There was a notable enthusiasm for the audio demonstrations. The mean for "useful" was 0.57 points above the next highest score for the other sessions and "interesting" was 0.47 points above the next highest score. That these scores were roughly a half-point higher than already positive scores for other sessions is telling of the potential for audio demos as educational tools. The success of this component also suggests a need to further develop this type of format for future events.

4.2.1 WRITTEN COMMENTS

The questionnaire also left room for participants to write free format responses about what they liked and what they thought could be improved.

Regarding the morning session, participants commented on the “diverse” and “interesting” presentations from “competent experts”. Two people mentioned appreciating the distinct building blocks with their useful lessons. They suggested the following improvements and comments: researchers tended to speak too long and didn’t have enough time for questions; brochures summarizing the topics would help; and that presentations could contain even fewer academic diagrams.

Session	Prompt	Mean	Sample Size
General questions	I am sensitive to sound in my daily environment	4.25	N = 24
	I consider sound in my work practice	3.92	
	This event influenced the way I consider sound in public spaces	4.29	
Morning session Presentations and Building Blocks	I found the session: useful	4.18	N = 17
	I found the session: interesting	4.41	
Afternoon session Co-design workshop	I found the session: useful	4.00	N = 13
	I found the session: interesting	4.08	
Laboratory demonstrations	I found the session: useful	4.75	N = 16
	I found the session: interesting	4.88	

Table 2 – Results of follow-up questionnaire on different parts of the Animating Pedestrian Zones in the Sonic Dimension workshop

For the afternoon session, participants enjoyed “the ability to apply [their] new knowledge to a concrete situation” and having an “exchange with experts about their perception of urban noise” ; however, a participant thought the presentations and activity were too detached in time. Other appreciated aspects of the afternoon breakout session were: noting how it was “great that the City of Montreal participated”; coming up with “creative solutions”; interacting on a “live” project with a “hot discussion”. Suggestions for improvement included: the desire for even smaller groups, fewer questions on the worksheet, and the need to make sure that there were enough experts outside of sound at each table.

For the laboratory demonstrations, participants liked the “passionate” experts and the “striking” demos, getting to “hear someone’s actual research”, and living an experience that is normally abstract. They were impressed by the “technical expertise and professionalism” and thought that the demo was a good way to help them understand decibels more in depth. They hoped that the city would be “able to use these types of demos for serious projects.” Suggestions included: a guide for elected councillors and urbanists related to the revision of noise regulations; an awareness campaign among noise makers; and a method for testing out soundscape designs in advance of an intervention. Suggestions for improvement included: wanting more time with the demos, particularly the immersive virtual demo (this was suggested by most of those who responded to the prompt); and having participants suggest modifications, especially to test their ideas for the pedestrianization interventions.

Participants were asked separately about their ideas for improving the collaborative experience of the workshops. They indicated wanting even more information about the intervention site, making sure every participant understands the exercise brief, more time for the worksheet activity, and even smaller groups.

Lastly, participants were asked how they would like to learn more about soundscapes. The following examples were given with the question: presentations, workshops, soundwalks, and online content. Of the 13 participants who responded to this question, 6 want access to more presentations, 8 want workshops, 8

want soundwalks, and 3 want online content. Other respondents suggested: “a survey of interesting examples of places that use sound creatively”, sound installations, “urban interventions constructed with noise and sound in mind”, artistic approaches, “simulations”, presentations about soundscape from non-soundscape experts, and a “toolkit for designers”. One participant said that the workshop was “good enough...to start concerning myself with soundscape in my daily life”.

5 DISCUSSION AND CONCLUSION

5.1 SUMMARY OF WORKSHOP AND FINDINGS

Sound is surely not the only factor that can “make or break” a project; however, sound can be used as a lens for diagnosing and imagining urban spaces. Thinking about sound may help us to understand why a space is not being used as intended, whether certain envisioned activities are compatible with the existing environment, and how creative solutions can reinforce the qualities of a space. While spaces can certainly be designed in the absence of sound considerations, soundscape planning can help improve outcomes by: reducing wasted resources; helping avoid conflicts that may arise at the latter stages of a project; promoting a more collaborative approach between various professionals of the built environment, the City and citizens; invigorating spaces; and highlighting the importance of the participation of the users of a space in the process for designing it. Sometimes, when no other options remain, the appropriate soundscape intervention can still be to mitigate problematic noise. The traditional noise mitigation approach can thus be considered an option within the broader soundscape approach.

The workshop benefited most fundamentally from first-time interactions between professionals and academics in sound and planning disciplines. Discussing soundscape gave participants novel opportunities to interact with one another and iterate on their ideas. As previously mentioned in the workshop summary, the further along a project is in its planning phase, the more difficult it is to meaningfully intervene with soundscape ideas. This is exactly why those who advocate the soundscape approach over the noise mitigation approach believe that sound should be considered as far in advance as possible in the planning process.

What will remain a challenge is the ideal group size for soundscape discussions. Too small, and the risk is that not enough of the expertise will be present to represent all of the project aspects; too large and each person will not be able to speak their share.

The pronounced success of the demos and the comments that accompanied the scores indicate that the demos struck a balance between having accessible, compelling content as well as a perceived “scientific authority” of the hi-tech laboratory with equipment and technically-oriented presenters in their “natural habitat”.

5.2 THEORETICAL CONTRIBUTIONS

Facilitating collaborations between researchers and practitioners as equal contributors has the potential to dramatically improve the quality of our urban environments. Furthermore, studying the barriers and facilitators that prevent or encourage practitioners to seek out research information on environmental topics is important to address the research-to-practice pathway. We were encouraged by the enthusiasm for the laboratory demos. Our research findings on these barriers and facilitators could also benefit other domains where established research expertise can be used to help practitioners make more informed decisions (e.g. controlling wind and reducing urban heat islands).

After hearing from some of our collaborators from the City during our 2-day event, it became clear that their timelines for projects are often extremely tight and sometimes unrealistic. Politicians often influence or set their timelines and this often doesn’t take into account a realistic process for all phases of the projects. It’s difficult to explore innovative options and considerations when you’re under tight and unrealistic deadlines to bring a project from concept to reality. This is where academia could potentially add significant value to the city and vice versa. More collaboration between the city and universities could not only lead to more information sharing about relevant topics, but also to potential avenues for collaborations

on project. Universities may provide a nice platform for the cities to test and prototype ideas that they wouldn't have time to do otherwise. It would also give students and researchers an opportunity to work on real world projects, learn by doing and develop professional networks.

5.3 PRACTICAL CONTRIBUTIONS

The workshop format provided a collaborative environment where we were able to test the appropriate content, media, and tools for communicating with urban planners, designers, city officials, a variety of students and professional, and the general public about soundscape concepts. In doing so, we worked toward bridging the gap between soundscape research and planning and design practices, which allowed both sides to contribute equally to the discussion, build on each other's ideas, and focus on content that was simultaneously useful, usable, and interesting. This approach offers great potential for shaping the future of urban noise management, because it encourages planners, designers, and city employees to incorporate sound considerations into the conceptual phases of their projects. It also sensitizes all parties involved to the necessity of incorporating the public in the process, as they are the users of the environments and often hold key insights and aspirations for the spaces.

5.3.1 POTENTIAL IMPACT ON MONTREAL'S SOUNDSCAPES

What kind of impact has the November event had on the Montreal design and planning community? Local Montreal practitioners of the built environments who attended the event should have a better understanding of the soundscape approach and some of the soundscape-related resources that are available to them. Furthermore, we hope that the soundscape approach will provide professionals, city officials, and citizens with a heightened awareness about the impactful role that sounds plays in their urban environments. This may lead to some very real changes in Montreal, even in the short-term, whether it is the creation of a one-way street to reduce uphill-bound traffic noise, collaborations on new pedestrianization projects, or through other changes to come under the purview of the Sounds in the City project.

5.4 FUTURE WORK

What kind of future projects do we see on the horizon for the Sounds in the City team? For starters, the team is focusing on creating a best practice review of urban noise management in Montreal and exploring ways of integrating insights from soundscape research into Montreal's current noise regulations and procedures.

Given the positive feedback and enthusiasm from participants following the November event, we aim to develop workshops on more themes that are relevant to planners, designers, city officials and residents. We also aim to demonstrate the importance of integrating the public's input and ideas into the conceptual process. Given the enthusiasm for the laboratory sound demos, we aim to develop these into more structured and beneficial programs for participants.

ACKNOWLEDGMENTS

The authors would like to thank the many organizations responsible for their contributions to the project: the Goethe-Institut Montreal, the City of Montreal, Canada's SSHRC, McGill Innovation Week, McGill's Institute for the Public Life of Arts and Ideas (IPLAI), the Dean of Arts Development Fund, and our host, the Centre for Interdisciplinary Research in Music Media and Technology (CIRMMT).

We would also like to thank some individuals who were key to the workshop's success: our collaborator at the City of Montreal, Marthe Boucher, Director of Permits and Inspections at the Ville-Marie Borough; Goethe Institute's Cultural Programs Director, Kaisa Tikkanen, and General Director, Katja Melzer; our photographer, Johannes Scherzer ; the three planner-presenters from the City of Montreal for sharing their

projects: Pierre Sainte-Marie, Hélène Benoit, and Romain Bonifay; and lastly our four internationally invited soundscape experts: Andre Fiebig, Lisa Lavia, Martijn Lugten, Jochen Steffens.

ID 1680 | THE (IN)CONSISTENT COMMUNITY BOUNDARIES: TEMPORALITY IN MULTIPLE SOCIAL-SPATIAL INTERACTIONS

Tianyu Zhu¹; Qi Li²

¹Technical University Munich

²Beijing Tsinghua Tongheng Urban Planning & Design Institute
julia_0112@126.com ; 878184697@qq.com

ABSTRACT: Boundaries are temporal. The perception of a boundary is an interactive process in relation to specific social contexts. This article investigates the temporality of community boundaries, focusing on their social-spatial interactions through performatives, which contribute to both the inconsistency and consistency of the perceived boundaries, and analyzes the dynamic community boundaries in time with empirical evidences from two typical Beijing neighborhoods. Building on an analogy with theater performances, the article brings forward a conceptual framework for the understanding and analysis of community boundaries in urban space, with a focus on the stimulators of spatial-temporal transformations. The temporality of boundaries can be understood in two perspectives, situational and representational. While the former promotes inconsistency of boundaries with ruptures and shifts, the latter brings consistency to boundaries through bring diachronic, repeating perceptions to the contemporary spaces. The temporality of community boundaries implies a connection of the neighborhood and surrounding urban areas. The more a community is integrated, the more changes and shifts take place to the boundaries, which hence become flexible, tolerant, and porous with publicness.

KEYWORDS: boundary, temporality, social-spatial interactions, urban Beijing

1 INTRODUCTION

A community boundary indicates a transition from private or communal territories to open and anonymous city spaces. The demarcation of a community, as well as the distinction of self from otherness, is expressed in the definition of community boundaries. In mornings, people travelling from home to a city street, transitions of territories are marked by joints of streets, changes of openness and noises. During the day, senior citizens move through different places in a neighborhood, social thresholds are delineated by individual definition of identities, according to the relation between herself and other people. In summer, spaces are lively and crowded, the experience of boundaries become various and ambiguous, and more tolerance are given to strangers and foreign behaviors. In winter, there is little activity. Physical environment is more influential in the perception of boundaries. The variation in the perception of boundaries suggests that physical materials are not the only indicator of boundaries. Boundaries are perceived socially, individually and in interactions. Boundaries are in dynamic. This article investigates the dynamic boundaries in temporality, through which a facet of the social-spatial connections in urban neighborhoods can be revealed.

This article answers the question "what is the community boundary at this moment?" investigates how boundaries occur and change in time, and highlights the importance of understanding community boundaries dynamically in urban design and research. We analyzes the seasonal, daily and temporary changes of community boundaries in two typical neighborhoods in Beijing, point out the two perspectives of understanding the temporality of boundaries, and bring forward a conceptual framework for the understanding and analysis of community boundaries in urban space, based on theater theories on performatives. The research draws on a long term qualitative field research during 2013-2016 at the neighborhood Xinyuanli and the Ocean Express in Beijing (Figure 1). Each neighborhood is examined through original methods as well as notes, photos, participatory observations, in-depth interviews, mental maps, etc. Building on an analogy with theater performances, the article brings forward a conceptual framework for the understanding and analysis of community boundaries in urban space, with a focus on the stimulators of spatial-temporal transformations.

Figure 1 – Location and masterplans of the two neighborhoods, left, location; middle, Xinyuanli; right, the Ocean Express

Xinyuanli is a typical "neighborhood unit" in urban Beijing, which was built between about 1965 and the late 1970s. After it was completed the units were distributed to different danweis. After the economic reform of 1978, Xinyuanli went into the free immobile market, and slowly changed its social structure and close social relations due to the occupational connection from the danwei period. The Ocean Express is a typical commercial neighborhood and gated community which were built in 2004. The apartments were directly sold on the market and some are rented afterwards. The two neighborhoods locate near to each other, near the Sanyuanqiao Business District, which raises the average rents in both neighborhoods. While the Xinyuanli still accommodates some original residents from the Danwei time (senior citizens), as well as low-income workers in its basement and informal extensions, the Ocean Express with a higher price for management, is attractive to foreigners. The two neighborhoods can be representatives of "old" and "new" communities in Beijing.

Our perception of boundaries is both synchronic and diachronic. Merleau-Ponty (1945/2012) and the situationists focus on the first aspect by emphasizing the body in the perception of spaces. A space emerges only when bodily movements are seen and endowed with meanings for the spectator's understanding. Boundaries are "still here but already there" (Wolfrum & Janson, 2016, p. 87). Their own belongings, however, are ambiguous and to be defined, which requires understanding and interpretation in spatial situations. The second aspect is emphasized in the hermeneutics of Hans-Georg Gadamer (1975/2004) and Paul Ricoeur (1986/1991), where understanding and interpreting bring a text from one

context to another over time. At boundaries, bodily movements are understood and interpreted in each spectator's own context. This turns the perceptions of boundaries into an event of dialogs between various contexts (Zhu, 2017).

2 THE PERCEPTION OF COMMUNITY BOUNDARIES

The perception of boundaries is originated from the distinction of self from otherness. As Stavos Stavrides (2007) points out, boundaries both divide and bridges between the self and otherness. People encounter otherness, and when they consciously start to set up rules which distinguish themselves from others, boundaries are formed. For example, if someone watches at an open gate to a neighborhood, a strange would not boldly enter this gate, but a community member would do, or even have a small talk with the keeper. The community member does not think about his identity when he does so, while the stranger has to consider who he is and what the relationship between him and the community is at this moment. In this case, the gate is not a boundary to the community member, but a boundary to the stranger.

The perception of boundaries has a depth. As early as 1980s, the Japanese architect Ashihara Yoshinobu (1985) has paid attention to the boundary field where interactions between interior and exterior spaces take place. Kris Scheerlinck (2010) further represents the field into intelligible territorial depth. In different situations, people are allowed to reach the spaces at different depth, until where the boundary appears to them. At boundaries there is an uncertainty about rules. "Thresholds, like rituals, create conditions of intensity, transformation, the elevation of status and the blurring of social categories and rules" (Stevens 2007, P74). Boundaries rather appear in the perception of them, instead of being a law that preexists.

The relation with the surroundings is decisive for the perception of boundaries. Boundaries function as indicators of a territory only in the relationship with their surroundings (Norberg-Schulz, 1980). Keven Lynch (1960/1990) has mentioned the physical features decisive for the continuity of a territory - texture, space, shape, details, symbols, building types, functions, activities, residents, topography, etc. Boundaries are perceived where these features changes. Literatures on neighborhoods and society of China, along with first-hand observations and interviews in the two neighborhoods informed the focus on the followings features in the investigation for the perception of boundaries: physical stimulators, social interactions and management.

3 TEMPORALITY: SEASONAL, DAILY AND TEMPORARY BOUNDARIES IN DYNAMIC

3.1 SEASONAL BOUNDARIES

The boundaries of the two neighborhoods changes most significantly between winters and the other seasons, under the influence of the temperate monsoon climate of Beijing. The winter is cold and dry. The lowest temperature is about minus 10 degree Celsius, and can reach minus 20 degree Celsius occasionally. The air pollution is highest in winter. In 70-80% of the days in winter the PM2.5 index is above 100. Hence there are much less outdoor activities in winters. The springs and autumns are short in Beijing, and the summers are hot with rains sometimes.

