UP AND CULTURE -ORIENTED DEVELOPMENT APPROACH

Such development mode explains the natural developmental way and "bottom-to up" organizational method which would also inspire researchers to think about the value guidance during the long time process. Spontaneous formation: their natural formation process gives a stable basis about geographical relationship and family connection to long time self-organization. The strong historical accumulation also gives powerful belief and collective memory that will continue to influence the group in future.

A Self-help and management community: Independent environment and independent living habitat gives Hui people enough freedom to deal with the inner staff. Hui nationality has their admitted leaders, prestigious families and core organization. They can decide their staff independently, including the right to deal with their buildings and live like in traditional village. Area with spacial culture feature : Culture can strengthen community cohesion among group because that culture embeds in people's living habit during long history which leads to common sense and collective behavior at the same time, influencing personal sense of belonging. On the other hand, such collective action will also make their culture impressive then improve cultural influence.Refocusing on culture is not only a way to define themselves, but also to gain more respect from others.

3.4 LIMITS AND SHORTCOMINGS

In spite of above advantages, there are still some limits restricted to management. The current building appearance and structure is not well, but even government want to do some revolutions and change district layout, it is difficult to coordinate needless to say to take some measures due to the local self-management policy and governments' limit right. It is not easy to realize unified planning and large construction.

4 EXAMPLE B: REFUGEE POLICY IN GERMAN

Nowadays, refugee crisis has been regarded as the most difficult challenge since the second world war. Increasing number of refugees is flocking into European Union countries. Among these countries, German accepts the largest number of refugees and plays a leading role in helping other EU countries to solve the

refugee problems. But recent terrorist attack arises public's scare, the skeptics that come along also challenge the government's authority. So what is the double sides of German refugee policy and what can it bring to city's development.

4.1 CURRENT SITUATION

The German refugee policy has brought new newcomers to Germany and met new ethnic integration. Throughout history, we can see , after the second world war, a large number of Turks had been introduced to German and had lived in German through two or three generations' integration. For decades, although the German government try to make Turkey's Muslim integrate into the mainstream society through policies, but consciousness difference and national identity make it difficult. At present, the second fusion led by refugee policy has experienced test. Since January 1, 2006, Germany will start to repatriate those refugees who have not applied for asylum or without valid certificates . This new refugee policy is designed to control the number of refugees in Germany. Actually , in the past few years, Germany had insist on carrying out the "open welcome" policies for refugees, even public would call for the government to launch humanitarian aid. But the open situation had been changed after continuous terrorist attacks incited by extremist hided in the refugee group. And those attack events also arose public 's scare around Europe. Thus German government abandoned the friendly welcome refugees policy, and changed to "tightening" refugee policy. We can see the integration happened in German is governed by the policies, a kind of top-down approach oriented by policies. Political decisions and the public 'willing will influence the process of integration to a large extent. Especially in the western society, the public will have a great effect of policy implementation. So valid policy is the key to solve integration problems and get support from the public then to enforce top-down policy.

4.2 BENEFIT OF TOP-DOWN POLICY

Facing the refugee crisis all around Europe, such top-down and policy-oriented approach could control the situation better. From the international scope, it can balance the conflict and keep overall stable situation, and from national level , it can regulate resources and financial resources in order to supply more support.

4.2.1 GOVERNMENT AND FINANCIAL SUPPORT

In 2015, The federal government have taken 1.1 million refugees into Germany. According to the standard of placement, the government will afford 670 euros per person per month as refugee bonus, so it will cost vast sums for governments. We can see , related laws and regulations are the basis of the policy 's enforcement which can maintain stability and balance. Government can call up force and money to regulate the policies.

4.2.2 REFUGEE COMMUNITY CONSTRUCTION

Due to the existing camps cannot meet the demand of refugee resettlement in real situation. So the German governments and the state governments plan to rebuild the refugee camps in order to resettle refugees, like reusing abandoned barracks and old facilities. Then new refugee settlements appears and new ethic inhabit forms, which will also influence current urban spatial framework.

4.2.3 GUARANTEED EDUCATION AND BENEFIT

In order to help refugee group to integrate into German society, language courses and child care have been set, including social activities and visiting activities. But the language barrier and culture distinct cause more difficulties than people thought.

4.2.4 PROBLEMS IN REFUGEE CAMPS

How do the limited number of camps satisfy the increasing demand of large flocking refugee? Except building new settlements, most of refugee had to live in crowded room with dozens of people. Facing such lager social group, although this phenomenon is inevitable, it is difficult to keep the order, needless to say humanism concern and cultural construction.

4.2.5 DEPRESSION AND PSYCHOLOGICAL PRESSURE

Actually Refugees have beard the greater pressure in their living. For example, they are facing complex procedures and waiting for long time to eager to get the identification certification, and they do not have chance to work and just can stay at camps. As many reports explored, the poor living condition in the camps and helpless management system always lead to frequent incidents such as violence, theft and rape. It seems like that they escape from the war, but the fact is still suffered, their dream for better life still have not been came true.

4.2.6 THE LACK OF A MUSLIM CULTURAL ENVIRONMENT

In the new and unfamiliar environment, loosing their original cultural environment cause an embarrassed situation for them, which means loosing emotional sustenance and loosing their spiritual support. On the other side, their inherent national consciousness makes it is difficult to integrate, especially when meets language and cultural barriers. For themselves, they do not have ability to build a new Muslim homeland for themselves. So the missing geographical relationships makes such camps be a temporary shelter rather than a home.

5 CONCLUSION

No matter which kind of approach, the main problem is to solve people's living problem and build stable social environment. Though the "down-to-top" strategy, we can conclude that common cultural background is the basis of common living. So it is essential to build ethic community and management system. Similarly, though the "top-to-down" policy, we can see the importance of powerful national indication and the meaning of building spiritual home and supply cultural environment.

HIGHLIGHT AND LIMITATION

Though comparing two different ethic integration method in eastern and western context, the writer attempt to conclude the valuable approaches and views. And it is creative to propose these two approaches: "from down to top and culture-oriented" and "from top to down and the policy-oriented. In the further study, writer suggest the different urban spatial framework under these two approaches can be discussed deeply. Then the write has to admit the limitation of the article, due to language and culture problem, this article does not discuss deeply about the second part.

ID 1596 | FROM MACRO-LEVEL POLICIES TO MICRO-LEVEL PRACTICES: CHANGING GLOBAL ECONOMIC LANDSCAPES AND PROLIFERATION OF MIDDLE CLASS GATED COMMUNITIES IN MEXICO

Emma Regina Morales Garcia de Alba¹

¹University of Sheffield

trp11erm@sheffield.ac.uk

ABSTRACT: Gated Communities are a global phenomenon that has gained academic attention in the past three decades. The discussion about these fortified enclaves may have started in the United States of America (Blakely & Snyder, 1997; Marcuse, 1997; Davis, 1998; Low, 2001), but in the last decade, the debate has extended worldwide, particularly in contexts of large socio-economic disparities like Latin America. Gated Communities in countries like Mexico are no longer a “privilege” of the affluent classes but it has become a common choice for middle class groups. The conditions of insecurity, violence, and growing distance between socio-economic groups have normalised the presence of these enclaves to the point that municipal authorities, developers, financial institutions, and citizens, consider them as a desirable residential option for orderly urban development. The process of normalisation of gated communities in Mexico for the middle classes is not a simple matter of choice. On the contrary, the emergence and proliferation of gated communities can be linked to the policies promoted by global financial institutions. The proliferation of these large-scale enclaves for the middle classes could only happen in a context of neoliberal urbanism. Since the 1990s, national economic, housing, and urban development policies have aligned to global financial interests by deregulating planning, changing land tenure options, financialising housing development, and promoting a debt-driven economy (Zanetta, 2004). The “borderless world” of free market housing strategies is actually contributing to the creation of physical walls, fences, and gates segregating people by income. Segregation by design has become common in Mexico with tangible and intangible borders and the governance problems and tensions are already taking a toll. The growing inequality in the country is increasing strains between social groups fuelled by fear. Aspirations and anxieties are changing everyday practices decreasing shared spaces and increasing spending in security. The promised wall along the Mexican border by Trump is not that different from the walls separating poor neighbourhoods from middle class and high-income gated communities in most Mexican peripheries. The experience in Mexico where global economic policies have shaped modern peripheries can serve as an example to understand how trends are shaping political, economic, and spatial relations. European countries are known for urban development and housing policies that foster diversity, inclusion, multiculturalism, and sustainability. However, the current political context of fear, far-right movements, and anti-immigrant groups might aim to promote divisive urban developments like those in Latin America. Learning from the proliferation of middle class gated communities in Mexico can provide some hints of the challenges and the risks of these sort of enclaves in terms of urban governance in the long term.

1 INTRODUCTION

The phenomenon of gated communities has been analysed in academic literature since the late 1990s and early 2000s (Blakely & Snyder, 1997; Marcuse, 1997; Davis, 1998; Low, 2001). The earliest literature focused on socio-spatial segregation and the appearance of exclusive fortified enclaves for the affluent groups. However, the presence of gates and fences in housing developments has extended to different socioeconomic groups and there are examples of this all over the world. The analysis of these enclaves has left the residential realm, incorporating in the discussion more complex territorial challenges including governance, management, politics and social cohesion. In Mexico, gated communities are not new; there are examples of their existence for high-income population since the beginning of the 20th century (Scheinbaum, 2010; García P. & Hofer, 2006). However, in the past couple of decades, these residential fortified enclaves have become normalised, particularly for middle-income groups. In my doctoral thesis, I argue that the proliferation of middle-class gated communities in Mexico is not only a matter of choice of individual families self-segregating, but a complex combination of policies and practices, where municipalities, developers, and residents have more incentives to build, manage, and live in this sort of developments than in the traditional open street neighbourhoods in the inner city.

During my research, I found that residents, developers, and even public officials justified the “normalisation” of middle-class gated communities in Mexico due to the growing concerns in relation to crime and violence in recent years. However, the roots of these spaces can be found in transnational economic interests. After important efforts in the 1970s and 1980s of state-funded programs aimed at the most vulnerable population and the creation of valuable welfare institutions, Mexico’s political and economic policies drifted to an open neoliberal model, with clear socio-economic distinctions, and a more tangible spatial segregation. The presence of fences, gates, and other security features have become “the new normal” and this has had serious implications in social interaction, urban management, and overall urban governance, and that is why it matters to understand why these enclaves exist and how they became normalised. In the early 1990s, as part of the North American Free Trade Agreement (NAFTA), there were important changes in Mexican economic, political, housing, and planning national policies, connected to recommendations from global financial institutions like World Bank (Moreno-Brid, Pérez C., & Ruíz N., 2005; Vidal, Marshall, & Correa, 2011; Zanetta, 2004). The changes in land tenure and housing provision policies had clear macro-economic goals, but its impacts went far beyond the national housing and planning systems, reaching individual households. An open campaign to improve the quality of life of all Mexicans was expressed in reaching a middle-class status, which was tangibly shown through privately owned automobile, homeownership, and access to privately run services like education, security, health, etc. (De la Calle & Rubio, 2012; Walker, 2013). Middle-class gated communities boomed under these global economic policies, engaging thousands of families into the challenges of a debt-driven economy. In my thesis, I propose that the discussion about middle-class gated communities should address all these issues beyond the fortified enclave, and that is why in my research I focus of “gatedness”, a practice-based analysis of gated communities.

Middle-class gatedness or the proliferation and normalisation of gated communities for middle-income groups in Mexico is a relatively recent phenomenon, since middle classes lived until the 1980s and early 1990s in open-street neighbourhoods in central areas. In the early 2000s, an ambitious national housing strategy contributed to the creation of new suburban residential enclaves around the most important cities. Around the same time, conflicts between drug cartels and organised crime became more visible, and stories about kidnappings, burglaries, and extortions became more common. The “talk of crime” as Caldeira calls it (Caldeira, 2000), became part of daily conversations. In the last decade “talk of crime” passed from coffee shop small talk to Facebook timelines, WhatsApp groups, and dramatic media warnings. After living in the UK for a couple of years, I was very surprised during fieldwork to see how this fear had grown amongst my closest friends and family members, and how it was affecting everyday lives and choices. Restaurants were no longer chosen for the quality of the food or service, but according to safe parking conditions. Residents interviewed in the gated community Lomas de Angelópolis in the metropolitan area of Puebla-Mexico in 2013, shared significant security concerns that “forced” them to leave their old neighbourhoods, even though they were aware that the quality of the housing, location, and overall facilities were satisfactory. Fear of crime and violence has made every other person a potential threat, and gated communities embody this need to segregate physically from them.

Mexico’s metropolitan areas are full of fear-driven spatially segregated expressions, and they have reshaped not only the urban structure of the cities but also the capacity of social interaction. The challenges and risks of these changes in urban and social relations relate to growing inequality and subsequently increase in crime, corruption, delinquency, and distrust. The current atmosphere of fear in Europe, widely spread by far-right and anti-immigrant groups, is threatening principles of diversity, inclusion, multiculturalism, and sustainability. These valuable principles seem almost impossible to attain in Mexico under current circumstances. In this paper, I will discuss the role of global economic policies in the shaping of modern peripheries and the role of fear and distrust in the reshaping of socio-spatial relations. The aim is to give a general idea of the risks and challenges of the normalisation of these fortified enclaves. The article is organised in two sections. The first section is about the impact of macro-level economic policies in micro-level housing practices, using the example of the proliferation of middle-class gated communities in Mexico. The second section is a discussion about the difficulties of “building bridges in a time of walls”. This section focuses on the risks and challenges that come with the normalisation of a “gated life” and how it makes it more difficult to accomplish just, inclusive, and equitable urban spaces.

2 FROM MACRO-LEVEL ECONOMIC POLICIES TO MICRO-LEVEL HOUSING PRACTICES: MIDDLE CLASS GATED COMMUNITIES IN MEXICO

Socio-spatial segregation is not new in Mexico; it can be traced back to pre-Hispanic times and the Spanish viceroyalty. The Mexican nation after the independence maintained pre-existing stratified social structures. Even after Spanish ruling, characterized by high levels of inequality based on race, ethnicity, religion, or origin, cities were organised in a socially segregated way (Scheinbaum, 2010). However, for centuries there were “shared spaces”, places where different social groups could meet, such as churches, parks, promenades, green areas, and even streets. In recent years, this socio-spatial segregation has become more tangible and the number of shared spaces has diminished importantly. The emergence and proliferation of gated communities cancels the possibility of physical cohabitation. The changes in land, planning, and housing policies in the early 1990s in Mexico contributed to the privatisation of urban development and the financialisation of social housing provision. These macro-economic policies have had a very determinant role in “gating up” society because the housing market was seen as an economic boost tool, and the presence of privatised governments, securitised environments, and isolation from municipal governments was seen as economically convenient.

The financialisation of social housing institutions like INFONAVIT, the national salaried workers’ housing fund institute, is an example of the drift in housing and planning policies, which contributed since the early 2000s to the extension of sprawling metropolitan areas. The outcomes of this sprawling model of urban development has brought serious problems in the provision of adequate public services, health, sports and entertainment facilities, public transport, security, amongst others. One of the main problems of the housing production process since the 2000s is that the federal goals were mostly quantitative, and the lack of qualitative standards contributed to low-quality housing production in inadequate urban surroundings. Most of the new social housing developments from the 1990s and early 2000s were built in unserved peripheral land surrounded by poor infrastructure and agriculture land. This condition contributed directly and indirectly to the emergence of gated communities for all socio-economic groups. The isolation from the city became a motivation for fortification. On the other hand, the financial incentives for developers and people interested in acquiring a house were mostly concentrated in new housing developments. Therefore, the combination of the two situations made it easier for middle-income groups to buy houses inside gated communities. The incentives were not only concentrated in financial possibilities to build and acquire, they were also promoted by poor peripheral municipalities with no resources to provide the services needed. Municipalities joined developers and even created ad-hoc planning regulations, so that these private investors covered urbanisation, maintenance, infrastructure, and security costs.

The increase in housing production after the 2000s indicates how profitable it became, bringing the main housing developing companies to the Mexican stock market. The economically focused housing provision strategies are far from the original constitutional aim of providing adequate and dignified housing for all. The economic forces and stakes are so high that they can be seen as a way of transnational spatial governance. In this borderless world, where geographic boundaries are less important than economic flows, the housing market can become a dangerous tool. The moment national housing policies abandon the goals of adequate housing and leave it to the market; the risks of creating unequal urban environments are bigger. The physical fortification of houses, neighborhoods, cities, and even countries are as much as a result to increased fear and security concerns, as a global financial market outcome. Political conflicts and social unrest have become a motif for displacement not just from war torn areas, but also from formerly safe inner cities.

The walls and fences have become the tool to isolate from the surrounding hostile conditions and therefore the entitlement for its use becomes increasingly acceptable. There are conflicting positions around walls and fences and Trump’s proposed wall in the Mexican border shows the complexity. The wall-building phenomenon seen from a middle-class housing development in Mexico seems acceptable because of the individual and collective interests protected. However, the same people condemn Trump’s proposed border wall. The normalisation of the residential gated community and the opposition to the border wall raises several questions, which show how hard it is to determine individual and collective “rights”. The issues around gun control are similar. Middle-class gated communities are filled with armed private security guards. Inside this premises it is seen as acceptable. However, every other person with guns outside the gates or privately securitised spaces like banks, shopping malls, universities and even parks, is seen as a threat. The same is happening in some areas within the European Union. Principles of diversity, inclusiveness, and multiculturalism are under threat because the fears, risks, and security concerns of the

few, are shaping the physical urban spaces for the most. Transnational planning strategies coming from Europe focus of adequate public transport, liveable housing, quality public spaces, but the reality of fear-driven and unequal urban environments like the Mexican one, prefer copying spatial segregation strategies from places like the US. The transnational planning influence has left the official planning models of land use, zoning, and densities and prioritised the discourses of security and economic growth fuelled by anxieties and aspirations. The influence in policy is no longer expressed in national, regional, and local laws and regulations, but rather on “supranational” markets that profit from such aspirations and anxieties. The new tendencies of governance in privatised government-run spaces like gated communities show the disassociation between the tangible territory within the physical walls and fences, and the real city outside the gates.

The housing policies of the 1990s in Mexico have already shown the short-term impacts of segregated urban structures, such as the disconnection between residents with local authorities, connectivity and public services problems, and also an increase in everyday expenses linked to transport, maintenance fees, and payment of other privately run services. The transnational planning influence we are observing in this case is not a formal one, but the construction of policies built on economic interests and meanings. Healey (2013) provides conceptual and methodological tools “for the critical analysis of transnational flows of planning ideas and practices” (p. 1511). In the paper, the author goes through different theoretical approaches from globalisation and international literatures, and points out that the analysis should focus on the flows, rather than the origin of the ideas. For instance, Mexican housing policies since the 1990s are closely linked to the recommendations from the World Bank to enable housing markets to work. However, as Zanetta (2004) points out, the Mexican government chose to ignore the parts of the policy recommendations that were inconvenient for their economic growth purposes.

The kinds of transnational flows can also get “lost in translation” and accomplish different goals. One example in relation to gated communities, is how new urbanism principles of design have been used by developers to market their private enclaves which sell quality public spaces, community life, and walkable areas. The discourses are “perverted” for particular interests. On one hand, new urbanism principles that would aim to accomplish inclusive and diverse communities become ideal urban exclusive design. The discourses are also perverted for real estate interests. The “compact city” discourse is used for isolated high-rise building projects. In the case study I used for my doctoral thesis in Puebla, I analysed a whole section of a gated community with high-rise buildings completely unrelated to any of the values and principles of compact cities. The flows of transnational planning lose its value in translation in terms of meaning, for instance “the right to the city”, used for decades by the most progressive planners has reached main stream and has been interpreted by mid-level public officials to push all sorts of policies, projects, and activities. The flow patterns are no longer unilateral, coming from an “accomplished” planning system into a “third world” or “developing” country. The flows move in different levels and networks. “Good practices” come from all over the world. For instance, Medellín and Bogotá have become world best practice examples of social justice with their public transport, public space, and cultural facilities projects. Porto Alegre’s participatory budgeting has been copied and adapted in several countries. Therefore, transnational flows of planning ideas and discourses come from all directions but are also “lost in translation” in all directions. Developers inside gated communities conveniently include those ideas, policies, and practices that fit their purposes and the lack of adequate municipal planning systems give them the freedom to define their own strategies.

When it comes to middle-class gated communities in Mexico, policies and practices intertwine with each other in connection with aspirations and anxieties. Urban policies are transformed to fit private developer’s interests. In addition, policies and practices are designed according to fears, security concerns, and special interest groups. The planning model in countries like Mexico are still promoting modernist ideals, which have proved detrimental for cities, like the investment in car-oriented infrastructure, suburban isolated life, and sprawl. This shows that even if planners have knowledge that the current housing and urban development model is not the best one, they are unable to change it because of the strong pre-conceptions and meanings of economic growth, security, and competitiveness that come with them. The micro-practices in household levels become a priority for citizens over the collective rights and benefits. Therefore, discourses and practices that shape policies are clearly defined and modified by meanings (Wagenaar, 2011).

The transnational planning discourses and practices in gated communities in Mexico bring the combination of twentieth century modernist urbanism, with millennial dream community life. The policy discourse analysis focuses on the mentalities and how they become institutionalized into practices (Healey, 2013, p. 1517). Gated communities are places of metaphors, perceptions, dreams, and avoidance for individuals in designed communities. The value of planning under the privatisation of urban development has lost its collective appeal. Forty years of institutionalised planning in Mexico has not convinced the population on the benefits of state planning, locating private urban designers into a more powerful level. The main concern in Latin American countries is not how to plan but how to manage. Since the problem is not getting things done but what happens afterwards, that is another reason why gated communities have become so appealing. Private governments assume the present and future responsibilities. Gated community designers bring all the new elements of the “creative classes” into their developments to bring the youngest and the hippest population. It is important to look at the attitudes, the interconnections, the ideas, and the perceptions. As Shove et al (2012) propose, social practices should be analysed considering the “competences, meanings, and materials”, which means that it is not only the capacity of the state to propose planning frameworks, but also the capacity to materialise them, and most importantly how actors interpret them. A diminished state under the influence of the privatisation of urban development is a serious governance threat with potentially high risks in the future.

Micro-practices are connected to macro-level economic policies. If we pay close attention to global financial institutions recommendations, we can track how their impact goes down to individual households. The Washington Consensus and its deregulation, privatisation of state roles, and commercial liberalisation can be identified in national laws, policies, plans and programs, but they are also identified in the increase of private automobiles, home ownership, consumer debt, and changes in consumer consumption patterns. The neoliberal policies in households is one of the mentioned risks, because economic uncertainty can potentially affect middle-income groups with the risk of losing everything they own.

The problem with aspirations and anxieties defining planning policies, ideas, discourses, and practices is that they can throw back unintended consequences. The issue about middle class gated communities in Mexico is that the whole concept of a fortified housing residential enclave with a private administration has not only become normal but “desirable”, particularly under the current perception of insecurity and violence, which means that under these circumstances it is extremely difficult to “bridge gaps”. In the following section, I will address this issue in detail.

3 BUILDING BRIDGES IN A TIME OF WALLS

In Mexico, gated communities have become so normalised for middle-income groups, particularly in suburban areas, that it would seem that this is the only valid way to accomplish the goals of habitability, security, quality urban spaces, and community life. For residents and potential buyers, security or at least the feeling of security is the priority number one. A fear-driven urban development is hard to modify because it would require changing people’s perceptions, attitudes, and behaviours. When we talk about building bridges in a time of walls, it is easy from a theoretical position to show the advantages from open, diverse, inclusive and multicultural communities. However, it only takes one story of “talk of crime” to make the exclusive, segregated, safe and reliable gated community more appealing. Mexican planning is a bricolage of local traditions and knowledge with imported policies and practices. Since the 20th century, there have been attempts to experiment with foreign ideas, from garden cities to smart cities. The problem is that these influences in the context of fear-driven development produce highly segregated spaces. In a recent smart city exhibition in Puebla, the large majority of the companies exposing their products were surveillance and security systems. Some visitors even pointed out that it was more a “big brother” exhibition than a smart city one. The transnational planning ideas of securitisation have found fertile ground in Mexico, and even people living in supposedly safe gated communities continue investing in CCTV systems, electrified gates, and other security items.

The risks and challenges of modern Mexican gated communities is not just in the shape of walls and fences but the inequality and the physicality of segregation. It is not only the increasing gap between the rich and the rest of the population, but also the super-stratification of middle to lower-income groups. Gated communities in that sense should be seen as a dangerous urbanisation model in terms of governance. Case studies all over the world help understand the challenges of the changing transnational political economic landscape. In the case of Mexico we can see how crises and political uncertainty are

shaping and reshaping the urban structure. The difference between Europe and America, and the north and the south are an opportunity to learn from each other's mistakes. Particularly under the challenges of urban governance, climate change and economic turmoil, as they do not respect geopolitical boundaries.

The Mexican middle-class gated community I analysed in Puebla during my doctoral studies can be seen as an "extreme case" because of its large scale and multi-clustered structure (more than 21,000 houses located in stratified mini-gated communities). The research showed that residents felt judged by outsiders and considered they had valid reasons to live in a gated community and it had nothing to do with the exclusiveness, status, and prestige drivers usually mentioned in literature. There were three main issues why these residents considered that gated communities are not only desirable but necessary:

1. Municipal authorities are unable to respond to their needs and they feel that private administrations are more reliable and provide better services.
2. Their family's safety is more important than anything else is and if it takes a wall, a fence, a security guard, a camera, and an alarm, these residents would not hesitate to pay for all of these, because it provides them peace of mind.
3. The ideal of a shared space for all sounds good, but they would rather live amongst "people like them". The residents I interviewed do not consider themselves racist or discriminatory but defend their right to hang out with people with the same interests and tastes.

From a policy perspective, it becomes very hard to promote inclusive urban environments, because the meanings attached to this model of "safe urbanism" is so strong. The "new normal" makes the traditional city undesirable because it does not offer the same elements of beauty, security, reliability, and infrastructure. The risks and challenges of these urban segregated structures is that once they become normal, people become "numb" and stop feeling or realising the conditions of disconnection and isolation. Gatedness is becoming so desirable that it is leaving the residential areas and reaching public spaces, universities, state facilities, etc. In Puebla, even bike lanes and public parks are being gated, because people feel safer that way. Public and private universities are incorporating more access control strategies and increasing their security budget to fulfil their students' expectations. The problem with this normalisation is that it makes it more difficult to make changes in policies and practices. Scholars and planners are interested in regulation that would prohibit this sort of enclaves; however, what we have seen in recent decades is that planning regulations only work when residents are convinced of their benefits. Otherwise, they will not try to enforce such regulations. Most residents in the city of Puebla value the presence of 24-hour security personnel or safe and closed environments. These become more important than location in relation to work, school, or public spaces. In my thesis, I propose that in order to change policies and practices, we should start focusing on meanings rather than regulation and planning instruments. The research in Puebla showed that as long as the meanings attached to projects gave them a positive feeling, there would be no opposition. Even though they knew the project was not complying to federal or state law. The clearest example was the construction of the International Baroque Museum designed by the famous architect Toyo Ito. It was more important to have an outstanding architectural project from a famous architect than protect one of the few spaces left for metropolitan parks and public green areas.

The normalisation of gated communities in Mexico, gives us a glimpse of how the new normal justifies patterns of behaviours and understandings and therefore political discourses. Presenting my research in European planning conferences has proved a very interesting opportunity since it made me realise, that even myself as a researcher, I had grown so used to these developments that I could not see some of the issues. It also made me aware of how many students from European countries found these enclaves as a completely different reality from where they came from. However, an interesting issue I found with my research is that even Europeans who would probably live in tower blocks in the central areas in their own countries preferred the gated options once they came to Mexico. In Puebla, in the case study I analysed, several real estate agents chose houses within the premises for Germans working at the newly built Audi factory or the executives at Volkswagen. The support for this choice was based on security concerns, but that does not change the fact that residents have found at ease in these enclaves and would not want to move out. So, how do you build bridges if the benefits of building walls seem so much better? Perhaps the answer is in everyday life practices and recognising the value of shared spaces. Not just green areas and parks, but shared spaces for education, health, culture, entertainment, sports, etc. Elements that make our everyday lives better that help us fight our fears and security concerns.

The walls separating the poor from the rich and even the high middle-income resident from the low middle-income resident seem like they are here to stay as long as the incentives to do something different are not as attractive. The Mexican border wall or a gated community wall does not fix any of the structural challenges our countries are living, it only makes people “feel safer” and modify social interactions. Empirical research about gated communities has shown that these places are not immune to crime and violence, the difference is the type of crime. The same happens with other border control strategies aiming to stop criminal acts. The border is not a mind-changing threshold that immediately blocks and changes behaviours. Meanings become more powerful than the tangible objects. What can we do to regain trust? What can we do to increase tolerance to difference? How do we change our relationship with the outside? Mexican planning is facing a very difficult phase. Traditional institutionalised planning has failed and private urban development has promoted segregation, exclusiveness, and social discrimination. This is the time to search for alternatives in times of uncertainty. The alternatives are emerging out of other global economic trend: financial instability. Millennials are choosing cohabitation and other shared spaces housing and working strategies. Weather this is a temporary trend or a real policy solution, we should be paying attention to the meanings and values of these shared economies and systems, but also the risks of financialisation of shared economies to avoid the downfalls of Uber and Airbnb. This is a time to include meanings in policymaking so that implementation strategies are more effective. This is the time to work with future scenarios that show us the benefits of inclusive urban spaces, and the risks and challenges of segregated fortified enclaves. This is the time to regain our capacity to feel and relate to the other outside of my immediate circle.

4 CONCLUSIONS

The effect of gated communities is a sort of “numbing urbanism” in the sense that we do not even feel anymore. It is not the problem of how fear is shaping our lives, but rather how it has made us numb. Willing to sacrifice our freedom, our choices, and our feelings for security is putting our cities at risk. The normalization of gated communities is not just about how we want to protect from outside dangers, it is also a tangible expression on how segregation, exclusion and spatial discrimination have become the new normal, and how this new normal is shaping people’s perceptions, actions, and practices, but also shaping policies and discourses. The Mexican government has been aiming towards the middle-classification of the Mexican population. This process of middle-classification of people was an attempt to erase the memory of poverty and large inequality that prevailed since the Revolution. However, instead of creating a common ground and space for all, the economic policies that shaped this thought, has also been directly and indirectly involved in the shaping of newly unequal cities and metropolitan areas. This is the time to rethink the way we understand public and private roles in urban development, but also an opportunity to shape policies through the understanding of meanings in order to make cities more livable.

ID 1636 | SPORTS MEGA-EVENTS AND URBAN LEGACIES: THE 2014 FIFA WORLD CUP, BRAZIL

Eduardo A. C. Nobre¹

¹Faculdade de Arquitetura e Urbanismo da Universidade de São Paulo
eacnobre@usp.br

ABSTRACT: The idea of organising Sports Mega-Events had been defended by strategic urban planners as a way to attract considerable public and private resources to be invested in cities. In this respect, the city of Barcelona has been an outstanding example for the urban transformations as a result of the 1992 Olympic Games. The construction or renovation of ports, airports, public transportation and sports facilities, housing, hotels and tourism developments is regarded as the urban legacy of organising such mega-events. In October 2007, Brazil was chosen to organise the 2014 FIFA World Cup. Seemingly a natural vocation due to the country's historic relationship with football, the competition to host this mega-event was related to the political project of its governors during a period of rapid economic growth and the emergence of the country on the world scenario. Between October 2007 and July 2014 a series of projects in infrastructure, mobility and stadia construction was carried out at a cost of ten billion dollars. The aim of this paper is to understand the main results of the World Cup interventions in Brazil, which were its main urban legacy and who were the winners and losers in this process.

1 THE RATIONALE FOR SPORTS MEGA-EVENTS PLANNING

The idea of promoting sport mega-events has been defended by international urban strategic planning consultants as a way for cities to compete with each other for the 'scarce international investment' and achieve economic development in a 'highly competitive environment' of contemporary capitalism¹. They say that when hosting these events, a considerable amount of public and private investment in

¹ We refer here to the concepts of current capitalist development stage, where the global accumulation regime is given by the dominance of finance capital over the productive, made possible by international capital flows deregulation and the adoption of the neoliberal political and economic doctrine (Chesnais & Brunhoff 2005, Foster 2010, Harvey 1990, 2005).

infrastructure, services and employment-generating activities will be implemented in the city that would take longer to happen without them: it is the so-called LEGACY.

The mega-events are a short-term event requiring investments in a series of works for it to be carried out. In the case of sports mega-events, the two main and most important are the Olympic Games and the FIFA World Cup. From the late 1970s on, with the global television broadcast, there was a major transformation in their organisation, as the media worldwide exposure caused the event to become highly profitable for their sponsors. Thus, large multinational corporations, such as sports brands, automotive, beverage, electronics, food and telecommunications industries, have been investing billions of dollars expecting financial return from the exposure of their brands (Broudehoux, 2015).

The sports facilities needed (stadiums, arenas and gyms), transport infrastructure, telecommunications, hospitality (to accommodate the delegations, journalists and tourists) and related services have caused a series of works and investments in urban development, which many times had led to great urban transformations.

On the other hand, the global economic restructuring crisis of the 1980s has led to profound changes in the paradigm of urban planning and policy, making urban administrations to adopt a neoliberal approach, taking a more active attitude to attract economic development, adopting techniques of corporate strategic planning, moving from 'managerialism' to 'entrepreneurialism', in Harvey's words (Harvey, 1989).

The role that the city of Barcelona played in the 1992 Olympic Games is regarded as one of the first examples of this new paradigm, which uses the promotion of major event as integrant part of urban strategic planning, as can be seen in the words of Borja and Castells:

The response to the awareness of crisis has been facilitated in some cities by the ability to attract and make use of a major international event. Barcelona has become a paradigmatic example of this. The strategic plan would not have been the framework for an ambitious urban transformation project, now partly implemented, without the spur of the 1992 Olympic Games. (Borja & Castells, 1997, p. 93)

Since then, several municipal and national governments have struggled in the competition to host these mega-events, with the aim of promoting and transforming their cities to be 'sold' to the consumer market, becoming investment and tourist destinations on a global scale.

However, the sponsors' billionaire interests cause these interventions to result in strong physical-spatial and socio-economic impacts on the city and its residents. Sometimes, the combination of television, marketing and commercial rights sale of these events make these powerful transnational companies and the organizing committees to have a supranational decision power, dictating rules on the construction and location of the stadiums and equipment, even changing national and local legislation¹.

Many authors have explored the impacts of mega-events planning. Kassens-Noor (Kassens-Noor, 2012), after analysing the transportation planning for four Olympic cities (Barcelona, Atlanta, Sydney and Athens) came to the conclusion that the IOC - International Olympic Committee had a strong influence on these projects. They turned out to be quite different from what had been planned for these cities prior to the bid. Worse yet, they represent a strong shift away from investing to meet these cities mobility real demand and eventually become great 'white elephants', with little use by local people after the games.

Furthermore, the impact of interventions and works regulations of these events has generally resulted in losses for local communities. In this aspect the main 'winners' of this process were the entrepreneurs, landowners and big business at the expense of the most excluded population sectors, especially the low-income residents of the surroundings and the small local businesses.

¹ We remember here two emblematic cases: the first one was the demand of FIFA to change the location of Cape Town Stadium in 2010 South Africa World Cup for a photogenic place, with the sea in the background, avoiding its construction in the original planned location close to a poor neighbourhood and low income residential developments (Broudehoux 2015); the second case is the clash between the FIFA rules regarding spirits consumption in stadiums (since one of the main sponsors is a beer producer) and the national legal restriction on their consumption, which had to be relaxed in Brazil during the event.

Brimicombe (2013) evaluated the results of 2012 Olympic Games in London and came to the conclusion that the main legacy promises at national level were not met. First, the expenses for the event were much higher than the original budget (£ 9 billion against £ 2 billion), and the public sector was responsible for 90% of the total, despite initial promises on the contrary. The goals of transforming the UK into a sporting nation also did not occur: it was expected that one million young people would initiate sports activities for an hour at least three times a week after the games, and later this estimate was revised for just one hour once a week.

Even the urban legacy of the Games to London is questionable. Their location in the East End was proposed to promote an urban regeneration process in an area characterised by industrial transition with large environmental burden and strong presence of vulnerable low-income population. Considering the two main local goals, provision of social housing and jobs to meet local needs, the legacy also seems to have been a failure. Westfield Stratford City, one of the largest shopping malls in Europe, with GLA – Gross Location Area of 175,000 square meters, was built next to the Queen Elizabeth II Olympic Park, in order to provide economic activities and jobs to the area. However, according to the local plan draft conducted by the London Legacy Development Corporation only 20% of the ten thousand jobs created was directed to local population, in an area where there are serious unemployment problems (LLDC, 2013).

The Olympic Village was transformed into a luxury housing development, 'East Village London', and has been sold to the community. Prices of new homes skyrocketed: a new one-bedroom flat was selling at £ 300,000 in 2014, in contrast to two-bedroom terraced houses, which were being sold at an average of £ 230,000 (Zoopla Propriety Group, 2014). The Olympic Village building quality highly contrasts with existing vicinity homes and only 24% of the 2,818 new homes will be for social housing (Watt, 2013).

Four hundred homes have been demolished for the Olympic works and "Olympic-related gentrification and displacement processes associated with rising private housing costs have already been identified" (Watt, 2013, p. 104). The current low-income residents face uncertainty about the possibility to remain in the place in the future, bearing in mind that since the 1980s the Eastern Thames Valley has been subject to various urban regeneration projects, attracting many foreign investors such as Russian, Chinese and Arabs.

1.1 ORGANIZING A SPORT MEGA-EVENT IN A BRIC CONTEXT

Brazil is presently considered as a BRIC country. Due to its economy size and growth in recent years, Goldman Sachs chairman, Jim O'Neill, have coined this acronym to define the largest emerging market economies consisting of Brazil, Russia, India and China (O'Neill, 2001). After the Debt Crisis of the 1980s, Brazil overcame the economic crisis and controlled inflation with Plano Real stabilisation plan. However the economy continued to slide, growing at an average of 2.8% a year; the overvalued new national currency, the Real (R\$), and the free trade caused a deindustrialisation process and unemployment continued high (12.3%) (IBGE, 2014). In amidst of the Chinese led economic boom and commodities high valorisation of early 2000s, the Brazilian economy grew again at an average of 4% a year, reaching 7.6% in 2010, becoming the 7th biggest economy in the World¹ with a GDP at market prices of US\$ 2.3 trillion in 2014 (The World Bank, 2014).

The election of the leftist Luiz Inácio Lula da Silva² for president much contributed for these changes. During his office (2003-2010), Lula da Silva adopted a macroeconomic policy based in two fronts that became known as 'neodevelopmentalism'³ (Ban, 2012). First, an aggressive economy and exports policies

¹ Behind: United States (US\$ 17.4 trillion), China (US\$ 10.4), Japan (US\$ 4.6 trillion), Germany (US\$ 3.9 trillion), United Kingdom (US\$ 2.9 trillion) and France (US\$ 2.8 trillion) (The World Bank 2015).

² Luiz Inácio Lula da Silva (1945-) is a Brazilian politician. Former metal worker and trade union leader, he was one of the founders of the left wing PT – Partido dos Trabalhadores (Workers Party). After running three times for presidency, he was elected president in 2002 after approaching centre-left and re-elected in 2006. By the end of his term in 2011, he managed to elect his successor, Dilma Rousseff, also from PT.

³ According to Ban (2012) 'neodevelopmentalism' entails a new form of state activism. It is a national capitalist development program meant to guide the transition of developing countries away from the Washington Consensus. It is based on the adoption of a development strategy that allows domestic firms to seize global economies of scale and technological updating processes, but also innovation policy and an activist trade policy targeted at investment opportunities for domestic firms.

boost financed by BNDES¹, fostering the 'National Champions', major Brazilian enterprise groups in the fields of agribusiness, construction and industry (cement, beverage, food, petroleum oil and steel). Many Brazilian companies have consolidated as multinationals, expanding their presence especially in Latin America and Africa (Columbia Law School, 2007).

Second, the implementation of various economic and social programs to reduce extreme poverty. The minimum wage has had a real 75% increase, discounting inflation. 'Bolsa Famlia'² (Family Allowance), an income transfer program, was created to ensure the right to food and access to education and health for families in extreme poverty. And after almost twenty years of absence, the Federal Government returned investments in infrastructure in areas such as housing, sanitation, transport, energy and hydric resources through PAC – Programa de Acelerao do Crescimento (Growth Acceleration Program) with a prevision of a US\$ 237 billion investments for the 2007 three following years and in social housing production, creating in 2009 the 'Programa Minha Casa Minha Vida' (My House My Life Program) that initially aimed at producing one million homes, but reached three million units³. With these economic measures unemployment fell to 6.4% and 25 million people left extreme poverty (Bez, Rodella, Sharman, & Viveros, 2015).

It was in this favourable conditions context at national and international levels that Brazil jumped on the sports mega-events planning bandwagon, hosting the 2007 Pan-American Games in Rio de Janeiro, the 2014 FIFA World Cup and the 2016 Olympic Games again in Rio de Janeiro. The bids had the Government approval and even its proactive attitude from the beginning. More than that, organising such mega-events would crown President Lula da Silva political project, showing that the country, under his presidency, had finally the conditions to be recognised as an emerging power. In that sense the organisation of the 2007 Pan-American Games was a test for Lula da Silva's great ambitions, as can be seen in his own words:

Normally the Olympic Games are organised by the rich and developed countries. With the Pan-American organisation, we want to prove that we can do equal or even better than any rich country of the World. We are going to organise the best Pan-American Games ever so that we can dream with other realisations... We are interested on bringing two events to Brazil: 2014 World Cup and after that, the Olympic Games. (UOL, 2006)

Lula da Silva believed that organising such events would bring prosperity and political capital with the amount of investments that had to be done. In that sense, it represented the legitimate justification to boost the contractors (the 'National Champions'), national and local economies with public and private money for the works of new arenas, facilities and infrastructure.

1.2 THE 2014 FIFA WORLD CUP ORGANISATION

Despite wide criticism that 2007 Pan-American Games had received, specifically with regard to overpricing and the urban impacts (Mascarenhas, Bienenstein and Snchez 2011), the Brazilian Government had decided to compete for the right to organize the 2014 FIFA World Cup. After FIFA ratification in 2007, eighteen cities entered a dispute to host the event. Despite the fact that FIFA would prefer fewer host cities (between six and ten), the Brazilian government pushed for a larger number (twelve), justifying it due to the country's continental dimension. In reality, this would allow investment distribution among different regions of the country, promoting the host cities transformation just in time for 2014 national elections, as can be seen in the Federal Government rationale on the legacy below:

¹ BNDES is the Brazilian National Social and Economic Development Bank (Banco Nacional de Desenvolvimento Econmico e Social), founded in 1952 that has played a fundamental role in stimulating the expansion of industry and infrastructure in the country.

² Created by the Federal Law 10,836/2004, it is an income direct transfer program to families in poverty and extreme poverty. In 2015 the program assisted 11.5 million households (23% of the national total), transferring R\$ 25.4 billion (US\$ 6.5 billion) in benefits Fonte bibliogrfica invlida especificada..

³ In four years, it reached a total of more than three million of contracted units, 53.3% of which for families earning less than three minimum wages (Santo Amore 2015).

The objective of the Federal Government is to coordinate an investment program that will transform some of the most important capitals of the country, from North to South and from all regions: Belo Horizonte, Brasília, Cuiabá, Curitiba, Fortaleza, Manaus, Natal, Porto Alegre, Recife, Rio de Janeiro, Salvador and São Paulo. For all Brazilians, whatever the result of the World Cup will be, an important legacy in infrastructure, job and income creation will remain, promoting the country's image globally.” (Brazil, 2013)

After the host cities definition, the Federal Government, under the Ministry of Sports, started to develop the necessary projects to carry out the World Cup. They were divided into three major groups, called planning cycles (infrastructure, support services and operational actions)¹⁰. The infrastructure projects were those that provided the greatest number of physical-spatial interventions, causing therefore the greatest impact on cities. They were divided into four types:

10 These groups were divided into three planning cycles (Brazil 2013): infrastructure projects from 2009-2010 (stadia, urban mobility, airports and ports); support services projects from 2010-2011 (security, tourism infrastructure, telecommunications, energy, environmental sustainability and institutional communication); operational actions from 2011-2013 (airport and port operation; urban transport; energy supply, medical and transitory facilities)(Brazil. Ministry of Sports 2014).

1. Stadia;
2. Urban mobility;
3. Airports;
4. Ports.

In January 2010 the Minister of Sports, twelve state governors and twelve cities mayors signed the Responsibility Matrix agreement, where they committed themselves to carry out the necessary actions and works for the World Cup. The Federal Government was responsible for the renovation of airports (INFRAERO – Federal Airport Infrastructure Administration) and ports (Secretaria dos Portos – Department of Ports). However, as several airports have undergone privatisation, the franchisers also have borne the costs (58%). The urban mobility works were of various types, from building public transport systems and facilities, such as BRT – Bus Rapid Transit and LRV – Light Rail Vehicles lines, train or metro stations, to the construction of streets, roads and fly-overs. Largely the mobility works were related to the connection of the airports to the stadiums or to road adequacy in their surroundings. The costs were shared between the Federal Government (50%) and the local instance (50%), both state and city governments, depending on each case. The participation of Federal Funds came through CEF (Federal Savings Bank) loans under the PAC Mobilidade Urbana (Growth Acceleration Program – Urban Mobility mode). With regard to the stadiums, despite government promises to only invest in infrastructure, the largest amount of money was from public sources (92.7%). The BNDES has opened a credit line for companies with interest rates below the market. Municipalities and states granted tax exemptions, if not invested directly in the stadiums construction/renovation. Afterwards, public money, considering lines of credit, loans, tax exemptions or direct spending represented 84% of the 10.1 billion dollars¹ spent on 2014 FIFA World Cup organisation, being 51% from Federal Government and 33% from states or municipalities, as seen in table 1 (Brazil. Ministry of Sports, 2014).

¹ The total amount was R\$ 27.1 billion (Reais) converted at an exchange rate of R\$ 2.68 for US\$ 1.00 for 23 December 2014, according to Brazilian Central Bank (<http://www4.bcb.gov.br/pec/conversao/conversao.asp>). These values can present some little differences as between the Responsibility Matrix signature in January 2010 and its final version in December 2014, the Real devalued 14% against the Dollar, discounted the inflation. From that date until March 1st, 2016, the Real has had a strong devaluation, losing 49% of its value, mainly due to an economic crisis and severe recession Brazil has been suffering.

	Total Investment	Financed by Federal Government	Federal Investment	Local Investment	Private Investment
Urban Mobility	3,260.1	1,637.2	9.3	1,613.7	-
Arenas	3,131.7	1,425.5	-	1,477.8	228.4
Airports	2,346.2	-	994.8	-	1,351.4
Ports	223.3	-	220.9	2.4	-
Other	1,169.7	-	872.7	256.9	40.3
Total US\$ million	10,131.0	3,062.7	2,097.6	3,350.7	1,620.2

Table 1 – The final Responsibility Matrix investment by type of work

From a regional point of view, investments were concentrated in the Southeast Region, the country's most developed. According to table 2, the total amount spent in São Paulo, Rio de Janeiro e Belo Horizonte accounted for 42.8% of the total.

	Total Investment	Financed by Federal Government	Federal Investment	Local Investment	Private Investment	
São Paulo	1,899.6	149.4	255.9	385.7	1,108.7	18.8%
Rio de Janeiro	1,446.8	589.8	172.3	684.7	-	14.3%
Belo Horizonte	979.5	502.6	163.5	313.5	-	9.7%
Cuiabá	912.9	316.8	39.2	556.8	-	9.0%
Brasília	810.1	18.8	4.5	546.8	239.9	8.0%
Recife	625.1	402.7	16.5	205.8	-	6.2%
Fortaleza	613.5	284.4	154.1	174.9	-	6.1%
Natal	577.7	262.1	110.1	65.3	140.2	5.7%
Manaus	488.7	149.4	195.5	143.8	-	4.8%
Curitiba	418.2	162.9	64.9	93.0	97.2	4.1%
Salvador	354.5	120.9	66.8	166.9	-	3.5%
Porto Alegre	190.0	102.8	39.7	13.5	34.1	1.9%
Other (all cities)	814.7	-	814.7	-	-	8.0%
Total US\$ million	10,131.0	3,062.7	2,097.6	3,350.7	1,620.2	100.0%

Table 2: The final Responsibility Matrix investments by city
Source: Brazil. Ministry of Sports, 2014. Elaboration by the author.

In order to speed up the works, the Federal Government enacted a new public tender law (Brazil, 2011) that allowed contractors and contract requirements to be flexibilized, thus reducing the process time from 250 to 90 days. This new tender regime has received many critiques from engineers and architects professional associations for giving the contractors too much power as they became responsible for the basic and executive projects, allowing them to define the works, changing its characteristics.

Another controversial law was the General Law of the Cup (Lei Geral da Copa) which established among other things (Brazil 2012): end of spirits consumption prohibition during the event; the revision of ticket discounts for students, elderly and handicapped; street commerce prohibition around the World Cup facilities; Federal Government civil responsibility for incidents and damages during the event; extended and free visas for World Cup foreigner workers and athletes; etc.

At the local level, contractors, entrepreneurs and the land-based elite entered in competition for resources and projects from the Federal Government. In many cases, investments in infrastructure and stadiums were directed to areas of potential expansion of the real estate capital, not without causing the eviction of low-income local population and planning legislation flexibility.

The large volume of public investment and little public return of the works caused a great population reaction, who took the streets of Brazilian cities in thousands demanding for public transport, schools and hospitals at 'FIFA standard', and crying slogans such as 'Cup for whom?' or 'There will be NO Cup' (BBC News, 2014). Organised social movements, composed by workers, students and intellectuals has joined together locally in the Comitês Populares da Copa (Cup Popular Committees) and nationally in the ANCOP (Cup Popular Committees National Articulation) denouncing the values spent on the Cup and human rights violation against the poor population evicted for the works.

2 THE CONTESTED URBAN LEGACY

The 2014 FIFA World Cup in Brazil took place in twelve host cities between June 12 and July 13, resulting in 64 games, 171 goals, audience of 3.43 million people in the stadiums, public of 5 million people in the Fan Fests (Brazil 2014). Despite fears that the works would not be ready for the event and that insurgent demonstrations could compromise it, the event took place without major problems. In the end, the Brazilian team suffered a shameful seven to one defeat to the Germans at the Mineirão in the fateful July 8 semi-final and then another three to one defeat to the Dutch in the Brasília July 12 third place contention.

Nevertheless, the event had good results as a tourism booster: a million foreign tourists came to Brazil and three million Brazilian tourists travelled during the World Cup (Brazil, 2014). Research done by the main national research institute with foreign tourists showed their great satisfaction with the event (Datafolha, 2014): 83% of respondents considered the World Cup organisation as excellent or good, 92% considered the stadiums' comfort and safety as excellent and good, 95% considered the Brazilian a sympathetic and hospitable people, 76% considered good the transportation to the stadium and 69% said they would live in Brazil.

But, if from the spectacle and tourism points of view the event was a success, why was it antedated and followed by large popular demonstrations? What went wrong?

First of all, there is the question of the huge amount of public funds that were used for the World Cup organisation despite promises on the contrary. In a country where 35.5% of the 47.3 million households are not connected to a sewage system (IBGE, 2011), spending 8.5 billion dollars of public money (out of 10.1 in toto) on a mega-event organisation seems to be blatantly wrong. Having this in mind, it is easy to understand the indignation of the social movements that have made demonstrations against the World Cup, shouting slogans like 'We want hospitals, public transport and schools at FIFA standards'.

The very nature of planning consists of social justice, or at least it should/used to. However the 2014 FIFA World Cup organisation has much disregarded this fact. Considering the planning process, it seems that sport mega-event organisation in Brazil has only reaffirmed the trend towards neoliberal urban planning, based on policies that emphasize economic opportunities, mainly to the great capital.

The 2014 FIFA World Cup organisation in Brazil was followed by a more flexible and 'business friendly' urban legislation: density parameters were upgraded, environmental restrictions were relaxed, tax exemptions were given, everything to attract investments around the stadia and the infrastructure works. This can only be understood considering the so called 'neodevelopmental' policies adopted at a national level such as PAC (Growth Acceleration Program) and PMCMV (My House My Life Program).

Designed to boost the building and the real estate sectors, neither of them took into consideration their urban impacts. So, Brazilian biggest contractors and a diverse myriad of real estate companies took advantage of public money to boost new urban development. In this sense, it was shown in many chapters that the main 'losers' of the 2014 FIFA World Cup organisation were the lowest-income and most-excluded strata, exactly the strata urban planning should care for.

According to the Brazilian Presidency Executive Office data, about 35.6 thousand people were removed from their properties as there have been 13.6 thousand recorded removals (10.8 thousand households and 2.8 thousand shops and other sort of properties), either by expropriation or forced eviction (Secretaria Geral da Presidência da República apud. ANCOP 2014, p. 39). These figures are 34 times more than the 2012 London Olympic Games as seen in section 1.

Most of these people were living in informal settlements such as favelas placed near the works sites. Many families were replaced to housing developments many kilometres away from their original place, generally in more precarious situation considering urban infrastructure and public facilities, though sometimes in better housing conditions. Their removal has assured higher levels of profitability for the real estate sector new developments in favoured urban areas.

Figure 1 – Favela removed for mobility works in São Paulo. Source:
https://www.vice.com/pt_br/article/esses-sao-os-resistentes-das-desapropriacoes-da-favela-buraco-quente

Considering the urban legacy main promise, the mobility works, it was also disappointing. Certainly the two current biggest urban problems in Brazil are mobility together with access to housing. Historically investments have been concentrated on road works that generally favours motorised individual transport (automobiles, motorcycles, etc.), despite the fact that the great majority of trips, 69%, are made by either non-motorised (foot or bicycle) (40%) or motorised collective (buses, trains, metros, etc.) (29%) (ANTP, 2012)¹.

According to newspaper reports, one year after the World Cup only 21.4% of the mobility works were finished (Amora, 2015). The delays have majored the prices 33% in average, but sometimes have doubled or even tripled. Worse still, some works have been abandoned or postponed such as the VLT (light rail) of Cuiabá, capital of Mato Grosso State, whose trains (40) were purchased and are parked in a courtyard, as there are no tracks to put them on. Some have become ‘white elephants’ like São Paulo light rail, that left the State Responsibility Matrix since the stadium changed from its initial place and it now faces an undefined future (figure 2).

Figure 2 – Abandoned light rail works in São Paulo. Source: the author, 2016.

From the airports 10 out of 13 were ready (76.9%), however most of them were renovated by the concessionaires. The urban mobility promises failure has aggravated the political ambience since bad urban mobility conditions had been causing major demonstrations in many Brazilian metropolises since the famous ‘2013 June Journeys’ that took almost two million people to the streets (Watts, 2013).

Considered the stadia, eleven were finished and only one remained uncomplete (Cuiabá). However, the great question here is their usage after the end of the World Cup. According to a newspaper report, only football games are not sufficient to guarantee profitability in any of them (Terra, 2015). So, all of them have to search other financial return sources such as shows and other sports competitions to keep the budget

¹ The report was done for 438 Brazilian cities with a population over 60 thousand inhabitants, representing 64% of the national population (ANTP, 2012).

balanced. From the twelve built stadiums, three of them (Brasília, Cuiabá and Manaus) had ended 2015 with a deficit of R\$ 17.6 million (US\$ 4.5 million).

From the twelve stadiums, nine belong to the states and Federal District governments and three belong to local football teams (Atlético Paranaense in Curitiba, Corinthians in São Paulo and Internacional in Porto Alegre). Amongst the public ones, five are renovated and are now managed in a PPP scheme. All of these have caused a rise in ticket values that together with the FIFA standard renovation have caused the gentrification of the spectacle. Five stadiums are now managed by two of the Brazilian biggest contractor corporations, Odebrecht (first place) and OAS (third place), that are now being investigated by the Operação Lava-Jato¹ (Car Wash Operation) in the largest scandal of corruption involving Petrobras, the Brazilian Petroleum Corporation, five contractors and many politicians.

Finally, after the mega-event euphoria, Brazil faces again economic and political uncertainties. If the planning of the sport mega-event began during a period of great optimism and economic growth for Brazil, its delivery occurred in a downturn, result of the exhaustion of the internal demand growth process, associated to less favourable international ambience. The 2008 international crisis, China's growth reduction and the end of the commodities valuation cycle due to oil prices sharp fall hit the Brazilian economy in full.

In the national arena, political crisis due to Operação Lava Jato media exposure, involving the ex-president Lula da Silva, has eroded the president Rousseff governance basis causing her impeachment. The delay on the Government response to the economic crisis and the worsening of domestic political ambience have led to market instability, foreign investment departure, a sharp 49% Real devaluation. The GDP fell from 2.7% growth in 2013 to 0.1% stagnation in 2014 and -3.8% recession in 2015 resulting in the downgrading of Brazil's investment grade by all risk agencies (Soto & Ayres, 2013).

All of these factors have altered the course of sports mega-events planning from now on in Brazil as the political and economic conditions that made it possible have now changed considerably. Unfortunately, it seems that for most of the Brazilians the 2014 FIFA World Cup left a bitter taste far beyond the defeat of their national team.

¹ Operação Lava-Jato is the largest investigation of corruption and money laundering Brazil has ever had. It is led by federal prosecutors and the Federal Police. The scheme involves Petrobras, major contractor corporations and politicians. Up to now, this investigation has resulted in 133 arrest warrants, 84 convictions and the search for R\$ 14.5 billion (US\$ 4 billion) of money diverted (<http://lavajato.mpf.mp.br/atuacao-na-1a-instancia/resultados/a-lava-jato-em-numeros-1>). The name lava-jato (car wash) comes from the beginning of the investigation that started investigating a car wash network that was used to launder money from criminal organisations.

yrwgrips@hotmail.com ; myrsinifot@hotmail.com

1 INTRODUCTION

This paper seeks to explore social segregation trends in Athens metropolitan area in the very first years of the economic crisis, and discuss the socio-spatial patterns of the metropolitan population, based on the 2011 statistical census data. The spatial aspect of social structures introduces a different dimension on social segregation trends, reflecting segregative outcomes of different socio-economic processes around the world. Varied and nuanced forms of social segregation present in various cities around the world, altering the way of measuring and evaluating the character of the progress. Nevertheless, a potential rise in social segregation depends upon certain mechanisms that allocate residential areas to different social groups (Maloutas, 2007). Hence, the contemporary economic crisis changes in turn the social impact of economic restructuring, and social segregation comes to terms with new realities.

Up until the early 2000s Athens hadn't undergone intense processes of socio-spatial division. Residential segregation in Athens remained relatively low by international standards before the outbreak of the economic crisis. During that period, the metropolitan area of Athens constituted a paradox paradigm of social segregation and social polarization, partially due to the spatial structure of the housing market and to the respective policy framework. Undoubtedly, eight years on since the outbreak of the crisis, the urban space of Athens has been exposed to the socially dividing effects of globalization, experiencing rising social inequalities, demographic changes, marginalization of lower income strata, reduction of social mobility, high unemployment rates, etc (Maloutas, 2007).

Exploring the factors that contribute to the development of social segregation patterns in Athens and elsewhere, one should certainly identify social polarization. According to some authors (Sassen, 1991), social polarization is the key factor for the generation of such phenomena. However, various approaches of social segregation claim that the impact of globalization on cities is more complex and diverse than social polarization alone. Hence, it has been underlined that both the formation of socio-spatial structures and the distribution of social groups along residential areas constitute dynamic processes whose roots are identified not only at the economic restructuring process but also at several other factors of regulatory, social, and cultural origin (Préteceille, 1995; Hamnett, 1994; Maloutas, 2014; Marcuse and van Kempen, 2002). Particularly in the case of Athens, the institutional and regulatory framework is considered to be the primary agent to define socio-spatial patterns. In this context, it is useful to draw attention to the particularity and the complexity of socio-spatial trends in the Greek capital city, and to approach social segregation as a dynamic and multifactorial phenomenon.

The idea of this paper is to designate the situation before the absolute sovereignty of the economic crisis in the Greek urban space, and should produce a basis for more effective social and spatial policies for the reduction of segregative trends. The first section of the paper introduces the social segregation context and the scientific discussion that has taken place approximately during the last decades. Emphasis is laid upon different approaches that have developed through the empirical analysis of the phenomenon in urban areas worldwide. The second section presents the methodological steps made in order to study the character of social segregation in metropolitan Athens. The third section discusses the research results, attempting also a comparative analysis based on previous studies. Finally, the concluding section provides some reflections about the socio-spatial composition of the Greek capital city in order to design the future of a metropolis in crisis.

2 SOCIAL SEGREGATION: A CONCEPTUAL APPROACH

The concept of social segregation was primarily introduced by the Chicago School (Grafmeyer and Joseph, 1990; Wirth, 1980). Following the economic restrictions imposed in the 1970s and their impact on the social composition of cities, social segregation constituted a large part of both social sciences and urban studies. The globalization process boosted the role of metropolises and cities in the advanced capitalist world, due to their attractiveness to new financial activities, banking services, IT systems, real estate management, etc. A major impact of this economic restructuring was the increase of social polarization and segregation tendencies, which were also expressed spatially. Social polarization refers to the increasing inequality between the transnational corporate elite and those at the bottom of the class structure, as well as to the higher concentration of people at these two extremes (Sassen, 1991).

'Innovative' spatial policies and strategies with a significant impact to the local housing and social composition of neighbourhoods, such as gentrification, have highly contributed to the establishment and the exacerbation of spatial division patterns. According to Sassen (1991), the gentrification process is defined as the appropriation of the urban space by the corporate elite – e.g. the new middle class – and, at the same time, the segregation of the impoverished population – lowest social strata, immigrants etc. Such processes, however, have not been so widespread neither in European cities nor in the Global South, confirming the multifactoriality of the segregation phenomenon. In this context, several authors claim that the process of globalization and its impacts on the socio-spatial structure include more complex and various stratifications and separations (Maloutas, 2014).

More recent approaches have highlighted the role of urban strategies and social policies, as well as the welfare state in the progress of social segregation (Hamnett, 1994; 1996; Marcuse and Kempen, 2002). Studying the metropolitan area of Paris, Préteceille (1995) has underlined determinants of segregation other than social polarization, such as the process of professionalization. Additionally, he has stressed the role of the welfare state as to the regulation of the impact of the economic to the social restructuring and to the determination of actual trends. Hamnett (1994, 1996) presented similar arguments regarding London. In the same framework, Musterd et.al. (2016) claim that there are four structural factors contributing to the exacerbation of social segregation, namely social inequalities, welfare regimes and housing systems, changing economic structures and the level of global connectedness.

The consequences of economic restructuring give some recognizable elements of polarizing and segregating phenomena in the post-industrial Western and Southern European cities. Recent studies have shown that social inequality has risen since the 1970s in many European countries. More importantly, research undergone by Musterd et.al. (2016) showed that, as far as European metropolitan cities are concerned, socio-spatial segregation is lower than North America, and that, among the European cities, segregation levels vary significantly. Moreover, in most occasions, segregation correlates positively with higher income disparities, more liberal forms of welfare regime and higher global connectedness. It is highlighted, however, that several factors can have effect well after a certain period of time.

The limited welfare state development in Southern European countries and the absence of policies against segregation tendencies attest the increasing difficulties to shape the outcomes of economic restructuring in terms of polarization, and to resist the rise of the social inequalities (Maloutas, 2014). It is worth noting that segregation stems from mechanisms that allocate the residential space on different social groups, and that it doesn't exclusively depend upon the development of social polarization. This is indeed the case in Southern Europe, where the processes of globalization couldn't gain influence against the traditional family

system, in the allocation of residential space (Allen et al., 2004). As Maloutas (2007) also showed, segregation in Athens has decreased since the early 1990s, despite the fact that inequalities and social polarization had actually increased.

These approaches stress the contribution of local processes with diverse social and spatial attributes in the global and general context. Nevertheless, a large majority of the existing literature agrees that the outcome of capitalistic economic progress is always a rise in urban division and social inequality. Castells (2000:164-165) describes segregation as the phenomenon of "multiple black holes of social exclusion throughout the planet in this new geography of social exclusion". In fact, segregation constitutes a pattern of socially diversified areas. Some other approaches stress that segregation processes are visible in homogenous and isolated micro-areas in cities defined by specific socio-spatial characteristics. All such areas inhabited by certain social groups – such as the high and upper middle class, the lower middle class, the working class and the immigrants – are characterized as ghettos or ethnic enclaves, in that they are inhabited by ethnic minority groups. Other categories of isolated and homogenous areas identified by their socio-economic status are defined as slums, squatter settlements or shanty towns and gated communities (Grzegorzczak, 2013).

Furthermore, the concept of social segregation proposes the hypothesis that there is a relation between social and spatial distance. Contrariwise, various examples of European cities underline that, even within socially mixed areas the social distance remains, due to the effects of the social structure itself. Most of the times, the analysis of social segregation is based solely upon the residential distribution. Residential division, however, isn't the only expression of segregation, as the latter can include and combine a number of other forms of the social hierarchy, such as social mobility and nationality (Frantz, 2011). According to Lajoie (1998), the concept of social segregation may be identified in its different forms as urban, social, residential or scholarly segregation. In their entirety, these forms of segregation are directly connected to socio-spatial inequalities, indicating each time a different 'type' socio-spatial injustice.

Thus, segregation patterns call for various approaches in different contexts, due to the complex pattern of the metropolitan areas, and to the complexity of the segregation mechanisms. However, enclaves of affluence, deprivation and ethnicity are dispersed across the metropolitan areas (Jalowiecki, 2010). In line with Jalowiecki (2010), the European cities are characterized by greater stability of social structure due to the lower spatial mobility of the residents and to the socially mixed city centers.

Based on the above analysis, this paper emphasizes the contextual diversity of determinant factors other than the market mechanisms, which in Southern Europe concern mainly the state and the regulatory framework, and can be described as the clientelist and familist social regulation, traditional family bonds, the traditional small-scale owner occupation pattern, etc. (Maloutas, 2004). In the next sections, the paper aspires to present the socio-spatial pattern of metropolitan Athens in 2011, two years after the breakout of the Greek economic crisis, under the assumption that the negative effects of the economic crisis haven't presented still. The policies adopted to counteract the economic crisis have had multifaceted effects, such as rising social inequality, ongoing deregulation of the labour market, tax relief and other accommodations for investors, a declining public sector, privatizations, increasing housing taxes, etc. The neoliberal orthodoxy set in motion has dramatically deteriorated living conditions in Greece, questioning any prospect towards social equality. In this regard, it is expected that more recent data would present a rather different image of socio-spatial trends and particularly of social segregation in Athens. Although more recent data are not available, it is indeed useful to study the situation on the early stages of the economic crisis.

3 METHODOLOGY OF THE RESEARCH

Initially, the research examined the composition of the population under study, the area under study and the geographic units which compose this area. After selecting the variables to be elaborated, the data have been extracted from the dataset of the 2011 Greek census (Hellenic Statistical Authority, 2011).

Although the breakout of the Greek economic crisis was in 2009, it is useful to examine social segregation, even in reference to a period when the impacts of recession weren't as strong as today.

The urban population under study consists of age groups between 20 and 65+ years old. The potentially economically active population, along with the retirees – on a case-by-case basis – are the age groups

which constitute the population that participates and contributes to the overall process of segregation. People under 20 years old have not been included in the overall research, as they mostly constitute dependent members, living in their parents' residences, scholar or university students and not economically active. Furthermore, the age group of 65+ was not included in the analysis of the employment and professional status variables, since it mainly consists of retired – not economically active – members of the population. This group has only been taken into consideration for the evaluation of the education level patterns in order to estimate the distribution of the educated population across the urban space.

Regarding the geographic zone, the Athens metropolitan area has been selected in that it constitutes a matrix of all the social groups and categories that we aim to investigate. Moreover, the geographic units under study are the 2011 census tracts, the lowest-scale units available from the Hellenic Statistical Authority at this time. The study area of metropolitan Athens is divided in 3.406 census tracts, after removing the 18 units of population less than 20 years old. Variables referring to socio-economic data as well as to personal characteristics and social mobility aspects – such as the education level, the employment status and the professional categories – are used in order to evaluate the "snapshot" of social segregation in Athens. It should be noted that, in absence of foreign-citizenship data at the census tracts level, this variable was studied at higher levels, as is explained in the next section.

Having elaborated the necessary variables for education, employment and professional status, and foreign citizenship concentrations, various hierarchical cluster analyses have been implemented according to each one of the aforementioned variables as well as personal characteristics and social mobility aspects. The objective of the analysis is to define an adequate number of groups clearly reflecting different levels of residential inequalities and disparities in the Athens metropolitan area.

Hierarchical clustering is a widely used data analysis tool allowing to successively merge data observations in similar groups of units (census tracts). The merging process is based on a measure of similarity as for example the Euclidean distance. It is a monotonic process in other terms, the similarity between merged groups is monotone decreasing with the level of merge. At the end of the process, when all units have been merged in a single group, the loss of information (variance) is maximal.

For each one of the hierarchical cluster analysis implemented, the main question was to define the most appropriate numbers of groups, reflecting the different patterns of spatial distribution of the population under study. This question has to be treated with caution, respecting two main criteria: (a) high intra-group homogeneity with high inter-group heterogeneity, (b) selection of a limited number of groups with limited loss of information. It is often admitted that this loss must not exceed 20%. Taking into account these two criteria, different alternative solutions have been systematically produced for each one of the variables. Through a cautious interpretation of each one of the selected partitions (different number of groups), it was finally possible to select the most adequate number of groups. Finally, the results of the different cluster analyses are presented in maps in order to reflect and interpret the spatial distribution of the Athenian population.

4 INTRODUCING ATHENS' SOCIAL SEGREGATION

4.1 PAST AND PRESENT SOCIAL SEGREGATION PATTERNS IN ATHENS

It is clear that in Athens, same as in all the Northern European countries, social segregation doesn't present with high levels of socio-spatial division, such as in Anglo-Saxon metropolises (Frantz, 2011). Based on this remark, social segregation in Athens has generally been characterized as 'soft'. In line with Maloutas (2007), three causes have conducted to the minimal segregation patterns which characterize Athens. Firstly, the increased importance of intermediate social categories, as well as the significant social mobility driven by the broad access to higher education until 1990s. Secondly, the highest and upper-middle social strata had similar housing practices to the lower social strata, reinforcing social segregation only after the 1970s, by their movement to the suburbs. The third cause was the absence of large projects and building companies because of the high rates of individual homeownership, the organization of the Greek family occupational system, the constitution of stable self-help networks in residential areas, the low residential mobility, etc (Maloutas, 2004).

Housing policies and practices in Greece is indeed a complex issue. The housing stock and the social composition of the metropolitan area were influenced by the self-promotion and the antiparohi systems¹. Multistorey buildings were constructed within most of the urban areas in and around the city centre, resided by low, middle and high social strata, provoking vertical social segregation patterns. Since the 1990s the higher and middle social strata have moved towards the suburbs of Athens, reinforcing horizontal segregation in the periphery. The demand of new housing was limited to the suburbs and the existing stock in the central areas was socially redistributed. Furthermore, the access to the homeownership started to decrease following the deterioration of the two dominant housing systems. At the same time, an increase in the land values and housing prices was observed until the end of 2000s (Alexandri, 2014).

For all the aforementioned reasons, Athens constitutes a somewhat peculiar case of social segregation. The cluster analysis carried out in order to categorize the socio-demographic characteristics of the population showed that the social composition of Athens has generally kept the same basic structure and characteristics in comparison to previous periods. An accumulation of affluence along with richer housing settlements persists at the north-eastern and south-western city districts, making the Athenian region socially polarized in general. It is worth noting the increasing polarization and the simultaneously decreasing social segregation in metropolitan Athens during the 1990s (Maloutas, 2007). The two extreme poles of professional categories have since increased. On the one hand, there seems to be a growth trend for higher professional categories related to professionals and managers. On the other hand, the lower professional pole has increased its share partly due to the immigrants' waves in the 1990s. "The demographic changes in the city have also had significant social effects" (Maloutas, 2014 :156).

Another important demographic change concerns the significant waves of immigration which arrived in Athens in the last three decades. People from the Balkans, as well as from Eastern European countries, represented the majority of immigrant population at that time. In the 2000s a new wave of immigrants arrived in Greece, originating from war or poverty zones in the Middle East and Africa (Kandylis et al, 2012). Thus, the city of Athens had a new experience of immigration. As a consequence, different immigrant groups present a differential social integration history.

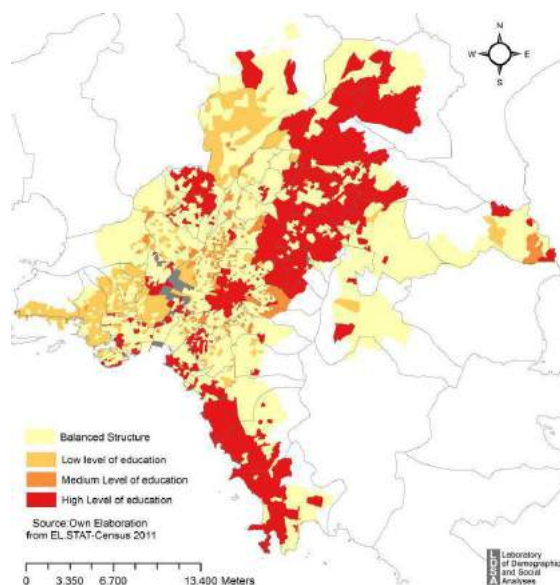

Immigrants who arrived in Greece between 1990 and 2005 were integrated socially, as well as into the local economies. They were occupied at various types of professions – the 2004 Olympic Games, housing markets and several other jobs abandoned by native Greeks. The immigrants arrived in Athens, settled in mainly abandoned and degraded housing stock, in neighborhoods around the inner city. It is worth noting that the central housing stock was abandoned before the arrival of the progressive waves of immigration, giving place to them. After 2005, the integration of immigrants in Athens and in Greece was more difficult due to their low educational skills and to the deterioration of the economic climate. Most of them are mainly men, originated from Middle East and Africa countries and they are confronted with the absence of immigrant integration policies (Maloutas, 2014). As a result, most recent immigrants are situated at the lower social strata areas and are faced with the danger of no mobility prospects and potential marginalization (Arapoglou et al, 2009).

As mentioned above, in the case of Athens – same as in other metropolises of Southern Europe – spatial proximity doesn't necessarily mean social proximity. The co-existence does not only have ethnic, but also hierarchical character, since the immigrants' origin and social status define the immigrant population hierarchy. Thus, many groups of immigrants settled in the same areas as the native middle or working class, but continued to live into much more degraded housing conditions. Second generation immigrants do not have the same social mobility prospects (Kandylis et al, 2012; Maloutas, 2014). The immigrants also didn't settle into areas of homogenous social categories but in the socially mixed areas of the antiparohi system contributing to the vertical social segregation patterns (Maloutas, 2014). The only exception is the Western side of Athens, which traditionally consists of areas resided by the working class. On the contrary, the foreign corporate elite and activities have been attracted by Athens in a small degree. Thus, the global corporate elite didn't put pressure to the distribution of the housing stock. Contrarily, the immigrants attracted massively by Athens belong to the lower social strata affecting the local housing stock (Kandylis et al, 2012; Maloutas, 2014)

¹ Antiparohi system is related to the system where promotion is co-exercised by small owners and small construction firms in ad hoc joint ventures to produce small condominiums" (Alexandri, 2014: 18).

4.2 MAIN FINDINGS OF THE RESEARCH: A COMPARATIVE ANALYSIS

Presenting the main findings of the cluster analysis conducted, the following maps (figures 3.1 to 3.5) depict the socio-spatial patterns of the Athenian urban population based on the 2011 census data which were extracted from the Hellenic Statistical Authority. The data with regard to the education levels, the employment status and categories, and the professional status have been elaborated at the census tracts levels, whereas the foreign citizenship data were only available at the higher census tracts level. The findings provide us with the opportunity to conduct a comparative analysis for the aforementioned categories.

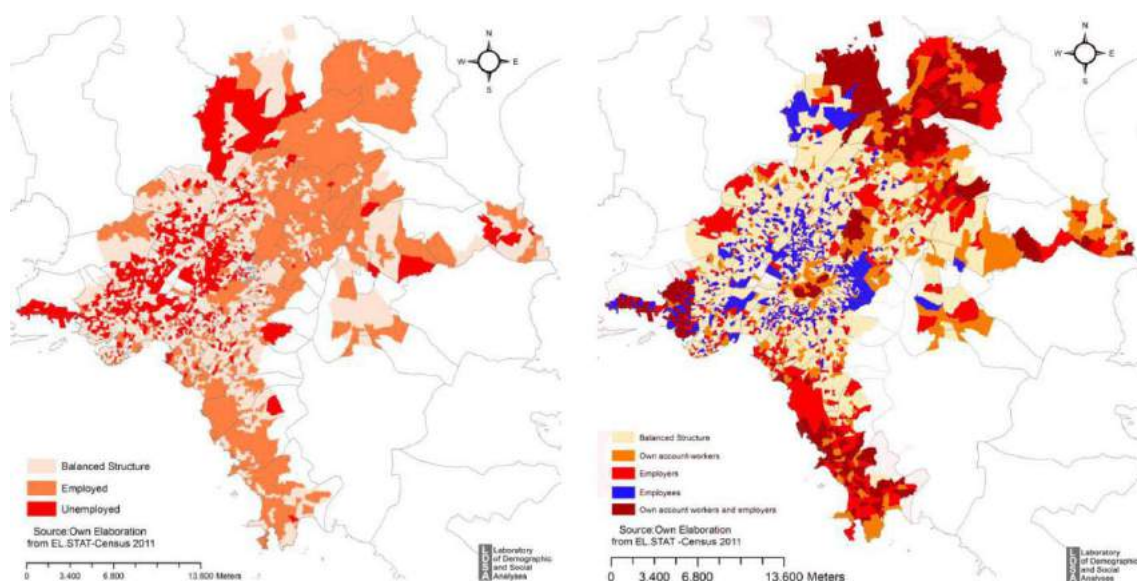

Map 3.1: Education level concentrations (2011)

Source: Hellenic Statistical Authority (2011), own elaboration (Laboratory of Demographic and Social Analyses)

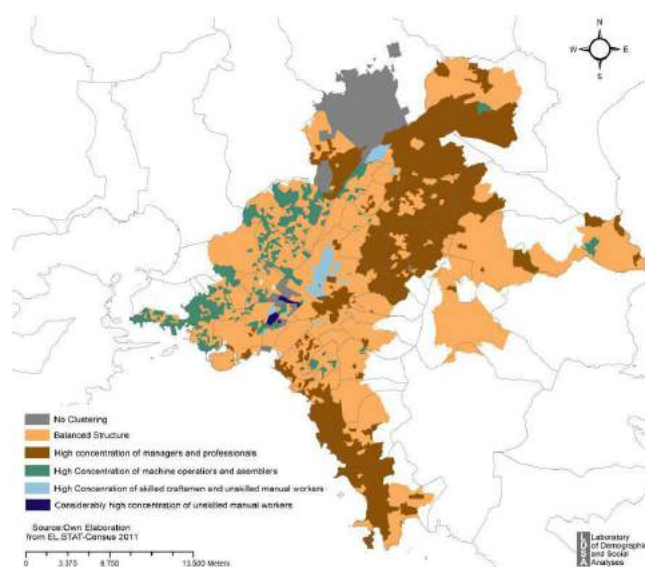

The analysis regarding population categories by level of education resulted in findings as depicted on map 3.1. Population with higher level of educational attainment represent people who have completed tertiary or post-secondary education. Respectively, medium level stands for people who have completed secondary or vocational/technical secondary education, whereas low level stands for people who did not complete primary or secondary education. The findings of the analysis show that a large proportion of the population follow a balanced structure regarding education attainment, namely all of the categories are allocated evenly, based on each category's average. Furthermore, there is a clear image of over-representation of higher education that extends from the coastal south-western to the north-eastern districts of Athens. People with low levels of education are mainly located in western and north-western districts, within and around Piraeus. An interesting note is that the two main categories represented in the Athenian urban space are low and high education levels. The distribution of people of medium levels of education seems to be fairly even. In this sense, the distribution is very clear and corresponds to composition findings of previous studies.

The metropolitan space is divided into three prevailing groups of educational levels, reinforcing the 'traditional' image of social segregation in Athens. It should not be ignored that higher education attainment is a strong indicator of social mobility: The spatial distribution of education level may indicate the correspondence between education credentials and position in the labour market. Thus, it is a way to interpret the social patterns in urban space concerning social segregation. Nevertheless, some highly educated immigrants and native population "systematically suffer from the incapacity of the local labour markets to provide jobs adequate to their skills and qualifications" (Kandylis et al, 2012:271, Labrianidis, 2011). In summary, the differentiation among the clusters of education levels is clear: the suburbs of middle and middle-high social groups as well as the city centre exhibit the highest level of education, while the western and inner city districts display low levels of education. The level of education is thus corresponding to the prospects for social mobility introduced in the middle and high class areas.

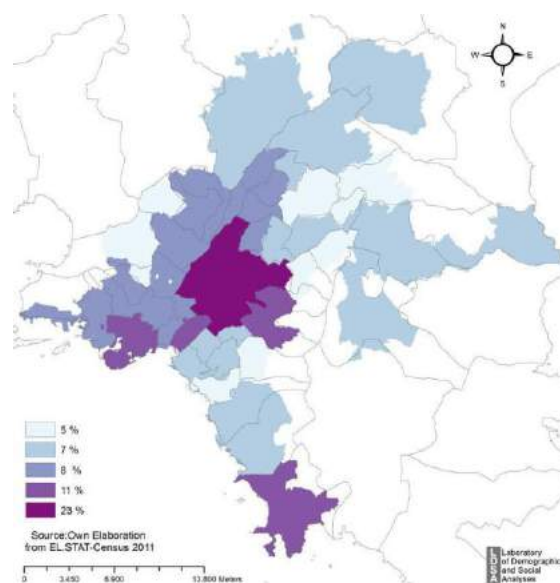

Maps 3.2-3.3: Employment status and employment categories concentrations (2011)
 Source: Hellenic Statistical Authority (2011), own elaboration (Laboratory of Demographic and Social Analyses)

Maps 3.2 and 3.3 depict the distribution of the population in regard to the employment status and to the main employment categories. As can be observed on both maps, there is a particular trend expressed in the metropolitan area. North-eastern and south-western districts display high rates of employment represented by the employment categories of employers and won-account workers, namely the middle-high social classes. On the other hand, high percentages of unemployment correspond to areas of high percentages of employees. These areas are located in districts around the municipality of Athens and towards the North-west, and have already taken effect of the recent economic crisis outburst. Close proximity to the city centre as well as relatively low property values are two main factors contributing to the choice of residence for these social groups. Own-account workers are concentrated mainly in the same areas with or in proximity to the employers, however there is a strong presence also in the city centre. This trend coincides with the traditional household structure in Greece, the traditional small-scale commodity production units and the freelance occupations of traders, architects, civil engineers, etc. Finally, a wider ring around the city centre of Athens is characterized by a balanced structure, as people from all social strata still choose to not abandon the city-center because of its significant importance, contributing to the mixed social distribution of the metropolitan population.

Map 3.4: Professional categories concentrations
 Source: Hellenic Statistical Authority (2011), own elaboration (Laboratory of Demographic and Social Analyses)

In respect to the professional status (map 3.4), Athens seems to be fairly divided. It should be mentioned that the professional categories of technicians, service and sales workers, and clerical support workers, which represent a significant proportion of the Athenian working population, were not included in the final cluster analysis stages due to their relatively uniform distribution across the study area. The categories ultimately selected were those indicating relatively high coefficient of variation (CV) levels: administration managers, professionals, technicians, skilled craftsmen, plant and machine operators and assemblers, and manual workers. In the north-east and south-west districts, as well as in some of the central areas, the dominant professional categories are both professionals and managers, members of the high and middle class of the urban population. This pattern is systematically present and expresses the need of higher classes to reside in certain areas. On the other hand, central and western districts are dominated by lower working classes, namely machine operators and assemblers, skilled craftsmen and unskilled manual workers, most of whom work in the remaining large industries of a broader area extending around Piraeus and Perama.

Map 3.5: Foreign citizenship population rates (2011)
 Source: Hellenic Statistical Authority (2011), own elaboration (Laboratory of Demographic and Social Analyses)

Map 3.5 shows the foreign citizenship population's concentrations across the metropolitan area. The research for this variable was conducted at the higher census tracts level, due to lack of lower-scale data. The available data are categorized according to the countries of origin into two groups, of intraEU and extraEU citizenship. This kind of information is useful for an analysis such as the present, however an interpretation at this level entails risks: a higher level census sector may be highly heterogeneous, consisting of municipalities or areas of divergent socio-ethnic features. A choice was therefore made to not present cartographically this information within the current analysis. In any case, some basic trends are present: north eastern and south-western districts are those with the most powerful presence of intra-EU immigrants, whereas extra-EU immigrants are located mostly in areas around the city centre, towards the western and north-western parts of the metropolitan area. Thus, most extra-EU immigrant groups live in areas accessible to the labour market or near neighborhoods with relatively low rent prices and a variety of accessible domestic services.

Bearing in mind the above remarks, as well as the fact that three out of four immigrants originate from countries outside the EU, the information provided in map 3.5 is not surprising. With the exception of the southeast high-level census tract, high concentrations of immigrants appear in the central and western districts of Athens. As expected, the municipality of Athens has the highest rates of both intra-EU and extra-EU immigrants, respectively 4.5% and 18.4%. The socio-economic facilitations and opportunities that arise from residing in the city centre are apparent for the vast majority of the social groups, regardless of country of origin or position in the social class stratification.

5 CONCLUDING REMARKS

The analysis conducted has shown that, although less in comparison to other major metropolitan areas, Athens is indeed segregated. Two basic spatial patterns have been revealed, confirming previous studies.

The first spatial pattern extends from the north-eastern to the south-western suburbs and in part includes the city centre. The areas composing this pattern are mainly affluent suburbs where the high and middle-high social strata reside. The populations in these areas are mostly well educated, employed, employers or own-account workers and administration managers or professionals. The population of immigrants residing there is relatively low and consists mostly of people of origin from a country-member of the European Union.

The second spatial pattern includes areas in proximity to the city centre and most significantly the western and north-western parts of the metropolitan area. Local residents are usually low-educated, while they are characterized by high rates of unemployment and of people whose status in the employment hierarchy is 'employee'. The various concentrations of machine operators and assemblers are due to the various industries that are located in or around Piraeus, Perama, Korydallos, Aigaleo, etc. Immigrants who originate from countries outside the European Union have settled in these areas, seeking to join the local labour market and to live in areas where the cost of living is relatively cheap.

The Municipality of Athens as well as certain districts around it present as socially mixed. People of any social strata or country of origin choose to live there, since there are more opportunities in terms of job variety, cheap housing stock, accessibility, etc. The predominant social groups of the city centre are highly educated, unemployed, employers and own-account workers and, in terms of profession, managers and professionals. Manual workers also have a strong presence in some districts, working in construction services, manufacturing industries etc. The social mixture formed expresses the multiculturalism of the capital and the potentials towards an optimum coexistence amongst different social groups. This 'snapshot' presented corresponds with the contemporary social structure characterizing the Athenian city centre. It seems that, even at the very first years of the economic crisis, dismissals were already rising and own-account workers were unable to manage financially, ending up unemployed.

Certainly, the impact of the economic crisis during the past six years since the last census has dramatically changed the socio-economic landscape of Greece, particularly of Athens. It is expected that more recent data would show an even more polarized image of the metropolitan area. What is to be seen is if the current economic climate is going to persist and, if so, how it will have impacted the spatial patterns currently characterizing Athens. Previous studies (Maloutas, 2007) had shown that a rise in social inequality does not necessarily mean a respective rise in socio-spatial polarization and segregation. An open question, therefore, rises as to the development of social segregation patterns in the event that social inequalities reach considerably high levels, as in the case of contemporary Greece.

ID 1736 | FRAMING THE SOCIAL AMPLIFICATIONS OF RISK IN URBAN TRANSFORMATION OF ISTANBUL

Pinar Ertan Saracoglu¹

¹METU

pinar1saracoglu@gmail.com

1 REDUCING DISASTER RISK AND ITS SOCIO-ECONOMIC DIMENSIONS

International disaster risk reduction framework concentrates on global cause and effect relations of natural disasters from a nominal perspective that hardly copes with developing countries relative socio-economic conditions and turns in to a matter of internalization. There is a requirement of a complementary perspective to observe and measure the socio-economic effects. From a theoretical research perspective, social amplifications of risk introduce us the how social and economic feedbacks in a social system could amplify or repress disaster impacts.

Common efforts on reducing disaster risk has been defined comprehensively through International Decade for Disaster Risk Reduction (1989). Yokohoma Strategy (1994) and Hyogo Framework for Action (2005-2015) were the concomitant procedures followed by Sendai Framework (2015-2030) recently. The general emphasis of sustainable development other than reducing disaster risks and poverty were determined as the main coordinated tasks. In order to reduce disaster risks Hyogo Framework (2005-2015) focused on national goals integrated to local action plans as the top priority and an institutional commitment. As a precondition of determining urban risk drivers in each country mainstreaming information, innovation and education were identified as urban scale targets that would lead to develop a prevention culture and resilience. In disaster risk management, objectives have been shifted from post disaster perspectives as

preparedness, response, emergency and recovery to proactive strategies as disaster risk reduction and mitigation. (UNISDR, 2004) Sendai Framework held in the 3rd World Conference of UN in Japan, makes clear determination in reducing disaster risks while preventing the new risks to generate in urban systems. Poverty, inequality, climate change and unplanned-volatile and rapid urbanization were depicted as urban risk drivers that generate the impacts of disaster risks. Last decade, the perspective on risk as a social phenomenon truly altered the risk perception from a sole physical statement in to a social statement affected by, social, socio-economic and cultural statements. The similar emphasis in Sendai Framework (2015-2030) reclaimed that reducing disaster risks, vulnerabilities and urban poverty demand new priorities from urban planning and disaster risk reduction.

Disaster risk reduction not only concentrates on the impacts of disasters but also vulnerabilities that imply potential dangers and gaps in the physical environment. Vulnerability includes the socio-economic attributes of disaster risks, and defined as the potential referring to physical, economic, natural and social losses and losses in human life. (UNISDR, 2009) Vulnerability and poverty have an intertwined relationship in urban system. Poverty is defined as insufficient nutrition, sanity, education and habitation conditions as well as safety and all other basic needs. (WB, 2001) As an urban component of poverty, squatters are in the first rank in reducing disaster risks for environmental degradation, policy changes, rural unemployment, urban immigration, strict building codes, and other physical vulnerabilities. In fact factors determining the urban poverty and vulnerability differs.

In society, all low-income groups might not be vulnerable to disasters while mid to high income groups could be vulnerable. (Bankoff, 2003) As stated in Sendai Framework, vulnerability to natural disasters, urban poverty and risk drivers indicate for explanatory qualities in determining disaster risks in urban environment. Distinct socio-economic groups in urban environment have been also exposed to disaster risk relatively distinct. In Turkey, low income groups have been faced with the major negative impacts drastically. Referring to recent approaches in Turkey and international frameworks this paper aims to seek authentic definitions for social amplifications generated by/doubling up socio-economic drawbacks and vulnerabilities in urban transformation process of Istanbul.

2 INTERNATIONAL APPROACHES ON URBAN TRANSFORMATION AND DISTATER RISKS

There have been distinct periods shaped the urban fabric of Istanbul that was initially triggered by industrialization and migration in 1950s, then by adaptation to neoliberal politics in 1980s and by the impact of disaster events after 1990s. 1980s were specific to new modes of urbanization and new urban typologies converted through the introduction of globalization. Industrial development shifted to urban development in Turkey in line with the sharp tendency of adapting in to global politics.

Bourdieu (1984) identifies 1980s as a period of reshaping urban realm through distinct classes, through the differentiation of their roles in production and consumption. The sharpness of spatial differentiation is visible in housing areas, offices and public space. Regarding Harvey's (1973)

redistribution of income, urban transformation is pumped for rearranging and reproducing urban processes. More, it has been utilized as a strong tool for rearranging the redistribution of income, increasing the flow of production to consumption and diversifying the spatial differentiation patterns in between urban poor and urban elite.

The entrepreneur local governments, promoted policies and implementations to advertise historical fabric of cities to attract capital and human. Production spaces as the object of industrial production became in to consumption spaces subjected to tourism and recreational facilities under deindustrialization. In scope of these changes, flagship projects including EXPO areas, stadiums, theme parks were all concentrated on large-scale events in UK, USA and North America. (Ünsal & Türkün, 2014) In short term, best use, highest revenue and capital transfer were targeted other than urban renovation. Late developing countries are eager to utilize urban transformation for this purpose to integrate in to global production by maintaining service sector and housing-led urban development.

The nucleus of post-industrial city had been framed via the segregation of urbanization, labor and economic development. Agricultural production was pressured by IMF policies through cutting subventions

to the small producers. (Ünsal & Türkün, 2014) Migration to large industrial cities and decentralization of industry generated housing areas settled as urban corridors. (Davis, 2006) Squatter areas developed rapidly at the periphery of industrial cities had been a common picture starting from 1960s especially in Mexico, Venezuela, Peru and Nigeria. (UN-HABITAT, 2003)

After 1980s in western countries urban transformation developed to endorse sales and privatization of housing areas. Inevitably in 1990s, drawbacks of the previous term has been observed as unemployment, poverty, social exclusion and socio-spatial segregation. (Crump, 2002) Housing policies once defined as a solution to eliminate impoverishment became an instrument for rearranging the redistribution of income despite offering urban poor and low-income groups affordable houses. In order to attract mid-class families to urban deprivation areas, mix-use and mix-class projects were developed in many western countries to impede class segregation in urban environment. As a reflection of neoliberal tendencies on housing policies, in USA; privatization of housing areas was supported by facilitating redevelopment and sales of the former social housing areas. (Ünsal & Türkün, 2014) In UK, urban renaissance was adopted as renovation of housing areas settled at urban centers to prevent emerging housing units at suburbia and diminish spatial segregation. By the support of IMF and WB neoliberal policies with increased impacts have been emerged in new forms of policies such as sustainability, livability, good governance, competition and financial accountability. (UN-Millennium Goals, 1999) On contrary public policies have been focused on poverty, inequality and environmental problems. UN-led urban policies propose alternatives to planning in squatter rehabilitation based on increasing the efficiency of market, civil society and NGOs; collaborative and active partnerships in between local governments and private sector, legalizing squatter areas by integrating them in to housing sector. (Nijman, 2008)

Recently in determining new problems and priorities in today's cities, there has been a requirement for introducing a new research field in scope of the relation in between disaster risks, urbanization and poverty. According to the new statistics of increasing frequency of natural disasters, population density and urbanization movements; reducing natural disasters becomes a top priority. UN identifies global risk tendencies as rapid urbanization, urban impoverishment, global warming and climate change. Global disaster impacts initially affect urban development tendencies in developing countries. In mid-scale to mega cities and being exposed to natural disasters is primarily related to geographical distribution, scale and urban functions. UN states that recently, $\frac{3}{4}$ of 1000 large scale cities are exposed to at least one natural disaster. Low-income groups and urban poor have been mostly affected by natural disasters. (UNISDR, 2014)

When international frameworks focusing on managing disaster risks and urban processes have been reviewed; resilience, sustainability, reducing poverty and squatter rehabilitation are set as effective goals including main projects of redevelopment and urban transformation. As a pre-disaster approach, urban transformation has been developed as a part of a broader plans and programs based on reducing future losses and existing vulnerabilities. In post-disaster approach, urban transformation is basically implemented as a redevelopment process that targets to eliminate demolishing impacts of natural disasters. On the other hand, international case studies and UN reports declare that as a redevelopment process in post or pre-disaster approach, urban transformation stimulates rapid urbanization, haphazard development typologies and increase potential hazards during disaster.

3 THE CASE OF ISTANBUL: URBAN TRANSFORMATION AND REDUCING DISASTER RISKS

In Turkey, the relation between urban processes and disaster risks is weak and unstable in consonance with the urbanization trends. Urban transformation had started in 1950s by the transformation of squatter areas. Until 1960s, urban transformation was set for providing social housing to the new comers in immigration movements but latter it got commercialized. (Keleş, 1990) As a template for today's urban transformation, Squatter Law 775 was enacted for coping with informal settlements. However, in 1980s squatters changed by economic policy. New development movements brought housing speculations and rent competition by economic change and large scale urban transformation projects. The problem of titling squatter dwellers as illegitimate income generators certainly promoted the efforts of legalizing squatters to get political votes via housing development plans.

After 1980s the entrepreneur role of local governments weakened the authority of central government and accelerated privatization movements in urban areas. Mega projects, shopping centers, office areas as well as housing grants for mid and low-income groups and social housing projects were mushrooming by global tendencies in Istanbul. For facilitating large-sale international investments, a legislative, administrative and practical re-structuralization had been employed by authorities. Not only an economic one but also ideological and cultural transformation had been adapted. The visible impacts of this transformation were observed on large-scale urban projects as the second Bosphorus Bridge while invisible impacts were only seen in housing areas of urban poor and low-income groups. The transformation of Istanbul from industrial to post-industrial city; and production space to consumption space has been called as the first steps to become a world city.

Before 1999, urban transformation was developed accordingly to inner dynamics of capital and political processes such as migration, inadequate infrastructure, and privatization. The most observable and measurable consequences of political changes had been squatter amnesties. In between 1983-1984 legalization process of squatters was supported by private deeds offices. Under Prime Ministry, the Mass Housing Authority (TOKI-1984) was established to provide social housing. Though the distribution of ownerships by reclamation plans in squatter areas was failed as the law no 3414 was established and had given squatter dwellers the right of transferring their dwellings to others which led to housing speculations immediately. By these implementations the squatter areas were settled and left in urban centers differing from the previous forms settled in peripheral areas.

The Great Marmara Earthquake (1999) was a turning point for legislative and administrative restructuring for accelerating urban transformation. More than 18.000 people died and 100.000 buildings were demolished. The extension of duties and rights of the Mass Housing Authority (TOKI) by Urban Transformation Law 6306 (2012) given TOKI the authority to construct new housing areas at public land (2003) and to establish partnerships with local governments.(2005) Through the revisions adapted in TOKI Law 2985, it has become the full authority to clear, rehabilitate and transform squatter areas. The law on Conservation by Urban Regeneration (5366, 2005) was also an unclear implementation by the limits of conserving and regenerating historical urban areas that totally pillaged many historical districts and opened them for gentrification.

After 1999, urban transformation was restructured by a new form of legitimacy based on externalities likewise earthquakes. Planning and other development tools were excluded by the dichotomy of providing earthquake-safe housing and redistribution of income. Urban processes have been governed by the central political authority and the rights and interests of differentiated socio-economic classes were opened for competition. Urban transformation expanded rapidly in Istanbul and around Turkey for the purpose of reducing earthquake risks. The background of disaster management in Turkey is rather responsive to political change. Starting from the Republic Period, post-hoc laws and administrative reforms had failed to generate a holistic approach and institutionalization. Post-disaster framework concentrating on a long term post-disaster redevelopment after damages and demolitions.

4 CONCLUSIONS ON SOCIAL AMPLIFICATIONS OF RISK

As a supporting theoretical framework, the social amplification of risks by Kaspersons has been developed in the mid-1980s in scope of institutional risk assessment. Risk events are experienced through physical harms and society create interpretations of risk as social and cultural processes. Social and technical aspects of risk and various theories related to social science perspectives as communication theory, and referring findings are gathered in a holistic framework. Through assessing risk technically, the main theory relates psychological, cultural, sociological perspectives and risk-centered social behaviors that express the risk perception. Although risk perception is prioritized within the framework; the fundamental hypothesis is that risk and impacts harm humans and ecosystems directly while social amplifications of risk harm economy, social institutions and socio-economic differences in society indirectly. At first glance, social amplifications of risk primarily occur in the information flow in society and then in response mechanisms of society accordingly. Risks are sensible to information flow with the aspects of psychological, social and cultural processes and by increasing or diminishing the risk perception. In fact, responsive social behaviors or reactions could hold secondary social or economic impacts that alter the structure of risk by its perception in society. Physical risks and their impacts could be duplicated by

decreasing their visibility while they could even be decreased by increasing their visibility through political notions and manipulations of specific socio-physical indicators and structures.

Within this scope, the social amplification of risk refers to a socio-economic criterion focusing on the relation of urbanization and social structure through amplifying the physical impacts of disaster risks. The fundamental relation of the theoretical analysis is the correlated relation in between disaster risks and transformation-led urbanization that is both steered by and led to socioeconomic differentiation. Urban transformation in Istanbul has been grounded in socio-physical facts such as disaster risks, social amplification and vulnerabilities. Though, their physical and so-called impacts on urban system could be clarified by developing a holistic approach.

Theoretically urban transformation for the purpose of reducing disaster risks has two outcomes. At first, there are two separate sets of means and ends within the same process and their quantitative impacts are led to transformation-led urbanization. Secondly, urban transformation process and impacts are concluded in to distinct outcomes for differentiated income groups.

Rather than focusing on the amplification process of risk through the social medium or social stations, secondary impacts of disasters based on behavioral and communicative responses are identified. In scope of the socio-economic criterion; secondary impacts go beyond individuals or groups but the whole social system. In Turkey, during the process of urban transformation in disaster prone areas in the redistribution of income, urban poor or low-income groups are neglected by absorbing the rent rise in to power actors such as the government, contractors or mid/high income groups. Low income groups are prevented from getting their share from increase in value by urban transformation are totally excluded by diminishing returns and the negative impacts of living in a disaster area. When free market inequality and the inequality imposed by urban transformation are compared it is found that the second one is much more oppressive, ideological and also targeting to consume the share of urban poor. Considering the urban transformation process by all of its complementary legal and defacto extensions, it reveals two major consequences. First, during the urban process; the emphasis on disaster risk reduction is switched to urban rent. Secondly, after the urban process; the requirement of a feedback mechanism regarding the impacts of urban transformation on reduced/prevented disaster risks in disaster prone areas is suppressed by the muddling arguments of reconstructing the new building structure.

Physical Consequences referring to physical attributes of disaster risks include both visible/natural and invisible/socio-economic/ideological risks that have physical outcomes as vulnerabilities and changes in the nature of risks.

Social amplifications in urban transformation refer to socio-economic vulnerabilities and disadvantages of urban poor as wells as ideological hazards and politicized risks. As an effective devise for the relocation and redistribution of disaster risk, urban transformation reproduces the built environment by its exchange value. The outcomes are measurable both as an input and output in the urban process. Harvey (1982) states that economic crises often intersect with the intensification in creative destruction through large scale projects and high rates of construction. Although urban transformation in Istanbul is set to reduce disaster risks; in common market-led interventions adopted by urban and regional authorities, the highest and best use is kept sustained during the process. More, the redistribution of income prioritizing disadvantaged urban areas is neglected because of the absence of planning mechanism. As social amplification risk becomes a commodity or a destructive good pertains the favorable conditions for extensive crises to reproduce means of production. Risk changes in to a liquidatable commodity and becomes tradable through power actors; governmental institutions, local administrations, contractors and dwellers.

1 INTRODUCTION

The paper aims at exploring the relation between processes of policy-making and cultural dimensions, assuming that cultural and symbolic dimensions are relevant in the ways in which both policy-makers and beneficiaries understand and respond to changes.

The frame is represented by the Horizon2020 project Re.Cri.Re.: between the representation of the crisis and the crisis of representations, started in May 2015 and involving several disciplinary fields: psychology, urban and territorial studies, economy, sociology, philosophy.

The research opportunity is given by the on-going Italian experience in national and local policies for inner areas called "SNAI" (Strategia Nazionale per le Aree Interne, National Strategy for Inner Areas). This policy, built in 2013, is operating in 20 pilot areas across the country and it will cover, in next years, all the areas defined as "peripheral" or "ultra-peripheral" of Italian peninsula, corresponding approximately to the 60% of Italian territory. In particular, our contribution will focus on the implementation of SNAI in one specific pilot area, Alta Irpinia, a Southern area located in the mountain part of Campania Region.

In the following pages we will briefly present the cultural approach to policy-making in general terms, as we are elaborating it in Re.Cri.Re. project. Then we will introduce local development and cohesion policies, framing SNAI and the implementation in Alta Irpinia, with some conclusions concerning how to incorporate a cultural perspective in the processes of policy-making.

2 CULTURAL PERSPECTIVE IN POLICY-MAKING

Re.Cri.Re. project¹ is built on the idea that in policy-making the analysis of cultural dimensions is highly valuable because they moderate the impact of policies, especially in time of crisis. With "cultural dimensions" in Re.Cri.Re. it is intended the deep structure of systems of meanings which allow human beings to produce their own interpretation of events (Salvatore et al., 2017). In time of crisis, the systems of meanings are challenged and interrupted, producing different potential scenarios: ruptures, closures, new adaptations, innovation. We know, by literature and experience, that the impacts of policies are not just the sum of their intrinsic characteristics, such as attended outputs, targets groups, tools; neither they depend just on the relevance of the contents (cohesion, development, gender equality...). Policies for local development are a quite clear example of this. In local development policies, "culture" is usually used as part of the immaterial assets contributing in creating the specific milieu, able or unable to support and to embody the changes required by the policies. Even if the existence of these local immaterial specificities is widely accepted, we experience a lack of professional approaches able to integrate the recognition of cultural dimensions in processes of policy-making. The experience in the analysis of the complex process of policy-making empirically showed that policy-makers often have a sort of sense of what are the prevalent directions of cultural dimensions at stake in the communities in which they operate, and they can use this knowledge in different ways and for different purposes. For example, they can use it to norm, considering cultural dimensions as a problem to be solved; or they may use their knowledge in functional terms, for example to adapt communication or interventions; or, eventually, they can consider cultural dimensions as a crucial part of human variability and as something to be addressed, something that can be generative in terms of change.

One of the goal of Re.Cri.Re. project, as result of cooperation between territorial and psychological studies, is to propose approaches enabling policy-makers to consider the role of cultural dimensions in their own practices in a dynamic and strategic way.

In the present paper, we will adopt the idea that the process of policy-making is a special kind of human interaction among policy-makers and beneficiaries, in which the issues of "future" and "change" are central. As every human interaction, it is based on the "idea of the other", grounding the actions, the tools for communication and the goals. With "idea of the other" we basically refer to the ways in which each participant represent the other, as a ground of the relation. The research, in this phase, is focusing on how policy-makers see, and consequently act towards, the target population in terms of their human variability: that is, the specific and context-based ways through which beneficiaries understand and interpreted the world, the resources and also the policies themselves. This approach allows to see policies, their failure and success, in a different perspective. In particular, three main questions grounded the analysis:

Question 1. Theory. Which aspects of the human variability are taken into account? Which type of knowledge concerning beneficiaries is produced during design, implementation and evaluation phases?

¹ see the website of the project: www.recrir.eu

This question is related to the set of information concerning the beneficiaries that policy-makers (and other relevant actors) consider as relevant in policy design, implementation and evaluation. It also includes the possibility to change, during implementation and evaluation, the aspects considered as relevant. For example, categories such as behaviours, shared values or social capital can emerge as unattended problems or issues during implementation, convincing policy-makers to include them as relevant aspects in describing the beneficiaries.

Question 2. Approach. How (strategies, methods, instruments) the human variability has been taken into account and eventually addressed?

The focus is on the tools used to address the human variability, namely the model of action chosen by policy-makers.

Question 3. Purpose. What are the purposes of the recognition and action related to the human variability in policy-making?

This question focuses on the ways in which the recognition of human variability is used, for which purposes. It allows us to understand the (often implicit) link between human variability recognition and policy-making. For example, the local cultures are sometime used as a reason to motivate the failures of policies itself. In other cases, the knowledge concerning human variability is used to improve communication strategy or to adapt goals and processes. In other cases, this knowledge is used as fundamental resource, as a vector of change and as a goal in itself.

3 TERRITORIAL COHESION AND POLICIES FOR LOCALITIES

Economic and social cohesion goals are part of the history of the European Union itself, since the Single European Act (1986) through which the Original Treaty (1957) is integrated with the aim to pursue an "overall harmonious development" in order to reduce "disparities between the various regions and the backwardness of least-favoured regions". At that time, the emergencies were related to the processes of de-industrialisation in Central and Northern Europe and to the marginalisation, especially in terms of infrastructures, of rural areas. Cohesion policy were strictly related to an ideal of European social model, in which the public intervention was intended to balance the inequalities and externalities produced by the market economy; more concretely, the policy is related, according with Faludi (2004), to the French model of *aménagement du territoire*, which is defined as "public action concerning the disposition in space of people, activities and physical structures based on a balanced notion reflecting the geographical and human situation in the area under consideration" and to the durable European Commission Presidency of Jacques Delors, spanning over ten crucial years, from 1985 to 1995.

Cohesion policy is still the most relevant expenditure of EU, covering approximately the 30% of the total budget and being distributed in all the Members countries. It is very difficult to judge the effectiveness of such an effort (see the introduction in Farole, Pose, Storper, 2011). Regional disparities increased in last 20 years, but at the same time this was also partially statistically related to the process of Enlargement; more recently, the global financial crisis strongly contributed in increasing poverty and disparities among European Regions (see the introduction of the 6th Report on economic, social and territorial cohesion, adopted by European Commission, 2014). However, it is not possible to know what it would have happen, especially to marginal areas, without a so complex and multi-shaped policy as the cohesion policy is.

Letting aside (controversial) general evaluations, the cohesion policy represents the European framework to which strategies of local development were related, in last 30 years. More precisely, cohesion policy faces some of the issues which are crucial for local development policies, such as how to produce development in a frame of spatial inequalities, how to deal with both growth and equity, and how to improve the processes of local policy-making through the involvement of local authorities and stakeholders.

In Italy, local development is initially related to the so-called Third Italy and to the passage from variegated experiences of economic and social development to the construction of a model, the "industrial district" in which the local factor was mainly conceived as an economic factor. During Nineties and 2000s, the focus on local development progressively shifted, and several authors (among others: Amin 1999; Pasqui, 2005)

contributed in enhancing the role of institutional, cultural and cognitive assets to explain why some regions show more proclivity to produce development than others.

Governa (2007), briefly sum up some of the main, well-known, criticalities raised by practices of promotion of "local development": the tendency in repeating the same processes and solutions for very different contexts, despite the common and rhetorical recognition of the uniqueness of "local" contexts; the apparently un-escapable problem of vicious circle, in which some local immaterial assets (such as good local governance, trust in institutions, capabilities to build visions for the future) are both a premise and an output of the process of development; the weakness of partnerships, often born for the sake of specific financial goals and then unable to produce durable changes. In other situations, most positive experiences seem to be produced by specific, "enlightened" actors such as a mayor, a group of deputy mayors or a public manager, in an idiosyncratic, unique way (Donolo, in De Leo, Fini 2012).

At the ground of the idea of "local" development there is the recognition that localities and their actors are necessarily the ones embodying the production of change. Consequently, the relation between the national or European policy-makers and the local stakeholders reveals to be crucial, as well as the relation between local stakeholders and inhabitants.

In the attempt to address both the limits and the potentialities of cohesion policy, Barca's report (2009) re-framed this relation through a "place-based approach". In his view, the role of European and national policy-makers is to provide the general aims of efficiency and equity, strategic fields of interventions, innovation and the tools to evaluate processes and results; while local stakeholders are the ones who hold the specific knowledge concerning available potentialities and criticalities. In Barca's view, inspiring Italian National Strategy for Inner Areas, the role of the national level is also to "destabilize" the local balance of power, which sometime are the main responsible of the lack of development at local level. This top-down "destabilizing" activity will correspond to a bottom-up activity which is in charge of local groups (both local decision-makers and civil society), in order to provide site-specific knowledge and to cooperate with the national level to find place-based solutions. The local is, in this view, in charge with the production of "knowledge chains", that is the possibility to identify the local assets and to connect them with a strategic view of the local context; and it is also the place in which local innovators are to be found, supported and possibly included in the process of definition of the local strategy, through a scouting process (Barca, 2016; Tantillo 2015).

4 THE DESIGN OF NATIONAL STRATEGY FOR INNER AREAS IN (VERY) BRIEF

The National Strategy for Inner Areas (SNAI) is a policy enacted by the National Italian Government starting in 2012 and promoted by Fabrizio Barca, at that time Ministry for Territorial Cohesion. SNAI is organised as an inter-sectorial programme, involving several Ministries: Territorial Cohesion and Southern Italy; Work and Social Policies; Education, University and Research; Health; Infrastructures; Economic Development. Presently, the programme is in charge with the Department of Cohesion Policies of the Presidency of the Council of Ministers. SNAI is a multilevel programme, promoted at national level and implemented through Regions at local level. It adopts a mix of sources, both European, national and regional: SNAI aims at combining 2014-2020 EU funds (ERDF, ESF, EAFRD, EMFF) with interventions to improve the provision of essential services through additional resources included in Italian Stability Law, in cooperation with National Ministries, Regions and Provinces. SNAI focuses on areas of the country which are significantly far from hubs of services and infrastructures: nearly 13 millions of people live in these areas (approx. 25% of Italian population), covering the 60% of Italian territory (UVAL, 2014).

The demographic trends, considered as crucial in defining inner areas, are described considering the last 40 years (1971-2011), as characterised by: reduction in the number of inhabitants; ageing of the population; increase of immigration, considered as a partial "mitigation" of the ageing and abandonment of inner areas; change in land use and productive activities (in particular agricultural activities are declining, favouring the growth of forests but also the increase of hydrogeological risks). SNAI team produced a very detailed and open access database concerning more than 100 indicators, useful to describe the socio-economic and territorial conditions of Inner Areas in Italy. They are also working to include more and more these territories in the political agenda of Italian governments.

Generally speaking, the strategy aims at inverting the demographic decline of these areas, in terms of emigration, ageing and low level of birth-rate. This goal will be pursued promoting two type of actions:

- ensuring adequate public provision of essential services in these areas (especially in education, health and mobility), also fostering cooperation among Municipalities;
- supporting local development strategies, through a place-based approach.

The strategy implies experimentations in each Italian region, choosing one or more pilot areas. In pilot areas, SNAI national team is cooperating with local stakeholders and mayors to define a specific, context-based strategy. Strategies will have some priorities in terms of fields of action, in particular: territorial safeguarding; valorisation of natural and cultural assets and sustainable tourism; agricultural business and production; renewable energy supply chains and energy saving; handicraft and local knowledge.

5 THE CONTEXT OF ALTA IRPINIA, CAMPANIA REGION, ITALY

25 Municipalities in Alta Irpinia were chosen to be one of the areas implementing the National Strategy in Campania Region. Irpinia is a historical and geographical sub-region located approximately 100-150 km East from Naples. It represents the hill and mountain area of Avellino Province, with several peaks overpassing 1500 mt on the sea level. The landscape can be described as a succession of valleys and mountains, very rich in waters and forests. Historical villages are often located on the top of hills, born during as fortified settlements. The area is classified as "high seismic risk", and this has been dramatically evident in November 23rd 1980, when a violent earthquake hit the area.

Nowadays, the pilot area includes a population of approx. 60.000 inhabitants, with very low density: only 2 Municipalities out of 25 reach 5.000 inhabitants (Lioni and Montella) and 4 of them are under 1000 inhabitants (Cairano, Cassano Irpino, Monteverde and Rocca San Felice). In the phase 1971-2011 these Municipalities lost the 25% of their population. Presently, the percentage of population over 65 years-old is approx. 24% of the total population, overpassing also the average of all Italian inner areas.