3.1.1 SEASONAL BOUNDARIES OF XINYUANLI

The Xinyuanli neighborhood is surrounded by big city streets, and is further divided into several units by small inner streets with car lanes. Each unit consists of several yards with one or two residential building, and spaces between them. The yards were fenced and gated in the past, but today most of the gates are unwatched and open to everyone. Privatization is common at the spaces in front of building, which are further divided, occupied or fenced into parking spaces, extensions or front gardens.

Physical stimulators dominate the perception of boundaries in winters due to the reduction of outdoor activities. Spaces in front of buildings are understood as private territories as long as any object occurs there. Pavement or height changes in the yard mark the boundary of these spaces and no pedestrian in

3.1.2 SEASONAL BOUNDARIES OF THE OCEAN EXPRESS

The Ocean Express is closed by annexes and fences. A guarded gate and a side gate in the east with digital lock are the only entrances to the neighborhood. In front of the main gate there is a plaza with old trees, which is visually connected to the inner garden, but is divided by fences from the latter. The street circling the neighborhood serves only two neighborhoods and some business towers. The north part of the street is separated from other nearby neighborhoods with walls, and the south part is accessible from the nearby old neighborhoods and a shanty area, in and around which there are many retails supplying the whole area with meals. Especially the restaurants along the south part of the circling street are very popular and the pedestrian road is fully occupied by outdoor seats and dinners. In 2012, the government built a wall between the pedestrian walk and the car lanes of this part and made the road into an inner restaurant street.

Similar seasonal contrast to Xinyuanli takes place in the Ocean Express as well. There are significantly more activities in the garden, on the plaza outside, along the pedestrian road of the south streets next to the retails from the Ocean Express, as well as in the restaurant street. Even in the north part of the circling street, which aims to serve cars only, there are resting deliverers and walking residents or employees from the business towers in summer. However, the contrast in the amount of activities does not bring many changes to the perceived boundaries. The functional divisions in the area are strict, and the using of spaces is similar in summer and winter. For example, in the first fenced, and then walled restaurant street, the dynamic of boundaries only moves from eating indoor to eating outdoor between winter and summer. The influence of activities to the perception of boundaries does not exceed the wall.

The Ocean Express has a close relation with the nearby areas, although it is gated. It takes services such as dinning, shopping, home service, baby sitting from the outside, and at the same time shares the plaza and its garden with outsiders. One of the towers in the neighborhood is designed into SOHOs. Due to the business visiting required by this tower, there is not much difficulty to enter the neighborhood. The employee shares the crowded rush hours with employees in business towers, activities after lunch and apartment buildings. Beside those, shops in the annex can open doors to both the pedestrian walk and the inner streets. Some residents use shops as a short cut. According to a shop owner, "people walk through my shop. Some of them are my customers who support the business at times. They are welcomed. Some ask for the favor and appreciate it. They are welcomed as well. However some others who I do not know walk through buying and saying nothing, which is really a bad behavior." Yet all these connections beyond the gates of the neighborhood are necessary all the year round, and do not change the boundaries from season to season.

Same as Xinyuanli, the boundaries set up by property management of the Ocean Express do not change seasonally. The neighborhood has a professional team, and it regulates behaviors in the neighborhood strongly. Technically outsiders are not allowed to access the neighborhood, but actually strictly controlled entries are those of leaflet distributors, homeless, strollers, cameras, street sellers, etc. these regulations are normally invisible, and maintaining the regulations need quite a lot work - the entire open spaces are under the surveillance of cameras. These regulations do not change with seasons or hours, so are the boundaries caused by them (Figure 3).

Figure 3 – Seasonal boundaries of the Ocean Express, upper row, summer; lower row, winter.

In both neighborhoods the physical indicators have stronger influences on the perception of boundaries in winter. As the amount of activities rises in summer, social interactions start to vibrate the fixed physical indicators. There are unshakable societal boundaries, such as management regulations.

Figure 4 - daily boundaries of Xinyuanli

3.2 DAILY BOUNDARIES

3.2.1 DAILY BOUNDARIES IN XINYUANLI

Except in winter, Xinyuanli is full of activities all day round. In early mornings, senior citizens doing their morning exercises or going to the morning market dominate the space. They greet each other when they on the way, and walk together in groups to the park next to the highway or to the neighborhood park. They stay in parks until after 10am, when the rush hour is finished. Their daily rituals have turned the related spaces into an inseparable part of the community space. During the rush hours, people leave their buildings and pass the yard gate, and the gate of the neighborhood. They experience boundaries at different hierarchy levels until they join the busy traffic in the main streets, when they realize they are leaving the neighborhood. In mornings and afternoons, senior citizens and the self-employed stroll and sit around in the neighborhood. With their moving, chatting, and visiting each other, divisions among different yards and units are dissolved. The street in the north of the neighborhood is favored by taxi drivers for gathering in the break. They sit and chat along a plaza next to the street. Their appearance at an inner place of the neighborhood changes the hierarchical arrangement of spaces. During the lunch time, there is few activity outdoors. Physical indicators define boundaries again. In last afternoons after the school is finished, pupils occupy all the spaces in the street, challenging physical definitions of boundaries with their game playing. In evenings, shops at gates and along the main streets lighten up these spaces where resident take a walk after dinner. The parks are lively with dancing and other sports. In the late afternoon and evenings, the mixture of people turns the streets into boundaries with spaces of their own. In the night, the streets turn dark. Some open gates are closed voluntarily by residents. Some groups continue talking in yards, which a separated like islands (Figure 4).

The perception of a boundary means to set up a certain rule, which separate one group from another. The changes of boundaries in a day challenge the rules and making new rules. In such situations physical indicators are rather chances for interactions between different territories and groups than barriers. In this way each individual present on the spot influences the process of rulemaking.

3.2.2 DAILY BOUNDARIES IN THE OCEAN EXPRESS

Closed by fences, the Ocean Express has significant physical boundaries. Yet an access through the main gate is possible. The neighborhood is functionally closely connected to the surrounding area. During a day, different relations to these areas are constructed.

The morning starts in rush hours. The flow in streets consists of not only residents leaving for work, but also employees arriving from the subway. In the streets between the neighborhood and the subway station, temporary street sellers offer simple breakfast to the flow. Senior citizens, who are the minority among all residents, come out especially at this time for take-aways. Different flows encounter in the several alternative routes, which are the boundaries at this moment of the day. In mornings and afternoons, nannies with children stroll in the garden and the plaza where senior citizens from nearby neighborhoods take a walk as well. The boundaries of the neighborhood are set back to the building entrances with digital locks. At noon, employees in the business towers crowd into restaurants in the shanty areas, while the restaurants in the annexes of the neighborhood are not as popular. After lunch, people gather at the plaza in shadows, and some of the employees enter the neighborhood into the garden. They stay in the middle where the seats are, and do not go deep into small paths. Some people like to walk circling the neighborhood. With lively movements the entire area tends to be open. The boundaries are pushed to the big city roads in front of the business buildings. In evenings, the restaurant streets turn busy - the residents in the Ocean Express are averagely young, who prefer to eat out than cook for themselves. Compared to the lunch time, people can go to restaurants in bigger distance for dinner. The spaces in between are boundaries for them. Most of the restaurants close late in the night, and in the area there are also a few bars. People do not like to walk long for the fourth meal. In the night, the garden, the plaza and streets around the neighborhood are dark. In contrast the restaurant streets are bright and noisy, which become the center of the area. People returning home in the night prefer to take the shortcut through shops. Thus the boundary at one side of the neighborhood is penetrated (Figure 5).

Figure 5 – Daily boundaries of the Ocean Express

The daily dynamic of boundaries in the Ocean Express is not as various as that of Xinyuanli. Connections built between community territories and the nearby areas are limited to the main gates and informal passages through shops, due to the strictly kept rules under a "good" management. Even so, there is a mixture between people of different income, educational and class backgrounds at boundaries - the residents from the Ocean Express have higher income than those in the shanty areas. However they have meals next to each other, sits in the same garden, and stroll in the same streets. both neighborhoods, the boundaries suggested by physical indicators are modified by daily activities. It is the freedom of people present at boundaries to follow the rules or challenge them. For example, knowing that the Ocean Express is gated, some employees from business towers choose to stay in the plaza outside, but some others can go in even through shops. The choices depend on the definition of the relation between oneself and the community of each individual. The management maintains rules in the neighborhood, and anchors boundaries to fixed places, despite that it can be against the will of residents themselves (If there were no fence between the annexes, people would not use the shops as shortcuts).

3.3 TEMPORARY BOUNDARIES

Except for the annual and daily dynamic, boundaries are also changed occasionally by temporal behaviors or constructions. When a temporal boundary is reassured by repeated behaviors, it also may become a pattern of long term boundaries and enters the annual or daily dynamic.

In Xinyuanli, the most typical temporary boundary which has turned durable is that at open spaces in front of buildings. Residents from some buildings oppose to government's benefiting from collectively share spaces. As a protest, they put out private objects like flower pots, furniture or even professional parking locks to occupy or reserve their own parking spaces. "the spaces in the neighborhood belong to all the residents, the government has no right to take it away". A resident says so. The action of putting out private objects aims only to mark parking spaces, not to block the pedestrians, but they perceive a boundary out of the objects and do not enter the spaces any more. Despite the temporary look and movability of these objects, they bring changes to the boundary. Another example is about the green areas in the neighborhood that are in bad condition due to the lack of maintenance funds. A local governor Mr. Ding promoted a project to allow residents who are interested in gardening to voluntarily take responsibility for a plot of green area. Unfortunately the project was rejected by the upper municipality, and the boundaries designated to the volunteers do not exist anymore. In contracts, some residents from the ground floor have already planted their gardens in the green area in front of their windows illegally. They managed to redefine long term boundaries without being controlled (Figure 6).

Figure 6 – places where temporary boundaries occurred in Xinyuanli

Such temporary boundaries are rarely seen in the Ocean Express. The seasonal and daily dynamic of boundaries is stable without transformations.

4 PERFORMATIVITY: PRESENTATIONAL AND REPRESENTATIONAL BOUNDARIES IN PERCEPTION

The perception of community boundaries related to activities and behaviors of people can be understood as an event of emergence, which is a result of performative actions.

The term "performative" stems from philosophy of language. John Austin (1962) creates the word to indicate the situation when the utterance of specific words is itself an action. The term was introduced to the field of architecture by Sophie Wolfrum (2010/2015) in the book *Performative Urbanism* to describe the understanding of architectonic space as a situation of emergence, when space appears through the perception of and interactions with it. As an example of understanding movements in urban space as an analog of theater performance, Peter Brook writes "[a] man walks across this empty space whilst someone else is watching him, and this is all that is needed for an act of theatre to be engaged" (Brook, 1968/1996; P7).

Performatives produce meaning, which is not brought in by a plan or the intension of the actor, but brought up with the aesthetic act of an individual. The performative action is "event-ness" (Fischer-Lichte, 2004a). In other words, through performative actions individual "searching for meaning" and collective spirits shape each other and evolve together. The trigger of the event is the perception of a juxtaposition of "the order of presence" (based on individual corporal experience) and "the order of representation"(based on social norms) "(Fischer-Lichte, 2004b, P. 10). The spectator perceives herself as a perceiving subject, as well as

her body as a carrier, presenter, or challenger of rituals. As one of the participants in spatial situations, the individual transforms social norms through staging her movement, and hence partially forms the emerging space. The perception of boundaries as rules distinguishing self and otherness is a consciousness of in-between states between the two orders. Van Gennep (1909/1960) has introduced "liminality" to explain the phase in between two conditions in the rites of passage. Draw on theater theories of Erika Fischer-Lichte, we apply two perspectives of investigating dynamic community boundaries - the boundaries of presentation and the boundaries of representation.

4.1 BOUNDARIES OF PRESENTATION

The presence of a boundary is dependent on the corporal movements in the spatial temporality. Bodies occupy space, and are always defining the boundaries between self and other, which is not at the outline of the body, but in the spaces it influences. Other people's proximity in this space is dependent with his intimacy to me. Therefore my appearance in an open space already defines a boundary. However, only through conscious perception my corporal movements can become performative, and changes in behaviors can be symbolic or even paradigmatic. When we recognize a boundary from our own bodily movement, the boundary comes into being. For example, in the street between two schools in Xinyuanli, shops owners carry out living activities in front their shops in the day. Pedestrians walk in the car lane and do not move between the furniture of the shop owner. A boundary is presented due to the behaviors of both the shop owners and pedestrian.

Boundaries of presentation enhance or challenge physical indicators. In front of the gates of both neighborhoods, a stranger hesitates whether he is allowed to enter. If he watches many other entering without being questioned, he might be encouraged to make a try. On the contrary, if he sees from a distance already that other people are stopped by a guard, he might not even approach to the gate at all. Other people's behaviors are performative that presents us boundaries for them. These are referential hints on the rules for the stranger. As Kafka's parable "Before the Law" (<http://www.kafka-online.info/before-the-law.html>: Apr 2017) implies, a human constructs laws for herself, and only through the violation of them, he can see them. The boundaries presents to an individual when he hits them.

Therefore a boundary is a temporal presentation. It does not pre-exist in physical materials nor can be pre-defined by them. It is stimulated by them. Hence fences are not a sufficient condition for boundaries. It is because we perceived a boundary out of a fence that the fence becomes a symbol for boundaries. And this happening is temporal. A child perceives a climbing game on a fence. In this case no boundary is presented. The presentation of boundaries is also a presentation of territories. When this presence is challenged, so is the territory of a community. It is to be noticed that, the consistent boundaries in our perception consists of inconsistent events that "by chance" enhance the same presentation. There is the potential and possibility that the boundaries are changed in the next presentation.

The boundaries present in temporality, yet our perception is real. We don't experience reality in an empty physical space. Our perception of architectural reality is "far beyond its objective or visual features" (Wolfrum, 2010/2015, p. 13). Instead we experience it in process, in which all our senses, knowledge, and interpretations of other human beings, objects and their relations are involved. Our perception of a boundary endows its temporal presence with meaning. Thus it becomes our reality.

4.2 BOUNDARIES OF REPRESENTATION

Boundaries of representation reside in our interpretation of things out of convention. Gadamer (1975/2004) uses "ritual" to address actions, thoughts and speeches restricted by social norms, morals and customs. Human activities are always conformed like rituals consciously or unconsciously. As social creatures we have already been cultivated with rules of our societies. We unconsciously follow rules in most of our interactions with physical spaces. We avoid eye-contact in a crowded elevator, entering a building through doors instead of windows, and go to bathrooms to use a toilet. Yet differentiated interpretations can appear to a same thing. When it happens, we will be shocked, surprised, and be more conscious of the conventions that shape us. This is very important to the publicness of a space.

Economic activities influence the representations of boundaries. In Xinyuanli and the Ocean Express, retailers stimulate our perception of a boundary. That is because, a mixture of people can bring more customers to the shop, and the gathering of shops can attract more people to come. The accessibility of the people is important, so that the shops prefer a location convenient for both residents and outsiders. Finally, a reaction chain is built in our minds - shops-mixture of people-boundaries. Xinyuanli has a loose management and dynamic boundaries. That is because; it was built into neighborhood units which were dissolved after the economic reform. When it was built, the ideology encouraged this typology under the influence of the Soviet Union. The typology fulfills the urgent need for housing in the post-war reconstruction. This constructs another chain of representation in our minds: old neighborhood-neighborhood units-open community. A similar chain suits the Ocean Express: new neighborhood-commercial compound-gated community. The two neighborhoods are very typical. When we see from afar the towers like those in the Ocean Express, we believe a gated and unshakable boundary. When we have to pass through an old neighborhood with 6-7 floor buildings, we do not expect a guarded gate await us at the boundary.

We endow meaning to things perceived and they come into being. Where is the meaning from? They come from all the events we have experienced in the past. The experiences form our cultural and social backgrounds. When we give meanings to a temporal event, we overlap past ones onto it. If we were stopped once by a guard at a gate, we do not try again at the same place. Our experience tells us a guarded gate normally does not welcome stranger. We would not try in the first place. These are examples when we overlap meanings from the past event onto the current. However they do not match in all cases and this is the precondition that boundaries of presentation can appear.