We will focus on the history of Irpinia after the violent earthquake that hit the area in November 23rd 1980, killing approximately three thousand people and causing the displacement of 280.000 inhabitants. Before the earthquake, Irpinia was mainly an agricultural area, already experiencing demographic decline and emigration. This occurred in line with the two main trajectories of internal migration in Italy: from the South to the North; from rural areas to the major cities. After the emergency phase, the process of re-construction started, following some peculiar strategies. It was intended as an opportunity to push for the economic development of the inner areas of Southern Italy, which were the most deprived of the country. Several sites were selected and provided with the infrastructures to host industries; entrepreneurs were supported through non-repayable loans, in order to start their activities in the area, promoting industrial development through strong financial support in deprived areas (Sarno, 2009). In Irpinia, several industrial areas were built in few years, especially in the valleys; a very scattered diffusion, increasing also costs for infrastructures, that was then described as "one bell tower, one chimney stack", often damaging environmental conditions (Ventura, 2015). As M.S. and S.C. referred during the interviews (they are actors of local development starting their activities in those years), the process of re-construction was dominated by a blind trust in the entrepreneurs, most of them coming from the Northern Italy, and a deep distrust for local farmers and artisans. Moreover, the equation between industrial activities and development led to partially ignore the peculiarities of the area. Only some of them survived and are still active, such as Ferrero and Zuegg, in agro-industrial sector, respecting the local peculiarities in terms of agricultural production. Other industrial activities which are still relevant are in mechanical (FIAT in Melfi, in Basilicata Region), high-tech and in wood industry. Despite these relevant exceptions, most of the industrial activities, supported during the re-construction, quickly failed. In parallel to the national model based on industrialisation, an alternative model of local development was prompted by a group of professionals, following the experience of bottom-up local development promoted in Sicily by Danilo Dolci and Lorenzo Barbera. This experience was based on cooperation and cultural empowerment (see for example Ventura 2013, documenting the experience of women cooperative activities for re-construction and employment). However, it was pretty marginal compared to the enormous afflux of money provided by national initiatives oriented towards re-construction and industrialization.

The evaluation of the re-construction phase, the use and abuse of money, the effects on territorial assets, on local economy and social structure are very complex and still matter for debates: according to several local actors, those decisions and events are still at the ground of the present economic, social and environmental situation in Irpinia.

Surely, a the different political and administrative attitude occurred in Italy during Nineties, after the "Tangentopoli" phase. The use of public money for private enterprises was partially interrupted; the development was organised more and more through "negotiated planning", a form of planning based on agreements between public actors (at various level) and private actors, aiming at pursuing a more regular, planned and accountable process of development. In parallel, the last 20 years were also characterised by a new relevant political actor for local development, that is EU. In Irpinia, LEADER Programme and funds for rural areas were the most used tools to activate initiatives for local governance and local development. Nevertheless, during Nineties and early 2000s, the demographic decline went on, despite the efforts of the re-construction, the attempts to develop industrial production in the area, European funds and the new tools for local governance. In last years, the situation was described as a progressive "desertification" , in demographic and economic terms.

6 IMPLEMENTATION OF SNAI IN ALTA IRPINIA

According to interviews to SNAI staff, Alta Irpinia was one of the most controversial experiences among pilot areas. Alta Irpinia was chosen, thanks to the cooperation between the national, inter-ministerial team and the Region Campania, in late 2014. In January 2015, Ciriaco De Mita was chosen to represent the assembly of the Mayors. Ciriaco De Mita is the Mayor of Nusco and he was one of the most relevant Italian politicians during Seventies and Eighties; his activity was decisive in the prevalence of the industrial development strategy after the earthquake and he is still recognised as very influencing, also at national level.

In July 2015 the first draft of the Strategy was defined, as required by the national directives for the pilot areas. The Draft of the Strategy for the pilot area "Città dell'Alta Irpinia" has the form of a list of criticalities followed by a "to do's list" reflecting the double nature of SNAI, operating both in public services and welfare and in development strategies. Accordingly, the Draft of the Strategy is organised in "Comunità di Servizi" (it could be translated in "Public services Community") and in "Comunità operosa" (Industrious Community), referring to the need to improve the welfare and infrastructural system and to support local development. Municipalities were also required to introduce some innovations concerning institutional cooperation: the group of mayors of Alta Irpinia decided to work on producing a common digital real estate registry and on the digital infrastructure for the area.

During the implementation of the strategy in Alta Irpinia, some unpredicted and unexpected effects occurred. In particular, the assembly experienced problems in cooperation among members and with other local actors and in transparency and openness of the process of the strategy definition, despite the goals of institutional cooperation and development through local "innovators" promoted by SNAI.

Local conflicts among Municipalities where also increased by changes implemented by Campania Region in the distribution of resources for Rural Programme. The Rural Programme (financed through EU funds) supports cooperation among private and public actors to develop initiatives for rural development through LAGs (local action groups). LAGs, together with "Comunità Montane" , represented the main forms of organisation among public and/or private actors in Italian rural areas and particularly in Irpinia. The number of LAG financed in Irpinia passed from 4 to 2, several Municipalities of Alta Irpinia are excluded and the new LAGs cover areas which are significantly not homogenous in their historical, geographical and social characteristics. The attempt, failed, to create a new LAG among the 25 Municipalities of the pilot area produced an unclear and conflictual situation in terms of groups involved in local development in Alta Irpinia, which will beneficiaries of funds and regional and national support. There is also the real risk to break up the experience of LAG CILSI, which was pointed out by national and regional experts as the most active and effective in the area. In other terms, the decisional process in Alta Irpinia does not seem to exploit and develop the results which were already considered as relevant in terms of rural development.

The process of decision-making is described by the experts of SNAI, by some local actors and in several articles appeared in local press, as poorly open and too much oriented by the influential presence of the

Mayor of Nusco, having negative effects on the involvement of the civil society but also on the internal debate. Some of the Mayors of the assembly actively claimed for a higher level of openness of the decision-making process but they were partially marginalised. In December 2016, these "dissidents" (as they were defined by some local press) organised a public meeting in Calitri together with associations of farmers, artisans and other associations of the civil society. They met in order to propose an alternative view of the process, claiming in particular for an increased openness, for more efforts towards young people and for a special attention towards agriculture and environment issues and they produced a written proposal which was then presented in the pilot area assembly. This action was interpreted as a threat to the unity of the official pilot area assembly: the president of the pilot area and other members of the assembly considered the meeting in Calitri as an attempt to divide the assembly and as a problem to be solved with the marginalisation of their proposal.

The first draft was then re-formulated in the Preliminary Version of the Strategy, realised with the support of the national Agency of consultancy "Invitalia". Nevertheless, the passage towards the Framework Agreement (APQ), which is the final step towards the implementation of the strategy (and the full availability of financial resources) is requiring more time than expected (in March 2017 the APQ is not ready; however, only 5 out 19 areas in Italy already signed the APQ at this time). Moreover, in spring 2017, the Assembly of Mayors established an agreement with the Governor of the Region, for the total amount of 200 million Euros. The average financial support provided by SNAI for the implementation of the local strategy is 6-8 millions of Euros. The regional agreement reinforced the local Assembly, together with the explicit support provided by the national SNAI team

6.1 TYPE OF KNOWLEDGE

In this sub-chapter we will answer at the question 1: which aspects of the human variability are taken into account? Which type of knowledge concerning beneficiaries is produced during design, implementation and evaluation phases?

It is interesting to point out that this aspect was considered as central for the policy-makers and experts implementing the National Strategy. According to Natali (2016), one of the most interesting aspect of SNAI is indeed the approach for the collection and the use of information, and finally for the production of knowledge, concerning the local contexts. In her words, as soon as we look at inner areas from distance, they appear to be all similar: demographic decline, ageing, school drop-outs, lack of care of landscapes and cultural heritage. But these similarities are an illusion, because each specific place is facing these situations in its own way. She underlines the importance of "behaviours", which are rooted in systems of relations, powers, which tend to be an obstacle for changes. Each of them is inherently ambivalent, and it could be preserved or it could be changed, having reasons for both these attitudes. Again, Natali described the fieldwork activity as a passage from a schematic view to a more and more detailed one, including those people holders of "precious knowledge", with a point of view worth of attention and consideration. This process is both useful to incorporate the local knowledge and to involve this people in participative planning activities. According to Natali, it implies more efforts in and more time if compared to traditional planning activities, producing an inquiry (referring to the work of John Dewey) oriented to mix knowledge and action, social interactions and decision-making.

In terms of collection of information and production of knowledge, SNAI team work through both desk analysis and fieldwork analysis. The desk analysis was firstly based on demographic and socio-economic data. The definition of Inner Areas itself was based on specific quantitative parameters, based on the distance from primary services (mainly: hospitals, secondary schools, train station). During the design phase, the national team produced an open access database including more than 100 indicators for all the areas related to: demographic situation and historical trends; land use; employment and productive activities; health system; school system.

Together with these data, homogenous for all Italian inner areas, the national team cooperated with the regional team in order to produce a more qualitative analysis of the selected areas called "open diagnosis". In this phase, the collection of information was based on territorial analysis (focused on demographic trends; characteristics of agricultural activities and other economic specialisations; digital divide; cultural heritage and tourism; health performances; accessibility; education and school system; presence of NGOs); on the mapping of local actors and networks; on qualitative interviews (in Alta Irpinia they realised

96 interviews). In particular, the semi-structured interviews focused on the main changes occurred in the last 20 years and the vision for the future, referring to 2030. Moreover, they asked for the potential and existing resources of the area; the main obstacles and problems faced at local level; the possible solutions; the ways in which those potential solutions could improve the condition of limited development and the demographic situation; which other local actors could be involved. The synthesis of these interviews were organised through a SWOT model, with some elements related to symbolic dimensions, such as: a pessimistic view of the future; a general lack of trust in policy-makers and a diffuse sense of unproductive disputes; the idea of Irpinia as an area of hidden potentialities, having already missed its opportunity of development during Eighties and Nineties; the perception of the interviews themselves as something good, as an opportunity of inclusion and voice.

However, this knowledge, collected by national and regional experts, was considered as useless and negative by local policy-makers and by the mayor De Mita, for being too critical towards local administrators and inconclusive. In this sense, two different and partially conflictual representations of the local human variability were at stake: the one promoted by the national experts and the one produced by local policy-makers.

During implementation, at regional and national level, there was a recognition of the lack of openness of the decisional process and the charismatic role of the leader. Consequently, some adaptations were organised (see below).

6.2 APPROACHES

Question 2. Approach. How (strategies, methods, instruments) the human variability has been taken into account and eventually addressed?

One of the main tool of SNAI is the direct involvement of Mayors. Mayors of the selected inner areas are asked to be part in the place-based approach promoted by the SNAI, implying the definition of a local strategy with the support of national and regional experts.

Secondly, SNAI staff worked providing a robust set of data to the local policy-makers, highlighting some specific problems, especially concerning public services. In Alta Irpinia, for example, they registered low performances in schools; negative trend in people employed in agriculture, especially in the young generation (under 40); increase in the percentage of forest areas.

During implementation phase, the knowledge produced by the national level and the one in which local actors are embedded partially clashed, producing a negotiation among them. The national and regional team decided to support the local assembly reinforcing their competencies with the assistance of a group of external experts, mainly due to the difficulties observed in the process of implementation.

This negotiation was feasible because both of them had the same goal, that is reaching the stage of definition of a local plan; and it was solved through an increase of technical and also political support.

6.3 PURPOSES

Question 3. Purpose. What are the purposes of the recognition and action related to the human variability in policy-making?

In a first phase (that is, design and first part of implementation) the focus was on the production of knowledge for the selection of target areas and for the definition of local plans. That is, data concerning human variability were collected mainly with the purpose to delimitate the field of action and to provide local policy-makers with a set of qualitative and quantitative data, useful to define and to implement the local strategy. During the implementation, the collection of qualitative data and the observation of the process itself, in its effects on the local context, led to a partial change of focus, moving towards an increased attention to the role of local policy-makers (change in tools) and in communication (increase of national intervention at local level).

7 CONCLUSIONS

Despite the recognition of the role of immaterial dimensions in processes of local development, we are still far from theories able to include the immaterial dimension in operative terms. In the present paper and in Re.Cri.Re. project, we proposed to focus on the ways in which the relation between policy-makers and beneficiaries is built, in order to understand some of the implicit premises leading design and implementation of the policy.

Alta Irpinia is a very interesting context: in last four decades, it has been, and still it is, a sort of laboratory for policies for local development. The area experienced at least three phases. During the first one (1980-beginning of Nineties), industrial development was pushed. In that phase, it seems to prevail a view of the beneficiaries as unable to produce their own path for re-construction and change. The support to industrial production was realised through a highly other-directed model of development: entrepreneurs often coming from outside the area (mainly from Northern Italy), supported by national government, offering industrial jobs to people in an area which was clearly oriented to agricultural production and with high environmental quality. The alternative model, based on cooperation, was marginalised. In a second phase, in Nineties and 2000s, the attempt to promote an endogenous development mainly through EU funds was not able to slow down the demographic decline, to compensate the national policies and to produce cooperation among local stakeholders and policy-makers, with few exceptions. Broadly speaking, the cuts in public services in national peripheries and the image of eternal deprived area ended in supporting the abandon of the area by inhabitants and the economic decline, despite EU efforts.

In this last phase, Alta Irpinia is involved in a national strategy in which inner areas are seen as the site of important social and economic potentialities for the country. Local contexts are seen in multi-layered ways: they are seen as both the site where potential innovators live, as well as the sites for extractors of local resources and promoters of "close local communities", defined as "enemies of the inner areas" itself (UVAL, 2014). During implementation, the collection of qualitative information and the openness to adaptations offered the possibilities to let emerge more nuanced visions of local contexts.

However, in Alta Irpinia the goal to destabilize the local continuity with the past partially failed, and the national strategy appeared to be captured by local traditional systems of power and in some respects it ended in reinforcing them. As we observed, policy-promoters (the national level) and policy-implementers (the local level) produced two different and conflictual vision of the beneficiaries: at national level, they produced an explicit knowledge, potentially dynamic and dialogic, which was not included in the process of policy implementation by the holders of local, more implicit knowledge and power. The tools used to implement the policy reinforced the latter, even with some improvements in management and openness, with the main purpose to reach the formalisation of the strategy.

Two possible conclusions can be traced, taking into account the cultural approach. The first one is related to the culture of local policy-implementers: in a policy promoted by national government to be implemented at local level, the human variability of local policy-makers could be considered as a crucial variable, as well as the one of target population. Secondly, the representation of innovation as something promoted by "special" people, to be scouted as local talents, may prevent to know and to work within and on the local systems of meanings.

T21 | URBAN FUTURES: CHALLENGES AND VISION

CO-CHAIRS: PETER ACHE; PETER NAESE; DAVIDE PONZINI; EDUARDO CASTRO

"I've seen things ... you people wouldn't believe. Attack ships on fire off the shoulder of Orion; I watched c-beams glitter in the dark near the Tannhäuser Gate ... All those moments will be lost, in time, like tears in rain. Time to die."

In *Bladerunner* (Scott, 1982) replicant Roy paints in his soliloquy horizons no human has seen. LA 2019 is the setting for the cyber-punk movie, posing questions regarding citizenship, environment, technology, power, and democracy. The city is a gigantic dystopian machine.

2019 is close, just two years from the AESOP 2017 conference: where are the urban beams glittering in the future?

We invite papers to a track, which as a 'laboratory' tries to present experiments, either intellectual or practical, sketching out broad utopian views or developing concrete utopias (Bloch, 1986). Spatial horizons are not specified. Time horizons should reach far, helping us to escape the boxes of actual debate.

The track aims at fostering new ideas and ways of understanding urban futures. We encourage considering the possible evolutions of environmental, technological, political, social variables or conditions in the very long term. Scenarios can include, but are not limited to:

- the impact of radical climate change and radical mitigation strategies,
- pervasiveness of smart technologies and security measures,
- dismantling of statehood,
- radical modifications in current geopolitical order,
- massive migrations,
- decrease of international and intra-national inequalities,
- capacity to improve global national and regional governance,
- capacity to control the big financial powers,
- new urban structures favoring human interaction, or else.

Papers should be submitted to the track, approaching perspectives on above outlined themes or other relevant ones. We would like to hear from you, what the important relations and conditions that affect people and places in the future are and how we could react to this, counteracting problematic or enhancing positive developments, but in all cases dealing with "unknowable novelty".

The format of the track will be different, too. Together we will work during the track sessions on new horizons, which shall also be sketched out in experimental forms of interaction. Inspired by Harvey (2012, X) and Lefebvre, the track invites you to envision "an alternative urban life that is less alienated, more meaningful and playful but ... conflictual and dialectical, open to becoming, to encounters (both fearful and pleasurable), and to the perpetual pursuit of the unknowable novelty".

ID 1316 | THE CHANGE OF URBAN SPATIAL FORMS AND ITS INFLUENCING FACTORS – FROM TOWN PLANNING TO COMMUNITY EVOLUTION

Yufeng Yue¹; Liyao Wang¹; Yuci Huang¹; Haochen Shi¹

1 INTRODUCTION: THREE TYPES OF FORCES IN SPATIAL PLANNING

Since the 1980s, the Urban Regime Theory, which interprets the influencing factors affecting urban spatial forms was initially proposed in the U.S. Because of this theory developing a new way to interpret urban forms from the perspective of social science, it occupies the dominating position in the system of urban study theory. The founders of this theory, Logan and Molotch (1987) maintained that these factors could be concluded as three types of forces, which represented the interest of governing party, financial group and community organisation. Meanwhile Stone (1989) pointed out that the coaction of these forces decides most urban spatial forms at the material level. Based on their views, the aim of this essay is to interpret how the change of spatial forms is affected by each force and how these forces interact in deciding spatial form evolution. To start with, the theoretical model of urban regime theory will be introduced. Then, two cases about new town planning in UK will be discussed to evaluate the change of spatial forms and the different spatial characteristics caused by each force. Furthermore, the interaction of three forces in spatial evolution will be interpreted through the studying case in China. Finally, new conceptual model will be proposed, which could explain the relationship among three forces in influencing urban spatial forms. The conclusion indicates that the urban spatial forms are affected by three types of forces reflected in different aspects mainly including spatial structure, transportation system, land shape, land-use, density and accessibility of infrastructure etc. Depend on it, the cause of different spatial forms could be explained much clearly.

1.1 PRINCIPLE STRUCTURE OF THE URBAN DYNAMIC MODEL

According to the Urban Regime Theory, the Shaping and changing of urban forms is the reflection of three forces' interaction. To illuminate this interaction, the American scholar Zhang (2001) proposed two dynamic models which referenced the mechanical principles to analyse the interaction more visually. Through the perspective of urban dynamic model, each case could be analysed in more systematic way. More important, it becomes possible to compare spatial form with each other to evaluate their similarity and difference in unified standards and conclude the influencing factors.

Figure 1 - Resultant force model1 | Figure 2 - Covering force model2 . Source: Zhang, T., 2001. The Urban Restructuring of Chinese Cities in 1990s and Its Dynamic Mechanism. City Planning Review, 7, pp.7-14.

¹ In the resultant force model, each force is defined as equal weight in the resultant force model. The 'final decision' will be decided by the parallelogram rule of forces. For the reason that government force, market force and community force could usually occupy different weights, covering force model is created.

² In the covering force model, three forces possess unequal weights. At the same time, the decision order is adopted according to the order that the government force has the most powerful impact while the community force has the weakest impact. The force has covering feature which means the force with larger weight and higher decision level could cover other forces with smaller weight and lower decision level.

1.2 TIME AXIS IN CASE RESEARCH

The time span of this research mainly focuses on three periods (Figure 3). From 1950s to 1970s, three generations of new towns were built with different planning strategies because of changed government policies (Rydin, 1998). Around the same time, the Caoyang Xincun in Shanghai was built for working class. The community form had minute change before 1990s and after that housing policy had passed structural adjustment to accommodate market-economy regime (Goldman, 1997). Although these cases have different developing background, their form changing could be explained in the same method.

Figure 3 Time axis in research¹

2 EVALUATION: THE CHANGE OF NEW TOWN PLANNING

2.1 NEW TOWN PLANNING OF HARLOW AND MILTON KEYNES

In 1946, The New Town Act was passed by Parliament of UK, which provided a basis for the planning and building new towns to solve the main social problems after war, such as housing shortages and economic rehabilitation (Marmaras, 2014). The new town planning is usually classified as three generations. Harlow is the typical example in the first generation from 1946 to 1950, while Milton Keynes has the same status as Harlow in the third generation from 1967 to 1970s (Sun, 2007). Generally speaking, the first generation of new town was theoretically affected by Garden City to achieve better living environment (Gibberd, 1965). Firstly, the Harlow planning arranged lower population density. Meanwhile, residence zones and industrial zones were strictly planned in separated districts with large scale. In addition, the road structure consisted of ring roads and radial roads, which were planned to strengthen the connection between each residence zones (Figure 4).

In contrast, Milton Keynes planning created more different spatial forms (Figure 5). It primarily resulted from the increasingly social demands for various public facilities. Compared with the Harlow planning, the scheme emphasised on the integration of spatial function. What's more, the convenient connection with intercity transportation was recognised as key factors to build more successful town. At same time, ring roads and radial roads in previous case were replaced by the gridiron road system to improve the transport efficiency. Overall, the different spatial form between Harlow and Milton Keynes could reflect the change of social demands and concerns (Sun, 2007).

¹ The Harlow and Milton Keynes are the representatives of first and last generation of new town, which show the significant difference in spatial forms.

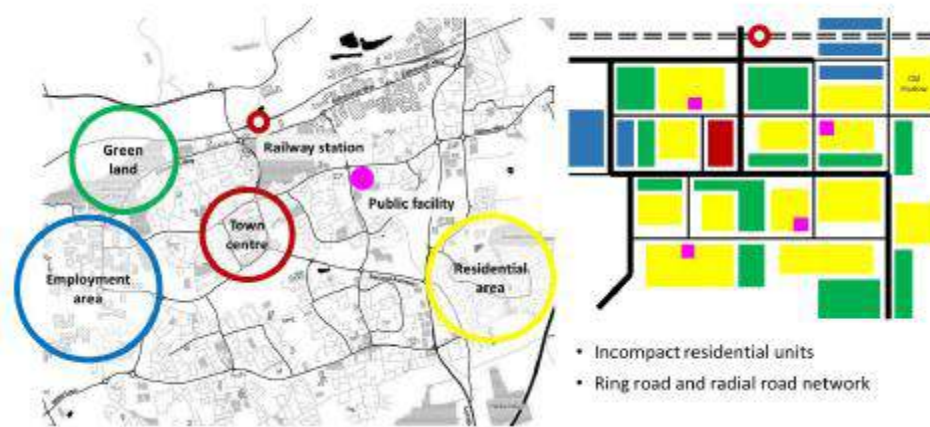

Figure 4 – Spatial characteristics of Harlow; Source: author supply.

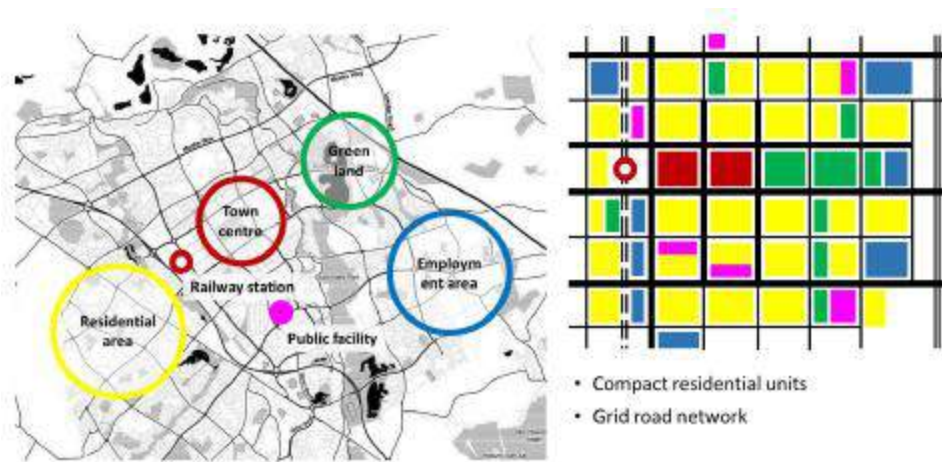

Figure 5 - Space characteristics of Milton Keynes; Source: author supply.

2.2 CHANGES OF PLANNING AFFECTED BY THREE FORCES

Based on the force model, the previous planning may be affected by government force, market force and community force. Each force could have its particular influence on the spatial forms (Figure 6 & Figure 7). Through the comparative analysis in general community unit, the influencing mechanism could be revealed to some extent.

Figure 6 - One community unit in Harlow | Figure 7 - One community unit in Milton Keynes;
Source: author supply.

2.2.1 THE GOVERNMENT FORCE

At first, the new town planning was recognised as a positive method of dispersing the population and creating better living environment for the working class. But from 1950s to 1970s, the motivation of planning new towns changed to developing the underdeveloped areas. To meet this economic development target, larger towns were planned which involved more diversified urban facilities. The new town was not just considered as a larger neighbourhood where to live, but also a small city which could provide most of employment opportunities to the residents (Duany et al., 2003). A modern city centre was planned with typical gridiron road system which was convenient to organise various function zones. Therefore, the government force could more focus on solving social developing problems, constructing the spatial structure and distributing the important infrastructures of whole transportation system (Figure 8 & Figure 9). The force is also frequently changed to accomplish policy target which may be recognised as key factor to develop the society by policy-makers.

Fig.8: Spatial structure of Harlow; Fig.9: Spatial structure of Milton Keynes;
Source: author supply

2.2.2 THE MARKET FORCE

The second point is about market force's effects. It had weak influence in the Harlow planning, while the force showed vital effect in the Milton Keynes planning (Figure 10 & Figure 11). With different from the government force, the target of market force is normally constant which is acquiring the largest profits. So the land value is one of the most important factors focused by the market force, which means the land could be divided into smaller pieces and more regular shapes. Moreover, the land-use density trends to be as high as possible to heighten the benefits and the mixed function zones could increase the value of land as well.

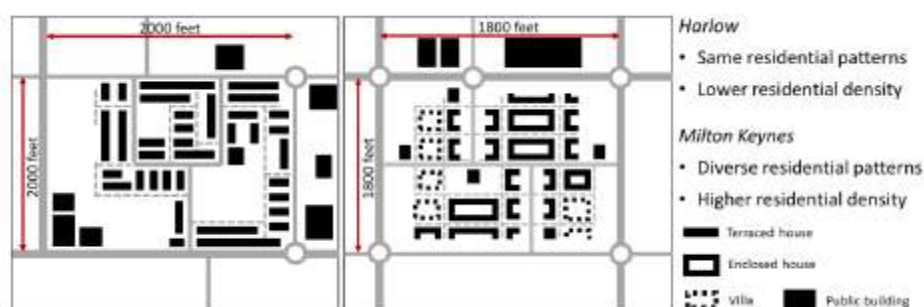

Fig.10: Building pattern of Harlow; Fig.11: Building pattern of Milton Keynes;
Source: author supply

2.2.3 THE COMMUNITY FORCE

The last force is easily ignored by the other forces, but it plays an important role in ensuring the residents' concern because the community force reflects the intention of commons and their benefits. Usually, it emphasises on the equity to use most of public facilities and have comfortable living environment, which was obviously embodied in the case of Harlow (Figure 12 & Figure 13).

All in all, the three types of forces could show their specific effects in the planning schemes, especially on the spatial structure, land development and living environment. Similarly, their effects are also evidently reflected in the urban renewal, especially in the community renewal.

Fig.12: Open space of Harlow; Fig.13: Open space of Milton Keynes;
Source: author supply

3 INTERPRETATION: EVOLUTION OF URBAN COMMUNITY IN SHANGHAI

3.1 COMMUNITY EVOLUTION OF CAOYANG XINCUN

The effect of community force is accompanied by the growth of a community in normal conditions. Without a long period of community development, the community force could not have the apparent effect in deciding urban spatial forms (Gaubatz, 1999). The spatial evolution of Caoyang Xincun would help to interpret how does the interaction of three force affect the community form.

As the first-built community for the working class in China since 1950s, the planning and construction of Caoyang Xincun in Shanghai shows the greatly attention to common class given by central government (Wang, 1956). Because of its sixty-year development, the spatial form in Caoyang Xincun contains diverse types. Broadly speaking, the spatial form in Caoyang Xincun has changed from a single form to diverse forms especially after the 1990s when the housing policy changing from housing distribution system to housing transaction system in China (Figure 14).

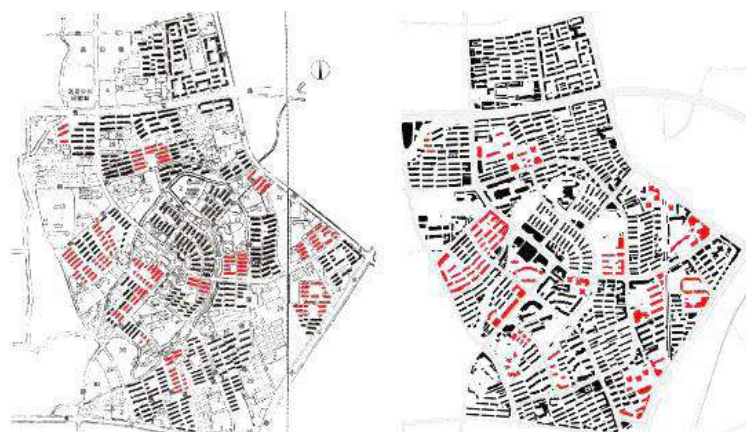

Figure 14 - Spatial forms in 1980s and 2010s¹; Source: author supply.

¹ In the figures above, the red colour means the building forms changed compared with different periods in Caoyang Xincun. For example, the early-stage terraced house was intermittently built from 1950 to 1977. Since 1978, the alteration and addition of terraced house has become more common. After 1992, the high-rise residential building began to replace the terraced house gradually.

3.2 INTERACTION OF THREE FORCES IN DECIDING COMMUNITY EVOLUTION

Resulted from sixty-year housing construction, the form change of Caoyang Xincun may show as the natural growth in disorder. The housing policy reform in the late 1980s destroyed the former warfare housing system which meant that the land development was not just decided by the government. At the same time, the commercial capital began to be involved in urban expansion and renewal (Wang et al, 2015).

3.2.1 THE GOVERNMENT FORCE

Briefly speaking, the evolution of Caoyang Xincun could be divided into two periods due to the housing policy reform in the late 1980s. During the formative period from 1950s to 1970s, the spatial structure took shape basically. From 1970s to 1990s, the extension forms become the mainstream gradually to meet requirement of increasing population. It could be concluded that the government force was the dominating force at that time to raise the housing numbers directly and ignore the living environmental quality for residents. It is probably because of the social contradiction concentrating on solving housing shortage crisis. Meanwhile the market force did not exist in housing distribution system during the formative period.

3.2.2 THE MARKET FORCE

Oppositely, Since the end of 1980s, the housing privatization regime and land marketization regime was set up, the market force showed powerfully influence on increasing the spatial density through the way of reconstructing the old neighbourhood and purchasing the industrial lands for real estate development. It could be recognised as the influence on spatial forms resulted from the growth of land value, because of the rapidly urbanisation in Shanghai greatly promoting its location superiority.

3.2.3 THE COMMUNITY FORCE

In addition, the community force shows its unique influence on the aspect of community management through the local authority. For instance, each piece of reconstructing land is required to build more public service facilities and more green land needs be redesigned in most old neighbourhoods.

To sum up, the early spatial forms was basically decided by the government force, which led to the unified spatial structure and similar housing forms. After the housing policy reform, the change of spatial forms was primarily effected by the final decision combined with the government force and the market force, which led to the rise of residence density and social stratum polarization. Besides, the community force begins to show its influence in some community renewal issues.

4 CONCLUSION: THE CHARACTERISTIC EFFECTS OF THREE FORCES

4.1 SUMMARY OF INFLUENCING FACTORS

Depends on the analysis of three typical cases, the difference of changing spatial forms could be summarised into three levels. The first level is the spatial structure and transportation system which is primarily effected by the government force, because the government could centralise the numerous resources to accomplish a policy target in normal condition.

The second level is land scale and land density which is usually decided by the market force. In general, the land value has closely relationship with the location and traffic accessibility, while the land scale and density is the reflection of its value in visible aspect. More valuable land commonly corresponded to smaller land scale and higher developing density, which means gaining more profits.

The third level is the accessibility of using public facility and living environment decided by the community force. It is insignificant during the stage of urban expansion and new town planning, but plays an important role in restricting the market force by directing the resources used for the local public concern.

4.2 CONCEPTUAL MODEL OF INFLUENCING FORCES

Based on the urban dynamic model, a new conceptual model could be created to explain the different spatial forms affected by three forces. In this model, each force's effect could be estimated on the vector axis and their connecting lines form a specific triangle. The red triangle represents the Harlow form with strong government and community force. While the blue one represents the Milton Keynes form with strong market force (Figure 15). On the other side, the green triangle represents the Caoyang form after 1990s compared with the former form in black (Figure 16). In general, the shape of triangle visually indicates the interaction of three forces, which help to explain to what extent they influence the spatial forms.

Figure 15 - The conceptual model for explaining different spatial forms in three forces; Source: author supply.

Figure 16 The conceptual model for explaining the change of spatial form in Caoyang Xincui; Source: author supply.

Though the cases analysed in this research essay try to interpret the influencing factors in changing the spatial forms, more materials need to be considered in various conditions to modify this conclusion. It could be concluded that the urban spatial forms are effected by three forces together through the regional planning and renewal. Under the effect of three forces, the urban society may be reconstructed with the change of urban forms as well. What's more, through the research perspective of three forces, the orientation of spatial planning should be rethought to find the balance point among three forces in dealing with urban development issues.

ID 1427 | DISSECTING THE URBAN(IZED) BINOCULARS. 'LOOKING AT' URBAN FUTURES

Robbert van Driessche¹; Peter Ache¹; Arnoud Lagendijk¹

¹Radboud University Nijmegen

r.vandriessche@fm.ru.nl ; p.ache@fm.ru.nl ; a.lagendijk@fm.ru.nl

1 INTRODUCTION

In current discourses and practices, 'the future' and 'the urban' are frequently connected: our society's future is expected to be 'urban', and, accordingly, the anticipation of futures for our cities and urban-society-to-come proliferates (e.g. Glaeser, 2011; Gleeson, 2012). In the practices and processes of such 'urban futuring', the discipline of urban planning plays a central role. By its very nature and functionality, urban planning engages with the 'not yet' of the city (a.o. Connell, 2009; Hillier and Healey, 2016). Indeed, today, urban planners together with a diverse range of stakeholders increasingly engage in anticipations for our urban futures: how will our cities and the urban-society-to-come look like?

Thus, it is common in urban planning to look into the future of cities and 'the city' more generally. Typically, an urban planner looks forward in time, to have some kind of impression of what the urban future might bring, and subsequently, hopes to influence and give direction to that future through the decisions and actions of planning in the present (Connell, 2009). Alongside and combined with more standardized procedures and tools, planners today have a variety of foresight methods and techniques at their disposal for their anticipatory action, ranging from forecasting and backcasting to envisioning and scenario-making (e.g. Ratcliffe and Krawczyk, 2011). To a greater or lesser extent, many planning efforts in this way aim to anticipate, to 'foresee', what the future city or city future will be like. As such, they are in various degrees

based on the assumption that one can make plausible anticipations or predictions of that future; that, to a certain extent, it might be possible to 'know' the future, and, by extension, to make more 'strategically prudent' decisions about the future (Borup et al, 2006, p. 296; also Connell, 2009; van Lente, 2012).

Yet, the future as such can never actually be 'known'. It is an abstract concept, and per definition not (yet) existing. Hence, the future is actively constructed in the present (a.o. Adam, 2005; Adam and Groves, 2007; Borup et al, 2006; Inayatullah, 1990). Therefore, it is also contingent upon the diverse and complex processes, practices, and contexts in which it is negotiated, represented, imagined, and thus shaped. The future is always in process, always a future "underway in the present" (Borup et al, 2006, p. 296). When one wants to know more about the future, it is therefore crucial to examine the active construction of futures and the effects thereof, as opposed to trying to 'merely' predict or anticipate the coming state of things. In other words, it is important to look at the future as opposed to, and alongside of, looking into the future (Borup et al, 2006; Brown et al, 2000).

The distinction between these two approaches constitutes an important backbone for this paper. The aim of this paper is to propose an analytical framework for the analysis of urban futures and urban 'futures'. Reasoning from the looking at the future-looking into the future division, I postulate here that urban planning practice and theory currently relate more to the latter, whereas an analysis of the future within urban planning needs to take a perspective informed by the former. Indeed, as Borup et al (2006) describe, 'looking at' the future is mainly the perspective of the analyst, while 'looking into' the future is principally the perspective of the practitioner (see also Adam, 2005).

Following this, one can diagnose that, in urban planning practice and research, an in-depth reflection and analysis of the roles and workings of the future is largely lacking. A general tendency in urban planning literature is to acknowledge the key role of the future in urban planning practices, processes, and discourses, but to not scrutinize this futures dimension thoroughly. Typically, attention has been given to other dimensions. For one thing, planning studies and urban theory have become increasingly centered on spatiality, thus leaving temporal relations and the dimension of time largely unexamined (e.g. Connell, 2009; Myers, 2001; also Adam, 2005). Also, the communicative turn in planning practice and theory has led much of contemporary planning research to be primarily oriented towards governance aspects and the process dimension, at the expense of more substantive issues (e.g. Allmendinger and Tewdwr-Jones, 2002; Fischler, 2014; Forester, 1999; Healey, 1996, 2006, 2007; Innes and Booher, 2015; Sager, 2009, 2012). Thus, the futures dimension of urban planning, though fundamental, seems to have become 'snowed under' (e.g. Abbott, 2005; Connell, 2009; Myers and Kitsuse, 2000). Calls and efforts to remedy and intensify planning's future engagement do occasionally arise (e.g. Isserman, 1985; May, 1985; Cole, 2001). However, there still appears to be an overall inclination to either bypass or only implicitly address planning's futures dimension, whereby it is often taken for granted and regarded as self-explanatory.

To be sure, though urban planners thus seem to approach the future rather confidently and uncritically, they are not meant to be portrayed here as wholly agnostic to the unknowability, uncertainty and plurality of the future, as if they shortsightedly proclaim and believe their own prophetic competence. The diversity of existing future-oriented planning and foresight approaches (envisioning, scenarios, etc.) already demonstrates that there is an awareness of, as well as reflexive attitude towards, the fact that the urban future can be addressed in various ways. Furthermore, in recent debates and experiments, both planning theorists and practitioners have more explicitly acknowledged and addressed the indeterminacy of the future and the ways in which planners could or should deal with this (see e.g. Balducci et al, 2011; Bertolini, 2010; Van Wezemael, 2010). However, even in such cases, the ultimate disposition of the planner – whether theorist or practitioner – is still to 'foresee' and act upon that future. In other words, urban planning is essentially very much concerned with strategically looking into the future.

As a consequence, a crucial issue tends to be largely overlooked and blackboxed: how is this done? How is the 'looking into the future' actually being performed? What exactly happens when planners and other relevant actors engage in future-oriented planning activities? How is the urban future, or better, how are urban futures thought about, represented, negotiated, circulated, and actively constructed within the practices and processes of urban planning? Accompanying these questions, one should then also ask: why is this so? (a.o. why these futures, and why do planners and other stakeholders 'future' in this way); and, how does this affect the planning processes and their outcomes? Inherent in these questions is the idea that both the urban futures produced and the ways and techniques of urban futuring can become performative and generative, meaning that they can come to affect and steer action and agency in

intended and unintended ways (a.o. Adam and Groves, 2007; Borup et al, 2006; Groves, 2016; Van Lente, 2012). This performative aspect of 'urban futuring' thus emerges as a vital point of attention when one wants to understand urban planning, and leads a researcher to scrutinize the reciprocal relationship between ideational and material dimensions of urban futures and urban futuring. In an approach based on these views, it is not the 'mere' anticipation of the future that takes centre stage. Rather, the focus is put on the construction, circulation, and performativity of urban futures and ways of urban futuring within the anticipatory processes and practices of urban planning. To put it differently, such an approach looks at the future within practices that look into the future.

This paper is strongly informed by this line of reasoning. It argues that, to better understand the practices, processes, discourses, and outcomes of urban planning, it is paramount to analyze the active construction of urban futures and the performative effects thereof within these processes, practices and discourses. The intention of the paper is twofold: firstly, to explain why the 'futures dimension' is essential in practicing, understanding, and transforming urban planning, and why this is currently a very topical and important issue; and secondly, to propose a theoretical-conceptual framework to analyze this futures dimension within urban planning. In its core, the framework provides a necessary critical and reflexive perspective on urban planning and urban futuring, and encourages a deconstruction of the ways of thinking, doing, and organizing urban futures. To conclude, the paper reflects on some of the challenges and further refinements of the suggested approach, while it also considers its potential to open up the future thinking and praxis for our cities and regions, and to help in imagining and realizing 'futures that would otherwise not be'.

2 WHY THE FUTURE?

In this section, two arguments are central. Firstly, urban planning and the city are characterized as intrinsically tied to the future. Secondly, and relatedly, it is explained why, in current times, this intrinsic future-orientedness of urban planning and the city has become both prominent and contested, and thus needs to be investigated.

2.1 URBAN PLANNING AND THE FUTURE

2.1.1 THE RUPTURE OF CONTINUITY: PLANNING'S ASCENSION

When considering the relation between the future and (urban) planning, it is important to take into account how the practice of planning originated. As Connell (2009) has pointedly argued and explained, planning's origination is intrinsically bound up with a historical change in the societal experience and construction of 'time' and 'the future'. It was only when the understanding of time allowed for the conceptualization of an 'open future' that planning became relevant.

Building on the work of historians (Koselleck, 2002, 2004), sociologists (Adam, 1990; Luhmann, 1976) and anthropologists (Lowenthal, 1992, 1995; Wallmann, 1992) that have addressed how 'time' and 'the future', as social constructs, have been conceived in the history and present of (Western) society, Connell describes how the concept and practice of planning emerged as a reaction to the 'rupture of continuity' (Lowenthal, 1992; Connell, 2009, p. 85). This rupture indicates the breach between traditional and modern society, and accordingly, between the traditional and modern experience of time. Before the Renaissance and the Enlightenment – roughly before the 16th century – the experience of time was cyclical and continuous. Being based strongly on the natural turnings of the sun, moon, and seasons, time was 'harmonious': past, present, and future were not qualitatively different from each other, but instead, interchangeable points in a repeating temporal cycle. This continuous understanding of time also fitted with the "grand eschatological framework" derived from – mainly Christian – religious scriptures, which described a fixed path from 'Creation to the End', without any differentiation between past, present, or future events. The future was held to be an extension of the past (Connell, 2009, p. 89). As such, the future could not offer anything that was intrinsically new. Therefore, it was knowable.

All of this changed between the 16th and 18th century, when the modern construct of time emerged (Connell, p. 89; Koselleck, 2002, 2004). In contrast to the traditional sense of time, this modern time was

discontinuous. Past and future were disjointed, and disassociated in time by the present. As Koselleck argues: “Finally, the divide between previous experience and coming expectation opened up, and the difference between past and present increased, so that lived time was experienced as a rupture, as a period of transition in which the new and unexpected continually happened” (Koselleck, 2004, p. 246). Conforming to this new experience of time, and to the gradual secularization of society, the religion-inspired eschatological framework was given up and progressively replaced by an increasing belief in the ideology – or ideograph – of progress (van Lente, 1993; also Morgan, 2002, 2015).

Within this modern construct of time, the future became discontinuous and thus more open. It was experienced as a realm of possibility and choice: the future could now be controlled and actively constructed (Connell, 2009). Accordingly, society became more and more future-oriented, and would continue to have this strong and relatively optimistic future focus until deep in the twentieth century.

It was in this context that planning originated. Society as a whole was rather unaccustomed to the new sense of time and the future, and in these conditions, the new concept and practice of planning came up for four interrelated reasons. Firstly, there was no vocabulary or language available to adequately express the new experience of time. No existing concepts or words could articulate what it meant to (be able to) actively construct the future, i.e. what it meant to engage in planning (Connell, 2009, p. 90). There was thus a need for the terminology of planning, even if just for the expression of the modern experience.

Secondly and relatedly, the relative openness of the future meant that decisions about that future could and should be made. The notion of a non-prescribed future, open to choice, possibility, and control, generated a “societal ‘need’ to know what future decisions need to be made today” (Connell, 2009, p. 91). In this context of “required decision making” (Luhmann, 1993), planning answered to this requirement. It acquired the societal function of connecting the present with the future, of importing the future into present decision-making (Connell, 2009, p. 91).

Thirdly, planning was meant to reduce the uncertainty of the opened up future. The modern future was bereft of the traditional and predictable expectations of things to come. This made the experience of the future precarious and somewhat frightening. Likewise, making decisions for the future was difficult and hazardous. Planning, therefore, aimed to ameliorate this by maximizing what is known, and minimizing what is unknown (Connell, 2009, p. 92). Connell (2009) argues that planning, in this way, served to ‘normalize’ the future, making it more stable and secure. Through binding the future to present-based, socially accepted expectations, planning reduced both risk and uncertainty.

Fourthly and lastly, the rise of planning was also related to the need for taking into account the future public interest. Modern society consisted of all kinds of systems and centres of control (e.g. economy, religion, politics, science), but lacked a channel for considering the public interest – especially the future public interest – within the public sphere. In the context of modern societal problems, like the deterioration of cities, the necessity of such a channel became decidedly clear (Connell, 2009; see also Hall, 2002; Luhmann, 1971, 1995). Planning also went to take up this societal function.

Taking together the elements of this socio-historical narrative of the relation between planning, society, and the future, Connell arrives at the following description of planning in modernity:

“Thus, in addition to planning’s function of binding the future in decision-making, the practice of professional planning fills the additional, specific function of binding the future public interest to present decisions. In this way, the function of professional planners is to normalize the future public interest by making it a visible part of the public domain” (Connell, 2009, p. 93).

What emanates from this account is that planning in the modern era was, and is, in its essence, linked to the future. Looking at it this way, planning is relevant to society exactly because of its future orientation; and the orientation towards the future is what characterizes planning.

Indeed, a survey of contemporary renderings of planning confirms this. Whether described as an “exercise of deliberate forethought” (Alexander, 1992, p. 13), an “explicit exercise in imagining the future” (Healey, 1996, p. 242), as “persuasive storytelling about the future” (Throgmorton, 1992, p. 17), or as “a forward-looking activity that selects from the past those elements that are useful in analyzing existing conditions from a vantage point of the future – the changes that are thought to be desirable and how they might be

brought about" (Friedmann, 1987, p. 11), it is evident that, to do and to think planning, is to 'do and think the future'.

2.1.2 THE RUPTURE OF DISCONTINUITY: PLANNING IN DISTRESS

Yet, although the future is always present within planning in some way, planning's commitment to the future is not constant. It shifts back and forth, as Freestone (2012) has also stated. He describes how the future engagement in planning can be said to follow a cyclical trend, going from more to less explicit and sophisticated and back again. Interestingly, in the past decades, the future engagement and orientation of planning has attracted criticism, as it has been said to be superficial, too present- and short term-focused, negligent, and unimaginative (a.o. Abbott, 2005; Connell, 2009; Freestone, 2012; Myers, 2001).

Such criticism clearly ties up with a broader change in society, which can be termed 'the rupture of discontinuity' (Connell, 2009, p. 93). Precisely the opposite of the rupture of continuity, the rupture of discontinuity has made the construct of time and the future more continuous again. Corresponding to wider developments associated with 'postmodernity', the 'post modern era' can be said to have an experience of time and the future which is connected to epidemic uncertainty and a "semantics of indeterminacy, incommensurability, variance, diversity, and complexity" (Connell, 2009, p. 93). Confidence in knowing the future and in the progress that the future would bring has been lost, and the societal experience and outlook have become increasingly predicated on the present, and on personal instead of collective futures (Lowenthal, 1995). This leads to a "shrinking" of the future, which steadily turns into a simple extension of the present (Nowotny, 1992, cited by Adam, 1990, p. 140; Connell, 2009, pp. 93-94). Other reasons brought forward for this are the acceleration of social change and its associated compression of the dimensions of everyday life, such as space-time compression (Leccardi, 2003; Rosa, 2003). In the face of an unsteady future and a contracted present, the future is almost merged with the present, which "appears to be the sole temporal dimension available for defining choices, an existential horizon that includes and replaces the future and the past" (Leccardi, 2003, p. 35).

These criticisms on the contemporary engagement with the future are widespread, and scattered over various academic fields, including history, sociology, geography, planning, and futures studies. Scholars have come to diagnose the societal future orientation as superficial, short-term and present-focused, and unimaginative (e.g. Abbott, 2005; Adam, 2005; Hayward, 2003; van 't Klooster and van Asselt, 2011; Lowenthal, 1992, 1995, 2006; Ratcliffe and Krawczyk, 2011; Slaughter, 1996). This is also echoed in critical commentaries which postulate a 'crisis of the imagination' (Ghosh, 2016) or a restraining hegemony of a 'capitalist realism'

(Fisher, 2009), which have incapacitated our ability to engage with the long-term and to think of futures which are qualitatively different from the present. This contemporary "temporal myopia" (Bindé, 2000), was already strikingly and provokingly perceived in the 1970's by Polak (1973), who identified a process of "defuturizing" (see also van der Helm, 2005): "We mean by the term defuturizing a retreat from the constructive thinking about the future in order to dig oneself into the trenches of the present. It is a ruthless elimination of future-centred idealism by today-centred realism. We have lost the ability to see any further than the end of our collective nose" (Polak, 1973, p. 195).

Of course, the 'rupture of discontinuity' has affected planning too. Surely, the escalation of uncertainty, the loss of confidence in the future, and the preoccupation with the present must have become reflected within planning, right? Connell (2009) confirms this assumption. The semantics of complexity, diversity, and indeterminacy tied to the postmodern experience of time have also found their way into planning and planning theory. Complexity is proclaimed on all levels (e.g. Byrne, 2003; de Roo and Silva, 2010; Healey, 2007; Balducci et al, 2011), and, in accordance, the future is less and less regarded as knowable or controllable: "Consequently, the 'post' modern semantics of planning emphasize adaptation and mitigation, rather than confidence and control, managing processes and designing livable cities rather than planning for the public interest, difference and diversity rather than commonality and unity" (Connell, 2009, p. 95)

Correspondingly, the focus of planning has been pulled towards the present. In a climate of intricacy and insecurity, articulating and constructing the future in a valuable and socially acceptable way has become a difficult, contested, and almost undesirable matter. Thus, haunted by the perils of disagreement and uncertainty, planning has reacted by largely resorting to the present, be it an 'extended' one (a.o. Myers,

2001; Connell, 2009). Shorter-term decisions are preferred, just as devices and analyses which are either more superficial or very technical, or both. Hence, an explicit, in-depth, sophisticated, and open approach to the future is lacking in much of contemporary planning.

Nevertheless, planning's relevance and function still rest upon its future orientation. To plan is to bring the future into the present, to make decisions in the now about what needs to be done and decided in the not yet. So, while the depth, quality, and emphasis of planning's future engagement may vary across time and space, and between actors, practices, and processes, there is no doubt about the intrinsic future-orientedness of planning: "...the function of planning is only relevant to a future-oriented society, and a future oriented society requires planning to function. Furthermore, although not all practices of professional planners are aimed at the future, the function of planning always is" (Connell, 2009, p. 97). Set against the rupture of discontinuity, its continuous construct of time and the future, and its associated tendencies to presentism, what one can find here is an inherent tension between the functionality and relevance of planning on the one hand, and the postmodern experience and construct of the future on the other hand. What can planning be in a society which can hardly be called 'future-oriented'? And what is to become of society if even planning does not adequately engage with the future?

In line with this problematic, and in reaction to the post modern milieu of uncertainty, complexity, and present-focused planning, one can discern a gradual upsurge in 'real' engagement with the future in planning, both in academia and practice (e.g. Freestone, 2012; Vermeulen, 2015). Scholars have expressed the need to "put the future back in planning" (e.g. Myers, 2001; Cole, 2001; Dalton, 2001). One way to contribute to this, they argue, is to establish a more active and deeper interaction between the fields of planning and futures studies. Another way could be to bring back utopian thinking within urban planning (a.o. Corijn and Vermeulen, nd; Friedmann, 2000; Ganjavie, 2012; Hoch, 2016; Maassen, 2012; Paden, 2001; Pinder, 2002, 2004, 2005, 2007, 2015; Sandercock, 2002; Vermeulen, 2009), or to reinvigorate strategic spatial planning (Albrechts, 2004, 2010, 2015). More radically, various authors have claimed it is necessary to thoroughly rethink planning and many of the assumptions and practices on which it is based, and to establish a 'post structuralist' mode of planning (e.g. Balducci et al, 2011; Hillier, 2011). Such efforts seem to have an effect, as Freestone (2012, p. 10) identifies a "current upturn", in which "the future is making a comeback into planning in various practical and innovative ways".

In any case, planning's relation to the future is a defining issue for contemporary planning debates and practices. Planning is inherently future-oriented, but presently faces various challenges, tensions, and criticisms in relation to its future engagement. Its capacity and willingness to deal with the uncertain future has been questioned and/or proven to be inadequate. This predicament is destabilizing planning as a field and has spawned an ongoing search for new ways of doing and thinking and organizing, most of all ways of dealing with the future. Hence, futures and futuring are topical concerns in the planning field, but as of yet rather unresolved and not sufficiently examined. Therefore, it is critical to thoroughly and explicitly study this futures dimension of planning.

2.2 THE CITY AND THE FUTURE

In the previous section, it has been explained that planning has an intrinsic relation to the future. When it comes to urban planning specifically, this inherent future-orientedness takes on an extra dimension. The 'urban' within 'urban planning' simultaneously specifies and expands the future engagement of planning: it specifically focuses on that which is related to the 'urban' and the city, and exactly because of that, it also extends the futures dimension, since its object - the city - in itself is a fertile ground for future imaginations and expectations.

The city is and always has been one of the most widely, diversely, and fervently imagined objects in human history. As the place where people, money, culture, technology, science, employment, education, resources, and much more agglomerate, cities arguably constitute the crucial category of human settlement (e.g. Weber, 1922; Glaeser, 2012). They are seen as the sites where the problems of human existence coalesce, but at the same time, the sites where most of the solutions to these problems are likely to be developed. Accordingly, cities are generally regarded as centres of innovation and creativity, and by extension, as the ground where social change and the future are fundamentally given shape (a.o. Bandarin and van Oers, 2012; Glaeser, 2012; Gleeson, 2012; Hall, 2002; Hodson and Marvin, 2009, 2010; United Nations, 1992, 2017). Today, in a context of ever increasing urbanization, this prominence of cities

and city-regions for the urban and societal future is professed even more vigorously (see e.g. Gleeson, 2012, on 'new urbanology' and recent urban triumphalism, and Brenner and Schmid, 2014, on the 'urban age thesis').

Similar to the discipline of planning, 'the city' itself from a conceptual, imaginary, and discursive viewpoint has typically had a clear link with the future. In addition to being crucial sites of contemporary life where the future is rather literally materially shaped and constructed through decisions and actions of planning and urban development practice, cities, future cities, and city futures have long been the conceptual, theoretical, imaginary, metaphorical, and discursive locus in which and through which social change is both apprehended and anticipated (a.o. Clarke, 1992; Duarte et al, 2015; Hall, 2002; Harvey, 2000; Neuman and Hull, 2009; Wunenburger, 2003). This was already the case in, for example, Plato's philosophical utopian thinking about the ideal city state in the Republic, in Thomas More's philosophical-literary Utopia, and, very clearly in our current lifetime, in the genre of science fiction (Clarke, 1992), where the urban these days is more frequently depicted as dystopic than utopic. As Clarke states: "for [at least] the past five centuries (...) the make-believe city has been the benchmark of all imaginary societies" (1992, p. 702). In such imaginaries, the future is almost always central: what will or could happen; what do we want to happen; what do we not like to see happening; what is possible, plausible, and/or preferable.

An aspect which plays a significant role in this imaginary and discursive connection between the city and the future is technology. Especially since the advent of modernity, cities and technologies have been inextricably interlinked (a.o. Duarte et al, 2015). Technology, in various forms and in various ways, has enabled and facilitated human life in urban settlements, and has thus given shape to urbanity as we know it (Tarr, 2008; also Castells, 1989; Hodson and Marvin, 2009). From such a perspective, the city itself could even be thought of as a technology (see e.g. Evans and Marvin, 2006; Hulsbergen et al, 2005, p. 171).

Such linkages and associations between the city and technology reinforce the futures dimension in the understanding of cities. After all, future expectations, whether promissory or unsettling, constitute a fundamental part of the development, perception, and 'being' of technologies (a.o. Borup et al, 2006; van Lente, 1993). When thinking about technology, the consideration of future possibilities, dangers, and implications is less than one step away. These future imaginations and expectations about technologies can, and do, get transferred to the imaginations, expectations, and discourses about cities. In particular, such dynamics can be discerned in relation to the technology-driven and technology-brimming cities of today. The contemporary epitome of these tendencies can be found in the 'smart city' discourse and imaginary (Kitchin, 2014, 2016; Merricks-White, 2016; Vanolo, 2014; also Caletrio, 2014): the idea of the city steeped in and animated by a multiplicity of advanced 'smart' technologies and applications, which as such is either conceived and propagated as a magnificent promise for the betterment of human life and society, or, increasingly, as a profoundly risky and undesirable type of future urbanity.

Overall, then, the city is an object of versatile imaginations, associated with a wide range of expectations for the future; expectations and future imaginations which are not only about 'the city' in general, or about specific cities (e.g. London), but which often also say something about societal futures at large. Such future imaginations and expectations vary in their normativity. Seemingly more descriptive and more specific predictions and projections exist besides and intermingle with 'grand narratives' and imaginaries of progress and hope (utopia) and of decline, apocalypse, and fear (dystopia) (a.o. Baeten, 2002). Hence, the city, as an imaginary and discursive field, contains an intrinsic hope and an intrinsic 'doom'; and, focusing less on normative dimensions, the imaginary and discursive field of the city and the urban is strongly futures-oriented.

In various ways and to various extents, the future imaginations for cities can then also affect and become embedded within the materiality and practices of the city. Most notably, urban planning - the discipline specifically engaged with shaping (the future of) cities - unmistakably draws upon as well as contributes to the discursive and imaginary renderings of future cities and city futures (e.g. Hall, 2002; Collie, 2011). This may be seen as a reciprocal, interactive dynamic: the practices, processes, and products of urban planning (including the academic sphere) are influenced by the future imaginations and expectations that circulate about the city as well as urban planning itself, and, conversely, these imaginations and expectations are of course also affected and shaped through and within those practices, processes, and products of urban planning. This supposed dialectical interplay, together with the intrinsic future character

of both urban planning and the city, make it particularly interesting and critical to research the future(s) in urban planning.