Boundaries of representation form another reality with have a span in time. The reality of presentation is a short one. When the action or perception stops, the reality ceases to exist as well. Representation is a way to endow events with a consistence in time. Through understanding and interpreting, representation put influence of the past to the present. "A narrative is an account of events occurring over time" (Bruner, 1991, p. 6). Representation connects the inconsistent boundaries into meaningful and consistent experience in the dimension of diachronicity.

4.3 THE TWO BOUNDARIES IN THE TWO NEIGHBORHOODS

The difference in changes of boundaries in the two neighborhoods can be understood with the two kinds of boundaries. In an old community like Xinyuanli, boundaries of representation have been slowly transformed by boundaries of presentation. The latter diverge from the former and bring vibrations in the community. The instability, temporality, and big amplitude are the features of boundaries of presentation. The new community is dominated by boundaries of representation, which tolerate smaller vibrations under the control of rules.

The seasonal changes of boundaries are smaller in the Ocean Express dominated by boundaries of representation, and bigger in Xinyuanli, dominated by boundaries of presentation. The seasonal changes of boundaries synchronize the atmosphere with nature. This can be perceived by resident, and are call in Beijing dialect "connection to the earth", a quality appreciated as healthy for one's life. The Ocean Express is often described with "fashion" and "quality", which we think, indicate that the stability of boundaries.

The daily changes of boundaries in Xinyuanli show a feature of penetration. The space of the neighborhood is porous, and the connection between residents and outsider take place in the major street between residential buildings. The changes of boundaries of the Ocean Express take place in the surrounding areas where the perception of boundaries is not restricted strictly by rules. The connection between inner and outer space of the neighborhood happens only at the guarded gate. The regulations at this gate are decisive for the daily changes of boundaries at this neighborhood. The daily dynamic of boundaries reveals the community's capacity of interaction inside and outside its general territories.

Temporal changes of boundaries take place only in the Xinyuanli, where boundaries of presentation may appear at any location of the neighborhood. The presence of temporal boundaries can be a public event that influences the social of the community, such as the participatory negotiation of parking places in Xinyuanli (now there are three parking modes, governmental management, spontaneous occupied, and

self-organized). To limit the possibility of temporal is to kill a possibility for publicness in community spaces.

Finally, both the two neighborhood have a stable boundary in both presentation and representation, thus, the walls.

5 FRAMEWORK: ANALYZING DYNAMIC COMMUNITY BOUNDARIES

Inspired by the observations and analysis of the temporality of boundaries in the two neighborhoods, and as a basis for new forms of analysis and discourses, this article proposes a framework of the most significant elements in the perception of boundaries changing in time.

Drawing upon the analog between theater and urban theories on performative actions, the text above has discussed the two different but interrelated perspectives of the perception of boundaries theoretically and abstractly. In combination with the discourses in the first part of specific changes of boundaries in time, we will provide practical and specific elements that influence the perception in four categories: physical stimulators, movements, regulation-participation, and interests-symbols.

- Physical stimulators: The stimulation of physical indicators is a result of both presentations and representations. There are significant physical stimulators, such as walls, gate, fences etc. are representation of social norms. Many stimulators are insignificant. They function in the interactions with humans. These stimulators include tables and chairs, flower pots, height differences and so on. The miss-use of some objects may change boundaries as well. For example, hanging clothes on fences, use flower beds as benches, accommodate or open shops in gate house, etc.
- Bodily Movements: Bodily movement influences boundaries of presentation. Some movements are temporal, such as pupils play with barriers in the middle of a street, residents play cards under a big overpass, people gather at a gate and chat, etc. some movements are durable, and may have impacts on physical spaces, such as building extensions or front gardens, regular street shops, etc. Some other movements repeat, but do not change physical spaces, such as traffic flow in rush hours, parents waiting to pick up children at the school gate, etc. These movements set up invisible boundaries at other times of a day, yet community members know them well.
- Regulation-participation: Regulations mainly influence boundaries of representation, and participation challenges or enhance regulations through presentation. Some regulations do not allow questioning, such as a door with a digital lock. Some regulations are presented through movements, such as private parking places without a mark. Only with agreement and support from the neighbors can it run good. Some regulations limit only specific behaviors, such as distributing leaflets, taking photos, etc.
- Interests-symbols: Interests-symbols support the formations of boundaries of representation. Economic interest drives the management in neighborhoods, and decides whether the boundaries are penetrable in different situations. Symbols in spaces or symbolic spaces are promoted by the drive for more benefits. Symbols are visualized desires for interests. In neighborhoods, symbols take the forms of splendid gates, slogans, uniforms etc. they enhance the distinguishing of self-other, and emphasize the exclusiveness of boundaries.

6 CONCLUSIONS

This article views community boundaries dynamically. The perception of boundaries is derived from the distinction of oneself and others. The seasonal, daily and temporal changes of boundaries in two typical neighborhoods in Beijing show that boundaries are results of both presentational and representational understandings. Based on theater and urban theories on performative, the article has argued, the differences in the boundary changes between old and new communities origins from the difference in the dominant type of boundaries. The presentational boundary dominated neighborhood tends to have intricate connections to the outsiders while the representational boundary dominated neighborhood has the connection outside in the surrounding area. The analyzing of dynamic boundaries in neighborhood

should consider the four aspects: physical stimulators, bodily movements, regulation-participation, and interests-symbols.

1. Evaluation of the temporality of community boundaries: Our observation in the two neighborhoods has shown: the more dynamic in time the boundaries are, the livelier the community is. Senior citizens make exercises, children play games, and employees take breaks - different groups of people in age and class encounter in boundary spaces. The tolerance to changes of boundaries promotes social interactions, which are positive aspects of urban life, and the urban development that Chinese government promotes.
2. The Chinese tasks: The dynamic of boundaries is relevant to the openness of the community. Hence an open community brings positive aspects to urban life. Closed neighborhoods were invented in China under the planned economy system. The strict function division segregates living, recreation, service, etc. Such arrangement cannot fulfill today's requirement on variety in life. On condition that there are still great amount of gated communities in China, opening boundaries has a profound meaning in the basic demand for communication and participation of the contemporary urban life. The Chinese government has already recognized the importance and urgent need of openness in communities. In February 2016, the Chinese government published the CCCPC's "Opinions on further reinforce city planning, construction and management work", which points out "urban blocks should be promoted in the new built residential neighborhoods and closed Small Residential Districts (SRD) should be in principle avoided. The already built SRDs and Danwei Compounds should be opened gradually. ...", open communities will be the main stream for housing in the future.
3. Duality and balancing: closed neighborhoods with boundaries of representation have stronger feelings of territory, which is better for security and maintenance. Open neighborhoods with presentational boundaries can promote interactions, liveliness and social coherence. In actual practices we should balance between the two types of boundaries and taking human activities into consideration.
4. Future works: Residents in China have the requirement of sense of security. This is the difficulty that open communities have to face. The future works should investigate design methods combining physical space and the behavior patterns of different groups of people at different times. Security and management methods of open communities, boundaries which promote social connections and coherence, and methods of opening existing closed neighborhoods should be developed in the future.

montejanoc@yahoo.com

1 THE SENSE OF PUBLIC SPACE IN THE CITY

In recent years, the topic of public space has taken a lot of force, leading to discussion with different perspectives in forums of international importance and intertwining it with issues of urban planning, culture, economy, politics, disasters or morphology to name a few. Its recent relevance is not only because of its new consideration as a subject of study, but mainly because of its importance in practice, that is, due to its use, function and design with the main focus of caring for the human being in his daily life in the city.

In the 21st century, the public space is known in different ways, it can vary according to culture and territory (different practices in each city), as well as in the form: parks, squares, gardens, streets or public institutional spaces. The complexity of its study does not depend on its approach, but on the integration of several approaches to address the reality of the city. In this sense, the urban processes that transform the society also impose new trends for the public space, that is, the economic, political, technological and cultural transformations are captured in the public space as a reflection of a changing society with demands that go at great speed.

With the assumption that it is essential for urban studies to include different approaches, and to pay attention to the processes that transform the city, three views are taken into account for the understanding and analysis of the public space: 1. The social vision in the human sense of habitability, i.e. the human condition of public space, 2. The inclusive vision regarding physical and social aspects of the public space and 3. Finally a vision in the globalized sense of the trends reflected in the space.

The social vision in the human sense of habitability for the public space. New forms of life have been generated in the city from the advent of modern technologies and economies that produce different needs to those of other times, such as: WIFI connections to enter an alternate public space, individual electrical connections, if they are used as a place of work, stations to recharge electric cars, bicycle stations, to mention some of the recent elements in public spaces, however, there are dynamics in them that cross the barriers of time and that are part of the daily life to live the city, such as: places of rest, recreation, encounter and sociability. Currently new public spaces are being created that reinvent the city, making it more livable and of course more desirable.

When we talk about desirable public spaces, it could be seen as something subjective. Each human being thinks differently and according to their cultural characteristics, and to that extent, needs could vary. But even in the same country the geographical or economic situation of each family would imply different demands. Something is very certain, however, and that is that we all have the need to co-inhabit. Each

species on this planet has its natural habitat, fish water, monkeys the jungles and forests, lions the savannahs. Habitat is where species are born, grow, reproduce and die, that space on earth where they meet all their needs. Even when human beings are governed by this general rule, there are two fundamental elements that make them different from other species: the first and most important is that their habitat is not natural, but artificial; and secondly, apart from the physiological needs they need to satisfy, they are also creative beings (Chain; 2010).

Habitability is defined here as the capacity of a place to meet human needs (Mues M., 2011), and although several authors consider that habitability refers only to the material and structural conditions of built spaces (Blanchera, 1967), (Saldarriaga, 1981), (Juárez, 2003), without taking into account the social aspect in the outside (Velazquez, 2011), habitability for man would be as much within the architectural element as outside of it. Habitability goes beyond the door of the house to the street, towards the public space, where the social function, the community, comes into play, because it is there where "the expression and social identification of the others is built", based on the expression and symbolic construction of the space (Carrión, 2002: 5-7), we leave our house behind to find a huge machinery concentrating the totality of our culture, but which also encapsulates international movements and trends we must incorporate during our journey.

The habitable public space is one that maintains a balance between the material and immaterial elements that intervene in the places of free access for all human beings, regardless of gender, religion, race or social class in order to satisfy the collective needs. Elements of habitability in the public space can be

measured and diminished, as appropriate, taking into account the global and local transformations, and the determinants of type of settlement, but ... How do we know if the public space is to a greater or lesser extent livable? For this we consider three theories:

According to the theory of human need by Doyal Len and Gough Ian (1994), needs are constructed socially and derive from the cultural environment. The authors take into account indices to measure the welfare between nations based on the needs of: Appropriate health care, security, economic safety, clean water, adequate food, shelter as a means of protection from the elements, relationships of recognition, safe working environments, relationships of recognition and belonging (Len, Ian:1994 in Reyes:2012; 132). The needs proposed by this theory are general and can be considered basic in different territories and different social groups. It should be taken into account, however, that the cultural and natural environment, the new technologies and even the policies for urban space, make human requirements more complex and even different. This is the case of multicultural cities and the public space should regard it as principle to meet the needs mentioned above.

Max Neef's theory (1994) to analyze public space in the area of habitability combines criteria from existential and axiological categories, where existential categories focus on needs of being referred to personal or collective attributes, having which contain the mechanisms and laws required, doing as personal or collective actions and interacting in those spaces of action and construction of needs, satisfactors and economic goods; while the axiological categories cover the requirements of: subsistence, protection, affection, understanding, participation, creation, identity and freedom (Neef: 1994 in Reyes: 2012; 131). This refers us, in terms of the existential category, to social action that allows us to build axiological relations that give meaning to space.

Schiller's theory (2000) is that of the qualities of the habitable public space where, from variables with a specific meaning and value, he measures the habitable public space, and the qualities space should cover for habitability are: permeability to allow open connections in the urban fabric by measuring them according to the size of typical urban blocks and the elements that can limit them such as railroad tracks or other types of barriers; vitality as a characteristic of the spaces to be places of social interaction measured through the activity there; variety to encourage the complementary uses of the city, variation of typologies and uses; readability to facilitate social and spatial relations from the variable use and density of those who use the city; and robustness which allows an adequate combination and variety of uses at any time of the day with the ability to adapt the space (De Schiller, 2000:4 in Valladares, Chavez, Moreno:2008; 10-11).

According to the theories above, analysis of the habitable public space must be made taking into account physical elements and the design of the space, and also considering the social elements of basis subsistence and even the more complex ones such as identity and legal duty. Therefore, we can examine the public space in two dimensions, where the different needs of humans can be encapsulated for the

analysis of habitability in the public space, the first, the physical or material dimension, and the second the intangible dimension, which goes from the social to the spiritual.

In the physical or material dimension, it is possible to concentrate the tangible and quantitative elements that are presented in the urban space, such as: public water services, drainage and light, street furniture, transport infrastructure with subway systems, metrobus, light rails, suburban trains, buses, combis, bicitaxis, bicycles, recreation areas, roads, streets, avenues, circuits, highways, communications infrastructure, public telephones, internet, police officers, security modules, road safety. It is important to mention that the city also has infrastructure for housing, education, health, among others. Similarly, in the immaterial dimension, which goes from the social to the spiritual, it would be the one where we find intangible elements such as: the urban social identity, symbolic interactionism, perception of security, culture, and social exchange.

The inclusive vision regarding physical and social aspects of the public space. The situation of inclusion has generated in this century a strong international interest impacting on issues such as education, housing, migration, health, public space. In this sense, the definitions of the public space towards an inclusive view of the city make sense mainly because they consider that they are by man and for man. Consequently, public places belong to all and are for all. They are spaces people can freely access with no distinctions of gender, religion, race or social class. Their inclusive meaning can be put at risk, however, on the one hand, due to the problems that arise in the city, such as: an uncontrolled population growth, global transformations, privatization, appropriation, fragmentation, segregation, among others; (Moreno, 2011) and it is complicated when "Environments, individuals and/or groups can be perceived as a threat, that affects access to the public space" (Tiesdell-Oc, 1998:648 in Asriany-Silas-Soemarno:2011; 163-167).

The 'inclusive' public space is the place where activities and discussions are open to all. It is the place where authorities have the responsibility to guarantee the existence of a public space where people express their opinions, assert their claims and use it for their purposes (Asriany-Silas-Soemarno: 2011; 163-167). However, if there is this concern about inclusion, it means that there are elements that make cities exclusionary so that inclusion-exclusion are studied in a dual way. To this end, two aspects of study are taken into account: 1. Social inclusion by exclusion and 2. Physical or design inclusion:

Social inclusion by exclusion. Public space historically has been valued as a factor of social inclusion, and as an inescapable instrument for urban planning. However, the loss of protagonism due to the weakening of previous forms of sociability (resulting in social inequalities and fragmentation) and the emergence of alternative forms of relationship (of communications and encounters introduced by technology, the feeling of insecurity), have sharpened the barrier between recreational and leisure spaces that are used by

different social groups. Not forgetting that people of higher income go to private places to recreate, using the street just to circulate, not caring about the state and the quality of public space, which often remains in the background and helps to generate what Bauman (2009) calls "ghettos of exclusion" (Vainer; Leicht; Varela; Rabellino and Musso: 2013).

Ramírez Kuri and Ziccardi identify as discriminatory practices those observed in the labor market, such as access to goods and services, the weakening of social cohesion; luxury consumption activities that can be dissolved by making effective economic, social, cultural and sustainable rights which encourage the integration of the society with the city; informal activities and social conflicts (Ramírez and Ziccardi, 2008: 23-48).

And on the other hand, we have physical inclusion or inclusion by design. In the search to determine the components that the public space has for inclusion, we return to the studies that have been carried out to identify the components of exclusion that Ramírez Kuri and Ziccardi analyze, such as: the location of the place to determine the quality of services and their infrastructure; the informal and established commerce that pervades the urban space and which fosters crime; the deterioration of the public space and its accessible design (Ramírez and Ziccardi, 2008: 23-48). However, these elements are taken in reverse, that is, on the positive side of that which the public space must have to be considered inclusive, such as enough urban infrastructure.

In the design of inclusive public spaces, it is essential to take into account the physical components that foster social integration. From the perspective of Sergio Zermeño, the following are identified as components of exclusion: inaccessible primary and secondary roads; public spaces of richer classes

appropriated by needy sectors; crossroads, roads, squares, parks, sidewalks, etc. which operate as frontiers, excess of surveillance, corridors watched by guards, police officers, cameras; and he also identifies social components such as: high risk of violence and virtual walls (Zermeño: 2008; 135-152).

A vision, in the globalized sense, of the trends reflected in the space. Cities, depending on their territory, are changing and growing at different and accelerated paces, fostering cultural exchanges and adopting trends that are fashionable in the urban landscape. For Manuel Castells, these global trends leave their traces in the public space, and make visible the economic, political, cultural and social differentiation that distinguishes the city in its local and metropolitan dimension. If we talk of divisions between public spaces through symbolic significations in the cities (Castells, 1977: 32); then places of public ownership are the expression of their society and culture in a temporality determined by the processes that influence on them.

Public-owned spaces must be able to adapt and survive to global transformations, which by their very contrasting nature absorb these changes in different ways, depending on their environments and the impacts public places are constantly having. Globalization, one of the strongest influences on a city in every sense, whether to its society, space or culture, reinvents them as great scenarios with strong economic and political rather than cultural and social alterations which irreversibly impact on the city's inhabitants. In this sense, the overall composition of the public space is witnessed in two aspects: The public space as an alienable resource, in the sense of appropriation and privatization; and the public space affected by its constructions, in the sense of transformations.

The public space as an alienable resource through appropriation and privatization of the space in a non-legal way. This causes scarcity of public spaces, mainly because of the wide commercialization of everything, a reflection of the globalization, bad economy, excessive appropriation and high delinquency, as this is fundamentally brought about by street vendors or informal establishments that create pervaded scenarios. The transformation of Latin American cities and their spaces are a consequence of social, cultural and technological phenomena. These changes create a new form of social organization, a new cultural model, which can be called postmodernity, globalization or neoliberal culture. This regards the space as a resource, a product, with social, sensual and symbolic policies, which appropriate, use and transform the spaces of cities (Remedi 2004: 15-19).

The public space appears increasingly blurred of the urban by obliterating the relationship between the public and private. This creates a new conception of the forms of organization in public spaces, which, for its better understanding, we will analyze in four different approaches: from the perspective of its transformations, looking for the historical context of its changes; from the point of view of actors who carry out specific practices, witnessing how social practices affect their structuring; from the local forms of appropriation and significance, and from the tensions and conflicts that their use and appropriation cause (Portal, 2007: 9).

On the one hand, there is a discussion about the detriment that has been caused to space due to this misappropriation and use. Duhau remarks that the intense use of public spaces for free transit, recreation, circulation and free access to commodities, as a crossroads of coexistence between strangers, etc., together with the public policies and globalization, has caused a crisis (Duhau, 2008: 137-145).+ On the other hand, there is the loss of quality of public spaces due to the effects of abandonment, deterioration, privatization and segregation, causing urban disintegration. Public spaces cannot be studied, disregarding the norms and regulations that rule them (Duhau , Giglia 2008: 45-53).

It is a reality that the deterioration of public space, and its privatization is a consequence of a badly planned or poorly governed city, but also of global inclusions not adapted to each culture but which are rather more generalized, and which are of a political or economic nature that benefits only the hegemonic class leaving aside the working classes. When this social segregation occurs, there are sometimes demonstrations of the people affected to defend places that are part of their daily life. This is also another way of appropriating public spaces. However, existing interests can be stronger, and appropriation of public spaces can become one of the most important factors of risk, which can lead to the destruction of public places. Appropriation contains social, state and private actors.

The public space affected by constructions, in the sense of transformations. It is evident that the production of public space in current cities has changed, the measures for its construction and even its activities are different, but, what is the cause? Although the causes can be many, there is still an ongoing

search for the logic that gives us elements to understand the urban transformations that have been tried to be defined with names that are sometimes even difficult to pronounce, composed or decomposed words or more than one to name what is happening: redensification, urbanization, consolidation, gentrification, multiculturalism, people participation, among others.

In Latin America, the study of processes such as gentrification is recent. Although it is true that the bases defining this concept are not new, the term itself is relatively young, invented by the British sociologist Rut Glass (1964), who observed the differences in social structure from the establishment of higher-cost housing in specific areas of central London, thus examining the invasion of middle and upper classes on working-class neighborhoods, displacing and changing the social fabric.

Later, the sociologists Bruce London and John Palen (1984) tried to explain gentrification by means of five theories that involve different aspects of the life in the city: the ecological-demographic theory, which refers to population and generational statistical aspects (baby boomers); the sociocultural theory, seen from the values, feelings, attitudes, ideas and beliefs of society; the political economic theory, which is based on two approaches: the traditional and the Marxist ones; the community network theory: the community lost and the community gained; and finally the theory of social movements and the influence of counter movements (London and Palen 1984: 4-26).

On the other hand, in 1987 Neil Smith's view proposed two theories to explain gentrification by observing the phenomenon from the economic and social point of view with the "production-side theory" and the "consumption-side theory". These theories address the problem of the automobile, urban expansion, changes in lifestyles, depopulation of the city center, transport and pedestrian spaces, where human relations are diminished, but above all, he focuses his research on the results of increased employment in business districts. The interest of this geographer in these elements is an answer to the very elements that have caused the greatest problems in recent decades and which have been part not only of gentrification, but also of the processes of redensification, rehabilitation and the numberless patches made cities (Smith, 1987: 462-465).

For gentrification to exist, it must be in a specific geographical space and it is considered to be happening when there is a process of investment and reinvestment of capital, when there are a series of transformations in the urban landscape due to the settlement of higher income social groups in these specific geographies and when there is a direct or indirect displacement of the existing social groups (Janoschka, 2011). In the current debate, Michael Janoschka addresses gentrification with 6 points: 1. Neo-liberal policies of Gentrification, all types of public policies that establish an alliance with the capital that is invested in the city; 2. Supergeneration, when a place has been gentrified at two different historical moments; 3. Gentrification of new areas, industrial areas or ports where there is no gentrification by direct expulsion, but through all the indirect processes that occur around these neighborhoods; 4. New geographies of gentrification: spaces that have not previously been identified as spaces of gentrification, rural and suburban neighborhoods; 5. Symbolic gentrification: virtual sale and placement of new economies; and 6. Resistance to gentrification: the congregation of the community to prevent the inflow of foreign capital. (Janoschka;2011). Thus, the integration of different urban processes affects constructions and make up, renew and transform the city, affecting the dynamics, practices and design of urban spaces, which is a witness of the reinvention of the city in smaller scales.

2 URBAN RECOMPOSITION IN MEXICO CITY

In the case of Mexico City, the last decades of the twentieth century brought a change in public policies and a depopulation of the central parts, especially due to the process of deindustrialization and the earthquake of 1985. This meant a reinvention of the city for this century, through standards that call for a Redensification and the opportunity to occupy spaces that were attractive to the private sector during the first decade. This meant that the city exceeded its limits, gentrifying spaces and consequently producing poorly rehabilitated residual public spaces or the creation of reduced spaces. New policies. The instrument for urban development policies called "Bando Dos", proposed to redensify the city with the specific objective of ordering the urban growth of Mexico City, preventing the construction of more housing in the outskirts of the city. The instrument was presented on December 7, 2000 by the then head of government (Andrés Manuel López Obrador). It had different objectives for the ordering of Mexico City, such as: To stop disordered growth; to safeguard the preservation of soil of the then Federal District (now

Mexico City DOF 05/02/2016), preventing the growth of the urban areas and thus avoiding covering the recharge zones of aquifers. It was determined that the districts that had suffered considerable depopulation were mainly four: Cuauhtémoc, Benito Juárez, Miguel Hidalgo and Venustiano Carranza, all located in the central area of the city. It was also assessed which had been disorderly populated, predominating the south and east. It was determined that there is little infrastructure in the city for a strong real estate development (Bando 2: 2000)

Among the policies implemented was the promotion of population growth towards the districts of Benito Juárez, Cuauhtémoc, Miguel Hidalgo and Venustiano Carranza to take advantage of the infrastructure and services that are currently underutilized, and the construction of housing for the lower-income classes (Bando 2: 2000). However, in these central districts, such as Benito Juárez, the project did not work as expected. At first there was a real estate boom, but if it was not successful was because of the high cost of housing and the poor infrastructure. In different neighbors, there was a wild transformation of the city landscape by cutting down trees, constructing big buildings: where there had been houses for 6 to 8 people, now there appeared buildings with 8 to 10 floors for many families. In these new buildings, however, not all apartments were sold. As a part of the first consequences, in 2010 the government of the Federal District at the time, together with the Ministry of Social Development (SEDESOL), the National Council of State Housing Entities (CONEREVI), The Autonomous University of Mexico (UNAM), the Housing Fund of the Institute of Security and Social Services for State Workers (FOVISSSTE), the National Workers Housing Fund Institute (INFONAVIT) and the Federal Mortgage Society (SHF), publish the guide for habitual re-densification in the internal city, in which they present a methodology to identify re-densification scenarios, as well as instruments to favor it so as to join the smart city growth system and position Mexico in the international environment in this respect, for which they are planned to address a series of issues, such as: Increase in the costs of displacements of the inhabitants of said areas; greater consumption of fuels and greater production of emissions polluting the atmosphere; loss of preservation areas, aquifer recharge zones and agricultural production areas; higher costs of urbanization that represent a significant burden for local governments; and social and economic segregation of urban space (GODF:2010).

The approximate ten-year wait for this guide to be published, to take measures on matters of re-densification policies, caused for constructions to be carried out during that time in different zones that lack integration with the social fabric, for it has been seen that elite zones are created, which keeps the population dissatisfied and afraid of being displaced. There was an unlimited number of claims derived from the implementation of the Bando 2, caused by: the fear of the modification of the environment, decrease of the quality of life, of safety, of the value of real estate, feelings of dispossession or feelings of injustice, for decisions were made that affected the territory without the main interested parties being informed, taken into account or heard, a loss of confidence of the population in the authorities and experts that promoted the project, above all when there is a tradition of local organization and mobilization, risk perception and a feeling of uncertainty. The technical and scientific studies that validated the project were questioned (Alba:2009;56).

Deindustrialization. With the economic opening abroad with the 1988 free trade agreement, there was a shift in the activities of the manufacturing industry that caused a process of deindustrialization. The industries were moved toward the outskirts of the city or even toward other territories (Asuad:2010). This process is not yet finished. There are still areas of the city with disappearing industries. With this movement and the change toward a tertiary economy, the reconfiguration of the city was affected on one hand due to the opportunity of land within the city, seized by the real estate power, and on the other hand due to the change of policies that did not work as expected. In Mexico City some of the areas that have passed through the process of deindustrialization at the end of the 20th century were the delegations Benito Juárez, Cuauhtémoc, Miguel Hidalgo, Venustiano Carranza, as well as Azcapotzalco and Gustavo A. Madero (Sobrino:2002;7). In recent years the mass production of housing has captured some of these areas, leading them to transformations that are a result of the inclusion-exclusion struggle that is reflected in the absent public space. An example of this is the case of the Granada and Ampliación Granada colonias, in the Miguel Hidalgo delegation, which has been a categorical place throughout History. From an economic point of we could say that it has gone through three sectors: agricultural, industrial and tertiary.

In 1920 the lands of the Hacienda de los Morales were divided, playing a significant role in the urbanization of the city of Mexico due to the fact that part of the space was used for the colonia Polanco

assigned to upper middle housing, in which the colonia project of the first half of the 20th century was based on public space. This was key as it grew until it was divided into five sections, sharply contrasting the Granada and Ampliación Granada colonias, which began to be industrially established without public spaces. The following are some of the factories in the place: the General Motors Factory in 1923, the Mexico glass factory in that same year, the Modelo Brewery and the General Popo in 1925, the Tabiques La Universal Factory, whose year of establishment is unknown, the Chrysler Factory in 1939 and thereafter until 1961, the Palmolive Factory, the Halaxtoc textile factory, Laminadora LMMSA, pharmaceutical industries, Factory in lake Andrómaco, Bolt Factory, Factories in lake Neuchatel, Furniture and Steel Factory and another Cotton factory (Palacios; 2010-79-96). Reconstruction of the territory. By the start of the 19th century, the Granada and Ampliación Granada colonias were changing their morphology, land use and population. The main change was the use of industrial land to residential land, which was attractive for real estate developers, who saw that its potential was supported by the urban image of the bordering colonia, Polanco. The two colonias were given different informal names following the first interventions: Ampliación Polanco, Polanco Bis, Polanco II or the Nuevo Polanco, however, a series of contrasts have been seen between Polanco and the Granadas (Ampliación Granada and Granada). The most significant contrast is the type of public space that there is between one and another, and in spite of the luxurious residential buildings that broke the specification of the Bando Dos and standard 26 to create housing construction of social and popular interest on urban land, and thereby re-densify the zones of Mexico City in which there is a certain lack of population, they lost the opportunity to create housing with quality public spaces (see figure 1).

Figure 1. Urban transformations occurred in the XXI century in the territory of Ampliación Granada (Expansion of Granada Neighborhood) and Granada Neighborhood in the period between 2001 and 2016. Source. Google Earth images from 2001 to 2007. Information from 2008 to 2016 is based on own field survey illustrated on Google Earth maps.

Due to the rapid and disordered growth in some areas of Mexico City, in 2013 the implementation of the standard that presented the redensification was detained due to the abuse of the land use and its changes in the type of housing that should be implemented. However, in that same year the Action through Cooperation System (SAC) was created, which is an instrument to manage and create policies that include public action, the intervention of the State, as well as the private party, that is, the participation of land owner companies to interact with each other in the interest of improving the city for which the Department of Urban Development and Housing (SEDUVI) is responsible.

One of the main characteristics of the area is that at its pace of development not only has housing been activated for elites, but commercial and service activity has also been developed, creating large office buildings or shopping centers with foreign brand stores. It has become common in the area for small shopping centers with convenience stores, mini-supers, restaurants, cafes and bars to be made in the lower part of housing buildings. The main problem was that there were no public spaces. However, far from providing a solution, due to the new constructions trees have also had to be cut down, trees that have been changed for ornamental plants that represent consequences for the environment and a deterioration in life quality. Thus the place only has what are now the public spaces of the 21st century, such as: pocket parks (three on the Cuernavaca Railroad), linear parks (that of the Cuernavaca Railroad) and low bridges (that of San Joaquín at the intersection with Moliere). In contrast with the wide parks and walkways that the Polanco has (see figure 2).

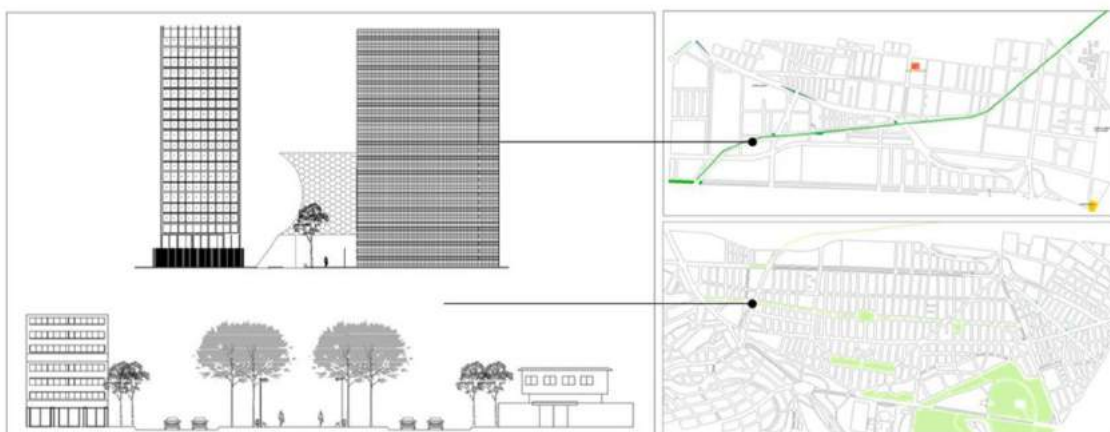

Figure 2. Urban sketches of public spaces in the Neighborhoods of Granada (left at the top) and Polanco (left at the bottom) and their location. Source. Own elaboration.