3 PROPOSING THE FRAMEWORK

In the previous section, it has been explained why there are plenty of reasons to explicitly and comprehensively investigate the roles and workings of the future within urban planning. More practically, the field currently struggles with the uncertainty of the future and associated challenges to planning's relevance and functioning. More conceptually and profoundly, urban planning is inherently tied to the future both in its 'urban' and in its 'planning' dimension, and virtually owes its existence and purpose to exactly that futures dimension. Extending the latter idea, the futures dimension could not only be seen as crucial to practicing and understanding planning, but, importantly, it could also be regarded as the fundamental sphere in which and from which planning should be transformed. Following this, it would precisely be the future engagement of urban planning – its futuring and its futures – which should be examined rigorously, to enable transformations that would help urban planning to become more effective, competent, and relevant for current times.

In that light, it is all the more interesting and surprising that efforts to do this have thus far been minimal. As described before, in existing research on urban planning, the futures dimension tends to be bypassed and/or regarded as self-explanatory. Neither the few exceptions (e.g. Balducci et al, 2011; Myers and Kitsuse, 2000) nor the recent “comeback” (Freestone, 2012) of the future in planning research and practice sufficiently make up for this shortcoming.

Therefore, this paper suggests to research the futures dimension in urban planning specifically, systematically, and extensively. The futures dimension in urban planning should be exposed and focalized, so that it is given the analytical rigor and attention it deserves. Only then can the analysis capture the particularity of the futures dimension, of the specific aspects, mechanisms, and dynamics at work when the (urban) future is being dealt with. Such an analysis needs to draw upon those fields and approaches which explicitly engage with the future and with anticipation, such as the sociology of the future (a.o. Adam, 2005). Remarkably, despite the relation between urban planning and the future, the insights and perspectives from these fields have largely been absent in urban planning research (and practice). To be fair, the field of urban planning has quite regularly been linked up with the field of futures studies, both in theory and practice (see e.g. Cole, 2001; Khakee, 1988; Ratcliffe and Krawczyk, 2011). However, the connection made here has mainly had an instrumentalist bias, whereby insights, methods, tools, and techniques derived from the futures field have been applied in planning, with the overarching aim to provide planners with various forms and degrees of “anticipatory competence” (Borup et al, 2006, p. 296), i.e. an (improved) capacity to anticipate the future and act and decide upon that future (see also e.g. Ahlqvist and Rhisiart, 2015; Son, 2015). Though useful and valuable, such an approach is still dominated by a disposition of 'looking into' the future, as opposed to one of analytically and reflexively 'looking at' the future, as outlined in the introduction.

In contrast to this, the suggestion here is to analyze urban planning by building upon those approaches which 'look at' the future; those approaches which take a critical and reflexive stance towards futures and ways of futuring and their natures, roles, dynamics, and effects within the present. More specifically, I propose a theoretical-conceptual framework which integrates three of such approaches: the 'critical-post structural' approach to futures by Inayatullah (1990), the sociology of expectations (a.o. Borup et al, 2006; van Lente, 2012), and the sociology of the future as outlined by Adam and Groves (Adam, 2005; Adam and Groves, 2007; Groves, 2016). Together, these are held to provide a framework which enables a thorough and valuable analysis of urban futures and urban futuring within urban planning.

3.1 THE CRITICAL-POST STRUCTURAL APPROACH TO FUTURES

To begin with, the 'critical-post structural' approach outlined by Inayatullah (1990) offers a useful base to reason from. Informed by a Foucauldian perspective on discourse, the critical-post structural approach to futures encourages and allows the researcher to investigate how the present and the future have come to be authoritatively created (Inayatullah, 1990, p. 136). The approach as such employs a constructivist perspective, which is also apparent in its theoretical underpinnings: time and the future are seen as

historical social constructs, and are thus not a way of describing but of creating the outside world ('reality'); and language is a crucial dimension in which and through which time, the future, and the world are constructed and constituted. The future emerges here as mainly constructed by language within discursive spaces and practices.

The critical-post structural futures approach puts discourses and epistemes centre stage, i.e. ways of knowing and ways of organizing knowledge. It reasons that the way we construct, understand, and know 'reality', 'time', and 'the future' now is not a description of reality 'out there', but rather that it is the result of the victory of one discourse over another (Inayatullah, 1990, p. 132). Time and the future are discursive and contingent. The ways in which – at a certain time and place – the future is constructed, understood, known, and organized could always have been otherwise. To research this future from a critical futures perspective, then, means to inquire into how the future is epistemologically constructed.

An episteme, for Inayatullah (1990, p. 116), denotes the "way we order the real and our knowing of it". Epistemes consist of all kinds of epistemological assumptions of the real (a.o. ideological-cultural assumptions, assumptions of language, assumptions in relation to the problem of meaning, etc.). Part of and implicated within such broader epistemes of the real are epistemological assumptions concerning time and the future. This is significant when one considers planning: every planning effort involves epistemological and philosophical assumptions, beliefs, and expectations concerning reality and how it is, can, or should be known; and, more specifically, regarding time and the future and how they can and should be known, performed, and dealt with. As Inayatullah states: "Every planning effort to plan the future is submerged in an overarching politics of the real" (1990, p. 116).

Clearly, such assumptions and ways of thinking are pivotal for practicing and understanding planning, since they influence how planning is done and organized. Yet, this is not a unidirectional phenomenon, since the ways of doing and organizing at the same time influence the ways of thinking. One can conceptualize this as a reciprocal dynamic between ideational and material dimensions: the epistemological assumptions and ways of thinking mutually interact with all kinds of expressions, discourses, and practices which continuously materialize, actualize, and also (re)shape the assumptions. When this conceptualization is transferred to the analysis of urban planning and its futuring, it means that epistemes, their epistemological assumptions of the real, and accompanying ways of doing and organizing affect how time and the future are understood, constructed, and performed, and, by extension, how planning is conceived and carried out.

Therefore, epistemes and their assumptions and actualizations should be examined, but the problem is that they are usually not (Inayatullah, 1990, p. 116). According to Inayatullah, epistemes are often not scrutinized and therefore left naturalized in planning efforts and debates: "Planning theories (...) thus often emerge as mentalities, frozen ahistorical categories of thought, ontological givens" (1990, p. 116). The consequence of this is that normalized and naturalized ways of knowing and doing can come to function and appear as self-evident 'systems of truth', instead of contingent and actively created realities based on a variety of assumptions and practices that could have been different. Under these circumstances, the fact that other ways of knowing, doing, and organizing are possible becomes obscured.

Thus, applying this critical futures perspective to the analysis of urban planning and its futuring, it becomes vital to investigate the epistemological construction of the future in urban planning. Through both genealogy¹ and deconstruction, one illustrates and deconstructs how actors 'know' and 'perform' the future through language and various institutionalized practices. Normalized ways of understanding and performing the future are thereby put to question. Furthermore, by doing this, it is also uncovered how current ways of knowing, doing, and organizing the future embody power relations, how they "reinscribe the power politics of the present" (Inayatullah, 1990, p. 134). Ultimately, such an analysis can help to open up the discourses and epistemes of the future in urban planning, by showing that alternative discourses, and alternative

¹ The concept and method of genealogy is rather complex and interpreted and used in various ways (a.o. Crowley, n.d.; Kearns and Hooper, 2002; Tamboukou, 2003), but it is beyond the scope of this paper to discuss that. Here, a general description in the context of this paper suffices: a genealogy of the future looks back into the history of the future in the now, and 'genealogically historicizes the present' of the future, by tracing and examining important influences on the current ways of thinking, doing, and organizing the future. The attempt is to understand how and why established ways of constructing 'time' and 'the future' have become the dominant ways of creating the world (Inayatullah, 1990).

constructions of 'time', 'the future', and 'reality' are possible. Deconstruction can thus enable and facilitate reconstruction.

3.2 THE SOCIOLOGY OF EXPECTATIONS

The critical futures approach rightly emphasizes that the futures and ways of futuring within the present should be problematized and deconstructed. Yet, it does not specify so clearly how this should be done, and which aspects or dynamics should be analyzed. The sociology of expectations can help in this respect. This perspective shares with the critical futures approach the overall ambition to deconstruct and 'dereify' the actively constructed future within the present, by, among other things, "developing on a detailed examination of the forms of action and agency through which the future is both performed [as a temporal representation] and colonized [as a spatial and temporal locus]" (Brown and Michael, 2003, p. 5). In contrast to the rather general outlook described by Inayatullah, however, the sociology of expectations takes a very specific point of departure for its analysis of the future: expectations.

Expectations, in this framework, are defined as "statements about the future – uttered or inscribed in texts or materials – that circulate" (van Lente, 2012, p. 772). As this definition makes clear, expectations here are practically analogous to the notion of futures. What also follows from the description, is that expectations, or futures, exist and travel in a variety of forms, types and ways. Originally developed within the field of Science and Technology Studies (STS), the sociology of expectations studies "the production and circulation of expectations in science and technology" (van Lente, 2012, p. 769). In doing this, the approach can provide insights into the nature and structure of expectations (i.e. futures); into the dynamics of expectations (how do they circulate, how do they come up and fade away, how do they interact with other expectations and future statements, images, etc.); into the force of expectations (they can legitimate, provide guidance, and coordinate actors and agency); and into the relation between expectations, strategy-making, and steering capacity (van Lente, 2012).

An essential theoretical starting point in the sociology of expectations is that expectations are performative. Expectations, as statements about the future, are not simply descriptions or ideas, but actually do

something. They create a new or adjusted reality. As such they are fundamentally generative: "...they guide activities, provide structure and legitimation, attract interest, and foster investment. They give definition to roles, clarify duties, offer some shared shape of what to expect and how to prepare for opportunities and risks (...)" (Borup et al, 2006, p. 286). Furthermore, expectations can bridge boundaries, dimensions and layers, and coordinate and broker relationships between actors. By engendering all of these effects, expectations and the futures within them are enacted, performed, and made real in the present. They thus shape scientific and technological as well as social and political change. Unsurprisingly, the futures articulated in and through expectations are therefore also highly contested.

Although originally meant to study developments in science and technology, the sociology of expectations can be equally valuable to investigate the particularities and workings of futures in other spheres of society. In particular, as van Lente (2012) has argued, the approach has value for the analysis of foresight exercises, regardless of their specific type or whether these take place in business, government, engineering, research, or planning contexts. After all, foresight exercises per definition deal with the future, and thus with expectations in their various forms, interactions, and effects.

It is useful here to distinguish between 'formal' assessments of the future on the one hand, and 'informal' assessments of the future on the other. Deliberate foresight exercises can be regarded as "formal articulations of possible futures" (van Lente, 2012, p. 769), which take place within and relate to a broader, informal environment of visions, promises, expectations, and future articulations and ideas. This informal "sea of expectations" (van Lente, 2012, p. 777) influences foresight exercises, and to a certain extent and in various ways can even guide and structure them.

As might be clear now, the sociology of expectations provides a very useful perspective for the analysis of urban planning, and its futures and futuring in particular. As argued above, urban planning and the city more generally are inextricably tied to the future. In other words, urban planning takes place in an environment where a great wealth and diversity of expectations, future images, and future imaginations about cities and the city are produced, negotiated, constructed, embedded, and circulated. The arena of

urban planning, therefore, constitutes the sphere in which the futures of the city are constructed and shaped.

Taking the perspective of the sociology of expectations thus enables one to conceptualize urban planning in this way, and by extension, to analyze it from this viewpoint. The theoretical underpinnings of the framework are crucial in such an investigation. Firstly, the performativity of futures is postulated. Futures are taken to have a fundamentally generative, performative, constitutive role within urban planning. Secondly, it is exactly this role which is further explored. A study of urban planning along these lines focuses on the following elements: what kind of futures are constructed and circulated?; how are all kinds of futures – both consciously and unconsciously – constructed and circulated, and why?; how do they intermingle and interact in various ways and forms, and through various actors and channels, and why?; and which effects does this have on the practices, processes, discourses, and outcomes of urban planning? Thirdly, it is kept in mind that the more formal articulations and assessments of the future within urban planning are situated within a broader field of more informal expectations, which can influence the contents and processes of futuring (van Lente, 2012).

When one extends the theoretical ideas of the sociology of expectations, and connects them with the definitions of urban planning which practically all emphasize its future-orientedness, a challenging theoretical-conceptual position emerges, related to the nature of planning and the role of expectations therein. When urban planning is intrinsically tied to the future, and when futures are taken as performative and generative, could it not be posed that futures are the buildings blocks and drivers of urban planning? Are not these future expectations what planning builds upon, is driven by, and exists for? Hence, are not future expectations then the 'raison d'être' of urban planning? It seems that, without such expectations, there would be no planning. Futures are thus situated at the base of what planning is and is meant to be (see also section 2). Following such reasoning, to examine futures and their performativity within urban planning means to research into the core of urban planning, both in its theoretical-conceptual and in its more practical and material dimensions.

One interesting facet that might be brought to light by such a dereification of the future within urban planning is to what extent, how, and why urban planning efforts draw from – and are thus bounded by – existing repertoires of expectations and futures. This is an insight that follows from the idea that formal foresight exercises happen within a wider informal environment, where a variety of expectations circulates (van Lente, 2012). The futures created within urban planning exercises are very likely to be constructed from an existing set of future articulations and assessments. So, whereas such processes are usually meant to engage with the future openly and to possibly engender alternative futures and ideas, they run the risk of contributing to path-dependency and lock-in (van Lente, 2012, p. 777). Planning efforts, just like foresight exercises, draw from “existing repertoires of expectations”, and, therefore, “will not generate many ‘new’ expectations, although ‘new combinations’ between elements of the repertoires are possible”, and thus, “they may reproduce images and arguments that are already circulating” (van Lente, 2012, p. 778). This could also be expressed as a “predisciplining of the imagination” (Borup et al, 2006, p. 293), by which former expectations and futures become the basis for new planning endeavors.

Interestingly, this may have effects on power relations (van Lente, 2012; also Nahuis and van Lente, 2008). The available and circulating repertoires of expectations are more often than not based on the expectations and future imaginations that are held or accepted by established actors and networks. Hence, though urban planning and futuring exercises might involve new stakeholders (a.o. Ache, 2011, 2013; Vermeulen, 2015), the dynamics of expectations might ultimately limit the degree to which these stakeholders actually contribute to a proper re-imagination of the future. Moreover, if one takes futures as being performative in the present, this would consequently mean that, on the whole, power relations and networks largely do not change, neither in the present nor in the future.

In line with this, it is also important to consider the influence of existing and circulating collective imaginaries when analyzing the dynamics and performative effects of futures within urban planning. Future expectations and imaginations of the city and urbanity within urban planning are undoubtedly related to broader, collectively shared imaginaries (Cabanès et al, 2014; Konrad, 2006). Collective imaginaries might even frame and partially structure expectations and expectation dynamics (Borup et al, 2006; Cabanès et al, 2014). One such imaginary is particularly interesting here, given the intrinsic relationship between the city and technology and the abundance of ‘smart city’ images nowadays (see a.o. Kitchin, 2016; Vanolo, 2014; Tarr, 2008): the socio-technical imaginary, defined by Jasanoff (Jasanoff and Kim, 2015, p. 6) as

“collectively held, institutionally stabilized, and publicly performed visions of desirable futures, animated by shared understandings of social life and social order, attainable through, and supportive of, advances in science and technology”. When researching futures and futuring in urban planning, one should thus be on the lookout for these imaginaries and their potential influence.

While the above might seem to indicate that the dynamics and performative effects of expectations play out primarily on the imaginary-ideational level, this is not the case. The sociology of expectations precisely indicates that it is important to consider how expectations can become ‘inscribed’ in texts, bodies, actions, objects, materials, and machines; how they can become materially embedded within and embodied by structures, systems, routines, and more (Borup et al, 2006, p. 292). This means that potential path-dependencies and performativities are not only be found in the domain of the imagination, but also in the realm of the socio-material. That is exactly the performative power of futures: they reciprocally affect both the ideational and the material in an ongoing dynamic.

So, taking the above together, the sociology of expectations provides a specific contribution to the outlined task to deconstruct urban futures and urban futuring in urban planning. In particular, it directs attention to the dynamics and performativity of the futures that are constructed and circulated within urban planning. Futures, both uttered and inscribed, can affect action and agency in intended and unintended ways, and are at the same time also affected by, for example, existing and circulating repertoires and collective imaginaries. Thus, futures influence futures as well as futuring in a continuous interaction between diverse ideational, representational, material, and practical elements. Only when this is taken into account and analyzed can one properly deconstruct the ways of thinking, doing, and organizing the future within urban planning.

3.3 THE SOCIOLOGY OF THE FUTURE

The sociology of expectations thus gives body analytically-conceptually to the overarching view of the critical futures approach. By conceptualizing and concentrating on how the futures within urban planning interact, circulate, and become performative, the expectations-perspective gives a more concrete form and focus to the aim of deconstructing ‘futuring’ in urban planning. However, a deconstruction along these lines would be incomplete and too one-sided. Futuring, or anticipation, cannot be fully understood and opened up by only examining future ideas, imaginations, and representations and their subsequent performative effects on practice and materiality. One also needs to consider the reverse relation: materiality and practice obviously influence representations of the future (and future representation-making) too, explicitly but also tacitly

(Groves, 2016). Anticipation is a combination of both representational and material elements, and both the material and representational are constitutive of anticipation. So, alongside the more explicit, represented, performative future, attention also needs to be paid to the more implicit, unconscious, and material dimensions of futuring. This material side to anticipation extends beyond the performativity of actual futures, and also has to do with the various future dispositions and potentialities that are ‘scripted’ into environments, technologies, practices and bodies. Accordingly, a thorough analysis of anticipation (futuring) does not confine itself to already ‘operative’ futures alone, but examines the reciprocal interplay between futures and the materiality and practices of futuring: it studies “futures-in-the-making” (Adam and Groves, 2007; Groves, 2016, p. 3). An analysis of urban futuring, or urban anticipation, therefore, should not only draw on a sociology of expectations, i.e. futures, but on a broader ‘sociology of the future’ as outlined by Adam and Groves (Adam, 2005; Adam and Groves, 2007; Groves, 2016).

As Groves (2016) states, much of the research into futures and anticipation has followed the sociology of expectations in focusing on the roles and performative effects of images and representations of the future. Such approaches usually go together with a tendency to focus on language and more conscious aspects of anticipation, and thus, with an overall inclination to ‘humanise’ anticipation too much (Groves, 2016, p. 2). Anticipation, however, has a dual character, and is just as much shaped by material dimensions as by ‘human’ dimensions. Therefore, it is important to take into account the “more than human” (Groves, 2016, p. 2) and the non-representational, material aspects when examining anticipatory action (i.e. futuring).

The influence of ‘more than human’ and material dimensions on anticipation operates on multiple domains and in various ways. Crucial point is that specific interpretations of the future and modes of futuring are

'afforded by' and inscribed into material environments in an often implicit and unconscious manner. One can roughly distinguish four interrelated spheres in and through which this occurs.

Firstly, there are 'future horizons' (Adam and Groves, 2007; Groves, 2016) or 'styles of anticipation' (Anderson, 2010). In short, these concepts designate the sets of practices and knowledges through which the future – in a specific place and time – is approached and anticipated. Within future horizons or anticipation styles, various types of social action, knowledge practices, and normative frameworks implicitly align into working compositions that generate and predispose a certain way of dealing with time and the future. Examples would be religious hermeneutics or empirical methods and ways of theory-building within science (Groves, 2016, p. 4). Such overarching attitudes are made up of several intersecting and mutually constitutive elements – practical, material, epistemological, ideational, normative -, which, together, enable time and the relationships between past, present, and future to be made sense of in specific ways. To a certain extent, the ways of knowing and acting that combine into 'styles of anticipation' can become rather routinized, and can thereby lead to the development of tropes and relatively entrenched temporal orderings. Analytically, the development of more concrete imaginaries and representations of the future can thus not be separated from this wider setting of anticipation styles, which are diversely sedimented into the materialities and practices of social life.

Yet, the styles of anticipation themselves do not come out of nowhere either, since they are inherently bound up with the material environments in which they are situated. The ways of knowing and acting the future are partly "stitched into" their surroundings. Most notably, this is apparent on a socio-technical and socio-natural level (Groves, 2016, p. 4). Socio-technically, one can discern a 'technological unconscious' in anticipation, by which scripts that are imprinted within infrastructures and technologies lead the future to be perceived and performed in specific ways. Socio-naturally, an 'environmental unconscious' can be postulated, where biophysical systems and conditions constrain and enable practices and ways of futuring. Technologies and environments are not simply tools and resources with which anticipation is carried out, but they are constitutive of anticipation (Groves, 2016, p. 4); of both the ways of futuring and the futures produced and circulated. They thus form the second and third domain where one can discern the influence of the more than human, material dimension on anticipation.

Fourthly and lastly, in between the more 'human' and more 'environmental' dimensions, anticipation is also influenced by various forms of emotion and affect. As Groves asserts, people are "invested subjects (...) whose engagement with socio-technical-natural environments is affective and emotional" (Groves, 2016, p. 4). They experience feelings such as fear or hope, and feel attached to or dissociated from certain places, practices, and ideas, including those that relate to the future and futuring. Hence, such affective aspects need to be taken into account as more 'environmental' (non-representational) factors implicated within anticipation.

When both the material and representational dimensions of anticipation are brought together, it becomes possible to conceive of anticipatory assemblages (Groves, 2016): heterogeneous compositions in which material, practical, representational, ideational, epistemological, and normative elements all work together to continuously constitute and enable each other as well as specific forms, contents, and ways of anticipation. Such assemblages are continuously produced, reproduced, and potentially reshaped through an interplay of the various forces and elements.

Importantly, anticipatory assemblages can become (temporarily) stable in their combinations, and thus, by extension, in their approach to the future. Through all kinds of connectivities, scripts, performativities, and co-constitutions, anticipatory assemblages can thus contain an implicit or embedded way of engaging with the future and its construction. When this is the case, and when the assemblages take on a rather self-sustaining, reproductive dynamic, anticipation can become patterned (Groves, 2016). Like a kind of template, anticipatory assemblages may order anticipatory action in such a way that a specific take on time and the future is dispositioned. Simultaneously, other ways of knowing, performing, and organizing the future are then not dispositioned; anticipatory assemblages can thus work to shut off other possibilities, futures, and ways of futuring.

Thus, the assemblages of anticipation operate and "hang together in specific ways at different times and in different places" (Groves, 2016, p. 4). Inspired by Foucault (1991) and Deleuze (2006), Groves (2016, pp. 4-5) conceives of the particular constellations of anticipatory assemblages as 'diagrams': specific sets of heterogeneous elements, which interconnect and perform in and through particular patternings, and

thereby predispose the ways in which the future is drawn into the present. Through such “diagrams of anticipation” (p. 5), the future is understood and acted on in specific ways, and not in others. A concrete example of how such a diagrammatization of the future might work is provided by Groves in relation to energy infrastructure planning and energy security in the UK:

“In policy responses to this problem, the future is brought into the present chiefly through the socio-technical apparatus of demand forecasting, a combination of knowledge practices, techniques, and particular socio-technical apparatuses (such as modelling software, demand measurement technologies, and so on). (...) this assemblage produces a disembodied view, a ‘present’ future in which is represented a snapshot of the future as the necessary product of a set of known mechanisms. This then allows the future to be cast in a concrete, congealed form, such as a demand scenario” (Groves, 2016, p. 5).

If anticipation – its futuring and its futures – is conceptualized along the lines of assemblages and diagrams, another significant facet emerges: the political dimension. After all, the notion that the ways of knowing, doing, and organizing the future are patterned implies that this might come to the benefit of some actors, while it can disadvantage others. Indeed, the specific patternings of anticipatory assemblages and diagrams also pattern the capability of actors to affect and act on their futures. Following Groves, the “socio-material organization of anticipation” should not be seen as a neutral process (2016, p. 2). The distribution of anticipatory capacity within and through particular anticipatory assemblages is uneven and unequal. One consequence of this is that the future tends to be selectively framed and translated in unfolding anticipatory processes, so that some aspects are turned into objects of public concern for the present as well as the future, and others are not. Evidently, this is a vital aspect of political struggle, in which anticipatory elements and assemblages can converge and connect but can also come into conflict and become contested. Seen in this fashion, it becomes necessary to consider the political implications of anticipation and anticipatory assemblages, and vice versa, to acknowledge and scrutinize the styles and configurations of anticipation when wanting to understand political conflict (Groves, 2016).

In line with the political aspect, a final feature that needs to be pointed out here is that of power. When specific anticipatory assemblages and diagrams are dominant, it means that particular distributions of futuring capabilities are generated and preserved, and that certain representations and interpretations of the future are produced and sustained. Anticipatory capabilities and interpretations of the future are likely to be connected here in a link of relative ‘necessity’ (Groves, 2016, p. 6): particular constructs of the future need specific actions, decisions, discourses, and actor and power relationships to be in place, and the other way around. A contemporary phenomenon which might be interpreted this way is the proliferation of ‘risk’ related representations and interpretations of the future. These ‘risk futures’ and discourses explicitly and implicitly establish a link between the idea of dangerous or undesirable prospects on the one hand, and the ‘necessity’ to counteract or manage such risky futures through certain acts, beliefs, and systems of mitigation, adaptation, and governance on the other hand (a.o. Adam et al, 2000; Anderson, 2010; Beck, 1992; Groves, 2010; Levitas, 2000). By implying the need for particular actions, decisions, discourses, and actor relationships and roles, and not others, such future dynamics can confer power onto some actors, while disempowering others.

Moreover, in a similar vein, specific modes of futuring and specific types of futures can tie in with the construction and distribution of expertise (Groves, 2016; also e.g. Anderson, 2010; Barry, 2001; Inayatullah, 1990; Seefried, 2013). To a certain extent, the contents and ways of anticipation that emanate from dominant anticipatory assemblages and diagrams of anticipation ‘rely’ on certain knowledge practices, socio-technical infrastructures, and networks. In other words, prevailing anticipatory assemblages go together with certain legitimized, standardized, and authoritative ways and techniques of futuring through which specific futures are made legible. Some actors (and non-human ‘actants’) can perform the needed practices and deliver the required knowledges, technologies, methods, etcetera, and others cannot. Thus, ‘futuring expertise’ is constructed and granted to some actors, organizations, and actants, and not to others. When certain ways of futuring are constructed as the ‘standard’, ‘legitimate’, and ‘authenticated’ way of doing things, in line with dominant anticipatory assemblages, then expertise also becomes bestowed upon those actors and elements that can ‘future’ in this way.

Expertise, in this fashion, can help to underpin, reinforce, and perpetuate certain ways of thinking, doing, and organizing the future. When anticipatory assemblages and diagrams effectively and continuously

operate to establish particular futures and ways of futuring, and when such modes of futuring also get to concentrate themselves around specific forms of power and expertise, the assemblages and diagrams can become even more effective and obdurate than they already were (Groves, 2016). The 'expert' styles of futuring thereby not only constitute but also strengthen and reproduce the anticipatory assemblages of which they are part. Of course, this has additional implications for power and further 'reproduction' capabilities, strategies and effects (of assemblages, ways of futuring, and power relations, in the present and towards the future), both on conscious and unconscious dimensions.

The picture that arises is one in which heterogeneous anticipatory assemblages have the potential to become strongly generative and performative, especially when they develop into 'diagrams of anticipation' and become intertwined with forms of power and expertise. This is not a problem in itself, but it can become problematic when certain actors and actants are deprived of any anticipatory capability, and when only certain futures can be imagined and produced. In such conditions, it becomes important to reflexively and critically deconstruct and open up the assemblages and their futures and ways of futuring. If one translates this to the field of urban planning, and the current struggles with its limited and inadequate future engagement, it is exactly a deconstruction of urban planning's anticipatory assemblages and diagrams which appears to be necessary. Only then can planning practitioners and theorists truly break out of their entrenched and increasingly questioned and criticized ways of knowing, doing, and organizing the future, to engage with the future more openly, more competently, and more effectively.

3.4 INTEGRATING THE THREE APPROACHES

Based on the sections above, it becomes clear that an analysis of urban futures and urban futuring within urban planning as formulated in this paper needs to draw on the three outlined approaches and weave them together in an overall analytical framework. In such a framework, the various conceptual elements of the approaches need to be taken into consideration: from the critical post-structural futures approach, especially the focus on epistemes, discourses, language, and discursive spaces and practices; from the sociology of expectations, the attention to futures (expectations) and their dynamics and performativity, and in relation to that, the presence and potential influences of broader 'seas' and repertoires of expectations and collectively shared imaginaries; and lastly, from the sociology of the future, the scrutiny of 'more than human', more material dimensions of anticipation and the conceptualizations of heterogeneous anticipatory assemblages and diagrams of anticipation.

The framework that emerges from drawing together these elements is clearly constructivist in its perspective. It regards urban futures as actively constructed in the present, and suggests to deconstruct and dereify urban futures and urban futuring by critically examining the (normalized) discourses, forms of action, and socio-material assemblages through which the future is understood, constructed, and performed. To this end, attention is directed to the epistemological, discursive, and rhetorical construction of futures, as well as the performativity of those futures. Moreover, attention is also paid to those dimensions and aspects of urban futuring that are 'beyond human', and more material, unconscious, and implicit, such as scripts inscribed into technologies.

Thus, the ultimate proposition is to dissect 'urban futures-in-the-making' on all its dimensions: the conscious and the unconscious, the material and immaterial, the discursive and non-discursive, the 'in-the-making' and the performative. Much like Groves' (2016) notion of anticipatory assemblages and diagrams, all these dimensions and elements are regarded as mutually constitutive and co-evolutionary, making up dynamic and mobile ensembles of 'becoming', in which they interrelate, connect, and interact with each other and can potentially crystallize into relatively performative and generative compositions or systems of urban futuring. Following this, a theoretical-conceptual perspective develops which invites a conceptualization and dissection of 'dispositifs' and/or 'assemblages' and 'diagrams' of urban anticipation (after Foucault, a.o. 1980, 2007, 2008; and Deleuze, a.o. 1992, 2006, see Groves, 2016; also Anderson, 2010; Braun, 2014; Hillier, 2011; Legg, 2011; Pløger, 2008, 2010).

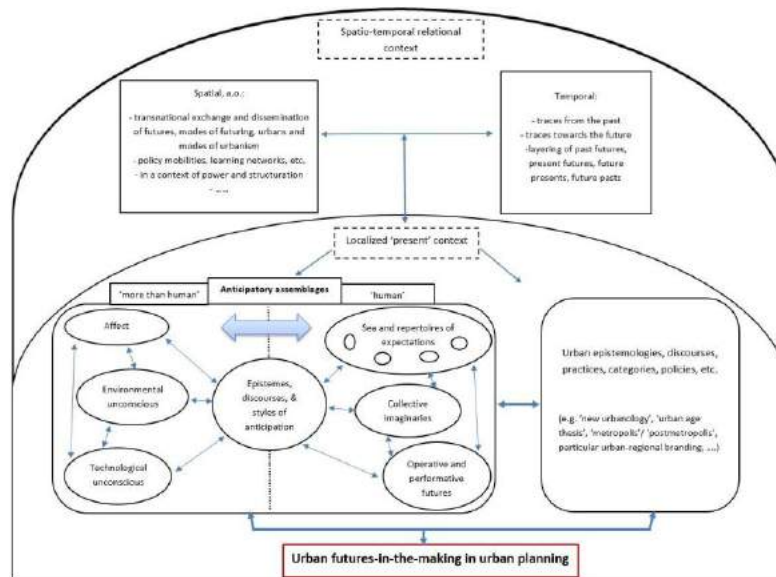

Figure 1. Visualizing the analysis of urban futures-in-the-making in urban planning.
Source: Author.

As figure 1 indicates, such an analysis of urban-futures-in-the-making within urban planning understands and examines any particular urban futuring exercise as constructed and influenced by heterogeneous assemblages, in which epistemologies, imaginaries, seas and repertoires of expectations, active and performative futures, and various material dimensions and aspects (practical, technological, biophysical, affective) all play a reciprocally constitutive role. Specific anticipatory and futuring efforts of urban planning are thereby situated within a broader environment, both in abstract-conceptual terms and in empirical spatio-temporal terms.

Concerning the empirical side, it is important to acknowledge that particular anticipatory exercises in urban planning, like a visioning process, are not isolated as one-time, bounded exercises – bounded both in time and space. Neither spatially nor temporally, specific futuring efforts are secluded from broader environments and developments. On the contrary, they are essentially relational, time-wise and space-wise. Regarding time, a futuring exercise does not simply take place in a defined ‘time-space’ in the (extended) present –with a clear beginning and ending –, but is inextricably tied to past and future events. For example, part of the futuring in a visioning process has already been done long before such a process starts, since the contents, directions, and shape of the futuring exercise have all been influenced by how the future has been constructed, understood, and performed before. This is why it is important to perform ‘genealogies of the future’ (Groves, 2016; Inayatullah, 1990) when analyzing contemporary urban futures and futuring: a genealogical historicization of the future engagement in the now is necessary to trace past influences on the current ways of thinking, doing, and organizing the future. Thus, analytically, one should not take the ‘beginning’ of an anticipatory exercise at face value, since the seeds for its futures and futuring have been partly planted in former times.

In a similar vein, futuring exercises are never really ‘finished’ either. In the very act of anticipation and futuring, traces towards the future are formed, strengthened, or disrupted in various ways and to various degrees. Most clearly, of course, there are the decisions, actions, and created futures resulting from many anticipatory exercises, which somehow concretely affect the present and thereby the unfolding future on both the ideational and material level. This relates closely to the very purpose of many futuring and strategy-making attempts in urban planning: to somehow give direction to the future through planning action. More abstractly and implicitly, however, the anticipatory action taking place within particular efforts of futuring can also help to create, reproduce, or break open anticipatory assemblages, dispositifs, and diagrams. In this way, futuring exercises and their futures can get bound up or come into conflict with existing and ongoing patternings of anticipation. They thereby become partly immanent and imminent to forthcoming developments, i.e. to the future, as well as to forthcoming anticipation, i.e. to the future of the future. This concerns a clear case of the future ‘in the making’, the future underway in the present, the future in process, the “immaterial future real” of latency and immanence (Adam, 2005, p. 11), and has to do with ‘future presents’ (Adam, 2005; Adam and Groves, 2007), which denote futures that are “already

set on the way” (Adam and Groves, 2007, p. 33). So, just as every futuring endeavor in urban planning is linked to future traces in the past, it is also always implicated in (future) traces towards the future (see also e.g. Hillier, 2011).

Alongside this temporal relationality of urban anticipation, one can also identify a spatial relationality. An urban futuring exercise is in all its dimensions (discursive, non-discursive, material, immaterial, etc.) never only unfolding in a specific, bounded institutional or local context or setting for a specific amount of time. On the contrary, it is related to and intertwined with all kinds of futures and futures epistemologies, discourses, repertoires, practices which are constructed and circulating intra- and inter-regionally, -nationally, and –globally; between cities and regions, nations, governments, institutions, people, learning networks, including summits, conferences, and so on (e.g. via the field of ‘futures studies’ or national and international futurist associations). At the same time, because of their ‘urban’ focus, these exercises are also related to and intertwined with all kinds of ‘urbans’, ‘urbanisms’, ‘urban categories and concepts’ and ‘urban epistemologies, discourses, repertoires, and practices’, which are also constructed and circulating between cities, regions, countries, institutions, cooperation networks, etcetera (e.g. via the field of urban planning, the OECD, the UN New Urban Agenda, the C40 network, etc.¹).

Certain institutions and actors, and urbanism and urban discourses and practices; how ‘western’ approaches to the future have become ‘normalized’, and have also found their way into urban policy, practice, and discourse, which influences the way that the urban planning profession and field has developed and has been engaging with the future/futures (see e.g. Ahlqvist and Rhisiart, 2015; Inayatullah, 1990; Kuosa, 2011; Mitchell, 2014; Seefried, 2013; Slaughter, 1993, pp. 843-845; 1998, 2008; Son, 2015; Stevenson, 2008; Veenman and Leroy, 2016; Williams, 2016); think here of e.g. the ‘ideograph’ of progress, and its link to cities and urbanism, for example still detectable in the ‘new urbanology’ (Gleeson, 2012); think of e.g. ‘discourses of risk and utopia’ (Levitas, 2000; also e.g. Beck, 1992), and their links to ‘urban resilience’ here, and looking at the ‘urban’ from a perspective of vulnerability; and more.

Every particular, localized, empirically distinguishable case of urban futuring – e.g. a visioning exercise for London 2050 – therefore takes place in an broader environment which is very diverse, relational, and expansive in both its temporal and spatial dimensions. Wherever and whenever produced and performed, urban futures and urban futuring are thus fundamentally relational. This relationality does not only include the heterogeneity of elements that make up anticipatory assemblages, but also involves the variety of spaces and times with which urban futures and futuring are entangled. Hence, the relational dimension should always be taken into account if one aims to understand and transform the futures and ways of futuring within urban planning.

Of course, any specific, empirical case will also always stand on its own, in the sense that it has its own contingencies and particularities. A particular, localized effort of urban futuring will always be ‘unique in its relationality’: the ways in which ‘future’ and ‘urban’ practices, discourses, epistemologies, etcetera, that are constructed and circulated across times and spaces combine, translate, and interact with ‘local’, currently existing specificities, such as ‘environmental’ factors of the place in question, the specific actors and their anticipatory capabilities and frames, place-specific histories and histories of the future, and so on, will always be unique for that specific urban futuring exercise only. Analytically, an integrative balance therefore needs to be struck between studying the wide-ranging spatio-temporal relationality and localized particularity of urban futures and urban futuring.

Nonetheless, bearing in mind the spatio-temporal relationality of urban futures and urban futuring helps to account for the larger contexts in which urban anticipatory action takes place, and to be critical and reflexive about these. It is one thing to dissect urban anticipation by analyzing how all kinds of epistemes, repertoires, assemblages, imaginaries and other elements perform, align, and/or collide in specific futuring efforts, but it is another thing to also somehow try to find out and explain how these efforts are potentially expressive of and influenced by broader historical-geographical conditions of power and dominant forces of structuration (a.o. Brenner et al, 2011). It is rather safe to assume that the various socio-material

¹ Think here e.g. of the article by Theodore and Peck (2011, p. 1) on the framing, development, and ‘coordination’ of a “transnational mode of neoliberal urbanism”, and similarly, McCann, 2013, on policy mobilities, policy boosterism and ‘Vancouverism’, and “global-urban policymaking”; think here of e.g. the historical development of futures studies and ‘futures expertise’, and the interrelations between specific epistemological approaches towards the future,

elements that assemble in particular efforts and places of urban anticipation do not just arbitrarily come together, but that their convergence and functioning ties in with larger societal contexts, 'structures', and relations of power, domination, and control. Hence, one should not turn a blind eye to these societal conditions if the goal is to properly understand and deconstruct why, when, and how specific anticipatory assemblages, futures, and ways of futuring are at work, and others are not. What this means is that an analysis of urban futures and futuring as proposed here should not remain stuck in mostly descriptive, presumably neutral accounts of all kinds of assemblages and relationalities at play in urban futuring, but that it should critically and reflexively engage with the (geo)political-economic contexts, formations, and forces against which urban futuring takes place. For current times, this would surely entail a critical view towards the dominance and impact of neo-liberal capitalism, which, in its various forms, guises, expressions, and 'structurations' arguably has had and still has a strong influence on everything related to urbanization, including the way the urban future is – and can be – addressed (a.o. Brenner et al, 2011; Fisher, 2009; Harvey, 1989, 2000, 2001; Lefebvre, 2009; Theodore and Peck, 2011).

Yet, while such notions of structuration should not be overlooked, it is simultaneously interesting to note which transformative implications the fundamentally relational understanding of urban futures and urban futuring might have. Before, it has been described that the various elements in an anticipatory assemblage can get to connect and perform in such a way that they become generative, performative, self-sustaining, and thereby potentially hegemonic, and restrictive in the futures and ways of futuring that they produce, predispose and allow for. However, the relationality inherent in such a view simultaneously points towards the contingency, fluidity, and variability of urban futures and urban futuring. By definition, the notions of relationality and assemblages imply continuous processuality and interdependency. Transferred to urban futures and futuring, such an interpretation counteracts blackboxing, and helps to see that the ways of knowing, doing, and organizing the future are not fixed but flexible. This means that, by extension, urban futures and futuring are mobile and changeable. In principle, the diagrammatization of anticipatory assemblages and patternings of anticipation are always temporary, and can be disrupted, reconfigured, and transformed through both inherent "lines of flight" (after Deleuze) and external impulses (see a.o. Deleuze, 1992; Groves, 2016; also Braun, 2014; Brenner et al, 2011, pp. 235-236; Hillier, 2011; Legg, 2011).

Admittedly, this transformative potential might be limited and difficult to actualize. Entrenched ways of understanding, acting, and organizing the future are not so easily overcome, particularly not when they link up with varieties of power, expertise, and political-economic structuration. Capitalism, to take an overarching as well as deeply rooted example, is renowned for its extraordinary resilience and its capacities to reappropriate shocks, innovations, and resistance (e.g. Fisher, 2009; Peck, 2010; Schumpeter, 1947; Wilson, 2014; Zizek, 2009): nothing truly new ever seems to be under the capitalist sun, which continues to burn unceasingly and widely, and, no matter how stormy the weather, always conquers the horizon again. Yet, despite this apparent obduracy, or, in fact, exactly because of it, it is surely critical to pursue transformation; especially if one considers the current predicament that urban planning and society find themselves in with their future engagement, and if one recognizes the promise that an improved future engagement holds for both urban planning and society. To this end, one needs to look at urban planning and its futures and futuring critically and reflexively, and, in the first place, aim to deconstruct the current ways of knowing, performing, and organizing the urban future. That is exactly what the framework proposed here makes possible.

4 CONCLUSION

This paper consisted of two main sections. In section 2, I explained why it is interesting and important to examine the 'futures dimension' in urban planning. Urban planning and the city were described to be intrinsically future-oriented, and the future engagement of urban planning was identified to be a prominent and contested but as of yet underexamined and unresolved issue in contemporary debates and practices. In light of this, it was postulated that an increased comprehension of urban futures and urban futuring was necessary, not only to be able to understand urban planning better, but also to enable transformations and improvements in urban planning practice and theory. In section 3, I brought forward a theoretical-conceptual framework to analyze urban futures and urban futuring within urban planning. This framework makes it possible to expose, focalize, and investigate the crucial roles and workings that the futures dimension has in urban planning, by drawing upon those approaches which explicitly engage with the future and anticipation. It integrates the critical post-structural futures approach, the sociology of

expectations, and the sociology of the future, and is based on the ambition to deconstruct the ways of knowing, doing, and organizing the future in urban planning.

Here, I want to reflect on some of the challenges and refinements of the suggested approach. To begin with, this paper mostly focuses on deconstructing the future and futuring in urban planning, but, in 'urban futures and futuring', the urban side should not be forgotten. 'The urban' and 'the future' are deeply intertwined in a study that follows the approach described in this paper. Thus, a deconstruction of urban futures and futuring does not only disentangle discourses, epistemologies, assemblages, and so on related to the future, but, at the same time, it should also 'denaturalize', for example, urban epistemologies, discourses, practices, conceptual assumptions and frameworks, and the naturalization and dissemination of specific urban concepts, practices, policies, theses, etcetera. Importantly, it needs to be taken into account here that futures-related discourses, epistemologies, practices, and assemblages and so on can entwine with urban-related frameworks, concepts, epistemologies, and assemblages, and that these can influence and mutually constitute each other. This is for example clear in Gleeson's description of the contemporary 'new urbanology' and Brenner and Schmid's depiction of the 'urban age thesis': both accounts show how various 'narrow' conceptions of 'the urban' can also imply and have embedded within them certain 'narrow' or very particular conceptions of futures and future possibilities (Brenner and Schmid, 2014; Gleeson, 2012). So, a deconstruction of urban futures and futuring should always be about both how the future is understood, imagined, and performed, as well as how the urban is understood, performed, and imagined, and, crucially, about how these two dimensions interconnect.

Secondly, an analysis based on the framework proposed in this paper should be cautious in its application of 'assemblage' thinking. As Brenner et al (2011) have rightly argued, an assemblage-inspired approach may overstate and exaggerate the relationality within concepts like assemblage to the point of relativism and "naïve objectivism" (Brenner et al, 2011, p. 233; also Sayer, 1992, p. 45). When almost all attention is directed to descriptively tracing and mapping the materialities and connectivities of assemblages and their elements, one risks to overlook how these particular relations and compositions are situated within historical-geographical conditions of power and structuration. Such an effort would present a decontextualized picture in which assemblages seem to be assembled and disrupted almost automatically and anonymously, as if they are detached from, for instance, political-economic forces and power dynamics (see also Bender, 2010, p. 305). Accordingly, it is not enough to only expose that elements connect to each other, but also necessary to analyze how and why they form (or disturb) functioning assemblages, and who (or what) is doing the connecting and 'structuring' to whom (Brenner et al, 2011, p. 236).

At the same time, however, it would also be too simple and inaccurate to explain the emergence and functionings of certain assemblages by broad-brushly referring to political-economic 'systems' or overarching forces like capitalism. It is exactly here that the assemblage-approach can help to specifically identify how various forms of 'power' and 'structuration' concretely and continuously perform through and within 'assemblages' of heterogeneous elements and actors, which generate particular ways of doing, knowing, and organizing, and not others. Hence, assemblage-thinking can add to and simultaneously needs to integrate perspectives that deal with the more political-economic dimensions of social life (a.o. Brenner et al, 2011).

Thus, regarding the framework brought forward in this paper, the assemblage-approach should not be pushed too far when analyzing urban futures and futuring in urban planning. It should be applied in such a way that it is conceptually, empirically, and methodologically useful, while acknowledging and incorporating political-economic aspects (Brenner et al, 2011): it should help to diagnose how and why all kinds of elements and actors connect into particular assemblages that perform in such a way that they predispose futures and ways of futuring that are, most likely, in line with hegemonic arrangements of power and structuration. Simultaneously, by deconstructing urban futures and futuring in this way, the perspective should also help to identify openings: ways out of the dominant anticipatory assemblages themselves, and by extension, ways to counter and reshape the broader systems and relations of power and control.

Thirdly, another challenging aspect of this paper's theoretical-conceptual cadre is the relation between past, present, and future. These temporal categories and their relationships and dynamics are never fully accessible or re-traceable. When analyzing urban futures-in-the-making, one should consider a whole set of layers of past futures, present futures, future presents, and future pasts that interpenetrate each other

(Adam, 2005). However, these various futures and their processes of emergence and functioning are not so easily susceptible to empirical research. This is a key reason why it is so difficult to sociologically and analytically engage with the social future and processes and effects of futuring. For example, this difficulty also permeates efforts to undertake 'genealogies of the future': it is never possible to truly 'reconstruct' the history of the future, and the traces that are found and formulated in such genealogies will always be partially subject to selection and interpretation by the researcher (see e.g. Kearins and Hooper, 2002; Tamboukou, 2003). So, although the theoretical-conceptual framework provides several concepts and insights to expose and analyze the interplay of futures and temporalities, this will always remain a topic of concern that should be acknowledged and reflexively and truthfully addressed.

Fourthly and lastly, it should also be noted that analysts of futures and futuring are themselves part of the world of futuring that they attempt to investigate (a.o. Adam, 2005; Borup et al, 2006; Brown et al, 2005). Researchers cannot freely detach themselves from the various futures, temporalities, and ways of futuring that they experience and enact and that are variously embedded within them and their own practices, knowledges, bodies, and minds. This means that it would be misleading and almost hypocritical to claim a neutral, non-normative stance in futures-related investigations. Analysts of the future are always also future makers, implicated in the 'futures of our making' (Adam, 2005, p. 14). They consequently also need to consider their responsibilities, accountabilities, and moral and ethical obligations, ambitions, and impacts (Adam, 2005; Adam and Groves, 2007). A study of urban futures and futuring within urban planning along the lines suggested in this paper, therefore, should also be committed to the 'ethics of the future' (Bindé, 2000). Moreover, this ethical concern does of course not only involve the researcher's own positionality (his or her futures, futuring, actions, decisions, knowledges, research designs, and so on), but actually constitutes a significant additional factor to take into account when studying his or her actual cases of urban futuring: how do the studied urban futures and ways of urban futuring relate to future ethics or ethics of the future, and how can ethical resources towards the future be increased (Adam, 2005; Adam and Groves, 2007, 2011; Bindé, 2000; Groves, 2009)?

Clearly, multiple challenges accompany the exploration of the futures dimension within urban planning that is proposed in this paper. However, I contend here that, on the whole, the advocated approach is very valuable, and deserves to be pursued. Its value, moreover, does not only lie in the increased understanding it will bring about urban futures and futuring in urban planning. A research project along these lines also has clear practical value.

An increased understanding of the natures, roles, dynamics, and effects of futures and futuring in urban planning will provide insights that will also create to possibility to change and improve the practices, processes, and products of urban planning. Already at its base, for example, an increased awareness of the 'sea' of expectations in which urban futuring occur is valuable, since it strengthens the reflexivity of the relevant actors involved, allowing them to take this into account when imagining and acting upon city futures and future cities. Based on a better insight into how and why these processes work, it will become possible to open up the field of futures and futuring for urban planning, thus eventually allowing for more imaginative, creative, and therefore potentially more effective planning practices, processes, and products.

This link towards the more 'practical' value of the approach can also be described in conceptual terms. When futures and futuring are conceptualized as being at the heart of urban planning, and, more importantly, as being crucially performative, constitutive, and generative of urban planning, then it follows that it is also in this futures dimension where transformation can be brought about. In other words, the future becomes an important site of transformative action. It therefore makes sense to target the future engagement within urban planning when changes or improvements are sought. This is another reason why the proposed theoretical-conceptual approach offers a meaningful, innovative, and crucially significant perspective for the analysis of urban futures and futuring within urban planning. To come back to the beginning of this paper: by looking at the future, opportunities for improving the practices of looking into the future open up. By extension, the capacity to construct and realize better and more desirable futures rises on the not-so-distant horizon.

ID 1439 | SHAPING THE CITY OF TOMORROW IN EAST ASIA: CONCEPTS, SCHEMES AND IDEAS FOR URBAN DEVELOPMENT FROM 1960S TO 2010, AND BEYOND

Raffaele Pernice¹

¹XJTLU - Xi'an Jiaotong Liverpool University
raffaele.pernice@xjtlu.edu.cn

1 INTRODUCTION

There is a growing interest about the urban visions and architectural ideas and vocabulary behind the formation of the large urban conglomeration in Japan, South Korea and China, and how the seeds of Western planning theories and architectural design practice have helped shaping and building the contemporary cities along the vast regions of Asia Pacific Region, and frame a local language in envisioning the city of the future.

Fuelled by an unprecedented economic boom in the recent decades, China has carefully planned a process of urbanization at a gigantic scale, supported by political will and determination in promoting a radical transformation of the economic system by shifting progressively from industry to services, and promoting the city as a fundamental element for this transition. South Korea and Japan are the models for this sort of urban transformation, both for the overall dynamics and the design and planning methods implemented, as South Korea experienced her fast urbanization process in the late 1980s whilst Japan has witnessed a great urban growth during the 1960s. Somewhat “old” concepts and ideas imported from the Western planning traditions, such as the design of new towns, neighborhood units, gated communities, green belts and garden cities, high-rise living etc. are still essential practical elements implemented for the planning and design of the modern/contemporary urban landscape, and are largely adopted in the planning processes used in the structuring and organization of the cities and suburbs built in the region. New progressive concerns related to environmental, social and technological issues such as the Climate Change, growing pollution, the need for sustainable planning and more energy efficient, smart and eco-friendly devices for transportation and domestic use, the constant ageing of the population, among others, call now for very new ideas and bold and innovative schemes in the design and development of cities in East Asia, as well as around the world.

Reflecting on the contributions from East Asia to the discourse of planning and design a city for the future as promoted by single actors, larger cultural movements and national elites fostering economic ambitions and political agendas of autocratic forces (e.g. from the experimental cities by the Metabolists in Japan, to the more “pragmatic” urban development projects fostered by local and national governments in South Korea and China), it can be worthy trying to explain some of the key socio-economic factors and planning engines which have dramatically and radically transformed the skylines of the most dynamic and growing influential area of the world at the dawn of 21st century, as well as briefly describe the origins of the various forms and elements of the modern built environments which have been shaped and molded by these same forces, and how/whether these urban forms embody a true genuine East Asian vision of the city of the future, and what is the current trend in terms of new urban forms and architectural design research at the beginning of 21st century.

1.1 BACKGROUND OF THE URBANIZATION IN EAST ASIA IN THE LATE 20TH CENTURY

Built on the lessons of other developed and developing nations which have adopted mass apartment buildings as strategy to foster modernization (Urban, 2012), a real estate revolution, driven by a powerful government-sponsored construction industry and the use of new technologies available, has been the engine which has led the processes of radical industrialization and frantic modernization from the second half of 20th century in Japan, and then in South Korea and China; this factor has consequently prompted a huge restructuring of the pre-existent urban fabrics and the progressive reshaping of city form, inner structure and urban landscapes. People mobility, infrastructure development, industrial modernization, growth of consumerism and of the service sectors, social restructuring have led an unprecedented

urbanization in this part of the world both in scale and rapidity, with very relevant implication in geo-political and economic terms.

Growing mega cities must accommodate a new class of urbanites and more immigrants from rural areas, with housing shortage being one of the foremost important issues. House as shelter and especially as status symbol characterizes the aspiration of the middle class generated by the economic success of Japan, China and South Korea, which follow a path set by other developed and developing nations, most notably the US, which adopted large scale planned communities and mass apartment buildings as strategy to foster modernization and create cohesive communities (Ellin, 1996; Urban, 2012). The Japanese live, work and move in the super-conurbation called Megalopolis of Tokaido, integrating infrastructures, productive zones and an intricate extension of residential urban fabric well represented by Tokyo skyline, which has developed in a sort of mainly horizontal and decentralized multi-polar urban entity (Kornhauser, 1976; Hirai, 1996; Sorensen, 2002); South Koreans live in a sort of “Republic of Apartments” whose main “smart” and “radiant” hyper-connected cities are composed by clusters of uniform and repetitive high-rise, dense residential compounds filled with shops, schools, services, landscaped areas and infrastructures inspired by Western planning strategies (Gelezeau, 2003; Lee, Choi, Jeong, Soon, 2015); likewise in the last decades, to fuel its urbanization and shift towards a market economy in a more globalized world, the Chinese government, to consolidate its political agenda has orchestrated the development of many modern new towns and futuristic eco-cities, reshaping the urban forms of many cities through the creation of vast extensions of new residential, commercial and business districts in the suburban areas around the major cities in order to promote both a modern urban development and lifestyle, and further support a larger industrial output and economic growth to foster their profile as true global cities on the international scene (Rowe and Kuan, 2002; Friedmann, 2005; Lu, 2006; Wu, 2007; Gregotti, 2009).

2 JAPAN: URBAN METABOLISMS OF A MEGALOPOLIS

Contemporary urban Japan was born from the ashes of the cities destoried during the WWII. The economy didnt recove till early 1950s, in coincidence with the start of Korean War and in the climate of the Cold War, and by the beginning of the next decade a new vision for the country, both modern and prosperous, unified the efforts and solidarity of the Japanese population and the central government. By the early 1960s all the strategic economic plans promoted by the government to recover from the war were completely fulfilled, and Japan joined the group of the most dynamic and advanced industrial power among the developed countries. The rapid economic growth brought the development of a modern system of urban infrastructures, a general improvement of the living standards, a unprecedented increase in the national wealth and fuelled investments to pursue a comprehensive technological progress. The economic success of the period however also caused new serious urban problems which posed a severe threat to the social life in the Japanese metropolises, which tried to keep the balance between the needs for a modern life with the persistence of the tradition (Woswo, 2002). Frequent cases of environmental contamination caused by high the levels of pollution (Ita-ita; Minimata, Yokkaichi) were reported, as direct consequence of planning flaws which for instance allowed for the co-presence of an high concentration of factories and industrial plants in urban residential areas alongside an high population density in the big industrial cities. The reason behind this was the need sustain an accelerated urbanization during the years of rapid economic growth which asked to privilege the industrialization and the economic development, which meant it was fine to set the industrial complexes in close proximity to each other and to the workers’ residential areas (kombinatos). In the early 1960s the rampant urban immigration and uncontrolled urban sprawl led to the formation of the so-called Tokaido Megalopolis, but also resulted in serious problems related with these phenomena, which became source of serious concern for the Japanese government.

Metabolism as architectural and urban avant-garde movement was a product of the post-war economic growth condition of Japan in the 1950s. In the context of the country’s economic regeneration and cultural innovation, Japan pursued a further stage of modernization through urban development, which fostered the construction of huge and extensive systems of infrastructures in the cities as urban and interurban networks of movement, communication and energy supply integrated with public spaces, industrial and residential zones, to support the fast urban growth. The Metabolist city, inspired my the myth of Futurism’ New City and the fascination for Le Corbusier’s Radiant City, intended to overcome the fixity and the mechanical structure of the Modernist City, whose theorethical fundamentals were in a state of crisis following the social and functional failure of many of the modernist urban renewal projects and schemes actually built in the postwar years. Many of the projects by the Metabolists presented high rinse mega-

structures made of support clusters of prefabricated apartment capsules, which could be modified and replaced according to their life cycles and the social demands and fashion. Rejecting the Modernist methodology based on the principles of Athens's Charter which focused on the use of a fixed master plan and zoning, Metabolists tried to control and plan the city through the tools available from industrial design methodology instead of the architectural principles. Indeed the idea of metabolic cycles of the Metabolist architectures, such as Arata Isozaki's plan for clusters in the air, derives from the vision of the world of technology and the functionality and flexibility of the assembly line of the industrial production system (Pernice, 2006; Koolhaas and Obrist, 2011).

Figure 1 - City in the Sky 1962 (Isozaki.co.jp)

The idea of mega-scale and of a total controlled urban system conceived on the acceptance of a hyper-dense and highly technological built environment, in order to control urban sprawl and give visual coherence and order to the process of city growth, as proposed by Metabolists and other visionary Japanese architects and planners was counterbalanced by a more pragmatic approach towards a regional and urban development, which found in the UK lesson of new towns development and the new research for mass housing provision the main response of the local and national authorities.

The first modern new town built in Japan was Senri in 1958, which was followed by 15 new towns

developed after a new law for the development of new residential areas was passed in 1963. Tama new town, the biggest of these cities designed as a satellite town of the main conurbation on the outskirts of Tokyo, was built thanks to both private and national capitals and its scheme based on a system of neighborhoods, and approach further refined in the following decades focused on the promotion of various new technopolises.

Figure 2 - Tokyo townscape (the author)

The cities which constitute the Tokaido Megalopolis, a super urban conurbation stretching from Tokyo to Fukuoka, offer a vivid example of what has been termed "railway urbanism", a form of urban growth where a regional area is organized as a system of cities structured as a hierarchical network of mass transport pathways (expressways, metro, railway lines), which intersect in sub-node-points always connected to major nodes of services and movement (major railways and subway stations) and which are central functional and visual points of large residential urban areas. Indeed the transportation infrastructure and especially the railways development have had a strong impact on the formation and development of the modern Japanese urban environment (Kornhauser, 1976), which present the main central urban areas of the cities, especially Tokyo, as the core of the national socio-economic system. Here new multi-level and multi-functional urban spaces were created in new districts of the cities especially since the 1980s, which

contributed in creating a complex urban townscape in which huge patches of extensive residential fabrics merged with newer residential developments in the form of clusters of towers integrated with cultural facilities, offices, retails and restaurant to form a multipolar urban structure in the city in order to organize key reference central nodes and balance the growing suburban sprawl (Sorensen, 2002).

Indeed the process of urban growth in Japan in the last decades has been driven by an unparalleled expansion and integration of the transportation development in the structuring of the city, well expressed by the case of Tokyo. As capital and most important cultural, political and economic center of the nation, Tokyo is a model of megacity whose urban landscape extends at regional scale, which needs an efficient, capillary and very extensive transportation network for the daily activities of the residents, who typically commute long hours from suburban residential districts to central working areas. The city is a clear example of what has been termed “railway urbanism”, a process of urban organization which disregard cars as main means of movement and, heralding the modern T.O.D. design approach and planning methodology, conceiving the city as a hierarchical network of mass transport pathways (expressways, metro, railway lines) which intersect in sub-node-points always connected to major nodes of services and movement (major railways and subway stations). The easy access of commuters and the special linkages between private railways/metro companies and commercial and market groups has created an urban landscape where the location of the main chains of department stores and shopping malls is essentially close or literally built around huge decks/plazas in front or above subway and railway stations or interchange stations, which are truly fundamental urban nodes and fundamental interchange link points of larger residential and mixed-used districts. The necessity to rely entirely on the efficiency of mass transport system in terms of movement and services has inevitable consequences on the development of a very peculiar urban landscape and lifestyle in a high-density city like Tokyo and other Japanese cities, whose dwellers are more and more compared to “urban nomads” living their existence commuting between vast artificial habitats of fragmented realities, often on the urban rural fringes (Desakota) of the large metropolises.

The challenges of constant natural disasters and the constraints of the limited space available in the city due to the rising costs of land and services, have both been functional in an approach to technology as a necessary tool to improve and make safer the daily life in the large metropolises, and in the appreciation for a living in low rise dwelling. Therefore the Japanese city, retaining from the past just the finer urban grain of historical residential areas and the apparent irregular layout of the streets and complexity of the townscape, is mostly defined as a complex mosaic of fragmented landscapes composed of scattered high-rise and high densities mixed used blocks, and vast districts of detached houses or row house residential enclaves.

What is peculiar to Japan is the limited number of large apartment blocks in the city. In contemporary Japan most people still preferred to live in ordinary low-rise single family houses, a trend quite interestingly different from the rest of East Asian countries. Indeed by the late 1990s, and after the 1980s economic downturn, it was not the apartment block but the (suburban) single family detached house with private garden and parking plot was the favorite urban residential typology as indicated in a survey of 70% of the Japanese, a trend further consolidated by the progressive transformation of Japan, like many other developed nation, in a ageing society (Hirai, 1998; Inabe and Nakayama, 2000). Less population, the need for more daily-care and a certain natural predisposition for acceptance and interest among the Japanese in new robotic technologies, spell clearly of a future of highly technological advanced “shrinking cities” in this part of Asia.

3 SOUTH KOREA: COMPACT APARTMENTS FOR SMART CITIES

The rapid modernization of the Republic of Korea become a priority for the Korean government in the second half of 20th century, following the end of four long decades of Japanese colonial rule in 1945 and the end of subsequent Korean War (1950-53), which split the country in two blocks. The priority was to promote a comprehensive modernization of many aspects of the traditional Korean society, from economy to industry and life-style, on the model of what Japan did at the end of 19th century. The development and construction of large housing complexes received a particular attention as this related directly with the necessities of larger redevelopment projects in the cities which could be planned, organized and integrated with new urban infrastructures and in general related to the broad process of industrialization, economic growth and eventually modernization of the country. Since the late 1980s and early 1990s the design of

new and larger (complex) high-rise apartment blocks was especially encouraged, and the Korean apartment block (Apatu Tanji) became also extremely important for the development of a strong and influential construction industry, and being functional to the formation of a growing middle class, especially in order to sustain the economic growth of Korea, turning the country in what many foreign observers define a “Republic of Apartments” (Gelezeau, 2003).

The evident and sometimes annoying repetitiveness in the design of the identical facades and exteriors of the Korean apartment blocks, and the standardization of the interior layouts of the apartments, presenting

the same basic spatial organization/features in several parts of the big cities and regions throughout the country, is balanced by the soundness of the structural technology implemented for high-rise buildings and by the high standards in terms of comfort and management, with organizational schemes of the residential towers which show several fundamental elements derived mostly from the British and the US planning traditions (Lee, Choi et al., 2015).

Figure 3 - Apartments complex in Daegu (the author)

Where South Korea have shown an original contribution and a pioneering spirit in promoting new forms of urban planning and design is in the promotion of Smart Cities. Koreans distinctive approach for this city model has been largely support by the capitals and know-how of large industrial conglomerates (chaebol) of international renown brands, mostly active in IT, such as Samsung, LG and Hundai. As the one of the most connected country in the world and a powerhouse in the production of semiconductors and investments in IT research, South Korea has embraced the ideas of Smart Cities and Smart Dwellings design with an enthusiasm which has few equivalent elsewhere. The most clear exemple of the infatuation for this idea of city is the city of New Songdo built from scratch near the port town of Incheon, East of Seoul. Songdo was built from 2005 on reclaimed land from the Yellow Sea as an industrial park and then a special economic zone in order to attract foreign direct investments of multinationals and international corporations, with low taxes and less regulation, in open competition with similar zones in East Asia. High tech industries and the government sponsored most of the works, with the idea of creating a fully networked and automated city, whose omnipresent sensors, diffuse cctv cameras, digital technologies and wireless connections assure a constant monitoring and instantly interaction between users and services (Townsend, 2013). In spite the loud slogans and the artificial appeal of the original project, this typical smart city planned for smart people presents a un-impressiver plan for mobility organized on grid of roads,

with clear zoning and vast park-like green spaces separating various districts. The typology chosen for the residential buildings is the apartment tower, which add the sense of vertical growth of the city, in stark contrast with the surrounding natural landscape which is essentially flat and with very few hills.

Figure 4 - New Songdo (sogdoidb.com)

Bundang new town is a good exemple of a series of new towns developments undertaken by the Korean government to consolidate the large area of Kyonggi-do, the regions which surrounds Seoul and is the economic, political and industrial core of the nation. (Shane, 2011) Together with a few more planned and developed new towns, Bundang was built as a large size satellite city set in the ring of land around the capital, which is a green and mostly restricted area where new housing could not be built, a zone clearly insired by the scheme of English green belt, which was established in the UK with the 1947 Town and Country Planning Act and initially was proposed by Patrick Abercrombie's Greater London Plan in 1944.

Inspired by the need to promote a modern blueprint in terms of city of the future, and developed by combining Western planning methods (mostly from the Anglo-Saxon lesson in regional planning), Japanese emphasis on transportation development and Singapore and Hong Kong well known approach to urban vertical growth centered along the main mobility hubs (subways, metro stations), South Korean planners and urban designers rush to implement the most updated know-how into the delivery of large and hybrid urban schemes of high density and strictly organized new towns, of which Bundang, designed and built by Korea Land Corporation in 1989-1996 is an exemplary model. The city was designated to host 1 million people and is organized as a linear settlement gathering a collection of neighborhood units as high rise residential and office towers enclaves, mostly gated, organized as a chessboard of superblocks. Most multistory and dense commercial zones are organized around the main streets axes, with the city presenting an elongated development along the main river and the metro line to Seoul, and with the major street network running N-S, an axial scheme which is surrounded by several different green areas constituting a system of urban parks for local residents. Here is very evident the idea of (re)creating the townscape as image of the city in a park, or a vertical city in the garden, a clear homage to Le Corbusier' Radiant City conceived in the late 1920s.

More recently South Korean government has embraced the idea to move the national capital from Seoul to a new site in the center of the nation, and the urban model chosen for the planning and design of the new capital is the Eco-green city. Since 2007 Sejong city has been developed as a multi-functional administrative capital city as an attempt to decentralize and decongestion activities and people from crowded Seoul. The program proposed by received a major setback though the plan to relocate most of the ministries and governmental offices is still on-going. Among other reason for the construction of Sejong city, which is still largely unexecuted, is the scope to create an urban pole able to promote a more balanced regional development of the country, as this new city is located in central area between Seoul and Daegu-Pusan metropolitan area, the second larger conurbation of South Korea. Like for many similar scheme of eco-cities, the key element of the project is the design of many energy efficient and futuristic shaped buildings integrated in a larger system of circulation avenues; the masterplan has been arranged with a loop-shaped lay-out and the city in the blueprints and renderings shows a somewhat conventional urban image made of towers insert in a series of layers of grids of low-rise eco-buildings featuring organic shapes and green roofs, long vistas of green parks and a fast mobility on broader road arteries, a sort of hybrid combination of Chandigarh and Milton Keynes.

4 CHINA: VERTICAL URBANISM OF GATED COMMUNITIES

Since the start of the policy of "Open Doors" in 1978, China has witnessed the largest urbanization process of history, with more than 300 million people moved from rural regions to urbanized areas, compressing in much shorter time what western countries and other Asian developed nations, especially Japan and South Korea had achieved over longer periods. This process of sustained urbanization in China during the last 3 decades is also the direct consequence of a radical shift in the economic structure and the massive phenomenon of immigration from the rural areas of the country piloted by the central government, which constantly operates in order to assure a progressive process of modernization and assure a more relevant geo-political role of the nation in the world economy (Rowe and Kuan, 2002; Friedmann 2005; Wu, 2007). Large numbers of works have moved from the West and central areas of the country towards the coastal cities, richer in services and infrastructures, real engines of the socio-economic life of China, and cultural cores of resurgent Chinese ambitions. The need to implement a specific plan to control the growth of the economy and the expansion of the main cities has fostered the development of planned cities and new towns in their suburban areas, though what effectively controls and influence the planning approach of the Chinese cities is the fact that the land is still property of the government and is "sold in leasing" for 70 years to private developers and individuals, and the system of Hukou, the household registration system, which in practice discriminate between the legal local residents and the external workers, to whom many urban services are precluded.

Among the most representative urban projects which have inundated China in the recent years and well represent the rush to modernize cities and view of the urban future for most Chinese are for instance the construction of SIP Industrial Park in Suzhou, a series of new prototypes of green and eco-cities, as well as bold program for new towns development around Shanghai Metropolis, the most global of the Chinese cities.

Figure 5 - Gated community in Suzhou (the author)

Shanghai municipality promoted the design of a series of model new towns called “1 City, 9 Towns Plan”, a system of satellite cities on the outskirts of the larger metropolis to be completed by 2010, whose design was based on different foreign styles and city planning traditions, in order to both create new growth poles and decentralize people from the congested center and to foster external investments and marketing the city and her position in the global economy (Den Hartog, 2010). Among these new towns set on the fringe of Shanghai, the most relevant are Anting (German Town), Pujian (Italian Town), Thames Town (English Town) and Gaoqiao (Dutch Town). In the case of Thames Town and Gaoqiao Dutch Town architects and planners designed these new towns as places for public consumption and for marketing the new urban revolution of China. The new towns projects in Shanghai like elsewhere, were proposed as the optimal solution to what are considered a series of fundamentals issues in the context of current urban planning approach in China: foster city branding in order to promote the image of a modern and prosperous country and attract foreign investments; introduce and diffuse a more international and modern (Western) urban life-style, rich in amenities as well as in urban services to promote social activities and thereby consumption of an expanding middle class, which ask for a luxury design and attractive, comfortable and visual appealing urban scenes.

In the effort to support further urbanization and escape from the choking air of heavily polluted industrial cities, China has funded the construction of new suburban districts and eco-cities and green towns, often resulting in desolated built areas of ghost towns. Eco-city Tiating, a model of sustainable city inspired by the

T.O.D. system and the integration of carefully planned and well landscaped and organized urban districts inspired by Singapore model of urbanization, and the plan for a new high density and vertical Forest City, a linear system of high rise blocks containing hanging gardens of trees and plants conceived by Stefano Boeri for Shijiazhuang, well represent the trend of adopting external green-sustainable planning concepts as well as the consultancy of foreign professionals hired to propose innovative design and technical solutions.

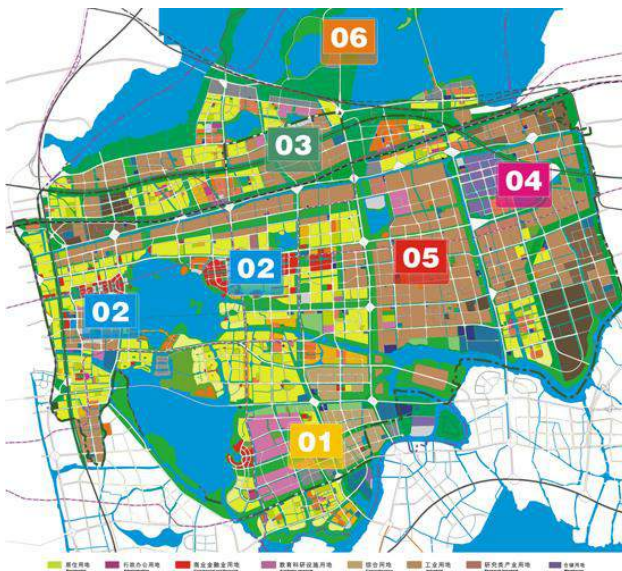

Figure 6 - Suzhou SIP Masterplan (Suzhou Planning Bureau)

The district of Suzhou Singapore Industrial Park (SSIP, now named simply SIP-Suzhou), set up in Suzhou, Jiangsu Province in 1994 as a joint venture between Suzhou Metropolitan government and Singapore government, was proposed as a prototype of a modern industrial park conceived on the most advanced

planning strategies and up-to-date urban design concepts, becoming a true model for other Chinese cities, in order to provide Suzhou with first class industrial infrastructures, clusters of heavily landscaped self-secluded residential complexes (mostly gated communities inspired by the concepts of Clarence Perry's Neighbourhood Unit) and high-standard services, while promoting and "branding" the image of the city at a domestic and international level. The entire park is a huge grid of roads and public parks constellated by foreign high-tech companies, industrial facilities integrated in a system of public services, research institutes, residential zones and green university campuses, inspired by a car-oriented urban development. As part of a good sample of planning experience, Singapore community planning patterns, the organization and design of neighbourhood centers, and public housing design methods were also introduced into SIP via regular visits by local management training teams to Singapore. Especially the model of Singaporean neighbourhood center, as a pivotal core of the local district social life and planned as a system of mixed used spaces filled with essential services to support a small population and with a very easy linkage to public transportation routes and metro stations, and the model of gated communities designed as dense blocks of high rise residential towers embedded in well maintained semi-public gardens and green spots, and integrated with communal spaces and collective facilities (a model also extremely popular in Hong Kong), have proved to be of particular interest and successfully implemented in the context of the fast growing Chinese urbanization, more and more inundated with copycat architectures and public space design projects mimicking Western or other exotic styles.

It appears that in contemporary China the urban morphology of the cities is more and more defined by the organization of newly built large urban blocks as secluded enclaves and gated communities of high rise towers (dis)-connected by broad avenues and streets, given that for several decades the only form of urbanization for Chinese cities was through the development of socialist working units (danwei) which combined factories, residences and other services, based on former Russian self-contained residential superblocks models (microdistricts or microrayon), which were transplanted to China since the early 1950s (Lu, 2006), and largely inspired by precedent 1920s concepts such as the German' Siedlungen and Vienna's Hofe, as well as the American concepts of Neighborhood Unit and Clarence Stain's Radburn's model of urban block (1929).

5 CONCLUSIONS

Among the several models proposed in the recent past to structure the growth of the city, 3 are for sure the most influential in the 20th century, namely the schemes proposed by Ebenezer Howard (dispersion), Le Corbusier (concentration) and Frank Lloyd Wright (extension)(Choay, 1965; Fishmann, 1977). Of these it seems is Le Corbusier' image for a city of towers in the park organized around a clear separation of mobility routes, with a preference for car transportation, that most than others has completely (re)shaped the current city development in East Asia, focussed on the needs of economic growth to foster a rapid transformation.

The models of urbanization and modernization of China and South Korea since the late 20th century show these countries followed a very clear pattern which was first evident in the case of Japan. Similar is for instance the prominence granted by the central governments which were driven by a strong ideological component based on the notion of importing models and schemes from more developed countries essentially from the West in order to promote and accelerate the modernization of the society and the culture, with inevitable consequences on the transformation of the pre-existent urban environment. The traditional elements of the natural landscape, and of the local urban milieu and the surviving relics of the old cities are, especially at the beginning of the urbanization, mostly removed or drastically replaced by the new urban and suburban developments.

Some peculiar cultural differences are evident in the form of urban life-style and the view of the city and urban landscape among Chinese, Koreans and Japanese. The process of fast urbanization in China during the last decades has disclosed several problems and contradictions which are typical of a country and a society that strives to modernize its economy, urban environment and cultural features rapidly: mobility and car-oriented urban development versus the preservation of the fragile pattern of the traditional city; industrial development versus the need to protect the eco-systems and natural environments; the social harmony endangered by the extremisms put forward by a rampant capitalistic model of economic growth, are among the most impellent issues to be fixed. Korea and Japan.

High densities, congestion, verticality, emphasis on circulation mainly intended as car mobility, and distance from the aesthetic and urban local traditions for sake of the myth of the Western culture which brought a rapid pseudo economic progress, are the key notes of current urbanization in East Asia, and still these appear to drive the view of the city in the near future, though new issues such as ageing society, crisis of wild globalization, ecological problems related to the unstoppable deterioration of natural environment and the inevitable transformation of the current economic model for the years to come may progressively dictate a new urban agenda and new concrete and truly innovative solutions in East Asia and all over the world.

ID 1476 | RESEARCH ON THE RELATIONSHIP BETWEEN SPACE OF PLACES AND SPACE OF FLOWS - EMPIRICAL ANALYSIS BASED ON GLOBAL SCALE AND LOCAL SCALE

Bowen Chen¹; Jia Geng¹
¹Tongji University
1967114471@qq.com

1 INTRODUCTION

In the process of reform and opening to the outside world and economic globalization, China has taken the initiative to integrate into the world economic system and has become the world's second largest economy. At the same time, the establishment of information and communication networks has greatly accelerated the process of global integration, and promoted the flow of information, knowledge and capital flows among cities all over the world. "Space of flow is constantly manifesting and becoming an important force to promote the world economic structure and the evolution of the urban system. From the original growth pole model to the central hierarchy, and now to the urban network, the development and evolution of the urban system has entered a new era. Since 2000, the research of urban network abroad can be divided into two major directions: enterprise organization and infrastructure. Among them, the former research is more mainstream, this is because the essence of urban network is the economic relationship between cities, and enterprise actors is the starting point of economic relations. In recent years, Chinese scholars have also conducted a series of urban network research based on the space of flow (Tang Zilai, Zhao Miao Xi, 2010; Zhu, Wang de chazon, 2014), and achieved certain results.

In fact, space of flow is not a unique product of globalization. From the origin and development of the city, city area as the economic subject, relying on the foundation to meet the demand for goods and services sectors outside the city to achieve its circulation and accumulation. The economic links between the city is inherent in the space of flow has always been there, just under the influence of globalization, enterprises can realize the function of deeper integration in a wider geographic range (Dicken, 2011), the economic ties are greatly strengthened and obvious, showing a trend of network. The space of flow is the economic network formed by information and capital flow, while the city as the space of place is the pivot or node of the economic network (Tang Zilai, Li Can, et al., 2016), and the two are interdependent. However, the current domestic and foreign academic research are mostly spatial logic expression quantitative description and visualization of city network based on space of flow and rarely consider the space of space and their relationship (Wall, 2009), it is difficult to explain the city regional spatial organization formation and evolution mechanism.

Can space of flow really replace space of place and become the dominant form of global and regional urban system? What is the relationship between space of flow and space of place? Based on the above doubts, this paper tries to construct the theoretical framework and analyze it from the perspective of enterprise organization, along the dual logical main line of space of flow and space of place, and deeply discusses the relationship between them to provide theoretical and empirical basis.

2 SUMMARY OF RELEVANT THEORIES AND STUDIES

2.1 SPACE OF PLACE

The space of place can be traced back to the cultural and geographical traditions of the regional differences opened by Kande, Humboldt and Hertner, where the "region" is a relatively bound, closed, and entity. Exploratory field surveys can explain in depth the differences between regions or regions. Based on the space of place of urban-regional studies, a number of important research results have been formed. For example, since 1980s, foreign scholars have come up with concepts such as world cities (Friedmann, 1986), global cities (Sassen, 1991), and global cities (Scott, 2001). These studies focus on cities or regions with geographical features, emphasizing the evolution of the attributes of cities or regions within the context of Globalization. In parallel with this, Chinese scholars since 80s began research on city or city group system, the majority of city size, population and economic attribute index based on the analysis of spatial organization of the city or city group system using qualitative and quantitative methods (Yao Shi plan, 1992; Wang Guanxian, Wei Qing, et al, 2003; Zhao Yinghui, 2010).

In the age of globalization, the space of place still has irreplaceable value. Space of place is rooted in the specific region, the one and only, the day-to-day activities of human beings (Michael, 2005), used to describe the difference in economic activities and the process of global, geographical space (Derek, Ron, etc., 2009). This geographical space is of great significance for the social organization process, especially for the production organization of enterprises (Dicken, Thrift, 1992). On one hand, the regional factor endowments of different space of place is different, is able to provide the geographical proximity, economic agglomeration, knowledge spillover, institutional thickness and other specific conditions, effects of location selection and the growth path of the enterprise. On the other hand, in the process of production organization, enterprises are reshaping the attributes of space of place. Therefore, the study from the perspective of enterprise organization under the city should not only focus on economic ties, but also must pay attention to the geographical space and attributes (Knoben, 2008), the traditional logic of the inheritance and development of the space of place.

2.2 SPACE OF FLOW

Space of flow first appeared in the Castell's "information city" (1989), and later in "the rise of network society" (1996) described in detail the "space of flow" concept, that the city no longer rely on its own things, but through the "the East West to get and the accumulation of wealth (Castells, 1996). In the space of flow logic, with regional or local features of the space of flow of the importance in the global city network tends to weaken, the city is become out of the zone, to the place of the node (Hill, Kim, 2000; Smith, 2014).

Space of flow concept, to a certain extent, the subversion of the traditional based on local spatial logic, greatly promoted the world city system and global city network research. Some scholars even propose "the death of distance" (Cairncross, 1997), "the end of geography" (O'Brien, 1992). These statements are not without foundation. For the production organization of the enterprise, the technological progress makes the capital under the control of the enterprise get rid of "the shackles of distance" because of "high mobility", and is no longer bound to a "place". For people's activities, people no longer need to be crowded in the narrow geographical space, and all social activities can be extended geographically. This means that local economic and social activities have lost their grounding in a particular place, and that the traditional space of place has been replaced by the new space of flow (Castells, 1989). Accordingly, in the process of economic globalization, the research on urban system has shifted to the quantitative calculation and visualization of the information flow, capital flow and network structure represented by urban nodes. With GaWC as the typical representative, of city network to the internal network based has been widely used, although criticized by some scholars, but it is still the most convincing quantitative research framework. As for enterprises and enterprises outside the network research, as data acquisition is difficult, mainly for a particular area of case studies, yet universal promotion.

2.3 COUPLING OF FIELD SPACE AND FLOW SPACE

Space of flow provides a new perspective and tool city network logic support on the city system under the background of globalization, however, the "hypothesis localization" is gradually challenged and questioned (Smith, Doel, 2011). Some scholars believe that, in addition to a small number of the most top tier Global City, more of the city in order to cope with the increasingly fierce global competition, better embedding efficiency of economic network, not only from the development of the region, but to strengthen the joint development and the region, forming a new space organization unit of economic globalization -- "global city area" (Scott, 2001). Thus, a "global city region" as a whole with local characteristics and advantages of the space of place into the global city network, there are complex networks on the other hand, the internal space of flow, as Castell's view, space of flow is folded into the space of place (Castells, 1999).

Bathelt put forward the "local buzz and global pipeline" model in specific geographical space in the relationship between enterprise agglomeration behavior and knowledge network formation, with convenient and frequent flow of information, knowledge communication, cooperation and competition between many closely related enterprises, the formation of rooted in the "local buzz". At the same time, the process of globalization to promote enterprises to expand the market, seek knowledge and increase profits, prompting global non adjacent geographical space to start communication through transnational and trans regional strategy, the formation of the global pipeline across geographical restrictions (Bathelt, Malmberg, etc., 2004; Barthelt, 2007). In essence, "local buzz" and "global pipeline" occur in space of place and space of flow respectively.

Therefore, the localization logic of space of place is not opposite to the logic of space of place. As Halbert and Rutherford pointed out, space of place and space of flow are not separable in the analysis. Space of flow can shape the space of space, and the space of place can also form space of flow (Halbert, Rutherford, 2010).

3 THEORETICAL FRAMEWORK

According to the theory and research above, under the background of globalization, the single dimension of space of flow under the logic of city network research is not thorough interpretation of city regional spatial organization formation and evolution, but also should be combined with the "flow" generation, operation environment, specific space of place to conduct a comprehensive analysis in order to get understanding, close to the real world. In view of this, the continuation of space of space and space of flow coupling logic, attempts to construct a "spatial-behavior-process" framework. According to the logical level of "space-behavior-process" (Table 1), the following assumptions are proposed: First, dialectical unification: space of place and space of flow are relative concepts, nested and concomitant with each other; Spatial agglomeration: multi location enterprise actor in the region, to promote the space of flow and space of place cooperative space reconstruction aggregation and dispersion; Action process: space of place can

influence the generation of space of flow, and space of flow can in turn reshape the attributes of space of place and be affected by specific social processes.

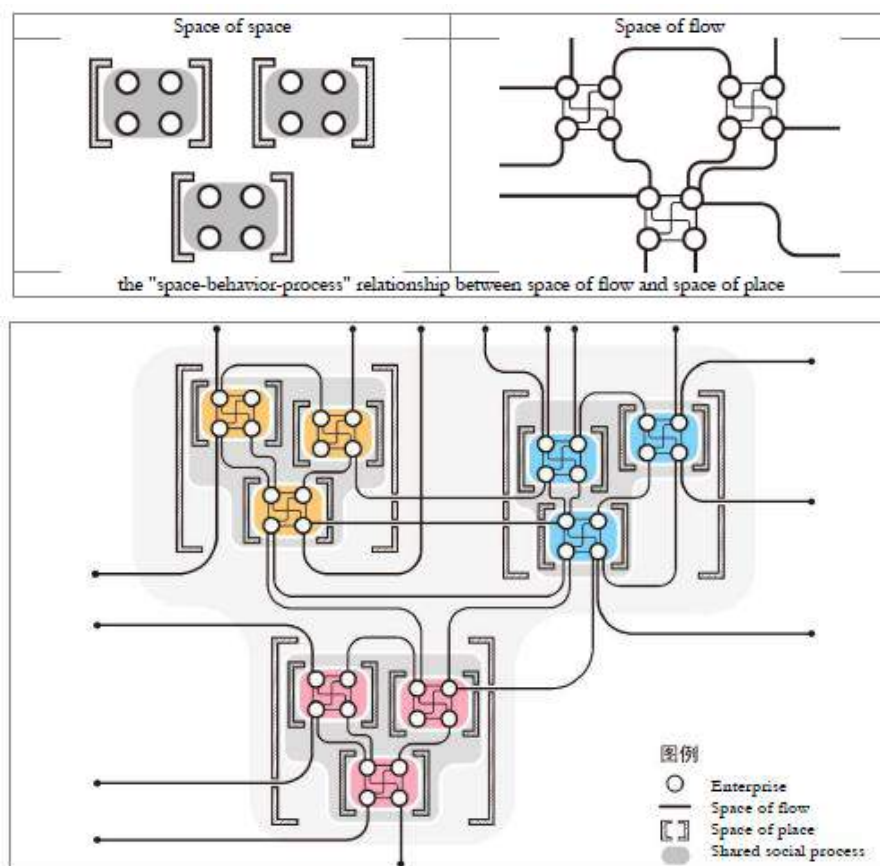

Table 1 - Framework to explain relationship between space of flows and space of places

In the following, we will discuss the relationship between space of flow and space of place and verify the hypothesis based on the perspective of enterprise organization and the combination of global scale and local scale. According to the above, the enterprise organization contains three kinds of relations, namely the enterprise, the enterprise and the enterprise external (Yeung, 1994), but some scholars have pointed out that the internal relation between flow than with other enterprises (Taylor, Hoyler, etc, 2001), considering the data available for this study, this paper mainly refers to the internal connection.

4 EMPIRICAL ANALYSIS AT THE GLOBAL SCALE

4.1 DATA AND METHODS

The related research pointed out that the analysis can start from the four dimensions of global scale city system: capital and capital control center service center, headquarters agglomeration and network related degree, outward radiation degree and agglomeration, within the central city and the gateway city (Tang Zilai, Li Can, et al, 2015). Taking into account the modern manufacturing industry developing city has an important position and the production service industry is relatively mature, the industry wide capital control from the perspective of analysis may have more explanatory power. Therefore, the paper selects Forbes's 2000 industry wide company's headquarters concentration degree (2014) and the Fortune 500, whole industry company's network correlation degree (2010) as the main data of the empirical analysis: the concentration degree of headquarters is used to describe the characteristics of space of place, using the algorithms of Taylor et al (Taylor, NI, et al., 2011); The network association degree is used to characterize the feature of space of flow, using the algorithms of Alderson et al (Alderson, Beckfield, et al., 2010). Among them, the degree of network correlation is composed of the degree of extraversion and the degree of inward clustering. The greater the number of corporate headquarters in the cities, and the more

branches that are sent by the headquarters, the higher the extraversion of the city; The greater the number of branches of a multinational corporation, the greater the city's introversion. The calculation is as follows:

$$O_i = \sum_{j=1}^k T_{ij} \quad (j = 1, 2, 3, \dots, n; j \neq i) \quad (1)$$

$$I_i = \sum_{j=1}^k T_{ji} \quad (j = 1, 2, 3, \dots, n; j \neq i) \quad (2)$$

$$N_{ij} = T_{ij} + T_{ji} \quad (3)$$

$$N_i = I_i + O_i \quad (4)$$

T_{ij} is the number of corporate headquarters in the city of i , branches in the city of j ; T_{ji} is the number of corporate headquarters in the city of j , branches in the city of i ; O_i is calculated, said corporate headquarters in the city of i , branch structure in the region of all other city the number of enterprises; I_i into, said the branches in the city of i , headquartered in the region all the other city the number of enterprises; N_{ij} between the city i and city j network connection; N_i city i network correlation degree, and the correlation degree of city network is i and all other areas of the city.

To the whole industry company headquarters agglomeration characterization space of place features, with the network association city to characterize the degree of space of flow characteristic, correlation and difference analysis of the two on a global scale.

4.2 RESULT

On construction of headquarters agglomeration degree and network correlation, outward radiation degree and two yuan a cluster within the linearity of the regression equation, the coefficient of determination R^2 were 0.571 and 0.492, the regression model of F test P value was 0, with statistical significance of the model. The residuals of the unary linear regression are further aggregated to represent the difference between the predicted and actual values. On the whole, the headquarters of the city agglomeration has significant positive correlation between the degree of association with the network, means that the company headquarters industry highly concentrated space of place is often corresponds with the other city is widely related to space of flow; a network correlation degree and out degree also has a certain positive correlation. But this positive correlation is weaker than the former. Some cities all over the world have high penetration and high output, and some cities in the world do not fully match their penetration and output. Specifically, the Shanghai headquarters of the standardized residuals associated with the degree of agglomeration of large network means, far greater than the concentration degree of Shanghai headquarters network related to this conclusion, and some scholars (Tang Zilai, Li Can, and other similar, 2015). The reason, in the company's headquarters in Shanghai agglomeration and no advantage, less local headquarters of multinational companies, the lack of control force field space ", but by promoting the reform of market economy and by 2001 Chinese the chance of joining WTO, to attract the modern manufacturing industry and producer service industry foreign direct investment, has been the development of agglomeration a large number of branch offices of multinational companies, greatly enhance the " flow space "penetration, so network correlation is also increasing.

Figure 1 - Scatter plot of headquarters index and degree

Figure 2 - Scatter plot of outdegree and indegree

In contrast, the concentration of the headquarters in Beijing is much higher than that in Shanghai, but the network relevance is slightly lower than that in Shanghai, which is similar to the conclusions of some scholars (Tang Zilai, Li Can, et al., 2015). The possible reason is that, in the context of a particular national system, Beijing gathered a large number of state-owned enterprises (Tang Zilai, Li Can, etc, 2016), has a broad and powerful control force in the country, but multinational state-owned enterprises index is not high, big but not strong, leading to "flow space" is not a high; at the same time, the development of foreign manufacturing industry in Beijing Tianjin Hebei region is relatively backward in the Yangtze River Delta, Beijing branch to attract multinational companies slightly lower than Shanghai, leading to more general network penetration, so the overall association degree of no obvious advantage.

Figure 2 - Relationship between space of places and space of spaces in global scale

To some extent, the empirical analysis in the global scale reflects the interaction of space of place and space of flow and the influence of social process: (1) space of flow can reshape space of place. Although the Shanghai headquarters less local multinationals, space of place property is not strong, but the policy opportunities and make full use of the rules of market economy, by actively attracting foreign direct investment to construct a high penetration and low degree of space of flow, also created a branch of multinational companies highly concentrated space of place. Presenting a "gateway city"; the space of place can affect the space of flow countries affected by institutional factors, state-owned enterprises in Beijing headquarters are highly centralized, with space of place advantage, but this advantage has not been fully played, the local state-owned enterprises foreign force. The force is also more general for foreign multinational companies, resulting in the space of flow space is mainly confined in the country, and the degrees are in general, both center city and the door Characteristics of households and cities.

5 EMPIRICAL ANALYSIS AT THE LOCAL SCALE

5.1 DATA AND METHODS

The research scope of local scale under the selection of core areas in the Yangtze River Delta, including Shanghai, Hangzhou, Nanjing, Ningbo, Suzhou, Taizhou, Wuxi, Wenzhou, Shaoxing, Jiaxing, Nantong, Changzhou, Yangzhou, Zhenjiang, Huzhou, Taizhou, Zhoushan and other 17 cities. The main source of data for the second national census of basic units (as of December 2001), the second national economic census (as of December 2008), the third national economic census (as of December 2013) of the enterprise information. Through the establishment of enterprise information database, SQL statement is used to screen out the matching relationship between the head office and the branch. At the same time, because of the large amount of data, referring to the existing scholars based on the industry category division value added (Tang Zilai, Zhao Miao Xi, 2010) and simplified enterprise into the low-end manufacturing industry, high-end manufacturing and producer services in three categories, which enhance the value of successive segments.

5.2 RESULT

5.2.1 CHANGING TREND OF SPACE OF PLACE

From 2001 to 2013, the spatial density of enterprises in three value regions of 17 prefecture level cities in the Yangtze River Delta region increased significantly, but the growth rate was different. Calculate the density growth rate to characterize the magnitude of the change. For the low-end manufacturing enterprises, the growth rate of the larger is mainly Nantong, Yangzhou, Taizhou, Suzhou, Taizhou, Hangzhou and other cities, and the outskirts of the city and suburban growth is greater than the center of the city, with significant diffusion trend. For the life of service enterprises, the growth rate of the larger for Shanghai, Suzhou, Nanjing, Ningbo, Hangzhou, Nantong and other cities, and the city center area increased more than the rural and suburban, has significant agglomeration trend.

Figure 3 - 2001-2013 spatial density of enterprise in different value chain sections

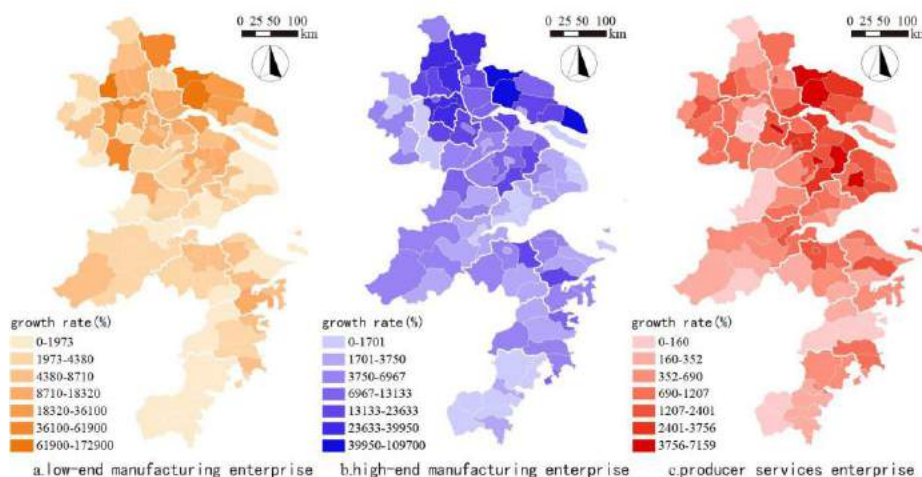

Figure 4 - 2001-2013 spatial density of enterprise in different value chain sections

5.2.2 CHANGING TREND OF SPACE OF FLOW

Using the former formula (1), (2) and (3) to calculate the penetration, the degree of dissolution and the degree of point of the 17 cities, the following results are obtained. From 2001 to 2013, the penetration and output of each city have been remarkably improved, and the economic ties among the cities have become increasingly close. The space of flow in the Yangtze River Delta has been constantly manifested in the process of globalization.

Figure 5 - Changes in indegree, outdegree and degree of cities from 2001 to 2013

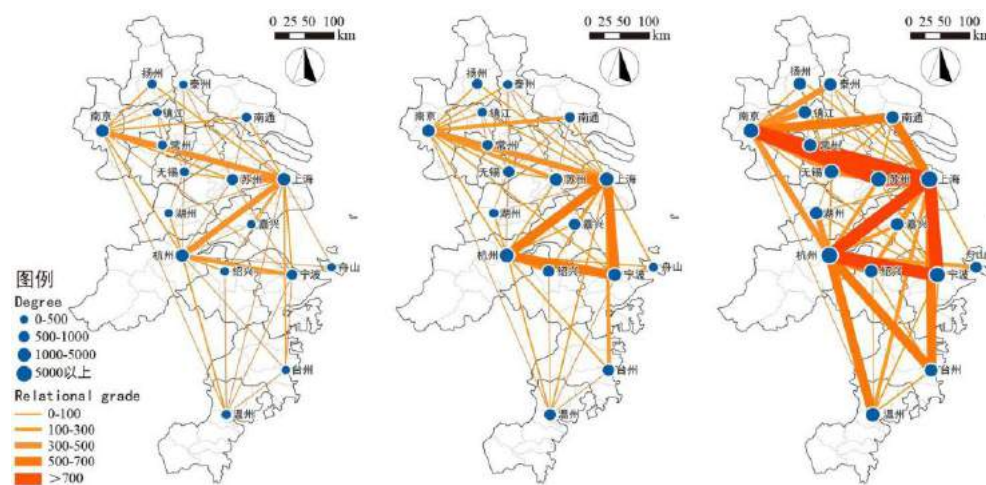

Figure 6 - Corporate networks of YRD from 2001 to 2013

From 2001 to 2013, the spatial pattern of the network in the Yangtze River Delta became obvious, based on the enterprise related urban network. The city between the space of flow experienced from no to have, from weak to strong development process. This is similar to the findings of other scholars (Cheng Li, Zhang Yishuai, et al, 2016). However, the barrier of the administrative division boundary to the space of flow has not been completely eliminated. That is, for the cities between Jiangsu and Zhejiang, there is no obvious change except for the network relevancy between Nanjing and Hangzhou. At the same time, the evolution of space of flow also shows the characteristics of agglomeration, mainly embodied in the "Z" corridor of Nanjing - Shanghai - Hangzhou - Ningbo, especially along the Shanghai Nanjing plain. Therefore, strengthening the economic ties within the enterprise is spatially selective, non equilibrium selection of space of place to the development of agglomeration space of flow, produce large flow of "corridor", city network skeleton structure increased branch differentiation. This change is synergistic with the strengthening of the "core periphery" pattern of space of place.

5.2.3 RELATIONSHIP BETWEEN SPACE OF PLACE AND SPACE OF FLOW

Linear regression analysis was conducted on the spatial density, penetration and yield of enterprises in different value periods under two time sections in 2001 and 2013. The regression model, F test, P value is 0, the model has statistical significance.

(1) Relationship between spatial density and penetration in low-end manufacturing enterprises

There is a positive correlation between the spatial density and penetration of low-end manufacturing enterprises, but the correlation between the spatial density and the degree of output is not significant. The space of place with more low-end manufacturing enterprises often corresponds to a higher degree of

space of flow. To a certain extent, it reflects the law of enterprise spatial organization based on the value section, and also confirms the spatial diffusion of the enterprises in the low price region of the Yangtze River delta. From the micro perspective of enterprise organization, industry value chain link not only has low labor intensive, capital intensive features, also usually enter the area of non core city or suburban areas to form branches. Although the level of economic development in these areas is not high, but local governments actively create supporting facilities, preferential policies, skilled workers and other rich conditions to attract more developed regions, the headquarters of the company's branches settled. Therefore, the space of place and the space of flow of enterprise agglomeration in low value areas are gradually formed. Compared with 2001 and 2013, the positive relationship between the two is more significant as time goes on. Visible based on spatial economic structure the value chain is the formation and significant, further confirms the conclusion of existing research (Tang Lai, Zhao Miao Xi, 2010).

(2) Relationship between spatial density and penetration in high-end manufacturing enterprises

Different from the low-end manufacturing industry, high-end manufacturing industry penetration, density and spatial correlation degree reached a significant level, and the degree of positive correlation. The space of place with more high-end manufacturing enterprises often corresponds to the higher and higher degree of the space of flow. This reflects, to some extent, the higher value segment attributes of the high-end manufacturing sector relative to the low-end manufacturing sector. The high-end manufacturing enterprises demand higher level of technology, human resources, system environment and so on. Both the headquarter and the branch are more likely to gather in the space of place of the value zone, share the agglomeration economy and overflow the knowledge. When the gathering of high-end manufacturing company in the form of regional headquarters in the core city or city center, will be formed and strengthened high value section of the space of place, and through the branches sent professional to the surrounding area, resulting in high degree of space of space. And when it is gathered in the form of a branch in a specific space of place, it produces a higher degree of space of flow. Therefore, the spatial density of high-end manufacturing industry is positively related to penetration and output, and the trend of agglomeration of headquarters companies in space of place is stronger, leading to a positive correlation with the degree of output.

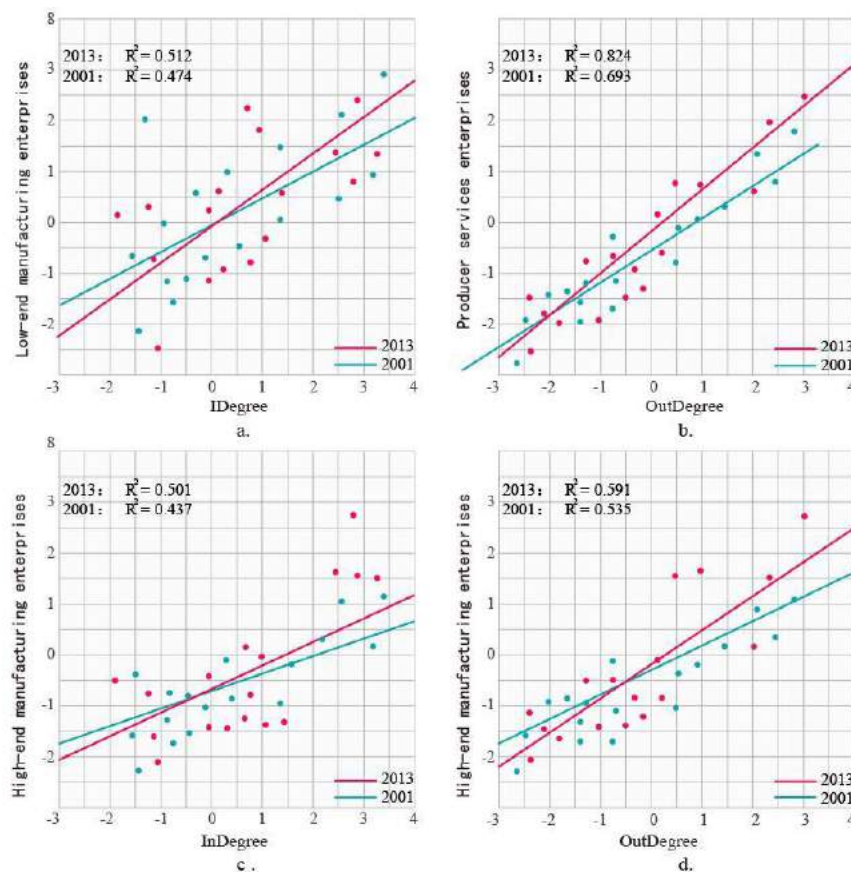

Figure 7 - Scatter plot of corporate spatial density and outdegree, indegree in 2001 and 2013

(3) Relationship between spatial density and penetration in producer service enterprises

Compared with the high-end manufacturing industry, the spatial density of producer services has a stronger positive correlation with penetration, while the correlation with the degree of output is not significant. The space of place with more production service enterprises corresponds to the higher degree of space of flow.

This is in relation to the highest value segment of producer services. Although some scholars believe that the producer service enterprise's location is not completely follow the other company headquarters location (Sassen, 1991), but in order to provide more efficient services, based on geographic proximity "face to face" is very necessary. Therefore, the two are still closely related in the space of place. At the same time, the production service enterprise itself is more inclined to the headquarters of Companies in the form of agglomeration in the region of CBD, continue to form and strengthen the high value section of the space of place, and sent branches to the surrounding areas, derived from the height of the space of flow. Over time, the high value section of the space of place and high degree of spatial interaction evolution, will exacerbate the region space of place core periphery pattern and alienation space of flow of the skeleton branch structure. It further confirms the conclusion that the high-end core agglomeration of the regional core city and the strengthening of the "Z" corridor.

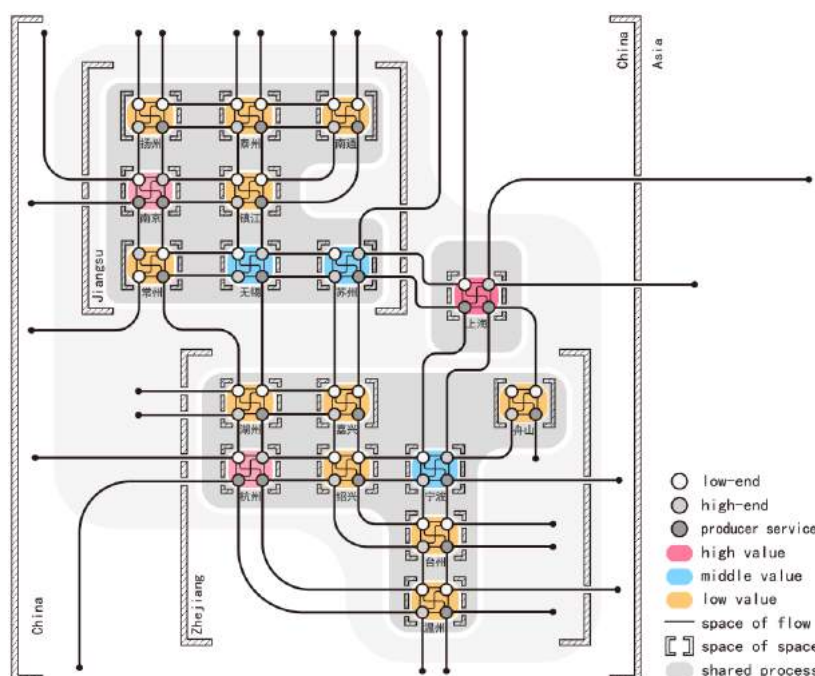

Figure 8 - Scatter plot of corporate spatial density and outdegree, indegree in 2001 and 2013

In the positive local scale to a certain extent reflects the space of place and space of flow the dialectical unification relations and spatial agglomeration behavior: (1) the space of place and space of flow is a relative concept, the two forms in different spatial scales will change. On the one hand, the Yangtze River Delta as a whole space of place in the global city region competition, on the other hand, the Yangtze River Delta from the second level of the space of place and space of flow, formed a relatively complete and mature city network, and with a reconstruction of the change of internal time. (2) the multiple choice of enterprise actors in the region promotes the coordinated evolution of space of place and space of flow. Gather different value chain enterprises in the area of some of the space of place, and selectively and some other space of place to establish economic relations within the enterprise, the unbalanced accumulation and diffusion result, space of place of the "core periphery" pattern and space of flow skeleton branches structure was strengthened, the two is the process of collaborative behavior of enterprises.

1 INTRODUCTION

1.1 URBANIZATION & CHINESE STRATEGY

Nowadays more than 50% of the world population has already been in urban areas and the rate of global urbanization are expected to be more than 70% in the next four decades, with about 90% of the urban expansion occurring in the developing countries. As a result, New Urban Agenda-Habitat III and other influential urban conferences have led to pay more attention to a better urban life. However, the development of rural areas should be emphasized as well. On one hand, although the proportion of rural areas is declining, they have their significance of existence, such as the supplies of food or other products, rural culture, etc. On the other hand, although there seems to be a wide gap between urban and rural areas, they still have their characteristic advantages which provides more possibilities for their dignified development.

The Chinese strategy to deal with the relationship between urban and rural development is called Integrated Urban-Rural Development. Its specific performance covers all kinds of fields, such as accessibility of traffic system, same standards of infrastructure and public service facilities in urban and rural areas, etc., which could reduce the distance between urban and rural areas, what's more, realize coordinated development and mutual progress. Smart rural development will be a tendency in China even around the world and will be a new symbol to measure the levels of urban development. So, Integrated Urban-Rural Development is so meaningful to provide a strong basis for the smart rural development. Zhejiang Province and Jiangsu Province are two good examples to practice Integrated Urban-Rural Development, whose towns and villages are much wealthier relatively.

1.2 CHINA'S RURAL DEVELOPMENT IN THE PAST

In 1990s, rural enterprises raised abruptly and played an important role in promoting the development of towns and villages. It's a bottom-up mechanisms that the grass-root government and farmers are spontaneous to push the process of urbanization. However, with the development of globalization, the process of urbanization took megacities as key points to have a breakthrough in the global competition. It was effective and efficient to promote the urbanization rate to be about 50% in China. The unbalanced development strategies between urban and rural areas, on one hand, waver the dominant role of rural enterprises and deepen the gap between urban and rural areas, while on the other hand, a large amount of rural population migrated to the cities which contributed to the empty and decline in many towns and villages.

Without any doubts, information revolution is a miraculous turning point in global development, which collapses the space-time distance and reorganize spatial network. Rural areas as well as other less-developed areas should seize this chance to build a new relationship with their close megacities or even any transnational strategic partners around the world.

1.3 TAOBAO TOWNS AND VILLAGES IN CHINA

Taobao is Chinese Amazon, an electronic commerce and cloud computing platform. To keep up with development of the information age, many towns and villages in China have developed e-commerce, one of which is Taobao. Suddenly, "Taobao Villages" and the further "Taobao Towns" has been more and more popular in the past decade. According to the Chinese Taobao Village Study (Ali Research Institute, 2014; 2015; 2016), the development of Taobao Villages started from 2009 and had a slow growth until

2013(Figure 1). However, Taobao Towns and Villages have been booming rapidly from 2014 until now. As of the end of 2016, there have been 135 Taobao Towns and 1311 Taobao Villages, covering 18 provinces or province-level municipalities. As excellent practicers in Integrated Urban-Rural Development, Zhejiang Province and Jiangsu Province have 506 and 201 Taobao Villages respectively, ranking 1st and 3rd in those provinces or province-level municipalities.

Figure 1 – Amount and rate of Taobao Towns and Villages(2009~2016).
Data from Chinese Taobao Village Study, 2014, 2015, 2016.

The outstanding economic and social value of Taobao Towns and Villages is the main reason why the amount has been rising so rapidly and spontaneously. It provides an open platform for the grassroots to obtain employment or even start their own business. While adding 1 online store, it will create 2.8 employment opportunities. As of the end of 2016, there have been over 300,000 active online stores and it could be estimated about 840,000 employment opportunities (Ali Research Institute, 2016). As a result, it has been a fast and feasible path for rural areas to cast off poverty and achieve the goal of prosperity. As of the end of 2016, there has been 18 Taobao Villages in state-level poverty-stricken counties, rising 80% over 2015.

Because of the valuable and sustainable development pattern of Taobao Towns and Villages, the government also has a series of policies to encourage and guide their or other e-commercial ones' development, such as "About positive guidance and promotion of Internet+ Actions", "Opinions on speeding up the development of rural e-commerce", "Action plan for promoting the development of agricultural e-commerce", etc.

2 ANALYSIS OF TAOBAO TOWNS AND VILLAGES

2.1 INHERENT ADVANTAGES AND DISADVANTAGES OF RURAL AREAS

2.1.1 CHARACTERISTIC NATIVE PRODUCTS

Different from the common products in urban e-commerce, there are many other local ones with characteristic culture and native natural resources. For examples, some villages abounds with Xuan Paper (Figure 2(a)) which is specially used for traditional painting and calligraphy (Figure 2(b)). As a characteristic Chinese product and national intangible cultural heritage, it has a long history about 1,500 years and a precious technological process, which will become a cultural name cards even brands of those villages. Some other villages has a craze of traditional ink paintings. They may buy Xuan Paper and other painting tools or produce some by their own, then train famers to be skilled painters, which also could improve the historical and cultural value of those villages.

(a) Xuan Paper (b) traditional ink paintings
Figure 2 – Characteristic native products in Taobao Towns and Villages. From Baidu, 2017.

However, the way of sale in the past is not advantageous for those characteristic native products to some extent. The process of traditional agricultural sale could be concluded as a chain - “production – transportation and distribution – wholesale market – distribution – retail”(Figure 3). It is so long that it leads to many problems. For example, the villages could not learn about the feedback information from markets freely, causing the mismatching between supplies and demands; the mediation agents would like to earn lots of share which cut down the profit space of farmers; the expansion of market is limited by distance, etc. They are the reasons why so many farmers chose to give up this way and prefer a job in the cities.

Figure 3 – Analysis of traditional agricultural sale chain. From author.

2.1.2 LOW COST

The cost of products is much lower than those produced in urban areas. The products obtain cheap local material and save transportation cost. They are made in factories or by handicraftsmen whose rents or salaries are low. It not only could create large profit space but also encourage farmers to have a try without any worry about failure.

The cost of rural life is another advantage. It's one of reasons why many migrant workers earn money in urban areas but go back home and consume in rural areas. It's a typical choice of farmers in China, because of conditions in both urban and rural areas. On one hand, cities especially megacities provides much more employment opportunities with higher salaries and more beautiful environment than towns and villages, which absorbs a large amount of migrant workers. However, owing to high price of housing and consumption but low deposit, migrant workers nearly have no chance to have a good life in cities. On the other hand, the cost of rural life is much lower. With the salaries from cities, migrant workers and their families could improve their life standards. In addition, the property of rural house and farmland is also an important reason why they have to go back no matter where they work.

2.2 NEW ADVANTAGES OF INTERNET+ RURAL AREAS

2.2.1 INTERNET+ CHARACTERISTIC NATIVE PRODUCTS

The Internet opens up a new outlet for those characteristic native products and changes the traditional way of agricultural sale. The e-commerce is a good way to solve those problems and improve the advantages of traditional agricultural production and management. Now the farmers just need a computer on the Internet. They could learn about the dynamic situations of market and make an adjustment of prices or supplyments at any time. Their incomes have an obvious increase, because it breaks the real economic chain and creates a new one – “production – retail – distribution”(Figure 4) which not only reduces the share of mediation agents but also enhances the efficiency of the whole transaction process. Also, the Internet will open up broader markets and absorb much more customers, no matter the location is far or close. As long as the profits is greater than the cost of production and transportation, the trade could be taken into consideration.

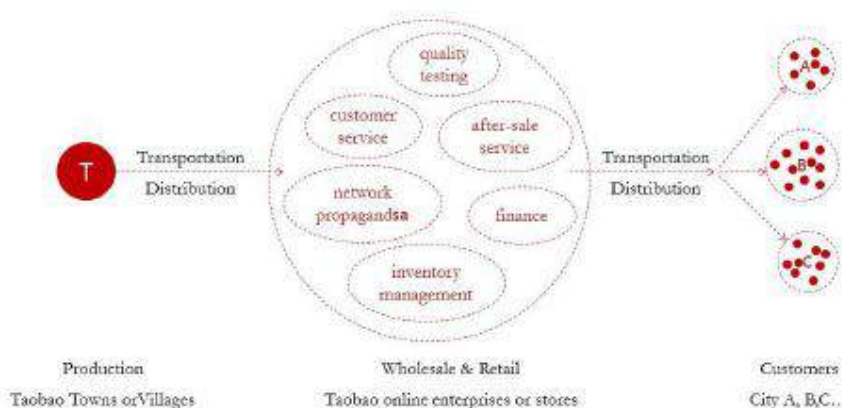

Figure 4 – Analysis of new sale chain of Taobao Towns and Villages. From author.