3 THE QUALITY OF PUBLIC SPACE IN THE 21ST CENTURY

Who builds public space in Mexico City? In Mexico there are various governmental instances responsible for intervening in or making public space, such as: The Department of Urban Development and Housing (SEDUVI), the Public Space Authority (AEP) or the different delegations. However, when the public space shows specific characteristics and values for which it has been cataloged as equity, the instances for intervening in it change, or they are accompanied by certain strict guidelines for their regeneration, such as the INAH, the INBA, the Historical Center Authority or the UNESCO, according to the case. Each one of the aforementioned instances intervenes in public space from different perspectives and with various actors. The Department of urban Development and Housing, for example, is responsible for designing policies applicable to the city, attempting for them to integrate society when acting and interacting with it, so as to transform the city in an inclusive manner. It creates the Programs of Delegations, Partial Programs and the Urban Development Program for the purpose of ordering the city in all its aspects; mobility, public space, housing, urban infrastructure, basic services, always with the idea of improving and positioning it as a safe city.

On the other hand there is the Public Space Authority (AEP), which is a decentralized entity of the SEDUVI. It not only designs policies to apply them to urban space, but also directly intervenes through the design of the space and the contracting and subcontracting of construction and design companies. Some of its programs and projects are: Ecopark, Bajo puentes, Pasos seguros, publicidad exterior, Parques de Bolsillo, Parques lineales, among others. The AEP was created in 2008. It works on the various projects

with different companies, for example: CTS Embarq with the model street, GABANA engineering and GCB Construcciones y servicios for the refurbishment of the street Torcuato Tasso, Proyecsa e Ingenieros, ANACE construcciones, group Q and B and Servicios integrados RUBE for the regeneration of the Alameda Central, Grupo Velasco, JM Constructora, Kassar Construcciones, 128 Arquitectura and Diseño Urbano para Espacios Públicos de Bolsillo, to mention a few.

With respect to the organization of the Historic Center of Mexico City, there is another decentralized entity called the Historic Center Authority, created in 2007, which proposes public policies for integration and promotes the refurbishment of public spaces located in this square. However, there are various actors that participate in the intervention and construction of public space. Even when the aforementioned entities are present, the participation of the citizens is already contemplated in almost the majority. Participating in the modifications of the urban environment means a social commitment more than a political one, but the action surpasses that which is social, political and economic.

Mexico City public space programs of the 21st century. Since the first decade a series of urban projects were implemented by the Department of Urban Development and Housing (SEDUVI) and the Public Space Authority (AEP), to create or intervene in spaces with characteristics of deterioration and abandonment in some cases, including economic activity, which addressed the demands of the inhabitants. On one hand, among the newly created public space projects were those that had a renewed design, with the minimum characteristics necessary to be used and enjoyed, such as: low bridge projects, public pocket parks or bonds of friendship. On the other hand are the projects of improvement and refurbishment of public spaces, in which there are: improvements of spaces with an inclusive design, refurbishment of heritage spaces, pedestrianization and semi-pedestrianization of streets, illuminate your city program, ecoparc and refurbishments of monuments (see Table 1.).

Mexico City public space programs of the 21st century.			
Newly created public space programs		Public space refurbishment programs	
Public pocket parks	Design of social interaction, identity and economic activity, in remaining streets or spaces between buildings.	Refurbishment of monuments	Its purpose is to rescue sculptural monuments, integrate them harmoniously into public space and recover them for interaction.
Bonds of friendship	Project in the development of cultural and political relationships between the two countries, through the donation of a sculpture placed in a newly created public space	Improvement of spaces with inclusive design	Improve pedestrian accessibility and the vehicular flow of the avenue that was inadequately designed for the intense pedestrian and automobile capacity.
Underbridges	This seeks to rescue abandoned or under-used public spaces, providing them infrastructure with high technical specifications to address the basic needs of the population, including spaces for commerce.	Illuminate your City Program	This unifies public lighting in primary and secondary roads to prevent the "zebra effect" from being produced, which is a phenomenon that creates variations in the intensity of the lighting of the streets.
Pedestrianization and semi-pedestrianization	Consolidate the pedestrian section of Public space of the Historic Center, promote sustainable mobility, optimize vehicular and pedestrian travel times, provide universal accessibility and optimize the heritage value of the area.	Ecoparc	Recovery of public spaces through the installation of parking meters. This improves the mobility of the city.
Mobile park	Spaces assembled in trailer parks, equipped with game tables for children, a rest area, green areas, with natural vegetation and chairs called Park-es. These are placed in spaces that are generally used as parking lots.	Refurbishment of heritage spaces	This complements the recovery of public spaces of the historic center, and additionally promotes the use of heritage spaces by optimizing their social function and spacing in benefit of the inhabitants.

Table 1 Public space programs activated in the 21st century in Mexico City. Source. SEDUVI

How is the quality of public space measured? With the history of the importance of public space in the City and the influence that urban interventions for luxury housing have had in recent years, as well as the recent public space programs, a Model is created to evaluate the quality of the public space in terms of inclusion or exclusion, measured using the following variables and instruments applied in the area of study of Granada, Ampliación Granada and Polanco (chart 2):

Variable	Instrument
Accessibility The degree or measure in which all people can use a public space	Plan or lines of public transportation (metro, bus, combi), plan for taxi sites, plan for bicycle sites, plan of virtual accessibility and crossstab plan
Balanced Residential Adjacency: The housing around public spaces must be balanced with the rest of the services	Land use plan (diversity of uses), residential land use plan, adjacent housing plan with real heights (2 levels, 3 levels, 5 levels, etc.), closed neighborhoods plan and Aerial Photography
Lighting, Temperature and Humidity: The characteristic of lighting in public spaces can determine their stay in them and their daily hours of life.	Height of buildings, luminaries, terrestrial photography, aerial photography, lux meter and thermometer
Urban Furniture and Infrastructure: The tangible and quantitative elements that are in the public space	Plans of the public spaces chosen with details of furniture, urban infrastructure plan of the space, adjacent urban infrastructure plan, terrestrial photography and aerial photography
Perception of the Urban Space: How the resident feels about the place. In other words, if it is safe, if they feel included or excluded.	Photography, interviews, graphs and charts
Control: Physical elements of security that control the space, such as cameras, police, surveillance modules, neighborhood watch	Security camera record plan, security module record plan, photographic record of human elements of security and interviews.

Table 2 Variables and instruments for analyzing the quality of the public space. Source. Personal.

For clear representation, the results are shown in a graph in a model of six concentric axes, forming two hexagons on the same axes. The perimeter of the hexagon is the coordinate zero, while the perimeter of the external hexagon is the coordinate +2 (a very inclusive space). The center of either of the two hexagons shall therefore represent a very high exclusion. In other words, the more covered the area of the hexagon is, the more inclusive that public space will be. The model was applied in all spaces of Polanco and las Granadas. The main result was that in the Granadas colonias, although they had the determinants for their space to be recomposed through public spaces as the base of the project, this was done in an isolated manner, causing for the new pocket public spaces and linear parks determined by the economic tendencies to be places of exclusion, due to the fact that, for example:

- A lack of accessibility is seen as there are no free internet networks in the public space and there is no bicycle parking as opposed to Polanco, in which there are. Although there is public transportation near the place, it has become exclusive due to the saturation of its use;
- The residential adjacency is not balanced, for although the land use is variable, the residential complexes in the area are very high, for closed neighborhoods are dominant;
- They show records of temperature, humidity and lighting that are not comfortable in shade, since in some cases they have little exposure to the sun, and the sun directly in others. All of them are highly humid and the records go from the lower to the upper limit, due to their low vegetation and the material of their environment.
- In general their urban furniture and infrastructure is normal, for they have benches. However, they do not have trash bins, much less fountains, sculptures or playgrounds. However, although they do not have their own luminaries, they have exercise machines.
- An urban space is perceived in low conditions for use and enjoyment due to the previous determinants. They feel that it is unsafe and feel excluded from some parts by the physical barriers that are in the place, such as the cyclone wire fencing that divides it.
- In general, personal control systems and surveillance cameras are excessive in some parts (see figure 3).

4 CONCLUSIONS

The implementation of urban phenomenon, such as re-densification and gentrification, must be treated with more care and with plans of action for all. Failure to do so may cause:

A change of identity after a short time, the loss of neighborhood values, the displacement of neighbors, an abstract public space, a collective trademark image, insufficient urban equipment, vanishing of traditional

trade, a lack of roads, scarce and exclusive public spaces, change of land use, excessive trash, among others.

The need to produce and intervene in the public space is going to be determined based on the type of urban growth of the city. In other words, if it is a disordered growth, the functioning of the public space will be directly affected and it will be socially weakened.

Interventions in the city in an unplanned manner can cause problems, for example, of communication in the social and spacial sense, of urban infrastructure and of insufficient public spaces.

The creation and intervention of public spaces in Mexico City of the 21st century have been governed by economic, political and social determinants immersed in a global world in search of publicly owned spaces that have inclusive characteristics.

On the other hand, the production of public spaces in this century has been resulting in residual or nook spaces that have undermined spaces that make them have a struggle between the inclusion-exclusion duality.

ID 1717 | REGENERATION STRATEGY AND EVALUATION OF SHANGHAI HUANGPU RIVER UNDER THE BACKGROUND OF TRANSFORMATION AND DEVELOPMENT

Ying Zhang¹

¹Shanghai Tongji University Urban Planning and Design Institute
495113462@qq.com

ABSTRACT: Shanghai, as China's economic, financial, trade center, as well as national historical and cultural city, is undergoing urban transformation, to the global city forward. Shanghai City Master Plan (2016-2040) put forward the "global city - innovation city, eco-city, the city of humanities," the goal. However, with the development of urbanization, Shanghai has entered the stage of inventory development. Connotative development has become Shanghai 's Development Strategy, including innovation dynamics, city vitality, city regeneration, inventory planning, city character. The research object of this article is the regeneration strategy of the Huangpu River area in recent 15 years. Huangpu River is Shanghai's mother river, 61 km from north to south, through the central city of eight districts. The Huangpu River series has a lot of historical features of the city heritage areas, including the Old City, the Bund, Origin of modern industry, Lujiazui modern financial district, the Expo area, the old dockland. Planning area along riversides is about 144 square kilometers. The leading group for the regeneration of the Huangpu River was established In 2002 by Shanghai city government, overall planning and construction. In this article, the policy analysis, planning interpretation, construction implementation and preliminary evaluation of the regeneration will be carried out by field investigation, interviews, analysis and comparison, and data analysis. This article will focus on Fuxing Dockland area. The dockland is located in south of the Bund and east of the old city, representing the modern inland shipping characteristics. It is a continuous evolution of the cultural landscape. The implementation process is analyzed from the aspects of special study, planning and design, key project advancement and overall reform. The implementation results are evaluated from the aspects of functional transformation, building conservation and reconstruction, historical preservation and human settlement improvement. Also discusses the gentrification, authenticity and continuity. Shanghai is China 's fastest region of urbanization process over 90% urbanization rate. The demand for development represents the aspirations of many cities. Shanghai has promulgated a series of regulations, standards, codes to promote urban regeneration. The government-led integration of business and personal strength system represents the local characteristics of Shanghai. New City Agenda in HABITAT III said, culture is the key source to what makes cities attractive, creative and sustainable. The urban heritage conservation and the scientific development of city will be taken seriously.

1 URBAN REGENERATION UNDER THE BACKGROUND OF TRANSFORMATION AND DEVELOPMENT

1.1 SHANGHAI UNDERTRANSFORMATION AND DEVELOPMENT

With the significant improvement of Shanghai comprehensive economic strength, industrial restructuring and upgrading speeding up, the Shanghai "four centers" construction promoted economic and social adjustment and transformation of the growing demand. 2011 Shanghai Municipal Committee promulgated the "the twelfth five-year" planning recommendations, clearly put forward "innovation-driven, transformation and development" of the general idea. "Shanghai City Master Plan (2015-2040)" outline the Shanghai city vision, "Shanghai: the pursuit of excellence in the global city, an innovative city, eco-city, humanized city." Urban development goals, the completion of the basic construction of the four centers in 2020, a comprehensive global city, international economic, financial, trade, shipping, science and technology innovation center and international cultural metropolis in 2040. "However, comparing with Paris, New York, Tokyo and other global cities, Shanghai's sustainable development capacity and urban innovation capacity still need to be greatly improved. At the same time, Shanghai is facing the negative growth of planning and constructs land, strictly control constraints of the population, the city put forward the "connotation development" model: the implementation of innovation and inspiration, the stimulation of urban vitality, the promotion of urban renewal, shifting to stock planning, enhancing urban quality and Spirit, leading the regional cooperation.

In this context, in order to improve the city's sustainable development capacity, Shanghai actively explore the "gradual regeneration model" based on the land use to meet the future development of space needs, while conserving and inheriting the diversity of urban culture. In the Shanghai development framework (see Figure 1), population, humanities, space, cultural elements constitute the connotation of the development of global cities.

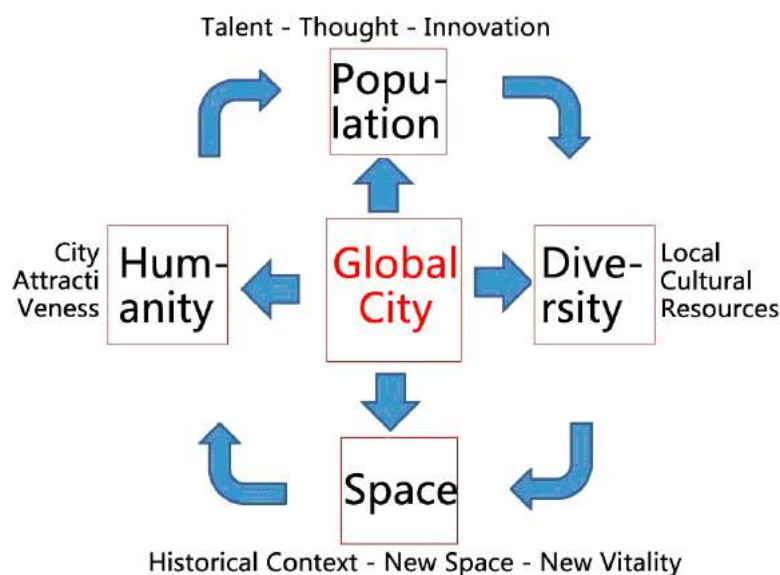

Figure 1 - The Composition of The Elements of The Global City
Source: "Shanghai City Master Plan (2015-2040)" Reports

1.2 REGENERATION OF SHANGHAI CITY

Shanghai's urban regeneration began in the 1980s, with urban housing reform and construction. The 1990s paid more attention to the market value of land and space. After the 21st century, it expanded into the connotative stage by extension, experienced renewal, urban redevelopment and regeneration.

So far, China has not yet a National City renewal, re-development and revival of special laws and regulations. However, some of the city's local regulations have been introduced or to be introduced, such as Shanghai, Shenzhen, Guangzhou and other cities. For example, the "Shanghai Urban Renewal Implementation Measures" was considered in April 2015. The term "urban renewal" refers mainly to the

construction activities of improving the urban spatial form and function of the city's built-up areas, including the improvement of urban functions, the strengthening of urban vitality, the promotion of innovation and development, the strengthening of community services, the improvement of public facilities, To improve the ecological environment, to strengthen the construction of green buildings and ecological blocks; improve the slow line system to facilitate the public life and travel; shaping the city characteristics, the protection of historical and cultural style, improve the urban landscape; improve infrastructure and urban security, To protect the public live and work, as well as the municipal government identified the need to improve the other circumstances. It can be seen that the "urban renewal" referred to in the Shanghai local regulations is close to the connotation of "urban renewal" in Europe and America. This article uses "urban revival", but the local regulations in the "urban renewal" is still using the original term (Renewal).

The scale of planning and construction land should be negative growth, "the transformation of land use mode to reverse the transformation of urban development" requirement, while the face of Shanghai built area of urban energy level is not high, lack of vitality, public space and service facilities are still a large gap, Urban slow-line system facilitation is not high, the city style protection is not enough and so on, urban renewal will become the tight constraints of resources under the conditions of Shanghai city planning the main direction.