In fact, the new chain is not as simple as mentioned. There are many divisions in the part of online retail, such as the network propaganda, quality testing, customer service, after-sale service, inventory management, finance, etc., all or parts of which are simultaneously held by farmers. Although it seems difficult, the farmers have more initiative to run whatever they want. The flattening of sales management creates relaxing and friendly work atmosphere which is better to inspire some valuable ideas about the productions or organization form.

What's more, it promotes competition and cooperation which inspires more optimization and innovations. With the improvement of life standards and demands, the products would better improve their qualities and integrate with innovation to satisfy all kinds of requirements and follow the trends of market environment. The competition in market is always fierce and it must be a kind of driving force to develop the current products. Meanwhile, it also provides a cooperative platform for many industries and professionals in different fields.

2.2.2 INTERNET+ LOW COST

There is no doubts that the medium-sized and small online enterprises or stores provide an accessible entrepreneurial threshold for the towns and villages. Those enterprises and stores consists of family members so the scale is very small even tiny. The investment could be high or low, so it provides more possibilities for those who have smart minds but no much money. Meanwhile, the Internet could create much larger profit space and broader market. As a result, it has been a driving force to spread and reinforce the development pattern of Taobao Towns and Villages in rural areas.

Low cost of the products and life is the main physical basis especially for those low-income farmers to start an online store or a Taobao Village in the initial stage. Even if it suffers a great failure, it doesn't matter that the loss is not much and the influence on their life is just slight. Every entrepreneur has to challenge once

and once to adjust to the markets. So what's important is to analyze the reasons of failure and develop the next steps.

Also, low cost of time provides the possibility of part-time jobs for farmers. With the great progress of agricultural infrastructure and technology, the efficiency of farming has been improved. The farmers would like to use such much leisure time to get additional income. According to the field survey, as storekeepers, the farmers change their schedule of work and rest. In general, the working hour gets longer and it has a close relationship with the activity of online customers.

2.3 DIGNIFIED PERFORMANCES OF TAOBAO TOWNS AND VILLAGES

2.3.1 LIFESTYLE: CLOSE URBAN-RURAL INTERACTION

The communication of information between urban and rural areas has been stronger and stronger, which provides more possibilities to have a deep interaction. "Double 11", "Double 12" and other shopping festivals organized by Taobao Enterprise also become the important days of farmers in a year. Their busy seasons keeps pace with the sales promotion in urban areas. So they have a closer communication with the urban areas and start a new life with the urban pace to some extent. Some farmers said that they loved their new life nowadays and they thought it even better than urban life, because they could take an enough rest in slack season and enjoy rurality in their beautiful farmland.

The accessible traffic system under the policy of Integrated Urban-Rural Development makes the actual connection more convenient. It's the basis of logistics transportation which supports the management of Taobao Towns and Villages. It's also the bridge between urban and rural areas. The farmers could go to enjoy the facilities of entertainments in cities, which will become a new part of rural life.

2.3.2 SPACE: BOTTOM-UP COUNTER URBANIZATION

Urbanization could be concluded into 2 main kinds. One is a top-down mechanisms planned and controlled by government, such as urban expansion, new towns, satellite town, etc. The other is a passive expansion because of excessive population and industrial aggregation, which presents mainly as urban sprawl. With the trends of urbanization, it leads to vast blind construction with a series of problems, such as land wastage, land leverage and so on, which make it meaningless and inefficiency. Taobao Towns and Villages find a new way to achieve the goal of development and prosperity.

In the last 3 years, the amount of Taobao Towns and Villages has been rising rapidly which has a strong agglomeration effect(Figure 5). From a few points to a network, it forms a spatial network of prosperous towns and villages which could not only divide into different groups with various divisions gradually and increase economic benefits, but also attract more towns and villages to join. It's a way to reinforce and develop the rural areas and control the excessive urbanization in China. However, as can be seen, the main agglomeration just appeared in the coastal areas instead of the whole nation land. It shows that the development of Taobao Towns and Villages depends on that of its surrounding cities to some extent.

Figure 5 – Agglomeration effects of Taobao Towns and Villages.
From 2016 Chinese Taobao Village Study, 2016, p. 8-10.

What's more, their internal mechanisms are presented mainly as a few new patterns, such as bottom-up development of their own, linkage of towns and villages, etc., which keeps balance of government-market-farmers Partnership.

2.3.3 INDUSTRIES: SERVICE MODERNIZATION

The traditional industrial development in rural areas is to follow the routine of industrialization of urban areas, then further promote the development of tertiary industry when secondary industry is full-developed relatively. The tertiary industry consists of some low-added value service industries, such as retails, hotels, etc. It could just meet the internal requirements of farmers and some tourists, but it couldn't have a close communication with urban areas, which contributes to its limitation of industrial expansion.

The internet could reconstruct either physical space or industrial structure. It provides a shortcut to leapfrog industrial development stage and develop tertiary industry innovatively. Because of the organization of Taobao Towns and Villages, it gathers a series of relative high-added value service industries, such as productive service, storage and logistics transportation.

3 REVELATION FOR EUROPE

In summary, "Internet+ less-developed areas" has been a successful and dignified match. Towns and villages have abundant characteristic native products and the low-cost advantage, which are an important foundation for an accessible entrepreneurial threshold and characteristic construction. Their three dignified performances are close urban-rural interaction, bottom-up counter urbanization and service modernization.

In some countries or territories in Europe, there is a wide gap between urban and rural areas, as well as developed, relative less-developed and developing countries. It worth considering and bringing the Internet+ urbanization into those less-developed areas in Europe. The Internet may be a significant catalyst to promote the development there. Comparing with in China, the life standard and economic development in the European rural areas are better in general, which is an advantageous physical basis to develop with the Internet and e-commerce.

The issue has grown its importance in the latest decades (e.g. Keil 1998; Smith, 2001; Sklair, 2002; Ploger & Becker, 2015). In the current debate in the research field, there is a duality between homogenization and integration trends can be observed, which finds reflection on many scales from global networks of capital and labor to the adaptation of local and translocal spaces within the city. Specifically, it is claimed by many authors (e.g. Beaverstock, 2002, 2011; Pow, 2011; Tandogan & Incirlioglu, 2004) that transnational migrants tend to integrate more with their international communities without investing significantly in local ties and environments and tend to hold to detached lifestyles. On the other hand, other authors (e.g. Moores & Metykova, 2010; Schiller & Caglar, 2013) argue that due to transnationalism many migrants demonstrate more integrity with international connections, but also with local ones, and they tend to develop attachment and sense of belonging in the framework of hosting localities. Thus, as identified by some authors, it is necessary to study both the dynamics of mobility and those of rootedness (Andreotti et al., 2015, p.6).

2.1 GLOBALIZING MIDDLE-CLASS PROFESSIONALS

While there is no agreed concept or definition of the high skilled, it can be discussed with the focuses on the circulation of capital, migration of skills and 'brain drain' approach, or through the acceptance of the idea of networks, human capital and global mobile workforce (Vertovec, 2002). Within the topic, authors might broadly refer to transnational elites, globalizing professionals, expatriate workers, nomads, global managers, service sector workers, etc., also considering a variety of professions and lifestyles. With these multiple levels of definition, it is important to clarify the borders of the phenomena adopted in the proposed research. One exhaustive definition is suggested by Vertovec (2002). By skilled migration, he means most broadly defined migrants 'in possession of a tertiary degree or extensive specialized work experience – including architects, accountants and financial experts, engineers, technicians, researchers, scientists, chefs, teachers, health professionals, and – increasingly – specialists in information technology'. He also emphasizes that the term 'migration' – particularly with regard to the highly skilled – may not be the most accurate. Instead, it is more suitable to talk about 'movement' or 'mobility', as migration has veins of permanence or long-term stay, while nowadays the movement of many highly skilled professionals tends to be intermittent and short-term (Koser & Salt, 1997). Furthermore, transnationalism of skilled migration advocates the approach to consider 'the attachments migrants maintain to people, traditions and causes outside the boundaries of the nation-state to which they have moved' (e.g. Bash et al.; 1992; Smith & Guarnizo, 1998). Illustrative to that, according to Portes (1997), 'through these networks, an increasing number of people are able to live dual lives. Participants are often bilingual, move easily between different cultures, frequently maintain homes in two countries, and pursue economic, political and cultural interests that require their presence in both'. That class of transnational high-skilled migrants is under consideration.

For the purposes of the current research, the term 'expatriate' is endorsed and applied throughout the paper in reference to the high-skilled transnational immigrants living in Moscow. Having said this, the paper acknowledges the deficiencies of the term limiting the scope towards the privileged migrants exclusively. However, the vast majority of the interviewees have themselves claims to be considered as expatriates rather than migrants.

2.2 SOCIOSPATIAL BEHAVIOR

Whereas there are a large number of studies on residential patterns of international migrants and ethnic minorities, particularly with regard to the spatial segregation in the cities, the localization patterns of the highstatus migrants were out of scope of academic focus before the 1990s. This negligence was explained with the fact that their arrival and integration are less 'problematic' than of the low-skilled migrants, which are considered potentially threatening for the social cohesion and national identity (White, 1988).

Initially, it is important to mention that the 'home-host context' has influence on the transnational outcomes, and therefore, the localization strategies. On the one hand, the spatial isolationism of the western expat communities has been proven to be typical in the globalizing cities of the east, like Dubai, Singapore, Shanghai, where the cultural and mental barriers between the migrants and local population were robust. At the same time, there are studies illustrating spatial heterolocalism in the contexts when the host and home countries of migrants had social and cultural proximity, e.g. British in Paris, Spanish in Brussels, etc. (e.g. Scott, 2004; Favell, 2008). In this respect, not only identity frontier matters, but also the geographical

proximity between two countries and the possibility for frequent flights. Thus, relatively small geographical and identity divide might be potentially seen as a factor reducing the need of localized transnational exchanges in the city. Particularly interesting to consider this notion when exploring the spatialities of expatriates in Moscow, the city that lies culturally, socially and geographically in between the 'east' and 'west'.

In the vast part of the transnational literature, general discourse about the spatialities of the expats in the host cities is focused on the discussions of localization and homogeneity of residence, work, and social activities, that consequentially lead to the formation of 'bubble living' (Kennedy, 2007; Beaverstock, 2011) in social terms, and 'expat enclaves' (gated communities, expat districts in Dubai, e.g. Walsh, 2009) in geographical terms. On the other hand, within the western contexts more diversity and variety is taking place in terms of sociospatial behavior of expats (Scott, 2004).

Spatial localization of the immigrants in the host cities has been explained by a number theoretical concepts taking routes in 19s century. However, along the evolution of views from assimilation and pluralist models, the heterolocalism model (Zelinsky & Lee, 1998) is the one that taking over the ideas of transnationalism. The model advocates that ethnic communities of immigrants can exist without any significant clustering, in other words when members of a particular group are scattered throughout a city. Four main attributes of heterolocalism claim that: spatial dispersion of immigrants is taking place in the host country; residence and work are usually spatially separated; community ties are maintained via modern technological means and visits in urban, national, regional and transnational scales; heterolocalism is conceivable only in modern socio-economic and technological conditions.

There is a need to examine the relations between skilled migrants and urban structures, since the contentious increase in numbers of international skilled migrants in the globalizing cities might have significant effects in many cities, for example, as it is illustrated already by some authors, they might trigger rise of housing costs in some urban areas and might potentially lead the transnational gentrification (e.g. Paris, 2017). Hence, guided by the established tradition in urban studies (Hannerz, 2003; Savage et al., 2005; Kennedy et al., 2007), it is important to explore transnational mobility practices together with more stable residential practices. As Andreotti (2015, p.25) puts it, 'living conditions and experiences are always embedded in the particular city'. Thus, the paper brings the light to exploring the interactions of high skilled migrants with hosting urban systems, dedicated to the spatial differentiation (White, 1998; White & Hurdley, 2003; Andreotti, 2015), residential choices and relations with the housing markets (Pow, 2011; Beaverstock, 2002; Tandogan & Incirlioglu, 2000) and localized activities that are making the experience and lifestyles (Hannerz, 1996; Smith, 1999; White & Hurdley, 2003; Scott, 2006) of the transnational skilled migrants in the cities.

3 CONTEXT

While Moscow is one of the largest European cities with a multicultural population of over 12 million people¹, the globalization processes here have left a rather distinctive imprint on the urban fabric than in other major European cities. In order to examine the current set of conditions that the high-skilled transnational labour flows had been driven into after the dissolution of the Soviet Union and continued to evolve in since then, it is important to investigate which major economic, political and cultural forces and processes were composing these conditions. This section presents the context of Moscow at first positioning the city within the network of other world cities, then it discusses the involvement of the city in international economic and business processes, and circulation of skills and migration, and then canvass the globalization in the scale of urban environment.

3.1 GLOBALIZING MOSCOW

First of all, globalization came to Moscow rather late. However, ever since the concept was introduced Moscow has always been on the list of the world cities (Kolossova et al., 2002). Preliminary, in the Soviet

¹ Source: Mosgorstat, 2016 http://moscow.gks.ru/wps/wcm/connect/rosstat_ts/moscow/ru/statistics/population/ (Accessed on 09/05/2017).

times Moscow has always been considered as an important world city for being a capital of the Soviet Union as a superpower. Later on, when Moscow has first appeared in the world cities rankings based on the statistical data, it took a highest position among the post-socialist cities (Beaverstock et al., 1999). Later on, Taylor and Hoyler (2000) in their factor analysis of corporate service complexes of 53 European cities included Moscow in the Eastern European cluster of “beta” world cities. Similarly, Fossaert (2001) again put Moscow in the list of cities within a “Europe in transition” zone in his analysis of the world system. At the same time in the “The World According to GaWC” rankings¹, Moscow was steadily strengthening its positions: while in 2000 and 2004 it was classified as a “beta+” city, already starting from 2006 to 2016 Moscow took a rightful place among “alpha” cities, along with other European cities like Milan, Frankfurt, Madrid, Amsterdam and Brussels.

Particularity of globalization process in Moscow is preconditioned by the rapid transition to the market economy after the disintegration of the Soviet Union and the subsequent alteration of involvement in global networks. In terms of economic changes, in the 1990s Moscow has undergone the process of rapid deindustrialization restructuring the economy towards the tertiary sector. Kolossov & O’Loughlin (2004) point out that during this process it was necessary to withdraw obsolete, polluting and labour-consuming branches of industry the city that nourished a major growth in employment in the fields of research, banking and insurance, telecommunications and construction.

As a consequence, firstly, of being a centralized node of power and functions for Russia and the whole post-soviet space, and, secondly, of acting a medium between the West and post-soviet space, Moscow managed to take advantage of its favourable position to establish control over the vast financial and commodity flows in the new capitalist conditions. That is particularly noticeable in the high concentration of global business services, presence of transnational companies, and rapidly developed financial sector. Particularly, by the end of 2002, two thirds of the world’s largest companies in the financial sector had offices, subsidiaries or partner companies in Moscow (Gritsai, 2003). In Russia, business services are strongly concentrated in Moscow providing about 30–45% of national employment in this sector. Moscow hosts offices of many transnational companies. Despite the fact that the number of Western companies entering Russian market remains relatively small due to the political reasons, yet some major Russian companies are performing their activities transnationally: for example, firms like PAO Gazprom (gas), Lukoil (oil), RAO UES of Russia (electricity), Rostelecom (telecommunications) and some banks have become transnational companies (Kolossov & O’Loughlin, 2004).

Furthermore, as an indicator of gradually expanding after the Soviet times involvement of Moscow in the interaction within the complex world system of cities, the number of international flights has increased considerably. Remarkably, only by 1996 the number of passengers of Moscow international hub – which included three international airports – had exceeded the number of domestic passengers. In 2012 the air hub of Moscow was used by 64 million passengers, placing Moscow on the third position among the most congested hubs of Europe, after London and Paris². By 2016 the number of airports serving Moscow has increased to four. Moscow increasingly orients towards the Western countries: the largest increase in the share of flights from 1985 to 1997 was with the Western Europe – up from 4% to 28% (Kolossov & O’Loughlin, 2004).

By and large, Moscow represents a large European megacity that for over two decades has been undergoing an accelerated globalization process along with the restructuring of the economy. Along with the political instability it brings the particular features to the globalization of the city on the other scales.

3.2 MIGRATION SPECIFICS OF MOSCOW AND RUSSIA

Moscow is a city of migrants and it has been one historically. It is very common to hear in the conversation the question “Where are you from?”; however, the salient feature is that this question is asked in Russian. The reason for that is the extensive migration flows supplying Russian capital for many decades sustained primarily by an internal migration from the regions and later on enlarged by the flows from the post-soviet states. Next to the enormous migration inflows ‘from the inside’, the exchange with other countries, which

1 Source: GaWC, 2016 <http://www.lboro.ac.uk/gawc/> (Accessed on 09/05/2017).

2 Source: Expert, 2013 <http://expert.ru/expert/2013/28/stalo-tesno-dazhe-v-nebe/media/201528/> (Accessed on 09/05/2017).

would represent the inclusion in the international circulation of skills, has always remained relatively low. The inflow of a transnational elite – professional and managerial workers, which formed a completely new type of community within the city, was an outcome of the expansion of the global BS companies in Moscow in the post-soviet period (Gritsai, 2005), and continued to expand in other sectors later.

Thus, the UN Report on International Migration has shown that Russia¹ is in the list of the major countries for international migration occupying the third place after the US and Germany. There is a large share of inflow migration that reached 11,6 mln people in 2015 (UN, 2015), which accounts for 8,1% of the country's population. The major source of this flow is a migration from the CIS countries coming to the major Russian cities in a search of a job and better living conditions than in their own countries. Along with that, refugees contribute to this number, with a major increase of migrants from Ukraine in 2014-2015. Another contribution to the inflow of migrants is related to the so-called ethnic repatriation, standing for the return of ethnic Russians who lived in the former Soviet Union countries other than the Russia – 2/3 of immigrants over the period from 1998 to 2007 were ethnic Russians (Nozhenko, 2010).

One of the strains for any study aiming to investigate quantitatively the skilled labour migration in Russian cities concerns the paucity of data. In part, accessible data sources can contain information about nationalities of the immigrants in Russia, or the skill levels without association with the departing country. Even less data available on the level of international migration in the urban centers.

As mentioned above, migrants coming from the CIS countries are the main contributors to the international migration in Russia (over 90% from the overall net migration) with Ukraine as a main donor. Historically, the number of the migrants from far abroad², was rather low but it was steadily increasing in the post-Soviet period. However, the political and economic situation of 2013-2014 caused a major drop in number of foreigners coming to Russia. Since then the number of foreigners from developed western countries keeps falling: from 2014 their number decreased by nearly 60%, while by some countries, even more (Table 1). So, the number of foreigners from the US and Spain fell by 80%, while that from the UK, by 83% (Florinskaya & Mkrtchyan, 2016).

	13.11.13	01.10.15	01.10.16

The US	220086	68367	53978

Table 1. The number of foreigners from some EU countries and the US staying in Russia as of the specified date, persons³

The average annual number of foreigners coming to the Russia for work (the purpose of visit is specified in the migration card at arrival) amounts to about 4 million people: about 3.8–3.9 million labor migrants from the CIS countries and 170,000– 180,000 are from far abroad countries (Florinskaya & Mkrtchyan, 2016).

At the same time, the number of high-skilled foreign specialist keeps falling as well. In 10 months of 2016, about 29,4 thousands of work permits have been issued for the skilled and high-skilled migrants – it is four times less than of the respective period of 2014 (there were 121,5 thousand permits issued). Among the donor countries for the high-qualified specialists (HQS) first place belongs to China. The major difference for the high-skilled migrants from the far abroad comparing to those from the CIS countries is the need to receive a special type of visa for HQS granted for 3 years, while for the former CIS countries there is simplified regime of patents that they can buy in order to work in Russia.

According to the estimations based on the annual data of inputs and outputs of international migration in Moscow and the data from Census 2010 on citizenship, the number of the international migrants in

¹ In terms of international migration, the city of Moscow and its metropolitan area, together with St. Petersburg region, are the main centers attracting migrants (e.g. Florinskaya & Mkrtchyan, 2016).

² From far abroad' is a category in the official statistics of Rosstat Bureau.

³ Source: Main Department on Migration of the RF Ministry of Internal Affairs, CDAFNSP

Moscow not coming from the CIS countries is around 33 thousand people¹. However, it worth noting that international migration in Moscow has been undermined in the recent years when after the economic crisis and political situation of 2012-2013 the major outflow of expats has started. In 2015-2016 the situation has slightly improved but still the levels of inflow international migration are not nearly similar to the period before the crisis.

Nonetheless, being a particular type of international migration makes it harder to grasp high-skilled transnational migrants with the official statistics. Temporality of their movements and strong transnational ties, on the one hand, question the very affiliation with the notion of migration as a type of spatial mobility. On the other hand, some of them for various reasons do not acquire the suitable visa (for the HQS) and instead prefer to renew the touristic one every three months.

4 SPATIALITIES OF EXPAT LIVING IN MOSCOW

The qualitative analysis of the expatriates is derived from 32 semi-structured in-depth interviews conducted in 2017, participant observation in the expatriate locales, and three months of Moscow-based fieldwork. Methodologically, as the adepts of 'transnational turn' advocate the necessity of the in-depth research of everyday life experiences of the migrants (Conradson & Latham, 2005; Scott, 2006), the major part of the evidence presented in the paper is acquired primarily from interviews and ethnographic data. One of the targets of the research was to access the manifold of expatriate types varying in terms of family status, occupation, age, sex, pertaining to both upper and middle classes, as well as diverse countries of origin. The interviewees were recruited through the snowballing personal contacts, the involvement in various expat community meetings, and the informal communication in expat locales.

Throughout the fieldwork a number of expatriate types were distinguished (Table 2). The first type represents young international professionals who have their work as a main priority, and use the employment opportunities in Moscow to build a career. The majority of them speaks Russian on a good level and has been interested in Russia's economic, political and cultural agenda for many years. For them, the relocation is a long-term though-out step that potentially could become permanent. In terms of sociospatial strategies, they show to be more sensitive about the qualities of the areas around their office and home, as they tend to spend more time there. The second type of expatriates is formed by the western families who moved to Russia for the work reasons of one of the spouses: for them, the contract is often limited to 2-4 years, their lifestyle largely exclude rooted experiences, the social circles are confined to the work connections or expatriate community.

With respect to the spatialities, the neighborhood of residence appears to be important, with easy access to a number of urban facilities (parks, sports, restaurants, shops). Additionally, the quality of the accommodation itself is significant: they choose spacious, well-maintained apartments; in some cases they even bring furniture with them. Type III is composed of mixed-relations families, which often had been formed before the foreign partner moved to Russia and that was partially a relocation motive. This type is to a great extent socially integrated, and in terms of sociospatial behavior follows the lead of local partner. Thus, the spatialities predominantly replicate the localizations of the middle-class muscovites. Type IV corresponds to the cohort of the early wave of expatriation of 2000s (before the economic crisis of 2008-2009) when the local economy was in demand of the western expertise, later on they stayed and in due course have transformed into the local market experts: in many cases, the field of their expertise is very place- and time-dependent, e.g. commercial real estate finance, so their expert value has become higher in Moscow than in their home countries. To some extent they intersect with the previous expatriate type, but the difference is that their spatialities have formed and evolved independently. The last type includes a mobile group of migrants that lead rather detached lifestyle, for them employment opportunities appear to have principally sustaining function for their transnational lifestyle, rather than add up to an international career path. Spatially, they give preference to the transnational places with a large diversity and density, in their choices they typically rely on the knowledge of expat community. All five types of expatriates contain the representatives of various western countries, with no clear evidence of relation between ethnic backgrounds and the chosen lifestyle. It is worth noting that a similar typology but with a larger number of

¹ Calculations of the author.

outlined types has been devised by Scott (2004) for the British expats living in Paris, that reinforces the likeness and comparability of various skilled transnational communities in other globalizing cities.

I. Young professionals (7)	II. Expatriated western families (3)	III. Mixed families with Russian partner (6)	IV. Russified experts (5)	V. Transient migrants (people "on the move") (8)
Career-oriented professionals, mostly two-folded relations between Russia and their country of origin	Characterized by isolated lifestyles ("bubble living") and predominantly expat social circles	Most integrated group, tends to reproduce sociospatial practices of Russian middle class families	Came in 2000s during the boom demand for western expertise and converted into local experts	Lead highly mobile detached lifestyles, often lived in several other countries before, mobility as a way of living
Permanent/ transient	Transient	Permanent	Permanent	Transient

Table 2. Lifestyle types of the expats in Moscow

One of the important dimensions of expat living is its geographical spread. Expatriate residents in Moscow demonstrate a range of locational options in terms of residence and also economic and social activity. As a general rule, they tend to follow the pattern of spatial dispersion, with minor degree of clustering. In this vein, the constraints of the housing market, the advancement or shortcomings of economic and technological facilities, and the diversity of local ethnic context all impose certain limitations on sociospatial behaviour of migrants.

While the geography of their transnational living is dispersed, however, there is a trend that expatriates to a greater extent tend to gravitate to the city center, either in terms of their social activities exclusively, or both their residence and activities.

"For me, Moscow is inside of the Garden Ring almost. A lot of my friends are artists or creative people, so they work sometimes and they hang out after work, but they all live in the centre... It seems to me that, at least socially, everything is either within or very close to the Garden Ring, and any place that I'd want to hang out in is definitely inside the Garden Ring." (T., 32 y.o., corporate lawyer from the US, Type I)

In part, this trend might be related not solely due to the livelihood and diversity of the city center, but also due to the differences in comprehension of the city size induced by their backgrounds. Hence, for some newcomers, Moscow might seem too large¹ in terms of territory to think of it as a whole city, so mentally they reproduce their own understandings of reasonable urban size and utilize only that part of central city.

"I guess Moscow stops where the new circle line stops (MCK - Moscow Central Ring), and then outside are suburbs maybe. That's because I do the analogy with Paris, because we have a big motorway that encircles Paris: inside is Paris and outside is not Paris anymore. ... Moscow is so large. Actually for us, Europeans, it's impossible to imagine that the city could go on... It's already so big and it still goes on. So I guess that for me after certain point it's difficult to count it as Moscow itself, though it is Moscow." (R., 24 y.o., Engineer student from Paris, Type V)

4.1 GATED SUPER-RICH

While this paper is primarily focusing on 'middling transnationalism', however, in order to illustrate a general settlement structure of expatriates in Moscow it is important to indicate the presence of gated communities among the residential patterns, both in the city and in its suburban settlements. Residential isolationism of the 'transnational elites' has been broadly researched in various cities by many authors. The residential patterns of expatriates living and working in the cities like Dubai (Walsh, 2009), Singapore (Beaverstock, 2002; Pow, 2011), Shanghai (Sander, 2014), and others, consort the processes of

¹ The area occupied by the city of Moscow is 2,511 sq km.

'homogenization' and 'ghettoization' in urban environment caused by the skilled transnational actors, that consequentially enlarges social polarization in the city.

There is a large presence of suburban communities with foreign involvement in the western and northwestern directions from Moscow. The northern-western inclination of these compounds is also noticeable inside the city of Moscow. This type of residence is represented by the exclusive townhouse communities that were built initially for diplomatic families. One of the developments of this type is Pokrovsky Hills, a gated community with over 200 detached and semi-detached houses and rents ranging from 6 to 10 thousand USD (Medvedkov, 2007). Another example is Rosinka, similar community located in the northwestern suburbs of Moscow and composed of 217 luxury town-houses scattered around a lake with a sandy beach. All settlements of this type provide a set of high-end facilities (Table 3), including 24h security, sport centers and swimming pools, tennis and yacht clubs, medical centers in line with western standards, and more importantly, international schools. For instance, the direct access to the largest Moscow Anglo- American School from its territory is claimed as competitive advantage of the prestigious housing estate Pokrovsky Hills, and consequentially pulls the settlement of expatriates. Rosinka residents can easily access the British International School.

Compound	Rosinka International Residential	Pokrovsky Hills, townhouse residential
	Compound 5 km from Moscow (from MKAD), the closest metro is Mitino	community Moscow, Pokrovskoe-Streshnevo area, between Tushinskaya and Voikovskaya metro
Offered facilities	<ul style="list-style-type: none"> - 20 clubs for sports, social and cultural activities; - Private beach; - 24h security; - 2 swimming pools; multifunctional sports courts; - medical center, school, kindergarten. 	<ul style="list-style-type: none"> Adjacent to the forest reserve park "Pokrovskoe-Streshnevo"; Close to the Khimki water reservoir, the Moscow Canal and the Khimki river; - 24h security; - Premium class townhouses; - medical center, school; - Yachting facilities.
Expatriate community targeting	<ul style="list-style-type: none"> • Website translated on 5 languages; • Main motto is "Your home in Russia"; among the advantages of the compound, the presence of international community is indicated; • Residents are diplomats, businessmen, top managers of leading Russian and foreign companies; • Families from more than 30 countries; • International School of Moscow is located here. 	<ul style="list-style-type: none"> • Designed to meet the needs of business elite and diplomats; • International architectural firms are involved in design of the complex; • Secured direct access to the Anglo-American School campus; • European Medical Center (EMC) on its territory

Table 3. Characteristics of two gated settlements with expats presence in Moscow¹

To a large extent, the residential choices in favor of gated community are driven by the ambitions of expatriate families to maintain the suburban lifestyle residing in private single-family houses while still living in a metropolitan setting, instead of inhabiting an apartment in multi-story buildings that represent the predominant housing model in Moscow.

Nevertheless, these residential scenarios have extreme constraints related to the high housing costs. The living costs in the gated compounds include the monthly rent of over 200,000 RUB (above 3200 EUR) on average. Moreover, these compounds tend to lack the direct connection with the public transportation system, thus, owning a car is highly anticipated from the residents. As a consequence, just as for the local population the residence in the gated townhouse compounds is extremely exclusive scenario, in the same way, this residential strategy is attributed only to a narrow group of transnational super-rich.

Having said that, it should be stressed that the presence of geographical residential enclaves is not representational of the expatriate ghettoization process. On the contrary, the spread of the upscale gated communities is typical for the local context of Russia, and this issue has been investigated in a number of studies (Lenz, 2006; Medvedkov, 2007; Zotova, 2012; Polishuk & Sharygina, 2016). In addition, even while

¹ The information is taken from the official websites of the gated settlements: <http://www.rosinka.ru/en>, <http://pokrovskyhills.ru/en.aspx> (Accessed on 09/05/2017).

living in the gated compound expatriates are comingled with the local population, although of the upperstatus background.

4.2 SCATTERED SETTLEMENT

As described before, there is little evidence found of the geographical enclavism of the expatriate living in Moscow. However, a certain level of differentiation has been observed between patterns related to the localization of the residential choices and the geographical spread of the leisure localities. Below follows the examination of, firstly, the basic locations, such as housing, work, and schooling, that correspond to the 'necessary' fixations in the city, and then, secondly, the locations of optional choices, related to socialization, sports and leisure.

One of the things that has proven to be crucial for defining the localization patterns is the companyprovided relocation packages, however, currently their determining role is decreasing, giving space to the other factors. In the previous waves of high-status migration, an extensive employer involvement in the housing provision or search was taking place. However, nowadays in the face of economic crises and outflow of investments from Russia, these all-inclusive relocation contracts are losing its weight in determining the expat localities. There is still a number of jobs that suggest particular residence for the expatriate on their arrival, for example, diplomats and the workers of international organizations, like Red Cross, can rent apartments with special prices in the buildings for diplomat residence, that often have central location, gated entrance and short-term contracts. However, to a greater extent the employers tend to include in the relocation package a particular monthly amount of money assigned for renting, and the expatriate worker is responsible himself of finding a place to live within the determined price range. That mostly applies to the top managers of the multinational companies. However, the expats that occupy lower career positions and salaries are not entitled to have these benefits, having to arrange the housing on their own.

In the current state, the ways used by the high-skilled transnational migrants to find apartment are diversified. Generally, there are four main ways detected how the expatriates have found the apartments where they currently live: 1 – pre-set accommodation: either they move in the apartment owned by a local partner, or in the apartment suggested by the employer; 2 – online search sources: this includes the use of aggregative platforms that collect rental options (like CIAN, The Locals, Domofond), and the public posts in social networks (in relevant Facebook groups and Couchsurfing); 3 – through friends: both locals and from the expatriate circles; 4 – real estate agents: not very popular option, there are frequent complaints against the choice or prices of apartments found by the realtors. Thus, the search of the apartments is diversified in terms of sources, sometimes expatriates use more than one way. As a rule, the process takes around 1-2 months; some of them declare that they had seen over 10-15 apartments before making a decision.

Accordingly, it could be asserted that the difficulties associated with the search of apartment are representational of the existing mismatch between the housing expectations of the expatriates and the opportunities of the market in the respective price categories. In addition, throughout the period of living in Moscow, among those who stayed for more than a year, the majority of expatriates have changed the apartments a couple of times. The only expat from interviewed who has never changed the apartment in 11 years since he moved, emphasizes that he was very lucky and it is important to keep good relations with a landlord.

"I was lucky because I like the flat and also the owner. Because I think the biggest problem in Russia is the landlords, since it's very unstable, they come to you, they say I need a flat, you should move out. A lot of friends had this kind of problem. Or - I want 10'000 RUB more a month - take it or leave it. My landlord is very decent. ... I've lived in the same apartment for 11 years now." (S., 44 y.o., real estate finance expert from Italy, Type IV)

At the same time the choice of the apartment is not directly contingent on the distance between the residence and the workplace. The proximity to work is among the potential factors that could explain the residential choices of the expatriates. However, the findings show that the distance from residence to the workplace varies significantly: from 10min walking to 1-1,5h by metro or car (due to the traffic congestion). On average it takes them about 30-40 min to get to work. Interestingly, the vicinity of metro, that could

potentially reduce travelling time, was not that crucial either: in many cases the apartments are located in 10- 15 min walking distance from the closest metro station. Therefore, the factor of the location of the office does not show to be significant for the residential choices.

"I spent six years living in Yuzhnoe Butovo, which was a good experience ... I've commuted for 2 years to Khimki, through the whole city, it was a nightmare. My record journey home, I believe, it was 11 hours from Khimki down to Butovo. It was close to the New Year, and the whole Moscow was 10 on Yandex¹ ...[On average] If I left at 6 o'clock in the morning, I could be there [in the office] around 7:20. But if I left at 6:30, I could be there at 10 o'clock in the morning. It was impossible to predict. And in the evening, if you didn't leave by 5 o'clock, it could be anything from 7:30 to 9 o'clock at night. You had to leave at 5 o'clock." (S., 33 y.o., construction consultant from the UK, Type III).

Another factor relates to the range of prices for rental housing and prices could be a limiting factor. They vary significantly, depending on the social and family status, area, and size of the apartment. On average, the middle-class expatriates pay from 80 to 120 thousand rubles (around 1200-2000 EUR) per month for an apartment of 2 and more rooms in central areas, while upper-status families often pay 200 thousand a month and more (above 3200 EUR). Some exclusive offers in prestigious areas, targeted at superrich, might reach 350 thousand rubles (5600 EUR). At the same time, there are strategies to diminish the costs, for example, single expatriates can share the apartment with 1-2 flatmates, occupying one room each, and splitting the overall rental price accordingly. This scheme is especially popular among young professionals of the Type I, who prefer to share but live centrally and in a lively area. Another way is to save on housing is to live separately but in the outskirts of the city, however, due to the high commuting time (can reach 1,5h), the majority of the expatriates prefer not to use this option.

As described by some authors the location of international schools might drag the residential choices of expat families. However, in Moscow the locations of international schools do not correspond to the residence localizations of the high-skilled transnational migrants. In 2017 there were 27 international schools in Moscow, and over a half of them have English as a main language of instruction (the clear western inclination is observable). Nevertheless, not all expatriate families send their children to these schools, as the fees are extremely high. It varies from school to school but on average the yearly fee for one child is around 25,000 EUR. Importantly, the fees are fixed in euros, while many expatriates, especially those out of multinational corporations employment, have their salaries in rubles. Thus, the economic crisis of 2013-2014 and the devaluation of ruble affected severely the schooling opportunities in expatriate families. At the same time, there is a significant number of mixed-families, in which children can speak Russian. For that reason, these children often get registered into local schools, although the foreign spouse would prefer them to keep dual language and cultural identity. For example, Frenchmen with children of Type III finds it difficult to cope with expensive school prices with the existing economic situation:

"When you are a foreigner, you always have some fees in your native country. For example, if I take my case, I also have to pay the school of the children here. ...It's a significant amount, and it's in euros. ... So that's why many foreigners with the local contracts left in 2014, and also in 2015 when the ruble devaluated very strongly. ... I don't travel much now. Mostly because of the crisis, and because it has reduced [the number of] business trips. Also my fees are always in euro, I have to do some savings." (C., 46 y.o., project manager from France, Type III).

Among the common reference mentioned across the expats with respect to the housing are the complaints about the poor quality of the housing supply. In general, there are three most repeated dissatisfactions with the housing in Moscow: 1 – bad quality of the infrastructural details, like dysfunctional wire system, bad plumbing and water pipes, high sound conduction of the walls; 2 – impractical layout of the apartment and irrational organization of furniture, appliances and finishing in the apartment; 3 – negligence and deprivation of the communal areas of the building, like staircases and entrance hallway. Also, it has been articulated in the interviews that inviting friends over to their houses for common dinners, parties, etc. is

¹ Yandex Traffic provides real time information about the congestion levels on the roads: from 1 – free road to 10 – traffic stopped.

less common here in Moscow, than in their previous experiences in their countries of origin. Particularly, all that might contribute to the fact that the vast majority of expatriates prefer to socialize outside of their homes, preferably in the areas in the city center.

Overall, the expatriates living in the city of Moscow have not proved to produce any noticeable residential concentrations, neither in central, nor in suburban city locales. When asked about having any neighbors who are foreigners as well, no one could mention more than one or two families within the same residential units. While there is no clear residential concentration of expatriates, however, in terms of preferred areas to spend time in, there are several districts that many expatriates articulate as attractive. They include Patriarshy Ponds, Kitay-Gorod, Chisty Prudy. These areas are described as the places to spend time but the expats not necessarily choose to live there. One of the possible reasons for favoring other locations for residence, less appealing areas, might be the housing market restraints, related to the high rental prices and the shortage of diversified rental supply in popular areas. However, these neighborhoods are extremely lively, providing multiple choices of bars, cafes, clubs and restaurants. One of the residents of Kitay-Gorod sketches the appealing side of that area:

"It has this really good feel about it. I mean there is a lot of diversity of people there, and shops, there are hipster bars and high-end restaurants and street bars. There's just so much diversity: there are drunk people, there are young people, business people. I really like that. There are probably other nice neighbourhoods where I could live... There are all sorts of other neighbourhoods, but this feels much more diverse, much more interesting. I like feeling that diversity of life." (T., 45 y.o., area director of hospitality company, from the UK, Type V).

In terms of social practices the circulation of information about the locales is of great significance. The choice of places where expats go is highly dependent on the social relations they maintain. Accordingly, the communication strategies tend to have the direct impact on the localization of the social practices. Crucially, the Russian language proficiency partially determines the expatriate communication strategies, and consequentially the localization of their activities. The knowledge of language is not that obligatory for the use of places, but it is important through which circles they get to know about the places.

5 CONCLUSION

The settlement patterns of the expats living in Moscow can be embedded in the heterolocalism model, as the evidence reflects the presence of four main principles of the sociospatial model: spatial dispersion, disjuncture between residence and workplace, ethnic community ties are sustained remotely, and time-dependence. The emergence of heterolocal model for the settlement of Moscow-based expatriate workers has shown to be relational to the urban planning structure of Moscow. Bringing into focus the city of Moscow - a large postsocialist European city with a growing international orientation striving to integrate itself into transnational economic structures (Brade & Rudolph, 2004) and global labour circulation – helped to discuss the theory of sociospatial intergation of migrants in the comparative perspective. The research intends to extend the understanding of the influence of the migrant class of globalizing middle-class professionals on the spatialities and social geography of the destination cities and its contribution to the globalization process.

1 INTRODUCTION

It is likely that the current generation that is growing up immersed in a technology filled world can perceive space and distances from a different perspective than those that come before. The speed by which technology is evolving increases day by day and, moreover, people and companies are discovering and consolidating different ways to take advantage of the current available possibilities that the devices with internet connection can offer.

In this context, an important concept is the “mobile ecosystem”, that in accordance with Berger et al. (2016) is composed of a set of tools that can be used while people are moving around to communicate and obtain information online independent of the person's location, i.e. devices that can easily be carried anywhere and have the ability of staying online at any time. The mobile ecosystem has changed the way by which people set about in their daily activities and interact.

According to Inman (2012), despite of the already existing literature on digital consumer, the growing diffusion of smartphones expands the possibilities of studies through researches on how an “always connected” environment can influence consumer cognitions and choices.

Kuhnimhof et al. (2012) highlights that the impact of Information and Communication Technologies (ICT) on travel behaviour is not clear and so, it should be studied focusing on those young adults who grew up with ICT and developed their mobility habits in the presence of such technology.

In this context, the mobile device with internet connection is re-defining, in some extent, the space, when activities are detached from specific places. The consequences of these changes have a high potential of impact in a city's layout and mobility patterns for the current and next generations. According to Castells (2000), the format of the cities is changing, having the network of communication as a guide, where the technological infrastructure that builds up the network defines the new space, very like railways defined

“economic regions” in the industrial economy. The distance intra and inter cities might be considered in a different way due to internet connection/access, making people, nowadays, ponder living in places that are not well connected by transit because the increase in easiness of obtaining reliable and real-time information about the services (including transport services) and buying products without the need of travelling.

As for companies, beyond the transport connection, that is highly important particularly in cases where its product should be delivered, the quality of internet connection available is a factor that is being taken into account when defining where the companies should be installed, aiming to lessen the risk of losses of data or laboring interruptions due to connection problems.

In this sense, this study sought to examine prospects for the future related to possible changes in mobility and living patterns due to technology for the current and next generations and what could be its implications in city's layout and mobility patterns. To achieve it, a literature review was developed aiming to identify tendencies and changes that have occurred during the last decades which affect the way people move around and choose places to stay. This work contributes to the knowledge by studying the links existent between these concepts and the evolution/variations in their relationships.

2 CITIES, TRANSPORT AND TECHNOLOGY

Since the beginning, the cities and transportation systems had a close connection, where their mutualism could be observed through their interaction: the development of one tended to lead to the progress of the other. If in earlier times the urban form was limited to what was considered suitable for mobility by walking or animal powered vehicles, after the introduction of motorized transport, accompanied by its infrastructures, this radius increased considerably, favouring the expansion of cities. It is also true that the opposite occurred: changes in the spaces and land uses have a significant impact on transportation, as such changes in the use of land or buildings, renovation of areas or deployment of new buildings that attract large flows of people (Trip generation hubs). As the functioning of a city is extremely influenced by the networks that compose it, Banister and Hickman (2013) highlight that the transport system in a city should be carefully analyzed and implemented as an integral part of city design, because it can generate adverse impact on the quality of the city.

Mok et al. (2010) discussed about these intrinsic relationships, adding the advent of the internet to the equation. They discuss the possibility of the cities and, the concept that they carry (physically concentrated networked area) lost their importance due to the internet. They expose that, in past, while cars, public transport and telephones had extended the possibilities of interaction to outside the metropolitan area, people remained restricted by the speed of transport modes or the level of interaction (only voice in case of telephones) and, in both case, had budget constraints to access it. However, for them, the popularization of the internet introduced the high speed of connection combined with the small cost that made such a revolution, only remaining time-zone differences to generate some constraints for immediate communication.

It means that, to certain extent, the space as a barrier has had its influence diminished along the years and only time constraints are still making difficult the real-time interaction between people physically apart.

Including the technologies and, more specifically, mobile technologies in this scenario, what we have nowadays is the possibility of an “always connected” environment, where people have smartphones working as “pocket computers” that can easily be carried anywhere, have access to internet at all times. It is clear to see that mobile technology has an impact on people on a daily basis.

The integration of technology allows cities to keep their character of “interaction maximizer”, but in an adapted way. The combination of local interaction with long-distance connectivity, dissolved the boundaries of cities, turning them into hubs (Mok et al., 2010). At the same time that spatial mobility is decreasing due to telecommunications, the telecommunication produces the desire for more personal face-to-face contact and hence physical mobility (Wegener, 2013).

In this sense, it could be said that the distance ends being re-signified for the new generation, as the concept of human extensibility developed by Janelle (1973) who presented the idea of lessen the distance

between places not through the travel in the space, but using the technology and communication to do it, i.e. virtually projecting/presenting/interacting as they and their ideas were physically present. It is about to expand the opportunity for human interaction, but dissociated from the space.

Due to its intrinsic features, this revolution has the potential to produce some effects in both urban form and mobility patterns. Janelle and Gillespie (2004) comment on “space-adjusting technologies”, arguing that when they are combined in different configurations, huge effects on patterns of human settlement, production, and trade can be achieved. The integration of ICT with the transportation systems, according to them, have impact on two areas of human social dynamics, beyond the transportation systems itself: individual mobility and urban form dynamics/development.

Knowing that, the following topics will approach new possibilities for daily life generated by advances in technology, as well as its present and future/expected changes and its existing/potential impacts in urban form and mobility patterns.

2.1 E-WORK AND E-LEARNING

Many studies have approached the subject of E-work (a.k.a telework) that consists in allowing the workers to develop its paid activities from their own home instead of commute to their workplace (Mokhtarian et al., 2004). For Dal Fiore et al. (2014) nowadays only a small amount of workers needs to be at their workplace, because the technology that provides the opportunity for individuals to choose where they want to be and access work and information from there, removing place-based constraints and consequently lessening the need of traveling. As some professions are being renovated and many are emerging due to technology advances, there is a strong belief that this trend of allowing employees to telework should continue to expand in the future.

Moreover, the positive results found in some studies (Dutcher, 2012; Pearce II, 2009; Hill et al., 2003) related to teleworking reinforce this believe. Golden (2006) found that the extent of telework (proportion of an average workweek that workers spend teleworking) is positively related to organizational commitment of the worker, and a negatively related to turnover intentions (the rate at which employees leave a company and are replaced by new employees). The author highlights also that not having to commute means accumulation of extra time and savings in energy resources: both are interesting products that teleworkers can allocate for work and/or family needs, improving their well-being and outputs.

The possibility of telecommuting has a huge potential of impact urban form and mobility patterns, because once commuting to work is no longer necessary (or, at least, not on a daily basis), people will travel less for mandatory work purpose and will have less constraints in choosing a place to live; without the need to consider the constraint of good connection between home and work places, the residence location choice becomes in some sense disassociated from the work-place and the effect in the urban dynamic is the decrease/mitigation of over demand for housing close to working related/concentrated areas.

Mokhtarian et al. (2004) found in their study that investigated ten-year data about telecommuting and residential/job changes of 218 workers in California that the residential location of telecommuters is much more probable to be in peripheral areas than in the city center. The authors were not able (based on the available data) to determine whether longer commute distances boost telecommuting or, telecommuting allows for residential relocation, allowing people to move away from their work locations. However, they believe that the supremacy is related to the second possibility of causality, because to moving towards distant locations were actions more likely to be avoid if they have to commute to their workplace rather than telecommute (Mokhtarian et al., 2004). According to Shen (2000), the flexibility in residential location can lead to a decentralization of the population; unregulated urban sprawl and polarization in residential location. The author also argue that the coverage of public transport will still characterizes a restriction on location flexibility for some population groups, as the city and the transportation network are strongly related and will still influence the remain activities need.

Similarly, to what occur with workers, it is happening also with students, that already have the opportunity of attending some courses without having to be in a specific classroom. As the easiness in dealing with technology and take the maximum advantage of it is a remarkable characteristic of the current young generation, this model of learning is a very interesting option to them. Leaving aside the discussion about

gains and losses in this model of study, what it allows is access to education without borders, which leaves the cost and time availability as the only constraints. As for University students, that sometimes no longer live with their parents, it means that they can choose the place where they want to live without having the university location as main driver and then choose for better benefit vs. cost deals around the city. In this sense, Zhou (2012) found that the greater the commute distance for university students, the higher are the utility of both carpool and telecommuting.

As for mobility patterns, knowing that these travels are not an end in itself, but rather happen because of the need to perform a mandatory activity at the destination, both cases are related to frequent travels that will no longer occur (totally or partially), meaning that travel patterns will change, with potential impacts on congestion, pollution, mode choice and more productivity in urban areas. Julsrud and Priya Uteng (2015), found that there is a strong belief between Norwegian experts that the distribution of commuting traffic (over the course of the day) will be possible due to the combination of the increasing trend of flexibility of the workplace and imposition of congestion charges.

Regarding urban form, without having to consider that much the distances for working places or studies, living place choices ends up being influenced primarily by budget, personal preferences and land use restrictions defined by local authorities. Being the budget, in general, the main definer of where to live, sprawl might arise. The differences of location will have less negative impact in mandatory activities regarding the accessibility to transport due the possibility of telework.

It is noteworthy that this does not mean that some places will no longer remain as the most desirable (as city centres and already consolidated areas that carries special meaning for the people -related to culture and subjective thoughts/norms established by the society) and some people will still choose these however, but the negative impacts of living outside the most desirable areas might have less of an effect on the daily mandatory activities of its residents due to technology. The higher the level of technological integration a city has, the higher the possibility of mitigation of negative impacts generated by low accessibility on its residents.

2.2 E-COMMERCE

E-commerce (a.k.a. online shopping) consists of a type of trade where products are made available online and purchased by people to be delivered at a specific place (usually the buyer's home). According to Zhou and Wang (2014) it is rational to expect that this technological form of acquisition of goods could lead to a reduction in the need of shopping trips, since the goods are accessible via door-to-door deliveries. However, one can argue that despite the decrease in personal trips, this process generates substituted trips that are the freight trips to deliver tangible products (Mokhtarian, 2004).

According to a research conducted by Weltevreden and Rotem-Mindali (2009) in the Netherlands, the business to consumer (b2c) e-commerce led to a decrease in the net number of personal trips for shopping related purposes and also lessened the distance travelled by consumers. However, they highlight that the effect on mobility could be positive or negative depending on the form of e-commerce, the trip-chains, modal split and the kind of products purchased.

Zhou and Wang (2014) found that e-commerce reinforces shopping trips while the opposite is not true, i.e. shopping trips lean towards the suppression of online shopping tendency. The study conducted by Ding and Lu (2017) had similar results, finding that people who frequently buy products online tends to perform more trips to shopping, making e-commerce complementary to in-store shopping rather than a competitor. They added that a change was visualized in mobility pattern related to "when to shop", because people who buy online, usually go in-stores shopping on weekends rather than weekdays, which may affect the distribution along the time of travel demand (Ding and Lu, 2017).

Farag et al. (2006) found that the group that are more likely to buy online are composed by people that live in very urbanized areas. Moreover, people who have relatively low accessibility to in-store shopping buy more products online. This way, as presented in the discussion about the impacts of telework, people who live in those areas end up facing less problems to develop their daily activities, as the E-commerce increases their accessibility. Wee et al. (2013) argue that some groups of people have a potential of be

more likely than average to use ICT as a substitute for physical accessibility (e.g.: online shopping, social media communication).

Rotem-Mindali and Weltevreden (2013) conclude that the existing academic literature suggests diverse inferences about how the e-commerce influences mobility. For them, it is important to pay attention in the respondents' sample, because choosing, for example, only respondents that potentially have affinity with internet use can impact the results in an undesirable way. Moreover, if both personal and freight trips generated/attracted are not analyzed the resultant scenario cannot be entirely constructed and then, the remaining aspects not included in the study should be exposed. They also argue that product type should also be taken into account when analyzing this subject.

As e-commerce is a relatively recent option, the entire picture contemplating all the factors that have influence and all the consequences generated by it on travel patterns and urban form remain unclear. Mokhtarian (2004) believes that online shopping will substitute in-store shopping in a limited way, nevertheless both trade forms will probably continue to increase and co-exist. Despite it, Rotem-Mindali and Weltevreden (2013) believe that considering a long term perspective, the freight transport resultant from e-commerce may act positively towards sustainability, through the optimization of distribution that overcomes the avoided trips.

As for urban impacts, it could be said that the E-commerce (including frequently deliver needs, e.g. groceries, personal products) and online services (e.g.: access to Social security, health care system for schedule appointments, bank account) are also contributing to lessen the constraints when deciding where to live. Products and services could be accessed and scheduled or purchased without the need of traveling. The desired mixed land use place could be replaced to some extent by the online environment, almost without borders.

Moreover, the time concept ends being put into a different perspective as the online world turns some products possible to be bought 24 hours per day, making some services/activities detached from both space and time. For the distributors, the E-commerce also have consequences in generating the necessity of restructuring and relocation (stores and/or warehouses) of some companies, as well as development of appropriated logistics for freight delivery travels and analysis of location of parcel lockers for last mile deliveries. Thus, the results of E-commerce in a city might mitigate the problems associated with living in not well connected places that have low accessibility to shops. (Mokhtarian, 2004) defends that the use of ICT allows the spatial and temporal fragmentation followed by their recombination.

As for trends in E-commerce, Ding and Lu (2017) found that age is a significant explanatory variable, related to individual socio demographic characteristics, being the younger adults the ones that are more likely to buy products online. This tendency may be related to the fact that those groups are more familiar with technological tools and therefore that as the population is being renovated, the E-commerce will increase, having more potential new customers each year.

It is important to highlight that the expansion or more rapidly growth of this form of trade is more likely to happen for some kinds of products that are not so dependent on visual assessment or experimentation or that have not much time constraints related to its delivery (e.g.: electronic goods, airplane's or event's tickets).

2.3 ICT FOR COMPANIES

For some companies that are immersed in a "fully connected globalized" world, beyond a good transport connection, it is essential the quality of internet and telecommunications available -Information and Communication Technologies (ICT). Yazar et al. (2016) argue that companies may require using fully fiber optical wire, which allows for high speed Internet connections. Thus, it could be said that optical fiber availability is nowadays a constraint for choosing the location of some businesses, being taken into account when defining where the companies should be installed, aiming to have faster interaction possibilities, less risk of interruptions in the work or videoconferences due to connection problems.

As the globalization have a crescent impact in world, it is expected that companies become multinational and the already multinational companies expand themselves into different countries. To enable this

growth, it is essential to keep an easy, fast and accessible communication between the main office and its local branches. Videoconferences allow companies, especially multinational ones, to schedule meetings without the need of all people involved travel to a specific place, generating less mobility in a wider scale.

In this sense, if in the past for a city be attractive and competitive for the location of companies, it should have a good transportation network, nowadays the integration of a good information and communication network is also essential to create an environment favorable to the development of activities.

The impact of it is mainly related to the urban dynamic, that is defined according to the level of technological connection that each zone offers. The companies' location ends up being restricted or more desired towards determined areas that gathered the best quality of ICT infrastructure. Despite of being decisive nowadays and probably have more impact, this is not a new trend, as it could be seen in the work of Goddard and Pye (2007), who argue that the office functions should be relocated to centers in order to avoid communication problems, common for offices in the development areas. As for mobility, the ICT allows the decrease in business travels, that are substituted by videoconference.

2.4 INTEGRATION OF ICT IN TRANSPORT

About the impacts of technology in public transportation system, due to internet and mobile communication, people nowadays are facing less problems living in places that are not well connected by transit, because the increase in information quality and quantity and the improvements in the easiness to access them, notable reliable and real-time information about the services, i.e., the restriction of transit schedule could be mitigated by transit information access, although peripheral areas could have simpler systems, with less quality and quantity of information provided. Brakewood et al. (2014) conducted a before-after survey for evaluating the impacts of real-time transit information on bus riders in Tampa (Florida), and found a significant change in the waiting time and the feelings associated with the waiting time after the availability of real-time information.

Nowadays it is possible to access public transport information through applications that can use the GPS system in the device (e.g. smartphone) and deliver door-to-door real-time information according to the travelers' movements, facilitating the trip. According to Hwang et al. (2006), improvements in the tools of the Geographic Information System (GIS) have enabled transport agencies to provide a variety of different map views and tools for its customers to meet the different needs and preferences.

Julsrud and Priya Uteng (2015), said that new technologies are the main significant parameter for future mobility, being essential to analyze it. Using Delphi techniques, they developed a web based survey involving 280 Norwegian experts, and found suggestions that the next decades may witness changes in choices and preferences regarding urban mobility due to technologies (notably mobile ICTs), as people already have access to real-time information and suggestions for optimal travel routes based on personal preferences, and the operators are using the information for continuously improving the management of public transport. Today the possibility of full time anywhere connection can lessen the cognitive effort associated to perform a trip, reducing the barriers associated with the use of public transportation, making this mode more attractive.

According to Lyons and Harman (2002), the public transport users are concerned about the convenience from the origin to the destination of the trip. Therefore, providing this information can make the physiological effort generally made to find the directions and important points during the trip to be dramatically decreased, since it is only necessary to follow the steps as indicated in the tool. Wardman et al. (2001), argue that a trip is inconvenient when it involves unexpected or unwanted physical, cognitive (or mental) or emotional stress efforts. In this context, the provision of clear and reliable information influence in the way of decreasing the cognitive effort, since this relates to the effort required to collect and process information before and during the journey. On the other hand, if the trip requires search for information or interpretation of information, this effort is likely to increase.

The information is important not only for travels in public transport but also for trips made by private modes. Consulting traffic conditions for different possible routes makes the travel less uncertain and increase the sensation of controlling it.

Another important amplification of possibilities generated by technology is to broaden the options to active use the travel time during trips (Frei et al., 2015). Previously the travel time on public transport would have been used mainly to sleep or read a book/newspaper, today this time can be used for a wide range of activities, such as checking emails, buying something online, getting information about the weather, accessing social media and even to follow the current journey in real time, such as their current position and estimated arrival time. This increase in multitasking and fragmentation of activities can be considered as an advantage in opting for public transport trips compared to driving.

Combining these changes mentioned above, the way people perceive the system, experience the travel and take advantage of the travel time in public transport, may potentially have affected also the perception that people have about its service, making them more likely to perform more travels by public transport and altering their mobility patterns.