2 REGENERATION AND DEVELOPMENT OF HUANGPU RIVER REGION OF BOTH SIDES

2.1 HISTORICAL LAYING PERSPECTIVE OF THE HUANGPU RIVER

Almost all the city is the result of complex processes of layering through time. These processes have both contributed to the shaping of the physical landscape inhabited today and also, much more subtly, created an atmosphere of use, a demarcation of physical and social space and an experience of sense of the city .

Shanghai was due to the ports and Huangpu River area is the city's important development axis. For more than 100 years, as the Shanghai economic center, industrial base, energy and supply base, plays a huge role in the city economy and social life. As the "mother river" of Shanghai, the Huangpu River is an important historical fragment of modern Shanghai. is Shanghai's water transport hub; after opening(1943), along the river's financial trade, port transport, modern industry gradually developed; Due to the development of Pudong in the 1990s, Lujiazui area became a financial and trade center, Shanghai landmarks. At the same time, with the transfer of manufacturing to the periphery of the city, the transfer of goods to the deepwater harbor, the function of the Huangpu River gradually is declining.

2.2 15 YEARS OF HUANGPU RIVER REGENERATION AND DEVELOPMENT

In January 2002, Shanghai Municipal Committee and Municipal Government announced the "comprehensive development of Huangpu River waterfront region", the development of Huangpu River waterfront region officially rose to the city's major strategy. The development of the Huangpu River on both sides of the leading group and the Shenjiang River Development and Construction Investment (Group) Co., Ltd. was established, the municipal level of the Huangpu River development and management of the main body and the development of gradually well-organized. The relevant series of research and plan gradually started, e.g. "Huangpu River waterfront region comprehensive development master plan". "Shanghai Huangpu River development and construction management regulations" and other relevant policies focused on the introduction. In the past 15 years, from the municipal level to the district level, the policies and regulations, development plans, technical guidelines and planning & design of the Huangpu River waterfront region have been gradually perfected.

Development Plan	Time period	Planning range	Strategy	Planning objectives	Development focus
Eleventh Five-Year Plan of Huangpu River waterfront region	2006-2010	Both sides region between Yangpu Bridge - Lupu Bridge	—	In terms of functions, the initial construction of modern service industry gathering zone; In terms of space landmarks, the initial formation of the Riverside landscape belt; In terms of cultural characteristics, the Chinese and Western cultural characteristics of the bloom.	Expo area; Shilupu - Dongchang Road area; North Bund - Shanghai Shipyard Surroundings.
Twelfth Five-Year Plan of Huangpu River waterfront region	2011-2015	Wusong mouth to Minpu II bridges between the Huangpu River, planning control area of about 144 square kilometers.	Enhance development; Coordinated development; Compound development; Orderly development; Sharing development; Green development; Continuous development.	Shanghai important core functional area; world - class riverside development zone; public high quality experience area of public activities.	Expo and surrounding; "Bund - Lujiazui - North Bund" area; Xuhui waterfront area.
Thirteenth Five-Year Plan of Huangpu River waterfront region	2016-2020	Wusong mouth to Minpu II bridges between the Huangpu River, planning control area of about 144 square kilometers.	People - oriented, the benefit of the people; Function first, to strengthen co-ordination; According to local conditions, classification promotion;	Significant improvement in public space quality; Infrastructure security gradually improved; Focus area to show functional image.	Huangpu South Bund; Xuhui Riverside; Front beach Expo area; Xin (Hua) Min(Sheng) Yang (Jiang); Yangpu Riverside.

Table1 - List of Five-Year Plans of Huangpu River Waterfront Region

2.3 HUANGPU RIVER WATERFRONT REGION REGENERATION STRATEGY

2.3.1 SUSTAINABLE SOCIO-ECONOMIC OBJECTIVES

Huangpu River waterfront of the regeneration and development is not just urban space, urban spatial structure development, but based on the promotion of urban energy level, promote urban economic development and improve the financial level, while improving people's livelihood, increase employment opportunities and urban economy development closely. In the process of urban regeneration, it aims to achieve urban sustainable development.

2.3.2 REASONABLE SPATIAL DEVELOPMENT STRATEGY

Urban regeneration as an important means of spatial reorganization, provides an opportunity for the reconstruction of urban space structure. There are a lot of functional recession or structural recession areas on both sides of the Huangpu River. From the perspective of economy, when the value of the surrounding land is higher than the value of the region, the necessity of regeneration is produced. From the perspective of the overall structure and function of the city, it is necessary to configure the city's major public service facilities, urban comprehensive functional areas, and generate new urban landmark areas. Such as the Expo area, by virtue of the opportunity to carry out urban renewal, to promote the Shanghai city function transformation and the surrounding area of the function of the upgrade, after the meeting to become a large enterprise global or regional headquarters, international cultural exchange center, cultural and creative base, international tourism exhibition center.

2.3.3 LOCAL CULTURAL DIVERSITY STRATEGY

In the context of globalization, local cultural diversity is the embodiment of the characteristics of the global city, historical resources is an important cornerstone of sustainable development. Huangpu River on both

sides of the rich historical layering, carrying Shanghai since the city since the unique cultural elements: China's first modern shipyard, Shanghai's first power plant, Shanghai's first trade port. Protect the historical resources, to maintain the historical features of the area, heritage local cultural diversity is one of the foundations of regeneration and development.

3 REGENERATION STRATEGY AND IMPLEMENTATION OF THE FUXING DOCK LAND

3.1 BASIC SITUATION OF FUXING DOCK AREA

Shanghai Fuxing dock land is the focus of the development of the Huangpu River waterfront area, from its own historical conditions, functional positioning, features and other aspects of view, the Fuxing dock land has a significant strategic significance. It covers an area of 16.40 hectares. It located in the Huangpu River West Bank, in north of the Bund, west of Shanghai old city, east of the Expo are across Huangpu River. As the premier freight terminal of Shanghai City, the birthplace of Shanghai urban industry and the concentration of historical relics of Shanghai Docks, It is the products of modern development of inland shipping of Shanghai.

After the regional recession of the function in the 1990s, the Fuxing dock land was once a large fruit wholesale market and officially launched to regeneration in 2004.

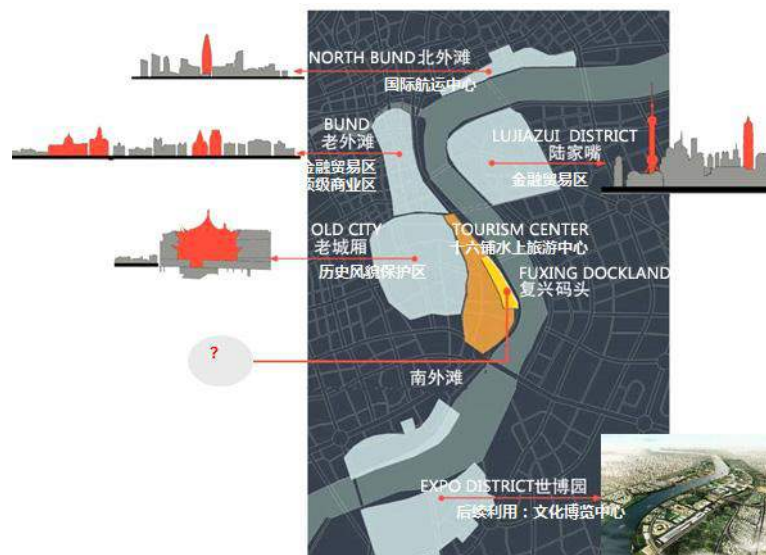

Figure 3 -Location Map of Fuxing Dock Land
Source: Research on Conceptual Planning of Shanghai Fuxing Dock Land

Figure 4 -Historical Pictures in 1990-1930
Source: Research on Conceptual Planning of Shanghai Fuxing Dock Land

3.2 REGENERATION STRATEGY OF FUXING DOCK LAND

3.2.1 REGENERATION BASED ON THE CONSERVATION

Figure 5 –Planning Concept

In order to extend the historical context, to conserve the existing historical buildings, "fish bones" street space, to maintain the atmosphere of the Shanghai dock land, from the creative lead, function upgrades, space combing, the authenticity of place, the plan aims to build the Shanghai characteristic historical area on the basis of integrity construction. From the perspective of space and life regeneration, to achieve protective development intentions.

3.2.2 INDUSTRIAL TRANSFORMATION AND FUNCTION UPGRADING

The terminal area will replace the original function of warehouse and fruit market, retain part of the traditional residential, add boutique hotels, business club, cultural show field, entertainment facilities. The function of the block has a mixed and flexible use, the specific function of the plots is not sure, but some single building with important significance is guided for certain functions. For example, the function of the seven warehouses in riverside is recommended for landscape restaurants, specialty hotels, cultural exhibitions and trade centers, folk art shops, galleries, themed bars and so on.

3.2.3 RESERVATION THE HISTORICAL SPACE ELEMENTS

Waima Road, Dock Street, Riverside Warehouse, river customs Building and other architectural relics, constitute a unique feature of the plot. Planning retains the "bund", "store", "warehouse", "block" as a feature of space elements for the continuation of the place space texture.

Figure 6 –Conservation of Space Texture
Source: Research on Conceptual Planning of Shanghai Fuxing Dock Land

3.2.4 CONTINUATION OF AUTHENTICITY

"Naked City: The Death and Life of Authentic Urban Places" said: "If the city can create a kind of origin of the experience, it is the original. The approach is to conserve the historical buildings and neighborhoods, to encourage the development of small boutiques and coffee shops and to achieve the unique cultural identity of neighborhood community ". Regeneration work start from small plots and construction based on the respect for the site historical information, in a sense, with progressive update content. "True urban places" should be in the context of a reasonable social change dynamic development, rather than being kidnapped for some reason to carry out certain mode and direction of development.

Figure 7 -Masterplan of Fuxing Dock Land
Source: Research on Conceptual Planning of Shanghai Fuxing Dock Land

Figure 8—Space Diagram of Fuxing Dock Land
Source: Research on Conceptual Planning of Shanghai Fuxing Dock Land

3.3 IMPLEMENTATION OF FUXING DOCK LAND PLAN

3.3.1 OVERALL ASSESSMENT OF PLANNING IMPLEMENTATION

The implementation of the regeneration area concentrated in the Riverside warehouse area, Jiqingli lane and along the build group along Zhongshan South Road. The plots in the neighborhood are being updated. The dock land has been initially set up a set of characteristics of commercial, cultural exhibitions, boutique hotels, urban tourism, riverside leisure functional system; It has been initially formed a convenient traffic, secured a strong infrastructure system; It has been initially promoted the riverside ecological environmental restoration and public environment enhancing; It has been the new landscape and new landmarks of the international metropolis, to attract urban public activities.

3.3.2 EFFECT OF THE IMPLEMENTATION OF REGENERATION

1. To conserve the history of buildings and space texture

Construction and implementation conserves the warehouse, traditional residential and other historical buildings, retains the street texture. The historical buildings and the reserved plots were all preserved and conserved, and the original intention of protection was well achieved.

2. Follow the planning guide for functional updates

Riverside warehouse area, Jiqingli lane well meet the planning requirements in the functional guide. 1,2,3 old warehouse along Huangpu River transformed into "Wofu 1846", features a unique bar, cafes, theme restaurants, high profile restaurants, garden clubs and so on. No. 1 warehouse is for the boutique club, No. 2 warehouse is for the music bar, No. 3 warehouse is for the whirlpool culture theme area. Jiqingli neighborhood composed of more than 20 buildings was renewed overall for the "old dock land creative park" by combination of creative office, commercial and leisure creative park. Built as a boutique hotel, music bar, senior clubs, high-end restaurants in the gathering place, the old dock land becomes a new landmark.

3. Create the Shanghai dock style area

Fuxing dock land has become a rich Shanghai dock style fashion landmark. City Music Week, Creative Market, International Beer Festival and other city festivals gathered a lot of popularity, creating a community atmosphere.

1 INTRODUCTION

What makes a good public space? There are many answers to this question, but no definite ones. This ongoing research focuses on perceptual differences within sequences of urban open spaces in the historical city centres of Zagreb, in Croatia, and Sheffield, in the United Kingdom, in the hope of providing some new insights. A harmonious historical setting is perhaps one of the most recognisable visual factors,

while soundscape is one of the most elusive. The former can be protected by law as cultural heritage, but the latter changes according to activities and weather conditions, regular or irregular daily or weekly rhythms, or even seasons. Yet both contribute to personal assessments of comfort in public space and in the end, directly to the quality of city life (Carr et al, 1992).

Both the chosen locations were recognised as containing sequences of acoustically specific urban open spaces, with different visual presence of historical elements. Studying their perceptual differences and similarities may lead to a better understanding of the importance that soundscape and the authenticity of a heritage setting have in the management and enhancement of urban open spaces.

The paper focuses on the sequence in Zagreb known as the Green Horseshoe. It consists of seven squares and one park of approximately the same sizes and shapes, with similar traffic regulation, but different ambiances in their central parts, due to different types of foliage, pavilions and activities. No square on its own conveys a particular aural experience, but in a sequence, they are worth investigating, as the fact that they are nearly the same shape and size eliminates the influence of these factors during comparison. The visual and acoustic properties differ from one square to the next, like the rooms within a Baroque enfilade from the salon to the boudoir – from the square housing the opera building to the Botanical Gardens. The complex was built in the late nineteenth and early twentieth centuries. Today, it forms a vital part of Zagreb's city centre, where the historical setting has been well preserved (Knežević, 1996). However, not all the urban open spaces in the sequence are equally important or adequately used in terms of their potential.

The research is primarily concerned with visual and aural perceptions and their congruence. Methodologically, it is based on onsite recordings, listening experiments held in laboratory conditions and software analyses of objective acoustic parameters. Monitoring was conducted in December 2013, February 2014, June 2014 and December 2016 in Zagreb; and in September 2016 and May 2017 in Sheffield. Monitoring enabled comparisons of the effect the different uses of the spaces through the seasons and subsequent changes in the soundscape have on the overall experience. This included temporary winter commercial activities during Zagreb's five-week Advent and Christmas Fair.

This research is part of the research project Heritage Urbanism – Urban and Spatial Models for Revival and Enhancement of Cultural Heritage (HRZZ 2032), funded by the Croatian Science Foundation and conducted at the Faculty of Architecture, University of Zagreb.

2 SEQUENCES OF URBAN OPEN SPACES 2.1 SOUNDSCAPE ASSESSMENT OF URBAN OPEN SPACES

Soundscape research started in the second half of the 20th century and has grown significantly in the last fifteen years. It is mainly concerned with finding holistic answers to noise mitigation. Noise has a negative effect on health and the overall quality of city life, and it affects people in enclosed and open spaces. The definition of noise is inherently subjective, so both qualitative and quantitative approaches are needed. Noise propagation models do not provide sufficient information for assessing acoustic comfort, which motivates ongoing research into models for soundscape quality prediction which could be implemented into urban planning and design (Aletta and Kang, 2016).

Standardisation of soundscape research is one of the most recent advances. It includes the descriptors for soundscape assessment defined by Axelsson et al (2010), along with the standardized soundscape assessment protocol and adoption of the ISO soundscape standard (Kang and Schulte Fortkamp, 2016).

The concept of soundscape is based on interaction between sounds, listeners and the environment (Truax, 2001). The acoustic features of urban open spaces in a strict sense are an important factor in the perception of urban soundscape (Maag, 2013). Urban morphology has a strong influence on sound propagation (Kang, 2007), while visual features influence both aural and visual perceptions (Marry, 2010).

Since every urban open space is experienced within its context, it is argued that the analysis of the sequences of urban open spaces is vital to assessment. The soundwalk is a soundscape research method that allows assessments of different ambiances within urban open spaces to be captured (Truax, 1999). Four major soundscape assessment methods have been recognised: soundwalks, laboratory experiments,

narrative interviews, and behavioural observations (Aletta et al, 2016). In order to enable comparison of the monitored locations, a hybrid method of soundwalks and laboratory experiment was used, by conducting a listening experiment based on the concept of a spatial sequence.

2.2 SEQUENCES OF URBAN OPEN SPACES IN ZAGREB AND SHEFFIELD

Both chosen sequences contain several squares, but are morphologically completely different. Both include a path leading from the square in front of a railway station to a central pedestrian zone. So both act as 'city entrances'. In Zagreb, the eastern and western parts of the horseshoe were planned as representative city axes – the eastern one forms part of the city's central axis, a straight line of almost 6.3 km, included in most 20th century urban plans, while the western one forms part of the axis connecting many buildings belonging to the University of Zagreb along 1.75 km. In 1913, it was planned to locate arts and cultural facilities in the eastern axis and science and education ones in the western axis (Bojanić Obad Šćitaroci and Obad Šćitaroci, 2004). The Sheffield sequence does not have these characteristics. It starts at the railway station at the eastern edge of the city centre and ends in a park in the west. The Zagreb sequence is more like a loop, with the station is positioned at the south eastern joint on the central axis. So the Horseshoe is morphologically similar to the grander sequence of public spaces around the Ringstrasse in Vienna. The squares in the Horseshoe are directly physically connected, square, in shape, and about 1.7 hectares in size. The squares in Sheffield's Gold Route are sometimes adjacent (Millennium Square and Peace Gardens) and at other times physically separated by up to 350 metres (Devonshire Green and Barker's Pool), and they differ in shape and size (from Leopold Square at 0.1 hectares to Devonshire Green at 1.4 hectares). However, it is the scale of the imaginary line connecting the squares that makes them comparable. Both are roughly 1.5 km long (the sequence in Zagreb is approximately 1.65 km and the one in Sheffield approximately 1.45 km), so they can be walked in thirty minutes (Figure 1, Figure 2). This study was motivated by key differences in the authenticity of the historical settings (high in Zagreb, in terms of surrounding buildings and urban and landscape design elements, and low in Sheffield, where only a few historical buildings surround a recently built public space) and soundscape features (the high presence of traffic noise in Zagreb, and low noise in Sheffield, with specially designed sound sources – water fountains). It is expected that that the comparison will determine the influence which different soundscape factors have on the quality of urban open spaces in relation to visual factors concerning cultural heritage issues. This paper, however, only focuses on the soundscape factors analysed in Zagreb, and the first deductions made from the different recordings made in summer 2014 and winter 2016 and the listening experiments conducted in winter 2014 and spring 2017.

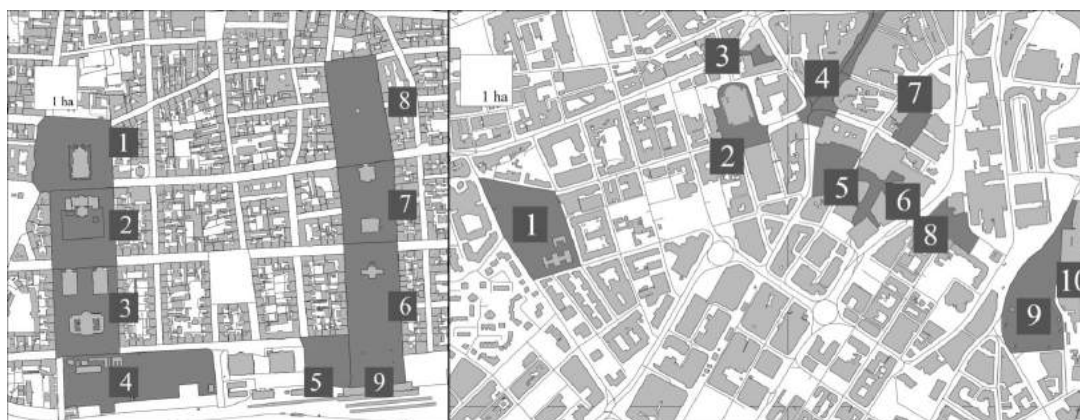

Figure 1 (left) – Map showing the analysed sequence of urban open spaces in Zagreb: 1) Marshall Tito Square, 2) Mažuranić Square, 3) Marko Marulić Square, 4) Botanical Gardens, 5) Ante Starčević Square, 6) King Tomislav Square, 7) Strossmeyer Square, 8) Nikola Šubić Zrinski Square, 9) Railway station.

Figure 2 (right) – Map showing the Gold Route in Sheffield: 1) Devonshire Green, 2) Barker's Pool, 3) Leopold Square, 4) Fargate, 5) Peace Gardens, 6) Millenium Square, 7) Tudor Square, 8) Hallam Square, 9) Sheaf Square, 10) Railway station.

It is also important to mention differences in typology, since the functional-spatial type of urban open space influences planning and design, the way it is used, and how it is finally experienced. Bearing in mind the areas covered in foliage, hence the name Green Horseshoe, the spaces in Zagreb could well be called parks instead of squares, especially when compared to Peace Gardens in Sheffield. The presence and position of adjacent public buildings has perhaps contributed to this typological expression.

3 THE CASE STUDY METHOD

3.1 THE CASE STUDY SITE

This unique sequence of seven squares and one park is variously known as the Green Horseshoe, Park Horseshoe, Lenuci's Horseshoe or Zagreb Horseshoe. Its shape was defined by the late 19th century orthogonal grid of Zagreb extending from the main square and Ilica Street in the north to the railway line in the south. The horseshoe was the result of keeping a linear sequence of blocks for the purpose. They form an almost continuous urban open space intersecting with the street grid. The sequence is discontinued only in the southern part between the Botanical Gardens and Ante Starčević Square.

Each square has one or more public buildings and therefore contributes to the city's social life. They

include the Croatian National Theatre, the Academy of Drama, the State Archives, the Important shopping centre underneath Ante Starčević Square, the Arts Pavilion, and the Academy of Sciences and Arts. The setting also includes the University of Zagreb's main building, the Academy of Music, the Museum of Arts and Crafts, the Museum of Ethnology, the Ministry of Culture, the main railway station, Hotel Esplanade, Hotel Palace and the Supreme Court.

Figure 3 – Noise propagation model for the analysed location in Zagreb – road traffic (Lden). The sound pressure levels measured in situ correspond with the expected values shown in the model. (Retrieved May 30, 2017, from <https://geoportal.zagreb.hr/Karta>)

Implementing the horseshoe shape in the grid of Zagreb's 19th century centre was not integrally envisaged (Bojanić Obad Šćitaroci and Obad Šćitaroci, 2004). It came about as a result of partial plans and clever ad hoc design solutions by the engineer Milan Lenuci, along with the unfolding of historical circumstances (Knežević, 1996).

Parks in 19th -century town centres reveal a culture of providing a complete sensory experience of public space, and were planned to provide relaxation, peace, and relief from the psychological effects of the hectic city atmosphere (Hauser, 2008). These characteristics could be considered as the design requirements for the Zagreb sequence. The noise map model shown in Figure 3 suggests that the sequence's soundscape has surrendered to the contemporary traffic.

However, the historical authenticity of its urban and landscape design elements and surrounding buildings contribute greatly to its ambient value. The Horseshoe is protected by legislation and urban plans, including its historical mid-19th and early 20th-century strata.

3.2 THE SEQUENCE

Like in a Baroque mansion, where one room follows another, varying in size, shape and acoustical properties along the enfilade, so one square follows another along Zagreb's Horseshoe. From the mansion entrance, the sequence begins with a marble hall, followed by a large dining-room, a salon with silk-

panelled walls suitable for chamber music, then a smaller room, and ends in a satin-lined boudoir suitable for whispered trysts (Rasmussen, 1962).

The west wing of the sequence begins a similar gradation from the north with Marshall Tito Square, designed to impress with the dominant central building of the Croatian National Theatre and surrounding flower-beds. During the day, teenagers and students gather and roller-skate, while it becomes the theatre forecourt in the evening. To the south lies Mažuranić Square, mostly covered in chestnut canopies providing shade for children's playgrounds. It is followed by Marko Marulić Square.

Between the western and eastern arms lie the Botanical Gardens, next to the railway line which marked the border of the 19th -century city and stills forms a clear morphological break between the block grid and the unfinished pattern planned and built in the 20th century south of the railway line.

The eastern arm begins in the south as the entrance to the city from the railway station, with vistas opening onto King Tomislav Square and its deep aerial perspective to the north and Ante Starčević Square to the west. Strossmeyer Square follows behind the Arts Pavilion building, hidden behind the former Chemical Laboratory, with bushes and trees designed in the 1938 by the landscape architect Ciril Jeglič. The eastern arm ends with the oldest square in this sequence, Nikola Šubić Zrinski Square, mostly built between 1870 and 1893, surrounded by public buildings, shops and restaurants, and largely covered by plane-trees which flank its two symmetrical orthogonal axes and frame its centre (Bojanić Obad Šćitaroci and Obad Šćitaroci, 2004).

3.3 COMMERCIAL ACTIVITIES IN DECEMBER 2016

Commercial activities in Zagreb's city centre during festive periods have been organized regularly by the Zagreb Tourist Board since 2002, and include many souvenir and food stalls. Since 2011, they have also appeared on some parts of the Horseshoe (Pauček Šljivak, 2016). Through advertising abroad, they have become a significant tourist attraction (Koretić, 2017). The entire eastern arm of the Horseshoe was covered in souvenir and food stalls, stages equipped with amplification systems on Nikola Šubić Zrinski Square and Strossmeyer Square, and a temporary ice-skating rink on King Tomislav Square.

3.4 MONITORING AND FIELD RECORDING

Monitoring of the locations was conducted in December 2013, February 2014, June 2014 and December 2016. It included recording visual and aural data at selected measurement points in the early afternoon on working days. Field recordings were used as representative samples for listening experiments and software analyses.

At each measurement point, as shown in Figure 4, aural data were recorded using an omnidirectional microphone and a first-order Ambisonics microphone. Ten-minute periods were recorded to obtain a representative sample, including various combinations in the exchange of dynamics according to traffic and the use of the space.

Visual data collection was performed by taking panoramic photos from the exact position of the microphones. In 2016, spherical panoramas were also taken to enable future experiments based on the partial virtual reality principle.

Figure 4 – Position of measurement points: D1 - Marshall Tito Square, D2 Mažuranić Square, 3) Marko Marulić Square, 4) Botanical Gardens, 5) Ante Starčević Square, 6) King Tomislav Square, 7) Strossmeyer Square, 8) Nikola Šubić Zrinski Square (Oberman, 2015)

3.5 TWO LISTENING EXPERIMENTS

Two listening experiments were conducted; the first in December 2014 (35 participants, average age 27) and the second in March 2017 (19 participants, average age 30). Both were conducted in the ambisonics-equipped auralisation laboratory at the Faculty of Electrical Engineering and Computing at the University of Zagreb. In order to isolate the influence soundscape has on overall perception and perception of visual features, identical panoramic photographs were used during both experiments. The first experiment was based on recordings made in June 2014, and the second on those made in December 2016.

In both listening experiments, the participants completed a questionnaire for each square based on the Swedish Soundscape-Quality Protocol, to provide information regarding the presence of certain types of sound sources (traffic noise, other noise, human sounds and natural sounds), soundscape perception descriptors, the quality of visual features and the correspondence between the aural and visual experiences. The results are shown in Figure 5.

4 CASE STUDY ANALYSIS

It was expected that the warm, sunny weather in June 2014 would result in a lively, vibrant soundscape, due to the many tourists who have been visiting Zagreb in the summer since Croatia joined the European Union in 2013 (Pauček Šljivak, 2016). It also turned out that the commercial events organized by the Zagreb Tourist Board during December and January transformed otherwise unused open places (due to cold weather) into busy ones.

The results of the experiment conducted in 2014 indicated several issues regarding the great discrepancy between visual and aural features, due to:

Figure 5 – Soundscape assessment results for (from top to bottom): dominance of sound source types in June 2014 and December 2016, soundscape perception values for June 2014 and December 2016, correspondence between visual features and soundscape appropriateness in June 2014 and December 2016 (Oberman, 2015)

- lack of human and natural sounds, and the much more noticeable presence of traffic noise at King Tomislav Square and Marko Marulić Square.
- the overpowering, unexpectedly high level of traffic noise in Ante Starčević Square and the Botanical Gardens, due to the adjacent railway which is not perceptible visually.

The results of the 2014 experiment also indicated the following positive assessments of this sequence:

- excellent congruence between visual and aural features at Strossmeyer Square
- excellent results of the assessment of visual features at Nikola Šubić Zrinski Square.

These made the temporary festive activities even more interesting, since they significantly changed three of the ambiances by adding amplified popular music, stages and stands, attracting large crowds. As Ante Starčević Square, the Botanical Gardens and the western arm of the Horseshoe were not part of these planned events, the assessment relating to them did not change significantly in the 2017 experiment. However, the change in soundscape caused the following differences in perception assessment:

- much better assessment of visual features and audiovisual congruence at King Tomislav Square
- Worse audiovisual congruence and assessment of visual features at Strossmeyer Square

The following are further discussed to illustrate the differences analysed: Strossmeyer Square, King Tomislav Square and Marko Marulić Square.

4.1 STROSSMEYER SQUARE

This square was assessed as the most audiovisually congruent in the first experiment. The central part is shielded from traffic noise to the north and south by the two buildings of the Croatian Academy of Sciences and Arts, while dense trees and bushes surround it visually to the east and west. The summer recording captured prominent human and natural sounds, and the soundscape was considered calm and pleasant. The addition of loud commercial activities and amplified music in the winter recordings shifted the assessment towards less congruent.

4.2 KING TOMISLAV SQUARE

The grand vistas from the railway station over the whole city to the north, in a deep perspective with the overlapping planes (from front to back) of the monument, pavilion, trees in neighbouring Strossmeyer Square, the cathedral spires and Mt. Medvednica in the distance, are well-known features of this square. They were deliberately accentuated, since the central part is approximately 1.5 m lower than the surrounding streets, pavements and buildings. This makes the pavilion on the north of the square seem taller and the perspective deeper. However, it also means that the ears of people walking in the square are at road level. The design of this urban open space is dominantly visual.

The square was assessed ambiguously and in complete discrepancy with its representative visual features during the first experiment, because traffic noise was the prevailing soundscape feature. This and the lack of human activities, meant it was assessed as less audiovisually congruent. The addition of features such as a temporary ice-skating rink and amplified music shifted the assessment towards more congruent and improved the assessment of visual features.

4.3 MARKO MARULIĆ SQUARE

The 2014 summer recordings of this square were sonically similar to King Tomislav Square, as were the assessments. Both King Tomislav Square and Marko Marulić Square are flanked on the east and west sides by residential buildings. Visually and spatially, however, they differ. Marko Marulić Square is less

imposing, despite the former National Library building, and its vistas are more enclosed. No commercial activities have been conducted there by the Zagreb Tourist Board. Although it proved to be characterised by the lowest sound pressure levels within the sequence, assessments were similar during both experiments: mostly monotonous and uneventful, audiovisually incongruent, and amongst the less pleasant places in the sequence.

Figure 6 – King Tomislav Square in June 2014 (above) (Oberman, 2015) and December 2016 (below)

Figure 7 –Marko Marulić Square in June 2014 (above) (Oberman, 2015) and in December 2016 (below)

The square changed its character when the National Library building became the State Archives in 1990s. Although the land use and academic character of the square have remained unchanged since 1910, the perception of it has changed drastically as the public space has become underused.

5 CONCLUDING REMARKS

This research report was motivated by impressions of the Advent in Zagreb Christmas Fair, which in December 2016 attracted more visitors than in previous years, and animated public spaces in Zagreb for five weeks in an unprecedented way.

At the local, site-specific level, the analyses showed that not all parts of the sequence were equally congruent, as some squares were underused by the public. The events organised in the eastern arm tended to exaggerate the contrast. Although there was no significant difference in average sound pressure levels, there was a high presence of traffic sounds throughout, and a significant difference in the frequency of sonic events of other sounds, such as people and music, was noticed. The temporary transformations have not changed how all the locations are experienced for the better. In the squares that were positively assessed before the introduction of commercial activities, the change was not great. But in the squares with poorly and/or ambiguously assessed soundscapes, temporary features such as the ice-skating rink and adjacent pop-up restaurants led to more positive assessments.

The effect of adding temporary commercial urban activities to public spaces characterized by low audiovisual congruence provided several insights which may be valuable for soundscape design. Added sounds changed the dominant perception descriptors, and also influenced assessments of visual features and congruence. Finally, it was not the weather conditions, but planned activities and advertising that contributed to more intense use.