It is important to mention the current observed flexibility in young adults' choice that show propensity to have a multimodal travel behavior that combined with integrated ICT on transport, potentialize this mobility trend. Figueroa et al. (2014) found that car use by young adults (18-64 years) in Denmark was transferred to other modes in high density settings. Kuhnimhof et al. (2012) discuss about "peak travel" in industrialized countries, highlighting that the decrease in automobile travel of young adults in Germany is due not only to changes in mode choice which thus reduce car ownership but also due the increase in multimodal travel behavior as reasons for this stagnation. It is worthy to reference that despite both countries cited being developed countries, one is well known for encourage soft modes (Denmark -walk, bicycle) and the other has a long tradition on car use (Germany), which evidence that this trend is not only due to local specificities, as such infrastructure and policies towards a specific mode. Wee (2015) defends the hypothesis that we are living a transition period that will led us to a more ICT-based activity pattern and accessibility; being the trend of decreasing in car use and the changes in travel behavior (in general) the signs of that.

Out there the traditional public transport system, the technology also allowed the conception and development of new forms to move around collectively. Systems of car sharing and bike sharing have been made available in several cities around the world. Through the GPS of mobile devices combined with internet access, it is possible to schedule a ride in few seconds choosing between total or shared expenses with other uses of the services (e.g.: Uber, Cabify, Lyft, Blablacar). These new travel options increase the physical accessibility of areas and constitute more affordable alternatives from a financial point of view.

Knowing that accessibility is an index that translates the relation between people, land-use and transportation, the urban dynamic becomes more homogeneously distributed due to the increase in the transport offer variety available. For Wee et al. (2013) ICT has the potential to impact on the awareness of activities' location at numerous locations.

Beyond the impacts in urban form and mobility patterns, Wegener (2013) highlights that it is possible to identify an increase in heterogeneity among urban lifestyles, mobility and location patterns and social networks, due to the increase in individualisation of society. He refers also that due to this dynamic, less emphasis should be put on preferences and choices and more on needs and constraints, that are more constant during time, when modelling.

2.5 TECHNOLOGY AND CARS

There is a crescent discussion about the negative impacts related to the intensive use of cars in cities. The climate changes and energy scarcity in the world are leading to the development of several policies to support sustainable choices, encouraging the decrease in car use and adoption of "more environmentally-friend" vehicles combined with mixed land use design.

Mácario and Marques (2006) points the currently commercially available Hybrids cars as one existing option to cut consumption and carbon emissions (30% less), as these cars do not require specific supply infrastructure in urban environments.

In this context, thinking about the future and motorized vehicles, Wegener (2013) predicted a future with scarcity of fossil fuels and climate changes, so the energy for transport will be limited and expensive, which will affect mobility and location behaviour in cities through households moving closer to their workplaces and firms closer to their customers, suppliers and workers. Higher-density and mixed-use of land, according to him, are essential to it. Fermi and Fiorello (2006) found in their simulations, which considers scarcity of energy supply, that in all scenarios simulated there was a tendency of decrease in the average travel distances per capita and by car, returning to levels found in 1990s and 1980s, respectively; contrasting with the number of trips by public transport that more than doubled. For Fermi & Fiorello (2006) climate changes and scarcity of fossil fuels are interrelated through the need of decrease in the carbon fossil fuels/emissions and changes in mobility and location behaviour, i.e. the solution for the problems can be achieved by a combination of technological and behavioural changes.

On the other hand, according to Arbib and Seba (2017), these problems will be solved by technology, with the use of TaaS (transport-as-a-service) that will provide the availability of on-demand door-to-door transport autonomous (or self-driving) electric vehicles. They also believe that the shift is motivated by technology, not climate policies, expecting that TaaS will be cheaper than most forms of public transportation and 10 times cheaper to run than fossil-based cars (near-zero marginal cost of fuel and an expected lifespan of 1.6 million kilometres), being the more convenient form of transportation in a close future. This scenario is in agreement with the argued by Lyons (2014), who already drew attention to the fact that we are living a transition toward a phase that will have as main features the decrease in the importance of ownership and use of cars (as we have nowadays) and the incentive of shared use of mobility resources. This scenario tends to favour less congestion.

The searching for flexibility in travels, notably for youngies, could be evidenced in the work of Karlsson et al. (2016), who developed and tested in Sweden one service based on the concept of Mobility-as-a-Service (MaaS). It was offered for families personalized transport services appropriate to the needs and requirements of each individual traveler, including as options the use of the local PT authority, one taxi company, one car rental company, one car sharing company, and one bike sharing company. They found that the users value very much the flexibility resultant from having multiple options available to use, being possible to select a mode according to each trip requirement. Moreover, the users reported that owning a car, bicycle or transit pass make them feel as they have no choice rather than choose that mode regardless specific conditions of each trip (Karlsson et al., 2016).

The expected impacts on mobility and accessibility conform said by (Arbib & Seba, 2017) are the improvements in the mobility for people who cannot drive or afford cars and for the population who lives in suburbs and the low density of public transport infrastructure, what can favour more urban sprawl.

3 CONCLUSION

The table 1 synthetizes the topics discussed in this work. It can be noticed that the technology and its possibilities related to transport, city and people has potential to transform/impact, above all, areas with low accessibility to services and goods, because it can mitigate the negative effects inherent to living in those areas. Banister and Hickman (2013) argue that there is a strong belief that technological solutions will be developed to solve/mitigate what are essentially social problems.

Technology associated product	Trends	Impact on mobility patterns	Impact on urban form
E-work / E-learning	<p>Increase in percentage of employees that are allowed to telework: some professions are being renovated and other created by technological advances.</p> <p>Increase in e-learning possibilities: current and probably next generations have such a facility in dealing with technology and taking the maximum advantage of it.</p>	<p>Less frequent daily travels (that usually happen in peak hours)</p> <p>Public transport less crowded (more comfort in the trip – potential impact in mode choice).</p> <p>Sustainable derivate impacts: Less traffic congestion.</p> <p>Less air pollution and more productivity in urban areas.</p> <p>Decrease in energy consumption.</p>	<p>Residential location disassociated from the work-place/University.</p> <p>Coverage of public transport still as a restriction for some population groups on residential flexibility.</p> <p>Decrease of over demand for housing close to working/university related/concentrated areas.</p> <p>Unregulated urban sprawl might arise.</p> <p>Residential location influenced primarily by budget, personal preferences and land use restrictions.</p> <p>Less negative impact regarding the accessibility to transport in suburban places.</p>
E-commerce	<p>As the population is being renovated, the E-commerce will to increase, having more potential new customers each year.</p> <p>It is expected that online shopping will substitute in-store shopping in a limited way, nevertheless both trade forms will probably continue to increase and co-exist.</p>	<p>Reduction in the need of shopping trips and generation of freight trips.</p> <p>Mobility effect can be positive or negative, depending on the form of e-commerce, trip chains, modal split and kind of products.</p> <p>E-commerce reinforces shopping trips, but the opposite is not true.</p> <p>Change in mobility pattern: people who buy online, usually go in-stores shopping on weekends instead of weekdays.</p> <p>Long-term perspective: freight transport resultant may act positively towards sustainability: optimization of distribution, overcoming the travels avoided.</p>	<p>People who use to buy more online: live in very urbanized areas and/or have relatively low accessibility to in-store shopping.</p> <p>E-commerce increase their accessibility, contributing to lessen the constraints for people when deciding where to live (residential location).</p> <p>The desired mixed land use place could be replaced some extent by the online environment.</p> <p>Distributors need to restructure and/or relocate, as well as develop appropriated logistics for freight delivery travels and analysis of location of parcel lockers for last miles delivers.</p>

ICT for companies	Globalization: companies become multinational or expand themselves through the countries. It is essential to keep good internal communication.	Decrease in business travels, that are substituted by videoconference.	Optical fiber availability: constraint for choosing the location of companies: more desired areas have good ICT infrastructure. The urban dynamic is defined by zone, according to the level of technological connection. To be attractive competitive for the establishment of companies, the city should a good ICT network.
Integration of ICT in transport	Access of real-time information and optimal travel routes based on personal preferences. Flexibility in young adults' travels: propensity to have a multimodal behavior potentialized by integrated ICT on transport. Transition period towards a more ICT-based activity pattern and accessibility, being the trend of decreasing in car use and the changes in travel behavior the signs of that. Development of new forms to move around collectively.	Consulting traffic conditions for different possible routes makes the travel less uncertain and increase the sensation of controlling the travel. Increase in multitasking and fragmentation of activities: + more and easier to find information, resulting in less cognitive effort = potentially change the way people perceive the public transport system, experience the travel and take advantage of the travel time in public transport, what may potentially affect the perception that people have about its service, making them more likely to perform more travels by public transport and altering their mobility patterns.	Increase in information quality and quantity and improvements in the easiness to access them, notable reliable and real-time information about the services make people face less problems living in places that are not well connected by transit. The new travel options (car sharing, bike sharing, Uber, Cabify, Lyft, Blablacar) increase the physical accessibility of areas and constitute more affordable alternatives from a financial point of view. The urban dynamic becomes more homogeneously distributed due to the increase in the transport offer variety available
Technology and cars	Futures: scarcity of fossil fuels and climate changes and/or presence of Saas. Availability of on-demand door-to-door transport autonomous electric vehicles. Searching for flexibility in travels, notably for youngsters: decrease in the importance of car ownership and use and the incentive of shared use of mobility resources.	Future with scarcity of fossil fuels and climate changes: Tendency of decrease in the average travel distances per capita and by car, returning to levels found in 1990s and 1980s, respectively, contrasting with the number of trips by public transport that more than doubled Saas: improvements in the mobility for people who cannot drive or afford cars and/or lives in suburbs and the low density of public transport infrastructure.	Future with scarcity of fossil fuels and climate changes: households will move closer to their workplaces and firms closer to their customers, suppliers and workers. Higher-density and mixed-use of land are essential. Saas: improvements in the mobility for the population who lives in suburbs and the low density of public transport infrastructure, what can favour more urban sprawl.

Table 1 – Summary of trends in technological solutions and its mobility and urban impacts

The relationship between transport and ICT, as discussed, seems to have a more complementary nature. However, Mokhtarian (2003) argues that it is necessary to study the longer-term complementarity effects of travels suppressed and generated, because for her all are happening simultaneously: substitution, complementarity, modification, and neutrality.

As for the urban impacts, Wegener (2013) believes that cycling and walking should be encouraged in cities and anti-sprawl legislation should be implemented and enforced. He also highlights the necessity of provide minimum standards of access to basic services (e.g.: health care, education) for the all strata of the population in urban, suburban and rural areas.

Shen (2000) argue that urban planners should take advantage of the moment and guide the metropolitan areas, conducting the possible growth to outside the ecologically complex sites and keep them spatially, economically and socially integrated.

The authors recommend further study on the spatial relationships between telecommunication and transportation. It is recommended also the development of empirical analyses in future in order to confirm or not the tendencies/forecasts presented and discussed.

ACKNOWLEDGMENTS

The authors would like to thank the CCDD-N/FEUP, INESC TEC and MIT Portugal for supporting the development of this work.

ID 1648 | WHAT ARE THE NEW MEGA PROJECTS? AN ASSESSMENT OF THE DIMENSIONS OF NEW LARGE SCALE DEVELOPMENT PROJECTS

Serin Geambazu¹

¹Ion Mincu University

geambazuserin@yahoo.com

1 THE NEW MEGAPROJECTS

The spread of neo-liberal political and economic ideology and the proliferation of global capital have created new opportunities and challenges for cities everywhere (Sassen 2012). Within the urban planning discourse, it is generally assumed that globalization leads to the same type of transformations and urban development trends everywhere in the world. However, it cannot create a certain prototype for spatial development or a new spatial order for cities. Rather, it gives a variety of spatial patterns, also called "global urban forms". Recently, these forms have identified themselves spatially within a series of "mega-projects", their intensity being felt in today's global cities, north-American and west-European, but with a domino effect, especially in the cities situated at the periphery of these capitalist economies.

In the last two decades, we witness a renaissance and reinterpretation of "mega projects" within the global cities as an exclusive model for urban development (Swyngedow et al. 2004). In the European and American context, after a hiatus during the 1980s, many of these cities have responded to the economic pressure and the process of globalization through major projects and mixed-use developments to attain investment opportunities, building new CBDs for multi-national companies and new sites for living¹. Total global megaproject spending is assessed at USD 6-9 trillion annually, or 8 percent of total global GDP, which denotes the biggest investment boom in human history. Never has systematic and valid knowledge about megaprojects therefore been more important to inform policy, practice, and public debate in this highly costly area of business and government. It is argued that the conventional way of managing megaprojects has reached a "tension point," where tradition is challenged and reform is emerging (Flyvbjerg, 2011).

As a response to the crisis of the comprehensive plan as the classic policy instrument of the Fordist age, the large, emblematic project has emerged as a viable alternative, allegedly combining the advantages of flexibility and targeted actions with a tremendous symbolic capacity. Essentially fragmented, this form of intervention goes hand in hand with an eclectic planning style where attention to design, detail, morphology, and aesthetics is paramount. The emblematic project captures a segment of the city and turns it into the symbol of the new restructured/ revitalized metropolis cast with a powerful image of innovation, creativity, and success. And yet, despite the rhetoric, the replacement of the plan by the project has not displaced planning from the urban arena. In fact, the literature reveals that in most examples there is a strong strategic component and a significant role for planning. However, in the process, there has been a drastic reorganization of the planning and urban policy-making structures and a rise of new modes of intervention, planning goals, tools, and institutions.

1.1 GENESIS AND DEFINITION OF MEGA PROJECTS

After WWII, the Fordist state engaged in a series of "mega projects" for the restructuration of urban tissue, the efforts to create a modern society with express ways and high rise buildings. Jane Jacobs (1961 pg. 25), ironically named those efforts and the city: "radiant garden city beautiful". Surpassing these critics on the left, critics on the right argue that these developments are an unnecessary intrusion of the forces of the government and have led to unjustified expropriations of private property. (Anderson 1964) Overcoming the social movements of 1960-70s, the restrictions of the government and the decentralization associated with neoliberalism, these types of developments unwind, but they do not totally disappear (Altshuler si Luberoff 2003).

¹ Definition here of "mega projects" is a comprehensive one; it includes essentially extensive costs and procedures, reconstruction, regeneration, rehabilitation. The implementation expands within a long period, involving a multitude of actors from different milieus- public/ private. Still, a fundamental condition is the change of functions of the existing territory.

Megaprojects are large-scale, complex ventures that typically cost a billion dollars or more, take many years to develop and build, involve multiple public and private stakeholders, are transformational, and impact millions of people. Therefore, these developments are not just magnified versions of smaller projects; rather they are a completely different breed of projects in terms of their level of aspiration, lead times, complexity, and stakeholder involvement (Flyvbjerg, 2011).

Large-scale projects have a calamitous history of cost overrun: since the past 70 years, one out of nine projects have cost overrun. Flyvbjerg calls this phenomenon as the "iron law of mega projects", representing over budget and overtime. The "break-fix model" of megaproject management it introduces as an explanation, therefore, these kind of developments are "easy to begin and difficult and expensive to stop" (White, 2012; also Cantarelli et al., 2010; Ross and Staw, 1993, Drummond, 1998).

One may argue, of course, as famously done by Hirschman (1967a: 12-13) with his theory of Hiding Hand, that if people knew in advance the real costs and challenges involved in delivering a large project, "they probably would never have touched it" and nothing would ever get built. Sawyer (1952: 199, 203) – in a study of early industrial infrastructure projects that he called a work "in praise of folly" – similarly identified what he called "creative error" in project development as, first, "miscalculation or sheer ignorance" of the true costs and benefits of projects and, second, such miscalculation being "crucial to getting an enterprise launched at all."--- "creative error" was key to building a number of large and historically important projects like the Welland Canal between Lake Erie and Lake Ontario, the Panama Canal, the Middlesex Canal, the Troy and Greenfield Railroad, and early Ohio roads

However, these theories are in fact corrupting for megaproject thinking, both academically and at policy level. An optimistic cost estimate is low and leads to cost overrun, whereas an optimistic benefit estimate is high and results in benefit shortfalls. Thus errors of estimation do not cancel each other out, as Hirschman would have it; the exact opposite happens, errors generally reinforce each other. Flyvbjerg (2009: 352) call this "inverted Darwinism", i.e., the "survival of the unfittest".

The concept- mega project- assumes two main typologies: major constructions with symbolic value for the city (Hamnett si Shoval 2003); huge development sites, complex in result (mixed-uses, smart technologies etc.) (Orueta si Fainstein 2009)

The existing new wave of mega projects does not represent a disappearance of old types of large-scale urban interventions, the major infrastructure (dams and reservoirs, river diversions, power plants, etc.), which are closely related to urban development. These, together with the construction of highways, tunnels, high speed trains are connecting the urban areas (Naredo 2006) and are part of the contemporary development model.

Depending on the type of the intervention, the new mega projects can be included in one or more of the following categories: urban waterfront regeneration; re-use and transformation of industrial sites¹; construction of new transportation infrastructure or extensions of the existing ones; renewal of old city centers and close neighborhoods; usually for attracting the middle-upper class (Zukin 1998; Loures 2001);

But what drives the megaproject boom described above? Why are megaprojects so attractive to decision makers? The answer may be found in the so-called "four sublimes" of megaproject management: political (megaprojects are manifest, garner attention, and lend an air of proactiveness to their prooters); technological (is a term variously attributed to Miller (1965) and Marx (1967) to describe the positive historical reception of technology in American culture during the nineteenth and early twentieth centuries, but Frick (2008) introduced the term to the study of megaprojects and here describes the technological sublime as the rapture engineers and technologists get from building large and innovative projects with their rich opportunities for pushing the boundaries for what technology can do); economic (given the enormous budgets for megaprojects there are ample funds to go around for all, including contractors, engineers, architects, consultants, construction and transportation workers, bankers, investors, landowners, lawyers, and developers. jobs etc); aesthetic (is the pleasure designers and people who appreciate good design get from building, using, and looking at something very large that is also iconically beautiful, like SanFrancisco's Golden Gate bridge or Sydney's Opera House)

¹ Generally, these include residential areas with a more or less office space, hotels, malls, conventions center, museums etc.

There is a striking physical similarity of the development of space- involvement of innovative design forms and international architects; and of the strategies and schemes of involving the private sector- the orientation towards real estate trends. These aspects are stated to be passive towards the geographic and political context. However, mega projects differentiate themselves by the way they combine social and environmental goals with the economical ones, the planning process and impact, reflecting in the same time the level of commitment that the host city has towards the concept of social equity (Fainstein 2009).

Hirschman (1995: vii, xi) calls such projects "privileged particles of the development process" and points out that often they are "trait making," that is, they are designed to ambitiously change the structure of society, as opposed to smaller and more conventional projects that are "trait taking," i.e., they fit into pre-existing structures and do not attempt to modify these. The framework of "exceptionality" associated with these initiatives favors a more autonomous, if not autocratic, dynamic marked by special plans and projects that relegate statutory norms and procedures to a secondary and subordinated place. "Exceptionality" is a fundamental feature of the new urban policy, based on the primacy of project-based initiatives over regulatory plans and procedures. These changes involve, as stated before, among other things, the emergence of new policy tools, actors, and institutions, and they have important consequences for urban policy-making in general and for local democracy in particular, considering the increasing inequality in access to decision-making.

These kind of projects often take place within fragmented and entrepreneurial forms of governance (Harvey 1989; Healey 1997; Gordon 1997a, 1997b; Feldman 1999; Feinstein 2001; Granath 2005; Butler 2007) represented by public-private partnerships, in a societal environment of increased capital mobility and inter-urban competition (Malone 1996). Hence, it is argued, that mega projects have been examples of new governance styles and policy targets, but also object of intensive local planning debates and conflicts based on different actors (authorities, planners, residents, environmental groups, developers, etc.) holding an equal number of views (Hoyle, 2002) which are often difficult to reconcile. Brenner and Theodore (2004) argue that an important analysis aspect to identify the impact is the role of the state in these kinds of interventions (provision of subsidies, land or special treatment in the tax, etc.) and the level of involvement and its loyalty towards the goals for the public.

2 URBAN WATERFRONT REGENERATION IN ISTANBUL: HALIC/ THE GOLDEN HORN

2.1 CONTEXT: PLANNING IN GLOBAL ISTANBUL AND DYNAMICS OF URBAN REGENERATION

Since the 1980s in Turkey's milieu, national policy intended to make Istanbul the focal point of a neo-liberal strategy approach to integrate the Turkish economy with global markets. This was visible also in the accelerating transformation of urban space, making it the showcase of the country's new era of internationalism (Enlil 2011; Uzun 2010, Çınar, C et al, 2006; İnalÇekiç and Gezici, 2005; Keyder, 2005; Karadag, 2010). Under this context, during the last thirty five years, investments have been located within the city in order to change the local landscape pushing it towards the global city image. Therefore, the city has been expanding with multiple mega-projects and naturally, a strong representative symbol of the global, emerged: waterfront regenerations in the valuable "soft" space of inner city usually modifying natural coast profiles.

In order to understand the planning processes of the regeneration of Halic's waterfront, a reflection is done upon the peculiarities of Istanbul's urban regeneration policies and the institutional framework at city and national level that have facilitated it. Urban regeneration is steered as a tool for development within a special legal framework (Law of Conservation- Law No. 2863) and while the purpose of the projects seem to be in the name of upgrading the built environment and improving the living conditions of the poor, the top-down approach, reduce the projects to just transformation of physical space and neglecting the social, economic and environmental dimensions, which along with the unwillingness of government to allow grassroots participation in the planning process become the focus of discontent and protest.

2.2 DECISION MAKING PROCESS: LATEST URBAN WATERFRONT DEVELOPMENT ALONG HALIC/ THE GOLDEN HORN

The first attempt to officially create a plan to regenerate the area of Halic, Camialti and Taskizak shipyards is in 2011, when all three shipyards come under the authority of Istanbul Metropolitan Municipality (IMM). The final goal is to create a comprehensive urban regeneration project and reconnect Beyoglu district with its waterfront along the Halic.

Being declared as a Conservation Area, the development is managed by the Department of Historic Environment Protection (DHEP, in Turkish Tarihi Cevre Koruma Mudurlugu is the representative body of Istanbul Metropolitan Municipality in the areas declared for conservation. It is empowered by the Decision No. 313 in 04/06/1999 and has a management role within the project, making sure that the project it is accomplished in line with the requirements of the Law of Conservation), which focuses on the restoration of the historical buildings on the site and change of the current functions in new ones according to the needs of the citizens. DHEP designates through a bid the task of making and designing the plans to Istanbul Metropolitan Planning (IMP- Bimtas S.A., is a semi-private company and also a research center for Istanbul Metropolitan Municipality. It has long lasting collaborations with academia, neighborhood associations and wide experience in planning in Istanbul, being also it is the company that made the last Master plan of Istanbul 2009 and many other important development projects).

In line with the requirements of the Law of Conservation, the Conservation Board No. II is added to the decision-making process. This Board is linked directly and represents the interest of the Ministry of Culture and Tourism, has great power on the project's outcomes, evaluating the plans and being able to cancel them.

The plans done for a preliminary project (in Turkish "avan proje") start on January 2011 and finish in June 2011, but without any request for participation from the citizens side and no reflection on the surrounding neighborhoods. The proposed functions for the area are: cultural, recreational, social services and commerce functions and are approved by the Conservation Board No. II in July 2012. The next step in planning process after the preliminary project, according to Main Law of Construction (Law No.3194), is the implementation project (in Turkish: "uygulama projesi") which did not continue with all three shipyards. Here a shift in the governance forms of the project changes the planning process along with rising concern on the project's future outcomes: just one of the shipyards went further to the implementation phase under the name of Halic Shipyard Conservation Project, when the area of the other two shipyards is being privatized. Holding the ownership of the land of Camialti and Taskizak shipyards, the Ministry of Transport Maritime Affairs and Communications (MTMAC) decides to withdraw the project from the authority of IMM.

In 2013, a new urban waterfront regeneration project is declared for privatization and classified by the Prime-minister Tayyip Erdoğan as: "miraculous project" ("muhteşem proje") which appears with the name: Halic Port Project. The urban waterfront regeneration project is initiated by the MTMAC, under the Law of Privatization, known as Built Operate and Transfer (Yap Islet Devret- Law. No. 3996) and is approved by Higher Council of Privatization (HCP); this also being possible because, according to the Law of Privatization, since 1994, the authority to make and approve plans concerning estates included in the privatization program was transferred from local authorities to the HCP.

The area is given to auction and is announced in the Official Paper (Resmi Gazete, page 28646) on 13 May 2013. The tender is taken on 2 July 2013 by "Sembol International Investment", "Ekopark Tourism" and "Fine Otelcilik Girişim Group"(Sembol Uluslararası Yatırım-Ekopark Turizm-Fine Otelcilik Girişim Grubu) for 49 years: 4 years for building and 45 years for usage. The requirements of the project are given beforehand to the investors, being decided by the MTMAC and approved by the HPC. These are: "two yacht ports, two five stars hotels, small shops, offices, museums, culture and a congress center". Taking into account these foreseen outcomes of the project, it can be argued that this development is not designed for the interest of all citizens of Istanbul or the neighboring community, but rather for tourists and high-middle income class. The promised outcomes of the project are presented in the media through the political discourse as the only information channel for citizens and therefore raised a big wave of criticism from academia and other expert's side, questioning the way decision is being taken.

Therefore, the planning process is lacking transparency and the Privatization Law gives central government power to privatize public land without any consideration of the civil society. Also local municipality has been taken out from the planning process and also the 1/1.000 plans that should be done

for the Camialti and Taskizak shipyards are developed by the private investor, this raising questions concerning the conservation of the shipyards.: The only actor from the government side having decision power over the outcomes of this project remains the Conservation Board No.II.

In contrast, the area of Halic shipyard is developed further by IMM within the Halic Shipyard Conservation Project. Major actors in the planning process here are: IMM, the initiator of the project, owner of the land and also the provider of the finance in realizing it; the DHEP managing the project, having mainly the responsibility to assure the conservation and restoration of the historical monuments in the area; the Conservation Board No. II, representative of Ministry of Culture and Tourism, having also the main responsibility to assure the conservation and restoration of the monuments; IMP in charge of the plans and design of the project and also IDO (Sehir Hatlari) - a private company of public transport on water, having currently the tender over the area of Halic shipyard.

In the interviews with representatives from the planning department of IMP, the team planning Halic Shipyard Conservation Project, it is revealed that the outcomes of the project will take into consideration the previous suggestions and that the project will respect the 1/1000 Plans of Beyoglu in terms of conservation of the shipyards, along with the recommendations of implementing cultural and recreational activities. Moreover creation of green spaces is emphasized, the vision being to open the waterfront for the broad public, the citizens of Istanbul. Proposed strategies concerning the development are: "conservation of the buildings, enhancing the transportation in the area, introduction of recreational and exposition areas, bringing the city to the waterfront, protection of green spaces and ensure the participation of the local people of the area."

However, the project contains no analysis of impact assessment such as: environmental, economic or social, this showing the physical focus of urban waterfront regeneration in planning, putting in doubt the success and purpose of this project. There is also no information provided for the broader public about the project or the request for any collaboration from the citizen's side. The chance to challenge decision making is possible at the end of the project. As all projects made by municipality, also this one is presented to the community at the end of the planning process, plans are hanged in the Istanbul Metropolitan Municipality building and within 30 days the interested parties have the right to contest the project through court. This leads to questioning the outcomes of the project because of this type of non-transparent planning process that leaves no input from the citizen's perspective.

Therefore, as seen and criticized in other examples of projects along the Halic, the project could also potentially enhance existing socio-economic problems, a matter that will be presented in the following part of the article, by analyzing the neighboring community in rapport to the project.

Looking at the current state of the transformation of the three shipyards, there are two urban waterfront regeneration projects with different governance forms. The area of Camialti and Taskizak shipyards is under the authority of a private investor and it can be argued if the project will benefit the broader public of Istanbul. The area of Halic shipyard remained under the authority of the government, but the planning process is un-transparent and the project is not shared or questioned within the interested public. In an attempt to compare the projects from the perspective of the information available, paradoxically, the Halic Port Project is much more known by the public than the project made by the municipality because of the exposure in the media. However there is a major gap of good quality information for citizens regarding both projects.

This was reflected in the questioners conducted with the neighboring community, academia, planners from Istanbul Metropolitan Planning and citizens participating to forums organized by the representatives of the resistance to the regeneration of the shipyards. An urban social movement appeared on 23 August 2013 under the name of Halic Resistance (Halic Dayansimasi). Other opposing parties are:

Bedrettin Neighborhood Association, Chamber of Architects, Chamber of Urban Planners, Assembly of Architects and Engineers, Chamber of Shipbuilding Engineers, Academia and other urban social movements.

2.3 THE STRUGGLE OF THE NEIGHBORING COMMUNITY: BEDRETTIN NEIGHBORHOOD

Bedrettin Neighborhood is a low income neighborhood (according to median monthly household income 2010) at the shores of Halic, in Beyoglu District. It was strongly connected to Halic, Camialti and Taskizak shipyards, being occupied by blue collar workers. Therefore, the neighborhood was much affected by the clearance process done by mayor Dalan in 1983, the first regeneration along Halic, its current problematic economic condition being outcome of the forced deindustrialization process of that time. Today, approximately 1500 people live in Bedrettin Neighborhood and are mostly divided as retired workers from the shipyards, people coming from Anatolian side of Turkey during the industrialization period and a considerable group of roma minorities.

Bedrettin Neighborhood was declared as Renewal Area in 2005 and, according to Law of Renewal, the neighborhood will go under a process of regeneration which will put in danger of displacement the poor citizens. Although 80% of the citizens living there, own their land, the houses built are not in good condition, being classified as "gecekondur", squatter housing, and have to be renewed and improved for their safety, this being a hard task for the majority of the community which is poor.

The reason for opposition, from the citizen's perspective was not only the fear of displacement, but also the difference between the new proposed plans and their actual needs. In the questioners conducted during the meetings of Halic Resistance, besides the fear of displacement answers also as: "to learn the truth", "because this project is being used strategically against us" were given.

Although, the citizens of Bedrettin Neighborhood are against the Halic Shipyard Conservation Project, outcomes of the questioners regarding what they would need in the future development were: green spaces, culture and education facilities, keeping the working shipyards, health facilities. In the discussions with the community, especially with the group of mothers, mostly staying home and taking care of their children, the need of closer public space and green areas was emphasized. It was found that families go to other parks along the Halic and make barbeques or just bring their children to play, this being the only recreational activity for these families. An intriguing vision of the children is the one of the "fisherman", a symbol of the waterfront of Istanbul which should not be blurred in the landscape of waterfront development for global economic gain given by projects in name of tourism and consumption.

Taking into account the vulnerable position of the neighborhood in terms of economic situation, the ongoing gentrification process at Halic's waterfront and the renewal project in the agenda of the government, it can be argued that Halic Shipyard Conservation Project will contribute to this picture considerably, creating social and economic impacts on the community. The community of Bedrettin Neighborhood is an important actor being the most affected by the project, but also by its potential to give inputs to the project. Due to the lack of consideration of this neighborhood in the planning process the true benefiting outcomes of the project will not be achieved.

2.4 GOVERNANCE DYNAMICS AND RELATIONSHIPS AND POSITIONS OF THE ACTORS

Relationships of the actors are "crucial in understanding the direction of the planning processes." (Nuissl and Heinrichs 2010). The relationships were established as outcome of the interviews conducted by the researcher and through participatory observation. When mapping the relationships, there are two clusters of actors that do not come together, this situations are reflected on the clash of interests and gap between civil society representatives and the government. One group represents the actors involved directly in the planning process and the other represents the strong opposition. The first ones has hierarchical vertical relationships by territorial responsibility of different governmental bodies and market based relationships by contractual agreements. The other group in opposition to the project is represented by collaborative and horizontal relationships of the non-governmental organizations, social movements and other civil society representatives.

Analyzing the actors in opposition and the horizontal network-like relations, overlapping interconnections among them can be observed. The boundaries between these actors are hard to be defined as they cooperate and interconnect with each other rapidly, using innovative means of communication in exchanging of opinions and in deciding common action. When the main actors from opposition, and ones involved in the planning process are considered for their relationship, there is a long lasting conflict between them which resulted from the interviews conducted with representatives of both sides, this

1 INTRODUCTION

The decisive impact of mankind on ecology from global to local scales has resulted in describing the current epoch as 'Anthropocene' (Crutzen and Stoermer, 2000: 17). In this sense mankind is considered 'a major geological force' (Crutzen and Stoermer, 2000: 18) which will continue to shape natural processes in the millennia to come. Thus, developing sustainable and inclusionary systems (Sachs 2015: 9) becomes 'one of the great future tasks of mankind' (Crutzen and Stoermer, 2000: 18).

Global development and environmental issues such as famine, illiteracy, the lack of access to clean water as well as global climate change, soil degradation and deforestation are two sides of the same coin (WCED,1987: 12-16): They are the result of spatially and temporally short-sighted actions and decisions (Nelson, 2010: 497) which have led to resource intensive practices, processes and systems that in sum exceed natural regeneration rates and result in megatrends that threaten human lives, biodiversity and ecosystems (WBGU, 2011: 33-45). Current trends of energy production and consumption and 'the enormous and continually growing use of natural resources' (Haberl et al., 2011: 5) represent an unsustainable societal trajectory which will further increase the speed and magnitude of climate change (Haberl et al., 2011: 5-8).

It becomes evident that sustainable development cannot be a question of iterative changes and technical adaptation to a changing natural environment. Rather, it requires the transformation of major societal systems and processes such as production and consumption, mobility and land-use patterns as result of an approach shared and promoted by the majority of current society. In other words, a transformation to sustainability is required. In order to realize this demand for fundamental societal change, the transformation has to occur in the three pillars our society is based on: energy systems, urban areas as main emitters of greenhouse gasses and global land-use systems (WBGU, 2011: 48) which can also be identified as the main fields of intervention to pursue broad societal change (WBGU, 2011: 265).

The spatial patterns of cities and city regions are urban systems which consume vast amounts of land and resources that exceed natural regeneration rates while degrading the environment. Furthermore, the vulnerability of cities and regions to climate change impacts and other biophysical and societal stressors such as the degradation of ecosystems and poverty (IPCC, 2014: 182) are consequences of long existing unsustainable societal structures and processes.

The concept of Green Growth intends to promote sustainable development through a more efficient use of natural resources and the application of green economies and technologies. It is considered to be a suitable approach to practically promote and implement sustainable development. This is reflected in

existing policies and strategic approaches on supra-national, national and sub-national levels. As such the concept of Green Growth unfolds considerable impacts when it comes to spatial development especially on regional levels which functions as crucial levels of implementation. Therefore, the current praxis of Green Growth strategies and conceptions nowadays influences urban and regional development. This raises questions regarding the impacts of Green Growth strategies on spatial development and more specifically on their ability to transform cities and regions to sustainability.

This paper aims to critically examine the correlation of Green Growth with sustainable development analysing their overlaps, focuses and effects on societal transformation processes. This is carried out by considering the required transformation process at the theoretical framework, and by elaborating how cities and region, the key to implementation, can be part of such processes.

Following the introduction, the concept of sustainable development as a normative concept to guide development is explored in chapter 2. The dimensions of sustainability and possible paths to realize sustainable development are also discussed. Then, in chapter 3 the concept of Green Growth as a path to implement and promote sustainable development is examined and current methods to practically implement Green Growth at the policy level are illustrated. Against this background, chapter 4 discusses the suitability of Green Growth as a practical approach to implement sustainable development. Focuses and weaknesses of existing Green Growth implementations are identified. The importance of the special level to implementation is discussed. In chapter 5, the theoretical understanding of transition theory and the idea of societal transformation are introduced to further enrich the discussion on processes of societal change to a more sustainable state. Transition theory is used as a theoretical basis to conceptualize transformation. Furthermore, the relevance of space, e.g. city or region, is introduced with regard to transformation and implementation. This allows discussing the relation between Green Growth and transformation in the final chapter 6 and to derive questions for further research.

The paper is based on desktop research and analysis of scientific papers, reports, documents of international institutions and think tanks and monographs covering the topics Green Growth, Green Economy, Sustainability and Sustainable Development. Scientific documents of relevant institutions such as the OECD and EU were included in the analysis. The paper discusses the concept of Green Growth on a meta-level based on the document analysis.

2 SUSTAINABLE DEVELOPMENT

Sustainability and sustainable development are words that are used a lot in politics, economy and society to mean any number of different things from 'slightly less harmful to the environment', to 'a net plus for the environment'. There seem to be as many different meanings of the term as there are organisations that use it. However, if we are to successfully discuss sustainable development and sustainability in this paper, it is necessary to set the boundaries of what we are discussing. In this chapter, we will first define and discuss the meaning of sustainable development. Following that, a similar discussion of the term sustainable development occurs in 2.2. Finally, the possible paths to sustainable development are looked at in 2.3.

2.1 SOME CONTEXT

The UN report 'The Limit of Growth' (1979) thematised the planet's ecological boundaries and the risks associated with these and crucially shaped the concept of sustainability. For the first time unchecked resource consumption and increasing environmental pollution were shown in relation to continuing population growth and unfettered economic growth (Meadows et al., 1972). This link between the economy and economic development and the environment was emphasized by the World Conservation Strategy in 1980. This formulated the need for an integrated approach to sustainable development (International Union for the Conservation of Nature 1980 cited in Hardy and Lloyd, 1994: 774). Such an integrated perspective leads to the recognition of the environment as the foundation for living and economic development. This key-thought was emphasized by the German WBGU (1994: 186). Guiding on this idea, the WBGU stated in 2011 that economic development within planetary boundaries means preserving natural resources with regard to their respective regeneration times. The regeneration capacity of the ecosystem is thus the key-element of sustainability.

The increasing globalisation of environmental problems, and thereby the time gap between cause and effect, requires complex and inter-generational problem analysis (Paech, 2006: 45). This approach was taken for the first time by the Brundtland Report in 1987 as concept of sustainable development with the definition: 'Sustainable development [is] an approach to development that 'meets the needs of the present, without Compromising the ability of future generations to meet Their Own needs' and highlighted the potential role of market mechanisms in securing an integrated approach to economic change and the environment' (Hardy, Lloyd, 1994: 774).

The model of sustainability must be understood as a 'contested concept' (Jacobs, 1999 cited in Heilmann, 2015: 50). The concept of sustainability only takes on concrete form and becomes problem relevant with discussion and argument (Heilmann, 2015: 50). This is because it's a holistic concept, which integrates sectors across borders and generations and emphasizes the interconnected nature of the economic, social and environmental aspects of any action. This suggests that sustainable development as a concept will also require discussion to be relevant, the observation of spatial and temporal dimensions, an understanding of the world as a system (van Zeijl-Rozema, 2011: 11). This system view is to be applied to different sized spatial and temporal frameworks. The system can be described as a complex adaptive system with characteristics such as a 'large number of nonlinearly interacting components, scale multiplicity in structure and dynamics, and self-organizing capacity' (Levin, 1999 cited in Wu, 2013: 1004). Taking the world as a system implies that smaller spatial areas can be viewed as sub-systems in the global systems context. Each spatial area can be viewed separately using the concept of sustainable development, but is always connected to the global system level. Sustainability at the local level can therefore not be viewed without an understanding of its place in the global sustainability milieu. Although sustainable development is grounded in the material and spatial needs of society and the spatial context is vital for specific applications (Morgan, 2011: 88), these always need to be considered as part of the global environment.

Sustainability can therefore be understood as a forward-looking process of social learning, research and design according to best usage-patterns (Lucas 2000: 19). Sustainable development can be considered as a (spatial) modernisation program (ibid.: 17) and evolutionary development of potential. This interpretation of sustainable development is based on the theory of ecological modernisation as developed by Huber (1982) and Jaenicke (1985) (Gibbs, 2000: 11). According to Huber (1982) there is need of a change in the relationship between the economy and the environment if a transition from an industrial society to an ecological organisation of production is to occur (Gibbs, 2000: 11). On the one hand, the concept of ecological modernisation can be used as a theoretical framework for the analysis of changes in key social institutions in the context of solving ecological crises, and on the other hand as a pragmatic political program, which is intended to produce a change in environmental policy (Gibbs, 2000: 12). This analytical framework approach is based on the concept of continuous learning processes. The concept of ecological modernization includes three core ideas (Gouldson and Murphy, 1996, Huber, 1985 cited in Gibbs, 2000: 12):

- A restructuring of production and consumption in relation to the environmental objectives: Use of clean production technologies and decoupling of economic development from resource use (input), resource use and emissions.
- The economization of ecology: Installation of an economic value on the nature and evolution of structural tax reform
- Connection of environmental policy objectives with other policies.

According to Hajer (1993 cited in Gibbs, 2000: 12), interpretations these three core elements of ecological modernisation fall into two main categories: first, the techno-corporatist approach with the 'economisation of nature and elitist decision-making' and second, a stronger understanding of sustainability, which includes not only considers changes in production and consumption, but also in democratisation, redistribution and social justice (Gibbs, 2000: 12). The practical implementation of sustainability can thus be viewed as a process of searching for sustainable utilization concepts, with the economy and economic processes seen as a key driver.

To enable further discussion, an understanding of the distinction between sustainability, development and growth is needed at this point. Holling (2001) defines sustainability as 'the capacity to create, test and maintain adaptive capability. Development is the process of creating, testing, and Maintaining opportunity ...'sustainable development', thus refers to the goal of fostering adaptive capabilities and creating

Figure 02: Three dimension and Interdependencies
(own presentation modified and based on Hansen, 2010: 23; Campbell, 1996: 298)

The three dimensions in the context of this spatial dependence can be understood as follows: The economy can be summarised as being local production, consumption, distribution, innovation, the labour market and new industries, around which local and regional competition occurs (Campbell, 1996: 297). The term society sums up, for example, communities, organisations and labour unions. In a spatial context a wide range of conflicts can arise between the society and the economy spheres, such as over the distribution of services or among different social groups (ibid.: 298) but also about property distributions and resulting segregation. The term environment includes all natural goods and resources. In the context of the economy, spatially differentiated material flows and resource usages lead to a resource conflict. This conflict exists because of the difference between the 'economic utility [of resources] in industrial society and their ecological utility in the environment' (ibid.: 299). This conflict is also closely linked to the growth-equity conflict (ibid.). This is the conflict between resource use to improve living conditions and resource protection in order to preserve the environment, although Vazquez-Brust and Sarkis (2012: 8) dispute whether there is a trade-off between societal well-being and environmental quality. Campbell (1996) defines economic growth as the basis for progress and development, and thus a force for social justice and environmental protection. His equal positioning of the three dimensions of sustainability is based on this argument. The thesis that economic growth measured by GDP does not necessarily imply improvement and development has already been discussed in section 2.1. GDP does not consider quality and potential.

2.3 APPROACHES TOWARDS SUSTAINABILITY

Sustainability as it is understood today is the result of a discussion on the environment which has gradually progressed over decades. According to Healey and Shaw (1993: 770 f.) there have been 'five environmental discourses' in the past century:

- A welfarist utilitarian approach (from the 1940s onwards): Nature as a resource to be used. Conservation linked to moral obligation to maintain an 'ideal' British landscape.
- A growth management approach (from the 1960s onwards): Conserve natural resources for exploitation to enable economic growth and technological progress.
- An active environmental care and management approach (from the 1970s onwards): Enhancement of natural resources linked to economic benefits of improved environmental quality.
- An asset management approach (from the 1980s onwards): Natural resources to be improved as part of an enhancement of 'asset value'.
- An adoption of the rhetoric of sustainable development (from the 1990s onwards): Planning limited to some extent by environmental considerations based on concern of human impact on nature.

The different attitudes and ways of looking at the environment and natural resources over the last 80 years progress from a moral consideration of a nature that should be tamed (from the 1940s onwards), towards nature as a resource for economic progress and technological developments. Nature is consistently and continuously seen as a resource, which is used extensively, despite ecological recovery times. Ecological regeneration ability is not respected and preserved in practice. This resulted in current global economic and consumer power exceeding the planetary limits by a factor of 1.5 (Global Footprint Network, 2014).

Welzer describes this economic and consumer power as a phenomenon where the system consumes its own conditions for existing (Welzer, 2013: 93). If we intend to reach a point where resource use does not destroy the environment, such a fundamental transformation to sustainability would have to adjust global economic and consumer power to be within planetary boundaries (factor <1).

The question is therefore what visions and means of action are available to meet the objectives of sustainability. Hansen (2010: 21) and Paech (2006) distinguish between two perspectives:

- The qualitative or 'technical' dimension
- The quantitative or 'cultural' dimension.

The qualitative dimension involves technical processes and the ways in which a particular need is satisfied. Going this route would involve reducing or ideally elimination the effects of economic growth on the environment by means of technical (e.g. increasing efficiency), process (e.g. closed cycle production) or systems innovations (e.g. considering sustainability risks in innovations management) (Hansen, 2010: 21). The growth paradigm is not questioned in this regard and the focus is completely on the availability of possibilities for adapting technical and organisational means (Paech, 2006: 48). This results in a problem solving focus on technical innovation without changing societal aims or values. 'Eco-efficiency' follows this line of argument with the aim to decoupling of economic growth and resource use (Boulanger 2010: 4). This approach has been criticised as effectively 'business as usual' with eco-products, thereby overwhelming resource savings (ibid.). The technical or qualitative dimension route follows the principles of efficiency and consistency. Efficiency is the increase of throughput rather than output (Nejkamp et al., 1991: 15), which involves minimising resource-use and innovating in the face of scarcity, which is a key principle of capitalism (Stigler, 2008). Consistency is the principle of changing the quality of material flows to the point where they are compatible with natural resource cycles (Gerlach, 2003:6). Harmful material flows should be replaced or made a closed-loop use of resources, in which all resources going into a product or service can be reused at the end of the product lifecycle. According to Schneidewind et al., (2013: 10) however, these dual principles alone have yet to show that a significant reduction of resource demand is possible while maintaining current paradigms.

The quantitative dimension or social route focuses on social aspects with regard to the extent of need (Hansen, 2010: 21). This route is linked to criticism of the growth paradigm and requires an adjustment of aims, following the principles of sufficiency (Paech, 2006: 50-52). Sufficiency is based on the 'how much is enough' strategy (Gerlach, 2003: 5) and suggests we need to adjust our consumption pattern towards what we need and away from consumption for consumptions sake, for example by replacing products with services (cars to car sharing, etc.) (Hansen, 2010: 21). Paech (2006: 51) sums it up with the following sustainable lifestyles aspects:

- What – the range of products available and the question of sustainable alternatives
- How – consumption routines and the possible replacement of products with services
- How much – how much do we need and the level of consumption

The qualitative path of following eco-innovation to solve environmental problems can be seen as an adjustment of the economy to suite ecological capacity. The quantitative route of changing lifestyles and consumption patterns will result in completely stopping consumption of some products. A great deal of power to create change and influence the markets rests with consumers in their ability to choose alternatives, through changes in patterns and reflexes as well as a desire to know more about each product.

The German Federal Environment Agency stated in 1997 that society's consumption practices are responsible for 30-40% of all environment problems (UBA, 1997: 221). This means our consumption practices are closely linked to our sustainability deficit. Given the above mentioned failure of the qualitative path of efficiency and consistency to reduce resource demand with its inherent environmental impact, the quantitative path also needs to be trodden to deliver sustainable development. So 'sustainable development [will] involve changes in existing patterns of consumption and investment in order to acknowledge the environmental dimension to economic and social welfare' (Pearce et al., 1989 cited in Hardy and Lloyd, 1994: 779). The challenge is to combine the ideas of sufficiency, efficiency and consistency (Gerlach, 2003: 6) with an attractive and dignified lifestyle, without moralising.

3 GREEN GROWTH

In this paper, the key concepts of Green Growth are discussed and how well Green Growth fits with the ideas of sustainability. The following chapter starts by showing the range of concepts currently being considered as possible solutions to current ecological problems in section 3.1 and where Green Growth fits within this range of concepts. Following on from this in section 3.2, green growth is examined in more detail and its key concepts defined. We look at the ways in which the concepts of Green Growth are promoted in policy in section 3.3. Finally, in section 3.4, Green Growth is critically examined based on its claims and sustainability criteria.

3.1 WHY GREEN GROWTH IS OF RELEVANCE

In the last few years, a number of concepts and approaches have been discussed and developed to deal with the increasing ecological and climate problems we face. Meyer et al. (2012: 7) distinguishes between four approaches as named below: growth orientated welfare (1.) also termed Ecological Modernisation – for example the Europe 2020 strategy or Green Growth concepts as proposed by the OECD and UNEP. This is based on continual economic growth combined with a ‘greening’ of the economy. A second proposal can be called comprehensive transformation strategies (2.) – e.g. the Great Transformation (Heinrich-Böll-Stiftung, WBGU, Vision 2050 by WBCSD). These additionally propose a comprehensive societal change and are critical of continued economic growth. Proponents’ arguments are based on ecological and preservation imperatives and follow the path of sustainable development with its quantitative and qualitative dimensions. A third approach can be called Zero-Growth (3.), as proposed by Jackson (Prosperity without growth 2009) and Victor (Managing without Growth). This approach completely drops the economic growth paradigm on the basis that continued growth cannot and should not be allowed. The fourth concept is De-growth also known as Décoissance (Latouche 2010, the term was originally introduced in 1979 by Jacques Grinevald and Ivo Rens) or the Post-growth Economy (4.) (Paech, 2009). These go even further and propose that the economy needs to shrink for the common good, because if it does not, we will destroy the basis for humanity to exist (Meyer et al., 2012: 7). All four concepts have in common that they more or less focus on the economy as the main area of action. A new type of economy is required, ranging from slightly greener to completely transformed, with associated societal changes.

With regard to these four approaches, many international and political bodies seem to consider the concept of Green Growth or of Green Economy to be an adequate route to take, by transforming the economy to meet climate and ecological goals. Consequently, this concept is given much consideration in policy. A plethora of political programs and papers have adopted the concepts of Green Growth, for example the Europe 2020 strategy or the EU 2030 policy framework for climate and energy (BMUB, 2014). Institutions that have published papers on green growth include the OECD, the World Bank Group, the Global Green Growth Institute, UNEP, the UN, Green Growth Leadership and the International Chamber of Commerce (ICC). The United Nations Environment Program (UNEP) developed a Green Growth program for the Far East with a focus on ‘environmentally sustainable economic progress to foster low-carbon, socially inclusive development’. Equivalent concepts amongst European states go under the name Green Economy (Vazquez-Brust and Sarkis, 2012: 7).

The Organisation for Economic Co-operation and Development (OECD) is one of the main proponents of the Green Growth concept and actively pushes for the acceptance of Green Growth in politics, with the result that most Green Growth political agendas are based on OECD concepts. In 2005 the OECD called upon its members to develop coherent policy for environmentally friendly growth (OECD, 2005 cited in Shim, 2009: 3). In 2009 the OECD started its Green Growth initiative and responded to the 2008 financial crisis with its Green Growth strategy. As part of this, the 34 OECD member states signed a memorandum for environmentally friendly growth with the aim of mitigating the crisis and stimulating economic growth (Federal Statistical Office of Germany, 2013: 8). Thus the green, environmentally friendly growth concept is also promoted as a solution to the financial crisis in politics.

The fact that so many institutions are considering the concept shows a change in thinking amongst economic decision makers (Meyer et al., 2012: 13). In the following chapters we will examine the now widely accepted Green Growth concept and analyse how well it meets its claims of sustainability.

3.2 DIMENSIONS OF GREEN GROWTH

Green Growth is a term that has been used to describe a number of different concepts in recent years. From Green Economy (UN, 2008) to Low Carbon Economy, from the Green New Deal (Think Tank New Economics Foundation, 2008) to growth strategies such as green investment, Green Growth covers a spectrum of ideas (Prognos, 2014: 6). The basic premise of Green Growth is to improve the economy by increasing resource productivity to the point of (eventually) decoupling growth from resource use. The concept is based on the theory that resource use and environmental damage can be decoupled from economic growth and that environmental protection offers economic opportunities (SRU, 2012: 9).

The Green Growth idea was originally based on the concepts of ecological modernisation (Bina, 2013: 1033). Ecological modernisation proposes to support social and technical innovations that allow the combination of economic growth and ecological sustainability. The concept implies a 'greener consumption and lifestyles, eco-efficiency and dematerialization' (Vazquez-Brust and Sarkis, 2012: 4). Most political papers and definitions therefore have an economical and industry outlook and barely distinguish between Green Growth and the Green Economy. The OECD, for example, describes green growth as ' [...] promoting economic growth while reducing pollution and greenhouse gas emissions, minimising waste and inefficient use of natural resources, and maintaining biodiversity. Green Growth means improving health prospects for populations and strengthening energy security through less dependence on imported fossil fuels. It also means making investments in the environment a driver for economic growth' (OECD, 2012). The indicator set proposed by the OECD to measure green growth progress amongst its member states highlights the fact that resources and technology are the focus. The success of green growth is measured purely by an increase in resource efficiency and a circular use of resources.

In another description by the World Bank (2012: 2), Green Growth offers the potential to increase resource efficiency, minimise negative environmental impact and cope adequately with disasters. By managing natural capital, organisations can be more resilient in the face of environmental dangers and disasters (please note, that the World Bank understands the concept of 'resilience' to mean a sort of comprehensive risk management). According to the German Advisory Council on Global Change (WBGU, 2011: 177), Green Growth stresses the compatibility of economic growth and decarbonisation combined with an inherent economic potential. This type of growth is proposed as a post-financial economic paradigm to reinvigorate the economy, focusing on investments of capital in environmental goods and services and the development of natural (i.e. green, sustainable) infrastructure (Vasquez-Brust and Sarkis, 2012: 8).

A number of publications have analysed and characterised the key concepts of green growth according to the available literature. Bina (2013: 1028) describes the main characteristics of Green Growth as a science and technology orientated progress with a focus on efficient growth and environmental economics. According to Vasquez-Brust and Sarkis (2012: 2) the discussion about green growth 'goes beyond growth balanced with environmental protection; green growth is quality-oriented, low-carbon, energy efficient growth with a focus on creating value through clean technology, natural infrastructure and innovation in markets for environmental goods and services. Green growth means making investment in the environment, as a driver for economic growth'.

Hammer et al. (2011: 15) have carried out a comprehensive literature review and systematically analysed key words that are linked to Green Growth. In 25 different reports discussing Green Growth, the most common links where industry and production focused, of which the main focus was on energy and utilities, green building, transportation, Clean-tech manufacturing and green manufacturing. The lifestyle consumption side of the equation is only poorly covered, by comparison.

According to Vasquez-Brust and Sarki (2012: 10 ff.) the quality of Green Growth depends on dimensions such as: policy integration, multi-stakeholders governance, flexibly regulation and dynamic policy mix, competitiveness, adding value, inclusion, justice and social cohesion, trust and collaboration and entrepreneurship. The main drivers of growth are: innovation, globalization and ecological urgency.

Figure 03: Green Growth Key Areas (own analysis according to World Bank, 2012, Hammer et al., 2011:15; Vasquez-Brust and Sarkis, 2012: 8)

Definitions of Green Growth can be broadly categorised as having either a wide or a narrow scope. The wide definition includes all areas of eco-innovation and economic growth in the environmental sector. Here the focus is on economic growth in green industries with no distinction made between sustainable and non-sustainable production methods and practices, applying the current growth paradigm to green industries. This paradigm has been criticised for fixating on growth in all production and turnover related areas regardless of method or environmental impact (SRU, 2012: 9). The narrow definition of Green Growth, on the other hand, includes a distinction between sustainable and non-sustainable production methods and practices, of which the latter should shrink and vanish over time. Although an increase in sustainable production methods can be promoted by policies and certification, a good deal of power lies with consumers who can decide not to purchase unsustainable products.

The key components of Green Growth, as synthesised from World Bank documents (2012), Hammer et al. (2011: 15) and Vasquez-Brust and Sarkis, (2012: 8), are represented in the diagram below.

3.3 PRACTICES OF GREEN GROWTH

We are of the opinion that environmentally friendly and sustainable practices must be a key building block of the Green Growth concept in order for it to be truly green. However, Green Growth policy seems to agree more with the wide definition of the term.

Green Growth policy aims to promote environmentally friendly resource efficient technologies with targeted subsidy programs. New developments are supposed to lead to economic growth without damaging the environment and using resources frugally (OECD, 2011). With the concentration of resources in 'green' branches, economic growth is to be promoted while simultaneously reducing greenhouse gas emissions. In this vain, the focus is currently on 'greening growth' and 'more efficient use of resources to minimise environmental pressures' (ibid.: 10).

According to WBGU the Green Growth framework focuses on national policies with the aim to canalise public investments in, for example, low GHG emission energy systems, climate mitigation activities (WBGU, 2011: 177). The Green Growth framework therefore offers government stimulus packages. Political measures to introduce Green Growth to enable a transition to sustainability therefore focus on political strategies and the creation of suitable financial instruments. These measures are included in climate and energy policy, economic, labour market, social and development policies as well as land use policy (ibid.).

A literature review by Bina (2013) shows, that Green Growth policy is mainly concerned with 'market mechanisms, investments in Innovation and green technology, and green consumption and production'

(Bina, 2013: 1035). According to research carried out by Vasquez-Brust and Sarki (2012: 10-18), the promotion of Green Growth in policy involves the stimulation and promotion of green technologies and market segments. Environmental aspects are limited to a consideration of environmental compatibility, a reduction of resource use and energy efficiency.

In summary, the practically implemented form of green growth is therefore concerned with promoting 'green' technology and 'green' innovation through market mechanisms and financial instruments. Little distinction seems to be made between green technologies and their production methods and, according to the definitions above, social aspects are not explicitly considered.

Research by Machiba (2010: 363), however, shows, that a technology alone does not determine how sustainably it is used. The way society functions and how it meets its needs determines how technology is created and used and therefore how sustainable it is. System innovations (a fundamental shift in societies' outlooks and way of functioning) can be assisted by tools such as technology. A focus on green technology without considering social structures and cultural values cannot make much difference.

It can therefore be argued that the focus of any policy aiming to create sustainability through Green Growth should be more on changing social structures and values. Changes in social structures and values are more likely to lead to the kinds of system innovations needed, rather than solely trying to solve problems with the same technology and growth orientated approach, which created them in the first place.

4 GREEN GROWTH AS APPROACH FOR SUSTAINABLE DEVELOPMENT?

Before we start considering the sustainability credentials of Green Growth, a summary of our understanding of Green Growth so far based on the above chapters is necessary. According to the definitions and policies mentioned in the previous chapter, the current Green Growth approaches and related policy focus on technology, growth and resource use. A desired direction is to be achieved by financial instruments and market forces. Social aspects are either briefly mentioned or not included at all in the definitions and policy documents mentioned above. A detailed proof of whether Green Growth as currently considered can lead to a truly resilient economy and consumption pattern remains open (Schneidewind et al., 2013: 10). One key point of discussion in this regard is whether growth and resource use can actually be separated at all (Jackson, 2009: 95). The success of the concept would be proven when economic growth is decoupled from resource use and carbon emissions. This would be shown by positive growth coupled with a stagnation or shrinking use of resources and reduced GHG emissions (WBGU, 2011: 177). Even then, the idea that a direct correlation between GHG emissions, environmental protection and Green Growth can be established should be viewed critically, given the complexity of the systems being considered.

The concept of the green economy is considered to potentially function as a central implementation strategy of sustainable development (Simon and Dröge, 2011: 4). This is despite the fact that it has been criticized for narrowing the notion of sustainability as defined at the Rio Conference in 1992 and thus only inadequately integrates the central aspects of sustainable development into the concept of Green Growth. Green Growth covers the adaptation of economic systems to new demands such as resource scarcity and increasing environmental impacts. Green Growth, however, focuses mainly on resources and technology and mostly ignores the social side of the equation (as shown below).

When considering the concept of Green Growth as a practical approach to reach spatial sustainable development, it becomes evident that the three dimensions of Green Growth (as discussed in chapter 3) overlap and show similarities with the dimensions of the sustainability concept. Both emphasise the interrelations between the environment, economy and society and try to influence these to shape them to allow future development. However, while the concept of sustainability (see figures 01 and 02) seeks to create a balance between social, environmental and economic aspects, Green Growth focuses on ecologic and economic aspects with technologies as an intervening factor between those elements (see figure 04). Thus, the social aspects of sustainable development are only indirectly covered by Green Growth conceptions; they are considered to result indirectly from an economic development that increases human well-being by cleaning up the environment with improving air and water quality. Improved environmental conditions are supposed to directly affect human well-being (The World Bank, 2012: 34). Additional human wellbeing is seen to result from economic growth based on green technologies

(although, as mentioned above, economic growth does not necessarily lead to development and the expected effects on the job market is contested (see below; Tol, 2012). Following this understanding, human well-being is only the result of a chain of effects of increased environmental conditions. Furthermore, the understanding of human well-being is fairly narrow focusing on green economic growth, improved environmental conditions and the creation of jobs and social welfare. However, well-being includes more than better environment quality – there are the specific living conditions, non-material aspects, health etc. (Wuppertal Institute, 2010: 18) which are not included in the Green Growth approaches.

As a growth-oriented development concept the notion of Green Growth is inherently connected with maintaining processes of continuous quantitative growth and the greening of economic processes. Ecologic systems are considered resources for economic growth and technological development. As such, the concept of Green Growth focuses on reaching sustainability through changes in systems and processes through technical progress. The decoupling of economic growth and environmental degradation is supposed to become possible as a result of technical, procedural or systemic innovation. As a technical approach it targets at increasing the efficiency and consistency of production and consumption processes based on minimizing resource input while increasing resource productivity and closing material cycles. Thus, the concept of sustainable development which implies qualitative change in the social, economic and ecological dimensions of processes is narrowed to an understanding of economic, quantitative growth. Technical and organizational adaptation and innovation is considered to solve existing problems of unsustainable production and consumption patterns and systems allowing basically business-as-usual societal processes and structures. Consumption patterns and the fundamental goals of economic processes i.e. quantitative economic growth are not questioned. Moreover, the underlying assumption of decoupling economic growth and resource consumption as well as generating continuous growth by increasing the efficiency of processes is contested by critics. They argue that rebound effects over-compensate efficiency gains and that decoupling economic growth from resource consumption is impossible (Jackson, 2009: 95; Santarius, 2012: 3).

On the other hand, the quantitative dimension of action to reach sustainable development (as defined by Hansen, 2010 and discussed in chapter 2.3) is not directly targeted by current Green Growth strategies. The current understanding of Green Growth neglects the cultural dimension of social change for sustainability such as the change of individual behaviour, consumer habits and lifestyles. Reaching sustainability through sufficiency, questioning the growth paradigm, adapting goals of economic development and targeting the sufficiency of (economic) processes, is not addressed. Current Green Growth approaches follow the techno-corporatist interpretation of ecologic modernization (see chapter 2.1) resulting in the 'economization of nature' (Hajer, 1993 cited in Gibbs, 2000: 12). Changes in (global) production and consumption patterns which are intertwined with questions of redistribution and social justice are neglected. Opening up new approaches to battle poverty and promote human well-being by promoting societal change towards an economy that is built on sufficiency, sharing and solidarity is not addressed (Meadows et al., 2005: 261). Thus, current Green Growth approaches distort the concept of sustainability towards its economic and environmental dimensions (see figure 04).

Besides not directly covering the social dimension of sustainability and cultural aspects of production and consumption processes, there are further risks connected with the technical approach of current Green Growth strategies. Even when consequently followed, greening economic processes and increasing technical efficiency is a contested approach when it comes to its implementation and effects to broader social and economic processes: In general, the Green Economy concept is considered to potentially function as implementation strategy for sustainable development (Simon and Dröge, 2011: 4). However, the actual implementation so far has been criticised as lacking consequence in implementing green technologies and reducing environmentally harmful practices (ibid.). Narrowing the multi-dimensional concept of the Green Economy to the environment and energy sectors is considered risky as this may result in neglecting the goals of ensuring market stability and fighting poverty (ibid.). The Green Economy Roadmap published in 2012 emphasises the role of the economy in combating challenges of climate change and promoting development (ICC, 2012). However, following Vazquez-Brust and Sakis (2012: 9) the concept of Green Growth can be criticised as only re-branding traditional neoclassical economic concepts. These apply the understanding of key factors of growth laying in eco-innovations.

Figure 04: Green Growth and sustainability (own presentation modified and based on Hansen, 2010: 23)

Furthermore, the technical focus of Green Growth bears the risk of triggering large-scale investments in technical infrastructures e.g. of the energy and transportation sector. With this comes the risk of creating path dependencies and lock-ins due to their long lifetimes which determine future action (Freeman, 1992 cited in WBGU, 2011: 79). Moreover, the current practice of dealing with the climate crisis has been dominated by reactionary action. The perception of the climate crises often results in short-sighted actions which counteract the concept of sustainability – especially after the global financial crisis (Bina, 2013: 1034). A central challenge of pursuing sustainability is proactively promoting sustainable development by connecting it with concrete mid- and long-term concepts.

Many scientific sources deal with the concept of Green Growth in relation to the energy system. For example, Tol (2012) argues for the energy sector constituting the core of Green Growth. The opportunities of Green Growth are considered to lay in the growth potential of the energy sector and related growth potentials in the labour market, increasing energy security as well as the need for GHG reduction (ibid.: 151-154). Tol critically discusses the first three arguments and notes that the energy sector only constitutes 3% of the overall economy. Thus, claimed effects on economic growth and job creation are relatively small and may thus not result in benefits for the labour market (ibid. 2012: 153). Thus, the underlying assumption of the concept of Green Growth that economic growth and technical progress will result in human well-being is contested when it comes to practical implementation.

Finally, the energy sector can also be used to illustrate the narrow focus of Green Growth on changes in sub-systems instead of overall societal change. It is now generally acknowledged that energy transition is not only a technical matter of energy efficiency, (renewable) energy generation and distribution but has broader social, economic and political implications (Berkhout et al., 2012: 109; Meadowcroft, 2009; Miller and Richter, 2014; Westly et al., 2011: 762) that constitute the 'social dimensions of energy transitions' (Miller and Richter, 2014: 82). However, the discussion often follows a quite narrow focus on how social and policy issues 'drive changes in energy transition' (ibid.: 77) and the process of technology development and diffusion (Berkhout et al., 2012: 110). This has resulted in approaches to energy transition which are too technical and do not take the various interconnections between energy systems and society into account (Haberl et al., 2011: 8). It has been argued that a comprehensive approach towards energy transition requires not only 'a radical reorganization of energy systems [but] simultaneously a radical reorganization of society' (ibid: 8).

To sum up, the ability of Green Growth approaches to promote sustainable spatial development is limited, due to its one-sided focus on the economic and environmental aspects of development hampering cultural and behavioural change and the establishment of new paradigms on economy. It builds on the unproven notion that economic development can be decoupled from resource consumption. Connected with the Green Growth approach is the inherent risk of not being able to meet this goal due to rebound effects and the lack of change of individual behaviour and consumption. Moreover, the assumption that investments in technologies and greening the economy will lead to job and wealth creation to a broader extent has already been contested. Positive effects might be strongly limited to specific branches and spaces without unfolding effects on economic processes in general and wider social and spatial dimensions. Additionally, even current Green Growth policy has not necessarily led to Green Growth initiatives (Vazquez-Brust and Sarkis, 2012: 7), with economic growth the main focus of much economic policy (Jackson, 2009). Finally, not directly addressing societal change may limit the opportunities to reach sustainable development, as

the reorganization of societal structures and processes is excluded as a source of innovation and transformation. Thus, Green Growth tends to promote economic growth for specific cities and regions with good initial conditions, rather than broader spatial sustainable development.

5 PROMOTING THE TRANSFORMATION TOWARDS SUSTAINABILITY

As illustrated above Green Growth strategies show some weaknesses and risks when it comes to promoting sustainable development. Rather than addressing the notion of sustainability in a holistic way, it distorts the concept toward its economic and environmental dimensions by applying a mainly technical approach targeting qualitative not quantitative systemic change. In order to understand the implications of this focus for its ability to reach change towards more sustainable systems and spaces, it is necessary to apply a broader understanding of systemic change. For this purpose this chapter builds on transition theory, which explains systemic change as result of a socio-technical transition processes (Geels, 2001). On this basis, the chapter aims to identify possible approaches to practically promote transformation processes to sustainable development by applying Green Growth strategies.

5.1 TRANSFORMATION TO SUSTAINABILITY

Transition theory (Geels, 2001 and 2005; Grin et al., 2010; Kemp and Loorbach, 2003; Rotmans et al., 2001) applies a socio-technical systems perspective and provides an explanation for processes of societal change within these systems. It suggests that dealing with persistent problems which result from a system's unsustainability, such as climate change and the need for climate change mitigation and energy transition, requires 'fundamental changes in the societal system and its subsystems' (Franziskani et al., 2012: 21), so called transitions or transformations. The term 'transition', which has been defined by the scientific discussion related to transition theory (Geels, 2001 and 2005; Grin et al., 2010; Kemp and Loorbach, 2003; Rotmans et al., 2001), is here used synonymous with the term 'transformation' (Rotmans, 2005: 11).

Figure 05: Dynamic multi-level perspective on transitions (Geels, 2005: 452)

Following the understanding of transition theory, fundamental system changes may result in the transformation of the overall system and the creation of a fundamentally new system configuration (Grin et al., 2010: 11; Park et al., 2011: 3). Thus, the transformation of a system is the result of cumulative effects of various actions of a multitude of actors affecting technology, economy, institutions, behaviour, culture, ecology and paradigms, introducing regime shifts and consequently new regimes (Kemp and Loorbach, 2003: 7; Westley et al., 2011: 763). Innovation in products, services, processes and projects which may occur on a rather small scale of sub-systems are assumed to lead to system innovation which drastically alter the relationships between societal actors. Thus, system innovations are characterized by new forms

of organization, cooperation and dependencies among actors on a comprehensive system level. These system innovations in turn may lead to broader structural societal change which involves changes in technological, economic, institutional, environmental and cultural structures, processes and developments (Rotmans, 2005: 11). This reinforcing process of different types of innovation on different systemic levels is also described as a 'cascade of innovations' (ibid.) resulting in structural societal change or societal transformation.

The idea of societal transformation as result of innovation is not unique to transition theory. In scientific debate on transformative change it is stressed that transformation to sustainability cannot be solely based on technical innovation but needs the introduction of 'social innovation as key factor for a sound transition to sustainability' (Mancebo, 2015: 3). It requires a new social contract as a basis for and a result of a social movement for change that simultaneously addresses the social, environmental and spatial dimensions of sustainability (ibid.). Transformation processes require breaking with unsustainable societal trajectories and establishing new development models as sustainability is 'impossible under socially and economically unsustainable conditions' (Haberl et al., 2011: 11). This needs a specific type of change, i.e. transformative change, which comprises a 'fundamental change in a system, its nature, and/or location that can occur in human institutions, technological and biological systems' (IPCC, 2014: 1107). Changing the distribution of wealth, risks, power and authority as well as establishing new forms of social organisations and a new shared agreement and vision of future societal development is an integral part of this transformative change (Miller and Richter, 2014: 79 ff.). This has led to the demand for a comprehensive societal change which goes way beyond technical innovation and has to constitute the third Great Transformation (Haberl et al., 2011; WBGU, 2011). As mentioned in the introduction, this transformation has to occur in the three pillars our society is based on: energy systems, urban areas as main emitters of greenhouse gasses and global land-use systems (WBGU, 2011: 48) which can also be identified as the main fields of intervention to pursue broad societal change (ibid.: 265).

Transition theory applies a multi-level-perspective (see figure 05) on complex societal systems as analytical tool and explanatory model for transformative societal change. Within this model transformation processes are the result of the interaction of niches on the micro-level. These compete against existing socio-technical regimes of established structures and processes on the meso-level. New developments and innovation which arise in social and technical niches may change regime structures when broader and global developments on the landscape level put established structures under pressure (Geels and Kemp, 2005: 13; Geels and Schot, 2007: 400).

To sum up, as current Green Growth approaches rather promote (technical) changes on the level of sub-systems of the economy (see chapter 4) their ability to promote comprehensive societal transformations to sustainability is questionable. Promoting social innovation and changes in institutions, behaviour, culture and paradigms is not sufficiently targeted by Green Growth strategies. Thus, the socio-technical systems perspective of transition theory and the understanding of transformative change outlined above can be used to indicate opportunities to further develop and broaden existing Green Growth strategies. The following chapter will highlight opportunities that cities and regions have to implement and affect the transformation process.

5.2 GREEN GROWTH AND TRANSFORMATION TO SUSTAINABILITY

As mentioned in section 5.1, transition theory proposes that transformations are initiated through niche innovations and their interactions at the micro-level (Geels and Kemp, 2005; Geels and Schot, 2007). These niche innovations, which can be either of a technical or social nature, can lead to much wider system innovations at the regime level, which in turn can result in a comprehensive transformation. Niche innovations are not necessarily spatially limited, but rather temporally, as they exist over a much shorter time frame than the regime level (Gibbs and O'Neill, 2014: 204). According to Gibbs and O'Neill (2014), towns and regions can be seen as having optimum factors required to promote niche innovations and can also create the link between the niche and regime level (Coenen et al., 2010; Truffer and Coenen, 2012 cited in Gibbs and O'Neill, 2014: 204). Gibbs and O'Neill refer to Cooke (2009) in their research who ascribes to towns and regions the authority and capacity to create administrative areas within which niche innovations can be supported politically. These created areas form a sphere within which the niche innovation is protected to a certain extent from regime pressures. Thus, towns and regions can act 'as the

source of niche innovations that will eventually transform regimes' (Healy and Morgan, 2012: 1049, emphasis in the original, cited in Gibbs and O'Neill, 2014: 204).

Given the importance of niche innovations for initiating transformations and the importance of towns and regions to niche innovations, it therefore seems likely that towns and regions will be the main action level within which a transformation to sustainability could be initiated and take place. Gibbs and O'Neill (2014) go so far as to say that towns and regions are the key level to enabling a sustainable transformation. Cooke (2009) describes these regions as 'transition regions', which can offer support for green industries at the sub-national level (Cooke 2009 cited in Gibbs and O'Neill, 2014: 204).

The various stakeholders and actors within spatial and regional development can therefore play an important role in enabling and supporting such a transformation process. Baker, Marston and McClure (2013) offer two action areas in this regard. On the one hand, a regulatory framework can be created to reduce regional vulnerabilities and increase resilience (Meyer et al., 2010 cited in Baker et al., 2013: 874). This is a solution orientated 'technical' approach. On the other hand, socio-political processes can be fine-tuned at this level (Davoudi et al., 2009: 16 cited in Baker et al., 2013: 874). Spatial and regional development actors have the ability to create arenas in which priorities and sustainability criteria can be discussed and decided upon. Thus, according to Baker et al. (2013) spatial and regional development offers a good combination of communicative participation and regulatory information. One of the main rolls of the state, whether at the regional or national level, is to support green branches via appropriate innovation policies and the development of new sectors (Barry and Doran, 2006 cited in Gibbs and O'Neill, 2014: 213). Moe (2012: 8) also describes this kind of political action as an elementary important top-down component of Green Growth. But he also demands that national political aims go beyond the support of technical innovation and investment programs for infrastructure (such as water, energy and transport) to include social aspects such as poverty reduction (Moe, 2012: 8). The Green Growth concept with its focus on the promotion of a green economy and technological development can be viewed as an incremental system changes. Moe (2012: 9) is critical of national policies which, up to now, have concentrated solely on the subsidisation of green branches, markets and innovations and view the acceptance of these subsidised market components as a requirement for their diffusion. This approach ignores that, according to Machiba (2010: 363), technology will only have an impact with associated with social structures and cultural values. Policies only see one way to include a comprehensive transformation of social aspects, namely the top-down approach. A comprehensive transformation to sustainability will also require a number of different bottom-up processes combined with niche developments that allow an alteration of lifestyles and consumption patterns.

Figure 06, below, shows a condensed form of the various approaches to sustainability and the societal choices that go along with them. Business as usual is what the current Europe 2020 strategy looks like currently. The strategy relies on classical market-oriented economic theory which explains that an economic advantage and growth can be achieved by innovating in times of resource insufficiency. The Green Growth strategy described as aims to create a 'green bubble' within a defined geographical area (the EU). The advantages that are envisioned within a specific green space (in this case the EU) are achieved at the costs of external spaces (e.g. resource extraction and refining areas). It can be argued that this kind of Green Growth simply replaces the 'vocabulary' used to describe the current system (e.g. 'growth' and 'competition') with one more acceptable to society (e.g. Green Growth and eco-efficiency) (Brand, 2012: 32).

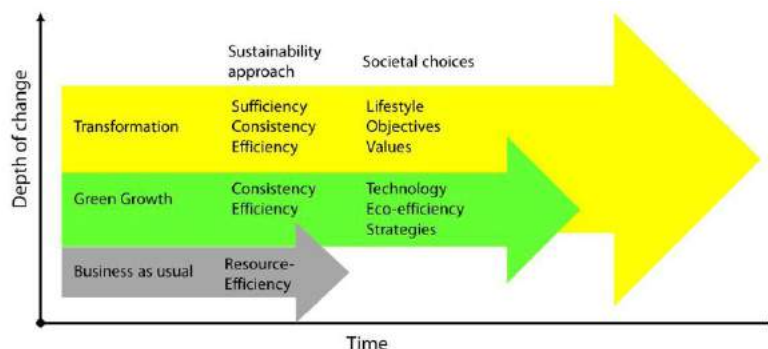

Figure 06: Green Growth, Transformation and the depth of change (own concept based on Khosla, 2013: 22)

The Green Growth approach in figure 06 is along the lines of the narrow definition described in section 3.2. However, given that growth does not automatically lead to a betterment of the human condition (as mentioned in section 2.1 and 4) and the highly controversial nature of the 'decoupling of growth and resources' theory, relying on this route alone to achieve sustainability is most uncertain. Figure 06 illustrates that Green Growth is not appropriate to promote, guide and implement a comprehensive transformative change to sustainability. Rather, it targets (technical) changes on the levels of sub-systems of the economy. The final transformation described above involves a changing of lifestyles and values together with a sufficiency approach to consumption and a stagnation of growth or even shrinking. In order to develop practical approaches to promote transformation processes to sustainability, the concept needs to be supplemented with further concepts which more strongly target social and cultural innovation as a driver for change, as well as changing the distribution of wealth, risks, power and authority. This will only be possible with a combination of top-down and bottom-up approaches combined with deep social engagement.

Actors and stakeholders in spatial and regional development are well placed to support this combination of top-down and bottom-up approaches. The two action areas available to town and regional development stakeholders fit well with the required approaches. The regulatory framework can provide top-down information and regulation on the one hand, with the possibility of creating safe spaces and direction, for example to desired niche innovations. On the other hand, a bottom-up approach can be supported with communicative participation promoted, for example in specially created arenas and networks.

ID 1689 | THE RIGHT TO THE CITY IN TIMES OF BIOPOLITICS - TACTICAL URBANISM IN A TRANSITION PROGRAM

Ana Farias¹; André Pedro Viegas Cabral Gonçalves²

¹UFG / ISCTE-IUL / Sobreurbana; ²Sobreurbana
carol@sobreurbana.com ; andre@sobreurbana.com

1 INTRODUCTION

The city is the greatest field of action of capitalism, but also the most possible field of resistance to it. Capitalism and urbanization feedback in a process where the former is always expanding, producing and concentrating geographically and socially its surplus in the city.

Harvey (2014) points out that to think of an alternative form of urbanization, it is necessary to build possibilities for an anti-capitalist turn, thus pointing to the urgency of recognizing the common and its potency. And it suggests that this route of escape must start from a convergence between the microcosm of the body and the macro space of globalization, two important topics of the current neoliberal phase of capitalism.

This convergence can be achieved in the affirmation of human and individual rights, a perspective that reinforces the importance of the concept of the right to the city, developed in the 1960s by Lefebvre (2016). A more collective right than individual, which encompasses all other human rights, claiming the participation of all in the construction and use of space and urban life.

Thinking about the global world has made it possible to recognize a common world with which to worry, to produce, to appropriate, and which is shared by all. For Hardt & Negri (2016), the idea of 'common' was also potentialized with the understanding of the concept of biopolitics, whose subjectivities will always be produced by apparatus of power, whether of the sovereignty of the Empire or the resistance of the multitude.

Thus, the 'right to the city' is considered as a strategy of transition from the current urban situation of the cities towards a situation of justice, of full realization of the common well-being. For the institutional redesign, necessary for this transition, Boaventura de Sousa Santos (2003) argues that, besides state and formal law, the forms of informal and unofficial law that he attributes to 'subaltern cosmopolitan legality' must also be considered. And to avoid wasting social experiences that seek to declare and exercise the rights that matter to them.

In this perspective, the author's Master dissertation research, from which a partial communication is extracted for this article, explores the potential that so-called 'tactical urbanism' has in promoting the right to the city. Here, tactical urbanism is understood from the studies of Certeau (2014), where the tactical action is determined by the absence of power, a calculation of strength that does not isolate the subject from the environment and that acts with no autonomy in a territory that was imposed. It is believed that the scale of the tactics better represents the biopolitical production by the multitude.

Thus, we seek to identify in the urban tactics used today, as in the immanent desires of the multitude, the ways it finds to move, inspire, emancipate and build itself in the full realization of the right to the city. In a collaborative cartography, actions of tactical urbanism were collected and organized according to a standard reading format, which information nexus was elaborated by Rosa (2015), exploring the local potentiality, the articulations created and the new possibilities generated. From then on, it became possible to visualize, discuss, and analyze the collected experiences in order to apprehend paths to the fullness of the right to the city.

Therefore, this research links a discourse that establishes the common as a desired utopia; the right to the city as the main strategy to achieve it; and the level of urban tactics as the time of experiencing possibilities that could lead the multitude to a condition of urban justice.

2 THEORETICAL AND METHODOLOGICAL REFERENCES

According to Harvey (2014), if in the Fordist capitalism the exploitation was centered in the factories, today it focuses on the cities, promoting from the financialization of the access to the earth to the production of subjectivities that control the desires and the daily life of the people.

Neoliberalism, the current stage of world capitalism, acts for economic liberalization in favor of free trade and the private sector. It acts on a global scale and, for this, depends on the regulations articulated by the states, counting on privatization policies and reduction of the state apparatus, and with the deregulation and fiscal austerity on the citizens. This way, dominant national and supranational organisms articulate themselves according to the logic of biopolitics to guide desires and ways of life that suit their interests. Thus space, or urbanization of cities, is also produced through the control and expropriation of the common wealth - nature and all cultural, social, subjective and artificial production common to all, which the idea of a globalized world allows us to perceive.

Biopolitics, according to Foucault (2015), is the way to govern populations from the 'management' of life through discipline, and the production and consumption of subjectivities that guide desires and instincts. Pelbart (2011) clarifies that biopolitics can be exercised through biopower, a power invested in life, dominating it and subjugating it to a sovereign. Or, through biopotency, the potency of life emanating from the multitude and thus representing its resistance.

The biopotency of the multitude is, from this perspective, the source from which forms of resistance must emerge from the predatory logic of exploitation of capitalism and, likewise, from the unfair logic of the production of space in contemporary urbanism. Hardt and Negri (2016) emphasize the necessary intellectual task of organizing the political immanence of the multitude, in the sense of apprehending the subjectivities it produces, which would point desires for other forms of life. In order to do so, it is necessary to build visions of a world socially shaped and encompassing all, the collective, the multitude. This is where the notion of 'human rights' comes in.

Despite several important counterpoints to the idea of 'human rights', Harvey (2015) relies on the body's political potential to defend the discourse of universality of rights as a way of uniting local singularities in search of global political and economic alternatives. Hence, the 'right to the city' today assumes renewed importance as a possibility of resistance to neoliberal urbanism.

It was Lefebvre (2016) who in the 1960s elaborated the concept of the right to the city as a demand of the expropriated class and understood as the right to the work, that is, the right to use the city as a space that accumulates the material wealth of human production, including knowledge, techniques, monuments and artistic sensibility. The right to use the city also for celebration, pleasure, prestige, enjoyment of freedom, socialization and individualization - right to habitat and living, to urban life; possibilities that capitalist production reduced, if not eliminated over time. However, this right should not be understood as a melancholy feeling of returning to the traditional city nor the acceptance of the city that is there, but the right to a dynamic city, capable of renewing itself, the right to a transformed urban life, to a different genuinely desired city.

Harvey (2014) updates the concept of the right to the city by proposing an approach where it is understood as the collective right to democratically control the production and use of the surplus produced in the urbanization process. An eminently political task of fighting for the right to the common, the production of space, the imagination and the experience of a new city. A task for the multitude.

Despite some legal apparatus and supranational agreements already formulated for the right to the city, it must be understood that rights are always demanded and permanently watched for their maintenance. The registration of any right in the books of justice does not guarantee its compliance nor does it guarantee that, in compliance, the previous condition of injustice will be overcome.

In this perspective, Santos (2003) raises the importance of observing the wide and diverse experiences of initiatives, groups, social movements, networks that already act against hegemony, facing neoliberal policies that are essentially excluding, and finding ways out. The author recognizes, in this space of struggles, the privileged field for such disputes against hegemonic, denominating it as subordinate cosmopolitanism.

In the same way, the interest of this research by the so-called 'tactical urbanism' starts with recognizing it as anti-hegemonic manifestations of neoliberal urbanism, and seeks to learn from it.

2.1 TACTICAL URBANISM - POTENCE AND TRAPS

This term is understood as the rebellious urban practices, in different measures, to the order and the bureaucracy imposed by the institutions, pointing to the city's wishes to which its practitioners aspire. Also considered here as tactics, these practices that are not necessarily rebellious, but act in a bottom-up direction in the processes of space production, sometimes even in collaboration with 'official urbanism', yet expressing new ways of doing it, forcing an adjustment of its *modus operandi* to the local realities of the most disadvantaged.

Observing various everyday practices such as cooking, talking, walking, Certeau (2014) defined the concept of tactics as the cunning of the weakest in capturing opportunities for action in the gaps of the dominant, strategic system. Ways of doing that resignify through the use, products, rites and spaces imposed by the dominant systems.

Activations of public spaces promoted by organized or unorganized communities, new ways of living the urban, time banks that subvert the capitalist logic of profit, engaged urban art and activism, reconstruction of landscapes according to the needs of a given community, made by the community itself - are examples of tactics used to escape the sovereign domination of the state and capital in the production of urban life and space.

And they are experiences in which the body plays an active, effective and affective role in space. Actions that reflect disputes in public spaces, which, by definition, are also political spaces, where conflicting individual needs are disputed. Hence, it is in the repositioning of the body in the political arena of the urban, and essentially in the experimentation of the otherness of the body, that the actions of tactical urbanism show their great potential in being an instrument of struggle for the rights of the body - in the contemporaneity, of the collective body, the multitude - for the construction, use and enjoyment of the polis.

However, apart from the enthusiasm expressed by many authors and practitioners about the potential of tactical urbanism, it is also important to note their weaknesses and possible traps. It is worth noting the overwhelming criticism made by Neil Brenner (2016) about an exhibition held at the Museum of Modern Art - MoMa in New York between 2014 and 2015, amid a period of great explosion of these practices, worldwide.

The third in a series of exhibits aiming to discuss issues beyond the themes commonly discussed in architecture, "Uneven Growth: Tactical Urbanisms for Expanding Megacities" featured a wide selection of projects and experiences that pointed new ways of intervening in six megacities (Hong Kong, Istanbul, Lagos, Mumbai, New York and Rio de Janeiro), in the current context of hyper-urbanization and the high level of informality of urban spaces. The curators' intention was on the collective and innovative experience of the multitude through urbanism in its considered tactical scale, believing in the capacity of these actions to promote social justice in the processes of urban space design and appropriation (BRENNER, 2016).

From the writings that made up the exhibition catalog, Brenner (2016) listed the following points of convergence on the understanding of tactical urbanism, as of the historical and urban context in which it is being discussed: a crisis of governance of cities, where the states and the market failed to deliver basic public goods and services; tactical urbanism encompasses a wide diversity of emerging, temporary, and experimental urban practices; they are practices conducted in a bottom-up direction; tactical urbanism deals with urgent problems through interventions of immediate effect; they are projects of great flexibility and openness, in contrast to the rigid codes of official urbanism; the actions of tactical urbanism promote participation, are based on practices, stimulate the Do It Yourself (DIY) culture, generally use open source and aim at the re-appropriation of urban spaces.

Thus, the practices of tactical urbanism were presented there - and consequently also discussed in different spaces - as an alternative to neoliberal urbanism. However, the author questions the real potential

of tactical urbanism to present some kind of difficulty to neoliberal urbanism, or even to corrupt it. In order to develop his analysis, he draws five possible scenarios of interaction between tactical urbanism and neoliberalism, among which only Scenarios 4 and 5 would offer, in the author's perspective, some kind of difficulty for neoliberal urban politics:

- Scenario 1 - Reinforcement: tactical urbanism alleviates the failures of neoliberal urbanism, but without facing its regulatory milestones;
- Scenario 2 - Entrenchment: tactical urbanism internalizes the neoliberal agenda of reducing the role of the state or opening up to market action, for example, contributing to its rooting;
- Scenario 3 - Neutrality: tactical urbanism coexists with neoliberal urbanism, acting in spaces that are not functional, without presenting risks to its processes;
- Scenario 4 - Contingency: tactical urbanism offers experimentation in the regulatory sphere, subverting neoliberal projects;
- Scenario 5 - Subversion: tactical urbanism interrupts the logic of urban governance growth, opening the agenda of inclusion, equality, democracy and social justice.

Thus the author warns of the risk of the varied and much localized tactical actions to diminish the capacity of facing the major challenges. For instance, the necessity to participate in institutions to broaden the reach of public interest actions and the importance of gaining public support for the social demands that actually contribute to socioeconomic inclusion (BRENNER, 2016). In this regard, design has a great role to play in the redesign of the city, the co-creation of new forms of living together and coexistence.

What is clear in Brenner's (2016) criticism is the necessary tactical approach to strategic policies if one wishes to achieve social justice and the fullness of the right to the city. Therefore, it is necessary to know how, where, under what conditions, methods, consequences, for whom the actions of tactical urbanism operate their new ways of making the city and of being urban.

2.2 STRATEGIES FOR RESEARCH ON TACTICS

This research seeks to understand the practices of tactical urbanism and to analyze the possibility of its effects satisfying the right to the city. Starting from a large and heterogeneous range of examples of these practices, it needs to map them according to categories that demonstrate connections, tensions, and trends.

Accordingly, a Taxonomy of Tactical Urbanism was setup on an online platform¹, aiming to list experiences and classify them according to criteria relevant to the objectives of the analysis. The examples are mapped according to the professional experience of the authors, who manage an urban interventions studio based in Goiânia/Brazil, and have an academic work through field surveys, research in specialized magazines and websites. Many are the biopotent aspects of tactical urbanism and the action of mapping their various manifestations demonstrates an enormous complexity and consequent wealth of particularities and points of convergence useful for future analysis.

The first steps of this research were guided by the interest in understanding the desires and subjectivities that motivate the actions of tactical urbanism, being this the first layer of categories created in this taxonomy. Identifying the desires of practitioners - the subjectivities that permeate their actions - is fundamental to understanding the biopotency expressed in their tactics. Next, a categorization was created to identify which types of practices are made. In this article, we discuss the addition of another layer to this taxonomy, a categorization that seeks to demonstrate the frictions between tactical urbanism and neoliberal urbanism, according to the five scenarios designed by Brenner (2016). Table 1 lists the categories proposed for the three layers and Figure 1 shows the connections arranged on the Taxonomy of Tactical Urbanism platform.

¹ Kumu is a platform that organizes complex information in a rhizomatic way, allowing the visualization of maps or relational views. Available at <<https://kumu.io/>>, is offered in open source and without costs for projects that do not aim at any kind of profit.

LAYER / THEME	CATEGORIES ¹
Desires / Subjectivities	[common] [participate] [anti-consumerism] [belonging] [singular] [transience] [daily life] [imagine] [empathy] [equality]
Types of Practices	[economy networks] [overcome lack of infrastructure] [new ways of life] [green agenda / brown agenda] [exploring the city / research] [art activism] [activation of public space / micro environments] [strategic tactics] [Political arrangements]
Tactics X Neoliberal	[reinforcement] [entrenchment] [neutrality] [contingency] [subversion]

Table 1 – Categories used in Taxonomy of Tactical Urbanism

Figure 1 – Main visualization of Taxonomy of Tactical Urbanism platform

It is worth emphasizing that the layers of categories proposed in this research aim to elucidate the complexity of the tactical actions in the city, contributing to a delimitation, even at an initial stage, of the concept of tactical urbanism. And in addition, the categories aim to provide criteria for analyzing these tactics from the hypothesis that tactical urbanism can be used to fight for the right to the city - which may be or not confirmed. Thus, the performance of the observed practices does not mean, for the research, an analysis of good and bad, right and wrong, more or less 'tactical', but levels, objectives, different ways of doing this tactical urbanism that, not always, has itself the objective that the hypothesis launched in this research tries to verify.

In addition to collecting examples and observing their arrangements, it is also important to learn from the experiences of those who seem to point to an urban reality of social justice, democratization of the city's means of production, and enjoyment of the city that is a piece of work.

Therefore, a reading standard² created by Rosa (2015) was adopted to demonstrate emerging urban practices organizing its characteristics according to three blocks of interest: 1) local potentiality, which seeks to identify the specificities of the fields of action (urban morphology), as well as of the project or action developed, and its actors; 2) articulation, which deals with the practice itself, seeking to understand the arrangement of objects, actors and their connections in concrete space; 3) and the opportunities that arose, seeking to understand the new physical and social codifications generated. It is suggested that the

¹ In order to better understand the proposed categorizations for the Desires / Subjectivities and Types of Practices layers, see the article "Tactical Urbanism and the Production of the Common - an Approach to Emerging Urban Practices" available at <<http://sobreurbana.com/pesquisa/>>.

² A caracterização das práticas adotada nesta pesquisa recorre a uma versão simplificada do padrão oferecido por Rosa (2015), cujo padrão completo, mais abrangente do que esta pesquisa exige no momento, está detalhado na bibliografia de referência ao final deste texto.

characterization of the practice precedes its categorization according to the proposed themes, in order to allow a more coherent inference with the action.

From here it is possible to analyze the ways of doing of the practices. This way, it is intended to contribute to the understanding of the tactical practices that emerge in contemporary urban centers which, once it was possible to perceive, offer great potential for renewal of the urbanism discipline in order to internalize agendas such as social participation, right to the city, inclusion, and urban justice.

3 PATHWAYS

Due to the interest in understanding the complexity of the arrangements made with the urban tactical actions, it was decided not to establish, for the assembly of this panorama, no territorial or temporal cut. The interest in this vast field of investigation is justified by the possibility of recognizing in different locations and times, similar solutions to the same problems, useful for strengthening common struggles.

From the contacts established between the researchers and their objects of interest, twenty-one practices have been collected so far from countries like Brazil, Colombia, the United States, France, South Africa, Portugal, Spain, Portugal, Italy and Peru. However, there is a greater number of Brazilian and Portuguese practices, two territories of interest and action of the researchers. It worth noting that the platform used in this research allows for connections as varied as possible and from them to extract partial views by crossing the information that currently interests the researcher, which makes this research strategic but open to tactics.

For the communication of this article, it is proposed the demonstration in Table 2 of the practice "Associação Renovar a Mouraria"¹, based since 2008 in Mouraria, a traditional neighborhood of Lisbon/PT. Figure 2 shows an image of the Association's main space of action.

LOCAL POTENTIALITY	
FIELD	Small pedestrian-restricted access between residential buildings up to 5 floors, in a neighborhood under gentrification process located in the historical center of Lisbon.
DESCRIPTION	The Association was created by a group of neighborhood 'friends', some of whom do not even live there. In order to host the activities it offers to the community, it rehabilitated a dilapidated building (which it called Mouradia) and thus activated the wide area in front of it, with the installation of furniture, decorative elements, events and the installation of a vertical garden. For the accomplishment of the activities, counts on the financing of the associates and public financing for specific projects.
CONCRETE SPACE/ CONTEXT	Square, stairs, alley, housing, nursery, local access, no vegetation, no urban furniture. Multicultural resident population, large number of daily tourists, and other sympathizers for the characteristics of the neighborhood.
NEGOTIATION/ OPENING	The rehabilitation of the building and the improvements carried out in the area have boosted the association's relationship with the community, providing greater interaction among its members, neighbors, workers and tourists. The improvements made in the square added layers of use to the space, previously used only as spaces of passage.
NEW CODIFICATIONS	The Association provides a meeting place, inside the building and in the square, stimulating the social integration and dynamizing the cultural diversity of the place. Through its social services (literacy training for foreign adults, community dinners, legal support for people and associations in situations of social vulnerability, etc.), it contributes to social inclusion. It also works as a point of support for the mediation of local conflicts, mediating interests between the various actors of the neighborhood dynamics and between these and the parish council.

Table 2 – Characterization of "Associação Renovar a Mouraria"

¹ Mais informações sobre a Associação Renovar a Mouraria aqui: <http://www.renovaramouraria.pt/>

Figure 2 – Mouradia –Headquarters of “Associação Renovar a Mouraria”

From the reading of the practice and its unfolding it is possible to infer about the categories with which it is compatible. In relation to the 'desires/ subjectivities' manifested by the practice, it is considered that it is driven by: the desire to appropriate the cultural production [common] of the individuals who live or work at Mouraria and to produce and inhabit the space where they are; [empathy] for the problems experienced especially by the residents in social fragility; desire to value and consequently to [belong] to recognized identities in the locality; inclusion and [equality]; playful experimentation of the city, attention to the ordinary, to the ordinary life of ordinary people, valuation of [daily life]; desire to collaborate, gathering intentions and collective actions, to [participate] in the solutions and in communicating, sensitizing, spreading the other.

Regarding the types of practices used by the Associação Renovar a Mouraria, we can observe the following: micro-interventions in urban space, provoking [activation of public space]; promotion of [new ways of life], based on the offered community and cultural activities; offer of social services that try to [overcome lack of infrastructure] that should be offered by the public power; [research] - practices that promote the experience of the urban spaces of the neighborhood, which seek [exploring the city], as well as collecting social and economic data that support claims and highlight issues of local interest; support actions, training and diagnosis of local commerce, strengthening a local [economy network]; and finally, it is considered that the practices of Associação Renovar a Mouraria, although understood in the tactical scale, are linked in a continuous planning that has a larger, medium-term purpose of social inclusion, besides seeking responses also in the public power (financing programs and other types of support) for community problems, thus characterizing themselves as [strategic tactics].

For the categorization according to the possibility of friction between the tactical practices used by the Association and neoliberal urbanism, it is important to observe the capacity of these actions to touch regulatory frameworks that support the neoliberal ideology - reducing the role of the state, expanding the role of the market, idea of development from unlimited economic growth, urban governance guided by urban marketing and other aspects. Although the Association offers important social services that in fact achieve a greater inclusion of the residents of the neighborhood, many in conditions of social and economic vulnerability, and although the improvements made in the area in front of Mouradia have contributed to increase the quality of that urban space as a space that serves for the social gathering, its actions do not impose needs of the political and urbanistic system, nor the market, to adapt to its demands.

On the other hand, the Association values the autonomy of its common space, in order not become hostage to either the state or the market: it leads to discussions that question government actions; it seeks its sustainability through the own generation of resources with the offer of services; it supports the traditional businesses of the neighborhood, strengthening the local economy network against big international brands, etc. Therefore, it is considered that their actions, at the present stage, offer [neutrality] to neoliberal urbanism. To contribute to the struggle for the right to the city, it must offer a greater dose of confrontation with the powers that operate in its territory, especially the touristification of the spaces and the gentrification of the neighborhood.

Thus, there are three paths, which are already sighted by Associação Renovar a Mouraria, that can lead to this confrontation: the combination of their actions with other entities fighting for the right to housing, in the current gentrification context of Lisbon's historic center; the legal and dignified integration of the immigrants, in the process of their reception in the neighborhood and in the city; and the creation of an 'alternative market' in Mouraria, through practices such as the time bank and the creation of an autonomous currency.

Leaving the observation made on one example and using the magnifying glass over the platform that hosts the Taxonomy proposed in this research, it is possible to observe that, considering the criteria raised by Brenner (2016), few examples collected so far offer some kind of difficulty to the maintenance of the *modus operandi* of neoliberal urbanism.

However, it is considered that from the reflections provoked by this act of mapping, characterizing and categorizing tactical practices, it is possible to observe the strengths and weaknesses of these practices, according to the analysis criteria used. And also, to infer possible ways to reinforce or redefine their ways of doing, according to their desires and purposes.

In this sense, it is important to note that, among the desires and subjectivities of the practices, there is a greater frequency of desire for the [common], followed by desires for [participation] and [belonging]. The least frequent desires in the collected sample are those related to [singularities], [equality] and [transience]. Of course, these occurrences depend on the eye of the cartographer and the collected sample.

On the layer that organizes the types of practices found in the collected examples, it is observed a greater frequency of those actions that promote the [activation of public spaces], followed by practices in favour of the [green agenda/brown agenda], the promotion of [new ways of life] and [strategic tactics]. The least practiced are those relating to [new political arrangements] and [new economic arrangements].

Location, scale, method, levels of participation, types of agents and sources of funding are themes that are not yet categories, but of relevant importance for this research. Information that should still be processed in the continuity of this investigation.

4 CONCLUSIONS

There is still much to explore in research on emerging urban practices, given the variety of their expressions and the complexity of arrangements they trigger. The data collected and crossed in this research, still in its initial stage, demonstrate, however, that if there is the goal of breaking the oppression and exploitation of neoliberal urbanism through urban tactics, much more remains to be done.

It is important not to forget what Pelbart (2011) says about the fact that even the affections of revolt can be kidnapped. In times of biopolitics, one must be careful and try to differentiate what is resistance and what is assimilation of the imposition of a hegemonic way of life. The plurality and singularization of individualist agendas, characteristic of postmodern society, hinder the universalization of the rights to vindicate and are a challenge for political action.

The predominance of practices that, at most, are limited to mitigating the harmful effects of neoliberal urbanism reveal the need for critical thinking to better subsidize such actions, rather than combating and weakening its tentacles, so that they can take the next step in the desired process of community empowerment, towards full capacity to build and manage the space in which they live.

This is a very open possibility when one observes who are the founding agents of these practices. There is a predominance of actions carried out by hybrid collectives of artists, architects and designers, in a process of reinvention (or adaptation?) of their professional practice.

That is to say, the committed background of the urban architect, the designer, the artist, and other areas, such as social assistance, law and communication, can be an important stimulus - especially when supported by useful tools - to carry out more and more experiences that question and subvert the harmful neoliberal practices of contemporary urbanism.

louise Ganz@gmail.com

1 INTRODUCTION

This communication will address the transdisciplinary research that I develop today, where I transit through architecture and visual arts, collective properties and other forms of communal ownership and management of the land. I conducted a series of interviews with activists, architects, artists, lawyers, indigenous people in different locations around the world, proposing to them a fiction: Assuming that a few hectares of land are available in their context for the development of occupation and livelihood projects, what would you imagine doing with such an area? This provocation seeks, through the imaginary, to know and debate forms of social organization of space distinct from private property, in order to be constituted as a collection of utopias.

We are facing a process of expulsion and a growing number of conflicts related to access to land, which makes the space increasingly restrictive and destructive of collective responsibilities, in the Brazilian and world context. Struggles and resistances trigger new regimes of sensibility and experiences of land repossession, and thus, the proposition of new forms of spatialization are necessary. What practices of land sharing can we imagine? What utopias can we construct to amplify the repertoire of the modes of occupation of the territory? These are the key issues. A construction of a map of utopias is an attempt to point out future social transformations.

In this context, the Thislandyourland artistic brazilian group, formed by me and Ines Linke in 2010, develops projects in the field of visual arts, with the theme around the use and access to land. Projections: 100 km2 of Caatinga biome is a work in process, which investigates diverse imagery related to the Caatinga, an specific brazilian biome. Starting from a fiction that suggests that an area of 10km x 10km of Caatinga is made available and donated for the development of projects, several people or groups are invited to receive this fictional land donation and during interviews, idealize and expose their projects to this land extension. In this presentation I will show some excerpts from interviews.

2 BRIEF WORDS ABOUT THE CAATINGA

Caa tinga, in the language of the Tupi-Guarani Brazilian Indians, means "bare forest" or "white forest", due to the loss of leaves in the long drought seasons, thorny vegetation and numerous xerophilous and deciduous species with branches calcined by sunlight.

The Caatinga is a biome characteristic of areas of northeastern Brazil, where the semi-arid tropical climate predominates, with few rains and presenting varied landscapes due to the geomorphological and climatic factors. During most of the year the plants appear as if they were dead, the environment has intense heat and great luminosity. For decades, the Caatinga imaginary has developed in Brazil as an inhospitable, desolate and miserable environment, receiving titles such as terra-nua, terra-seca, terra-hostil, among others. Compared with the other Brazilian biomes such as the Atlantic Forests or Amazonian Forest, known worldwide, the Caatinga was culturally and politically devalued.

However, it is an environment of great biodiversity and an exclusive Brazilian ecosystem. Researchers have been revealing the richness and importance of the Caatinga. Besides, it presents various forms of human occupation, both rural and urban. In this way attention must be paid to the endless layers of the Caatinga's environment, as specific local contexts, ways of life and modes of occupation and production, rich and diversified landscapes, as well as the knowledge and development of alternative technologies that allow the permanence and inclusion of the populations on earth.

Currently, rural sector has been transformed by the continuous introduction of systems that integrate technologies and capital, geared to the external market, such as agribusiness. Thus, we could imagine, in a simplified way, that the imaginary about the region passes from barren desert to a region favorable to the financial and agribusiness market, as a symbol of earth's saviors and richness. We need to be aware of this, to create forms of resistance and to produce other imaginary, closer to the history and the inhabited space, and to understand other meanings of richness.

3 THE POLITICAL CONTEXT OF LAND IN BRAZIL

Data from Incra (National Institute of Colonization and Agrarian Reform), raised from the owners' self-declaration, point out that land concentration and unproductiveness increased in this early century in Brazil. Data from 2010 indicate that 130 thousand landowners concentrate 318 million hectares. More than 100 million hectares have passed, in less than a decade, to the control of landowners, who average more than 2,400 hectares. The data also shows that the register of unproductive areas grew more than the productive areas, which points to the expansion of areas that disregard the social function.

Many of these landowners speculate on the land, use political "protection", are outlaws and avoid compliance with the Constitution. This one determines that areas that do not fulfill their social function are destined for agrarian reform. The constitutional text of 1988 posited the inseparable union between property and its social function.

Art.186 The social function is fulfilled when rural property meets, simultaneously, according to criteria and degrees of exigency established by law, the following requirements:

- I-rational and adequate use;
- II-adequate use of available natural resources and preservation of the environment;
- III-compliance with the provisions governing labor relations;
- IV-exploitation that favors the well-being of owners and workers¹.

Rural property has an even more evident social function, given its importance as a mean of producing goods necessary for human survival and social prosperity. In this way, rural property will fulfill its social function by producing in a conscious and adequate way, aiming at protecting the environment and respecting existing relationships. The conception was born of the idea that, as part of a society, man must make efforts to contribute to the well-being of the community to the detriment of solely individual interests.

¹ http://www.planalto.gov.br/ccivil_03/constituicao/constituicao.htm

Property is seen as an instrument to support the attainment of social ends, whose essence is its service to the community.

Thus, the concept of social function, like that of property, has undergone evolutions. At first, it was only considered the economic character of the property, that is, the economic productivity of it. The economic side remained, but other attributes were added to characterize the sociability of the function of the good.

It is important to distinguish the meanings of productive and unproductive in the context of the social function. It's usual to hear people talking about the Amazon Forest or the Caatinga, referring to them as "useless land", and claiming the necessity to transform it into "productive" land. Extensive areas are deforested for the purpose of planting soybeans and corn and raising cattle in the Amazon. These practices promote landscape transformations, not only in space, but also in the ways of its use and life of the population. The territory is redrawn by economic forces, which stimulate deforestation and the purchase of cheap and "useless" forest. Likewise in the context of the Caatinga.

The geographer Rogério Haesbaert points out that the hegemonic territorial paradigm "sees space as mere extension or surface to be transposed and substrate to be explored." Adopting an absolute vision, the company and the State homogenize and unify the space, making it equal and decontextualized. Land-territory is an "instrument of domination, a merely functional resource, within an economy based on the agro-extractive-export model", and the Capital speculation. This would be the concept of productivity in the hegemonic context.

Haesbaert points us to another paradigm -the counter-hegemonic -in which what matters is the inhabited, lived, diversified space of social relations. Unlike the homogenizing view, it sees the space densified by the multiple social and cultural relations that make the bond society -land. Therefore, from this point of view, productive land is not opposed to "useless land" because its function is not to enslave workers, to serve individual interests and to promote the expulsion of people from the land, but rather to generate livelihoods, labor, occupation of land and social emancipation.

4 PROJECTIONS: 100 KM2 OF CAATINGA

While traveling through Bahia in 2012, the group Thislandyourland crossed an área with the Caatinga biome, in the highlands of the southwest region, where the agropolo of potato plantation is located in an area of 70 km by 140km. A flat expanse of land with sparse rectangular volumes of eucalyptus plantations, pipes for conducting water for irrigation and some sparse cows composed the plastic landscape. On the way, only one truck carrying potato sacks for processing. In the fields, no one, not even a village. Just the signs of what is needed for production: water, flat relief, road and truck for product disposal. These elements give us the information of the type of production that has been developing in the territory; they inform us a kind of new geography without the society living within it, or rather, eliminating the historical time of the inhabited space.

Faced with this imminent disappearance of a biome and a culture, the Caatinga, the Thislandyourland group initiated a project in 2016, Projections: 100 km² of Caatinga. It is a work in process, which investigates diverse imagery related to the earth, starting from a fiction. It is suggested that an area of 10km x 10km of Caatinga is made available and donated for the development of projects. Several people or groups are invited to receive this fictional land donation, such as businessmen, representatives of the public power, third sector, class entities, politicians, activists, artists and researchers, and with them are made meetings and interviews, where they have the opportunity to idealize and expose their projects to this land extension.

What are the projections made by the most representative economic and political sectors of the country? Which perspectives point to the future? How do people think land is political?

5 SOME PROJECTIONS

Here are some excerpts transcribed from two interviews given by Brazilian environmentalists Paulo Petersen¹ and Fabio Feldmann².

This land your land: Paulo Petersen, you receive this land of 100km² in the Caatinga region. What would you do? What is the nature of your project, production, preservation or both?

Paulo Petersen: Both. We have the great challenge of reconciling the two things: developing economically and conserving nature. This path of conciliation has been very difficult because politics normally see things very far apart. Policies for economic development are very environmentally degrading and preservation policies are very socially exclusionary because they end up penalizing exactly those who have retained a certain region. The perspective of preservation does not see the human being interacting with the ecosystem. A population, which for generations has been in an area and has commitment, knowledge of the biodiversity and the resources of a place, is penalized. Therefore, conciliation is necessary and possible.

This land your land: How would you implement a project?

Paulo Petersen: The first thing to know is if there is a local population. Assuming they exist, there is already a way of occupation, and do not need settlements. Very often this population has a regime of collective use of the land. This type of community-based land use exists even in Bahia, where there are pasture communities. Indigenous, quilombola and peasant people have many difficulties. A series of conflicts exists exactly because the Brazilian state has difficulty in recognizing. Legally there is even a national policy of traditional peoples and communities that has a lot of difficulty in implementing it because the land issue is poorly resolved, although the Brazilian Constitution foresees this type of mechanism. Recognition by the state is still very limited.

For example there is a case also typical of babaçu coconut breakers. How do the women make the appropriation of land? They have an area that is of common exploit use of babaçu and the access comes from generations. Then they used to come in to remove the babaçu, but the owners of the land began to block the access of these women. It started to create conflict, but they are not invading the earth. These populations are then very vulnerable, but they exist in Brazil. So our land regime is very much hidden. Not legally, there is a forecast but it is not regulated. The Constitution of 1988 predicted this type of situation but because of the political game in the congress, dominated by a ruralist group, this was not regulated.

There are many situations of groups of populations who manage the territory in a common way. This is a very interesting way, but it is very little explored from the point of view of possibilities, including economic ones. Politicians and ruralist groups say that there is a pocket of poverty but it is not a pocket of poverty because they work in this system, but because they are abandoned. If they had schools, electrification, access to cultural goods, roads, etc., you would have another pattern without detracting from the nature of that kind of economy. The problem is not associated with the type of economy that leads to poverty. This is an interpretation that is always done: the peasant is poor and then he/she must be an entrepreneur. They are not poor because they are peasants, but because they are abandoned.

It then, at first, needs public and social policies, and investments in infrastructure, to create productive chains of resources of the biodiversity partner. To explore, in a sustainable way, the potential that biodiversity itself has in medicinal plants, in fruits and in agriculture, handicrafts, ecotourism. There is a set of possibilities of valuing the amenities of nature, of what it generates, and which at the same time heats up the economy, on the basis of it, conserving nature.

This land your land: Fabio Feldmann, if you receive this land of 100km² in the Caatinga region, what would you do?

¹ Petersen is the coordinator of AS-PTA, non-profit Civil Law Association for Family Agriculture and Agroecology, that since 1983 has been working to strengthen family farming and promote sustainable rural development in Brazil. AS-PTA participated in the constitution and works in various civil society networks aimed at promoting sustainable rural development.

² Feldmann was the articulator of the "parliamentary green front" and responsible for the creation of the chapter dedicated to the environment of the Federal Constitution. Elected federal deputy for three terms; candidate to the government of the state of São Paulo by the Green Party (PV) in the 2010 elections. Acts as a consultant on issues related to the environment and sustainability.

Fabio Feldmann: First, a campaign to try to put the Caatinga in the constitutional text, with the purpose of drawing attention, therefore, although this does not guarantee anything, would be an important step. The Brazilian Constitution of 1988 has an article dedicated especially to the environment, article 225 which considers, in its fourth paragraph, some biomes as national patrimony, such as the Atlantic Forest, Pantanal and Amazon Rainforest. What is the idea of equity? Something that has to be preserved. One of the important issues is to put the Caatinga in the constitutional text, even if this is not a guarantee of conservation. The 1988 Constitution will turn 28 years in October and the only biome that has its own legislation is the Atlantic Forest, because there was too much pressure from the society at that moment.

And second, perhaps a Caatinga legislation, to valorize these remnants of area, their species of plants, their history in the context of the country, the cultural issues of the Brazilian semi-arid.

I have the impression that there is a shortage of Conservation Units in the Caatinga. Every biome has a number of Conservation Units. For example, the Amazon may be the most valued area today. The

Atlantic Forest has some protected areas, but the Caatinga, as far as I know, would need to be certified as an important area in order to create parks and reserves for sustainable development. Also, find out what would be the best ways to protect these areas. And eventually even classify them as a Biosphere Reserve, which would have an international status.

Thislandyourland: Since you are talking about conservation, in the case of developing a project for the 100km² Caatinga, would you propose something around preservation, production or both?

Fabio Feldmann: There are several categories of Conservation Unit: there are those of integral protection, which do not allow human presence. There are those that are too restrictive and those that are less restrictive. Then I thought of RDS (Sustainable Development Reserve), because eventually you have activities that happen in the Caatinga biome, which you could even admit to remain as economic activities.

If I were to do this, first I would consult the map of the Ministry of the Environment and check what are the most important areas in the Caatinga from a biodiversity point of view and see which conservation sites already exist.

Thislandyourland: Do you think it is interesting a system that puts together preservation and production? Would that be an interesting prospect for the country?

Fabio Feldmann: The choice of the category depends very much on the peculiarity. In São Paulo we have a case that is the Juréia Ecological Station. The coast of São Paulo is a mosaic (the concept of mosaic), and has an area that is relatively intact, which goes from the coast to the mountains. So, since this area is the only left over, we have opted for integral preservation. But there are other areas where it is perfectly possible to coexist with traditional populations, or even with economic activities that are within the concepts of sustainability, which could be ecotourism, agroecology -depending on what exists in the area.

Thislandyourland: What would you do with a land with the dimensions of 10km x 10km in the semi-arid already thinking about a future perspective?

Fábio Feldmann: I would propose to design a sustainable development project, since it is a large area. In Brazil we have always worked with a very large territorial scale, so sometimes we think 100km² is not much, but it's really big. I would think about creating a sustainable development project where I would have all the elements of complexity, with some totally protected areas -assuming they are very important and have a rich biodiversity -and would think about economic activities that would generate jobs and income for the population that is there. If I were to win this land, I would try to make a project that could be a reference for Brazil and for the world of sustainable development.