T05 | GREEN INFRASTRUCTURES: FOSTERING DIALOGUE ACROSS SCALES AND POLICIES

CO-CHAIRS: ANNA M. HERSPERGER; STEPHAN PAULEIT; ISABEL LOUPA RAMOS

Green infrastructure principally refers to a multifunctional network of healthy ecosystems and serves the interests of both people and nature. We strongly believe that in the light of the implementation of the EU green infrastructure strategy (European Commission 2013) this is a relevant topic to be discussed amongst the European Planning community at the AESOP conference in Lisbon 2017 in order to foster the development of approaches and tools towards its implementation.

It is widely acknowledged in academia and practice in Europe and beyond that green infrastructure should be designed and managed as a multifunctional resource capable of delivering a wide range of benefits to humans and ecosystems, such as flood control, climate mitigation, biodiversity conservation, production of renewable energy, enhancing identity, cultural values and resilience etc. (see e.g. the project Green Surge in the 7th Framework program). Building blocks of green infrastructure are natural and semi natural areas, features and green spaces ranging from large wilderness areas to green roofs in urban environments. Green infrastructure is thus connected to many policy domains such as agriculture, forestry, nature, water, transport, and disaster prevention. Spatial planning as a part of public policy can provide an overall framework and individual methods and tools required for a successful implementation and maintenance of a green infrastructure from local to EU-scales. Spatial planning seems best suited to ensure the necessary coordination across spatial scales and policy sectors, to facilitate the adaption of spatial concepts to real landscapes and to include the relevant actors.

Thus a session on green infrastructure provides a great opportunity to critically discuss current research and praxis on the planning and implementation of green infrastructure and explore ideas of how to progress on these issues. The session will particularly explore green infrastructure planning from rural to peri-urban and urban areas. Following, a preliminary list of potential questions and issues to be explored in a session:

What is the status of green infrastructure planning and implementation in Europe? What are achievements and good practice? Where are the shortcomings?

How can spatial concepts for green infrastructure be developed and operationalized in the context of spatial planning from European to local scale?

How can relevant sectoral planning in e.g. regarding flood management, climate change and biodiversity and cultural heritage conservation be integrated into an overall green infrastructure strategy to maximize to provision of ecosystem services?

Which governance regimes are suited to ensure that green infrastructure, once in place, can persist long-term?

How can the maintenance of green infrastructure be financed benefitting from the integration of sectoral policies?

How do people perceive and value green infrastructure and what do they expect from green infrastructure planning?

ID 1339 | GREEN SPACE SYSTEM PLANNING BASED ON THE GREEN INFRASTRUCTURE - A CASE STUDY OF JI'AN, CHINA

Zhuojun Fang¹; Hong Geng¹
¹Huazhong University of Science and Technology
371313903@qq.com ; genghong999@163.com

1 LIMITATIONS OF CURRENT GREEN SPACE SYSTEM PLANNING IN CHINA

With the rapid promotion of China's urbanization, problems of rapid urbanization gradually threaten the healthy and sustainable development of the city. The theory and method of the traditional green space system planning is difficult to meet the basic requirement for modern cities, which embodies in: 1) Evaluates urban green space system planning and construction of urban green space by the green index, resulting in result in low benefit of many urban green space system planning; 2) Planning is mainly confined to the built-up area, and lack of consideration on the regional ecological integrity and the relationship between green spaces inside and outside the city. The green space system planning within the region is difficult to implement; 3) Lacks of mechanism to promote the effective participation of multi-subject. Planning Text often one-sided emphasizes on the harmony between human and nature, but lacks of the powerful means of space construction; 4) Green spaces and other construction sites are placed together and isolated in the city, and the result is that green spaces have been eroded by construction sites.

Therefore, the green space system planning in the new period must break through the limitations of the traditional green space system planning. The layout of the green space system must be based on the principles of Urban and Rural planning and ecological construction, and consider the green spaces within and outside the city integrated, systematic and ecological. This requires planning workers not only to consider problems with macroscopic spatial and temporal scale, but also implement specific work of meso and micro level. We should fully grasp the structure and function, form and elements of green space in a specific urban and rural environment, to make the artificial environment and the natural environment to form a coordinated system.

2 THE CONCEPT AND PLANNING METHOD OF GREEN INFRASTRUCTURE

2.1 CONCEPT

The concept of Green Infrastructure was proposed against the background of ecological destruction, environmental control and improvement brought by the industrial revolutions in western countries, as the requirement of modern ecological civilization and sustainable social development. Green Infrastructure (GI) was first defined in the U.S. in 1999, "Green Infrastructure is a national natural life support system, and a correlated natural ecological network (Williamson, 2003)". It was defined as one of the key strategies for achieving sustainable development objectives in the U.S., and its significance was promoted to the national natural life support system—a land and water protection network supports local species, maintains natural ecological processes, preserves air and water resources, and devotes to improvement of community, residents' health and life quality (Benedict and McMahon, 2001). In the past decade, concept and relevant practices of Green Infrastructure have gained popularity fast in the United States and Europe[1].

The ultimate goal of GI is to achieve the true integration of urban and rural green network, to integrate the city into nature, which coincides with the requirements of urban and rural planning and ecological civilization construction in China. Therefore, the construction of GI is an effective means to improve the living environment and improve the ecological quality of the city. Through the construction of the GI network, the green spaces can be promoted to the level of the urban infrastructure, to ensure the flexibility and priority of the green land boundary. On this basis, it can form a green space system with complete function (Tab.1).

Classification	Sub-classification	Type
Green infrastructure	Natural	Forest, marsh, water such as river and reservoir
	Semi-natural	Orchard and cropland
	Artificial	Landscape garden such as park, roadside garden
Gray infrastructure		Built-up land, involving residential, industrial, commercial and public facilities land
		Unused land, where all land covers have been cleared for development

Table 1 - Classification system of urban infrastructures

2.2 CONSTITUTION

Green infrastructure's components include a variety of natural and restored ecosystem and landscapes features that lead to a system known as "Hubs" and "Links"(Fig.1). Hubs anchor Green Infrastructure networks, providing origins and destination for the wildlife and ecological processes moving to or through them. Meanwhile, links are the connecting tying the system together and enabling green infrastructure network to work. Sites are also a type of green infrastructure network. Although the scale of sites are much smaller than hubs, and they are not necessarily connected with the regional protection system or the whole network, but are also important parts of green infrastructure.

On this basis, green infrastructure can develop into a more integrated network, including open space, low impact traffic, water, biological habitat and metabolism and so on. At the same time, GI can be extended to a social network which composed of residents, social organizations, green activities and practical projects.

Figure 1 - Composition of GI System

2.3 PLANNING METHOD OF GREEN INFRASTRUCTURE NETWORK

2.3.1 PLANNING PROCESS

Up to now, a lot of research and practice on GI have been done in many areas, through summarizing the existing outstanding cases, the planning step green infrastructure is divided into the following phases: 1) Set goals: determine the specific objectives on the basis of the existing planning, the interests of the main views, urban positioning and protection objectives; 2) Collect data: collect the basic information of the research area, especially the land use data, which is the most important data source of GI; 3) Analysis and evaluation: analysis and evaluation of land use types that may be used as a component of green infrastructure by overlay analysis or other methods. It's a key step to construct the GI system; 4) Determine factors: according to the characteristics of each factor, the hubs, links and sites of the green infrastructure in the research area are determined on the basis of analysis and evaluation, and then

determine the overall spatial pattern of GI; 5) Construct GI priority protection system: take the green infrastructure priority protection system as the basis, and then comprehensive factors such as urban and rural layout, strategic focus, the status quo of land use, historical landscape, per capita green space and green space accessibility and so on to modified the GI priority protection system(Fig.2).

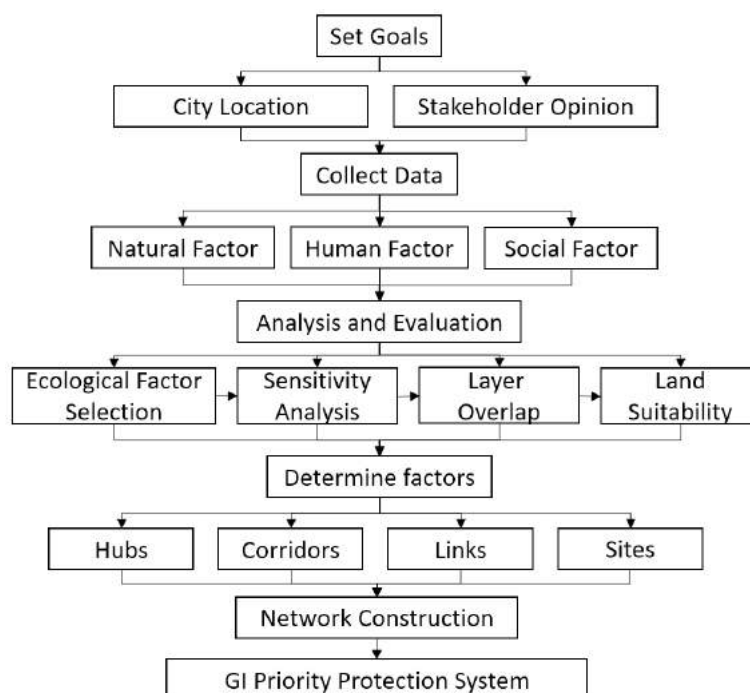

Figure 2 - The General Process of Green Infrastructure Planning

2.3.2 TECHNICAL MEANS

Superposition analysis method based on vertical ecological process[2]: process the basic data by using GIS and RS technology, and evaluate of ecological sensitivity in the study area by using the superposition method of vertical ecological process of McHarg. After the superposition of the influencing factors, the sensitivity level of each unit is divided, and the most sensitive landscape unit is the hubs or the source patches.

Spatial analysis method is based on horizontal ecological process: the minimum cost model is used to determine the location and pattern of the corridors. The minimum cost path does not necessarily mean that the species will use the corridor when moving between habitats, but should be considered as a potential path to reduce the cost of liquidity. Its meaning mainly refers to the potential ecological corridor is the lowest cost path. Through the resistance of the various factors on the horizontal movement of animals and plants, it's mainly to establish the resistance surface, using the minimum cost model to calculate the minimum cost path from the "centers" to the "hubs".

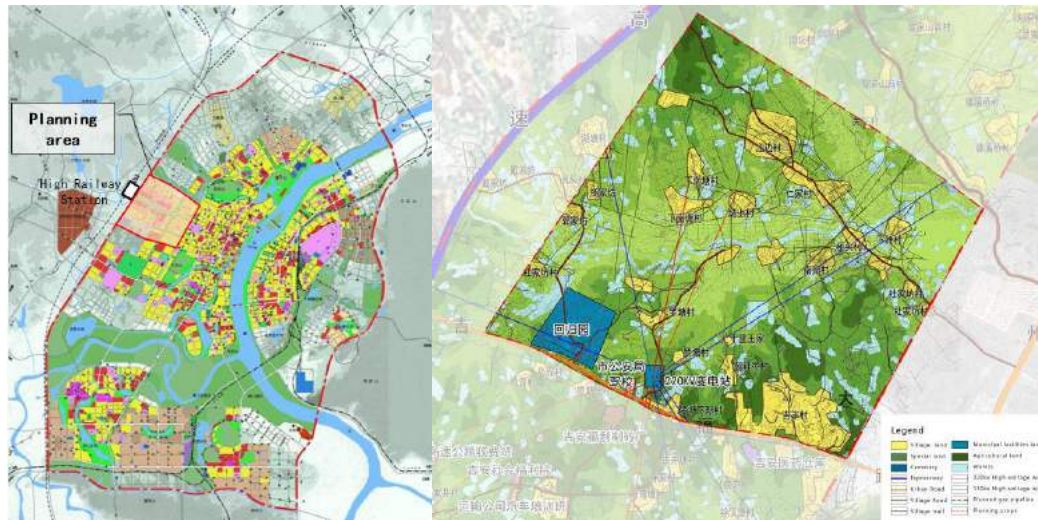

In addition, there are two kinds of methods, which are based on the graph theory and the analysis of morphological spatial pattern. But in this paper, we mainly use two methods: ecological superposition method and minimum cost model.

3 CASE STUDY OF JI'AN

3.1 REGIONAL OVERVIEW

The planning area is located on the west side of downtown Ji'an, Jiangxi, with a total area of 5.19 square kilometers. Planning area has obvious traffic advantage. After the completion of the Ji'an high-speed railway station, will further strengthen the central city of Ji'an in the central position of Jitai town group (Fig.3).

The planning area has the high terrain in north and south, and is low in the middle. Water runoff is from east to west, and the highest point of the terrain reaches 95.9m, to show a form of low hill crowded (Fig.4). The destruction of ecological environment is small, and the natural vegetation protection is good. In recent years, around the orientation of "Luling excellent in culture, Ji'an famous for landscape", Ji'an vigorously promotes the construction of theme parks, ecological corridors and country parks which possess high quality. In the past few years, Ji'an has been named the China Excellent Tourism City, the National Garden City, the China Characteristic Charm City 200, the China Habitat Environment Award, and has laid a good foundation for the green space system planning.

Figure 5 - Topography analysis

3.3.2 STORMWATER MANAGEMENT FUNCTION

GI construction is an effective way to reduce urban stormwater runoff. Countries and regions have gradually attached importance to the construction of GI, and rapid urbanization areas have upgraded attention to GI. The stormwater GI includes large reservoirs, wetlands, waterfront landscape, green street, rain gardens, detention ponds, ecological ditches and green roofs, reasonable planning and layout of the Rain GI has a significant impact on the hydrological characteristics, nutrient transfertation and combined sewer overflowing. Through the GIS analysis, we can get the main flow direction of the river and rain in the region, and control it through the GI (Fig.6).

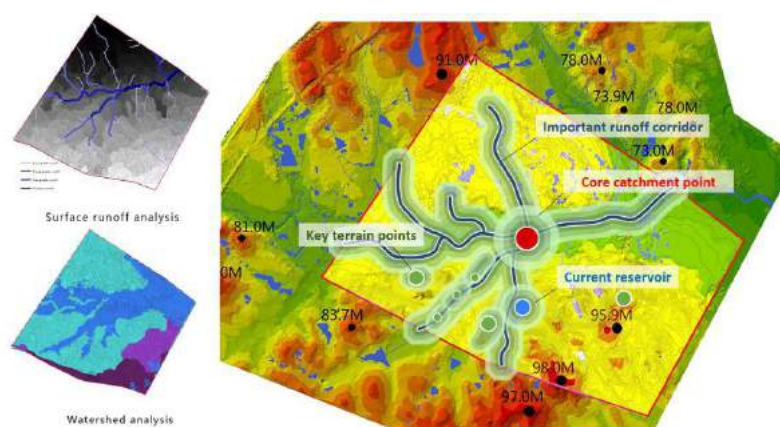

Figure 6 - Stormwater runoff analysis

3.3.3 ENTERTAINMENT AND LEISURE FUNCTION

The protection of green space system planning should not only pay attention to the natural environment, but also to provide a comfortable living environment for the city residents. It should provide leisure and entertainment places for residents, increase the "green" contact. The quantitative evaluation of entertainment and leisure function is to collect and screen the land use class diagram spot, and then extract the high representative recreation resources and active points.

3.4 GREEN SPACE SYSTEM PLANNING STRUCTURE OF JIAN

3.4.1 GI NETWORK

According to the above analysis, green infrastructure is a natural and artificial green space network system composed of hubs and links. Hubs and links contain various scales of natural and artificial landscape and ecological factors, such as green road, wetland, forest, park, shoreline and so on. The hubs are the

starting points and end points of GI, which provide habitat for wildlife growth or passage; Hubs and links connect to each other to ensure the ecological function of landscape connectivity, and to make the system to be a network; Sites are smaller than hubs, and may not be connected with the green network, but have an important contribution to the ecological and social value, such as the small open spaces and community parks.

(1) Building hubs relying on ecological background

The hubs of the green infrastructure of planning area consists of large areas of public parks (regional park, town park, local park and neighborhood park), existing private land (agriculture land, forest reserves and residential, institutional, etc.), cemeteries and undeveloped land (undeveloped open space and undeveloped committed future development). The hubs become the environmentally significant area to maintain the essential ecological processes, preserve the diversity of species, safeguard habitats, critical for the sustainable use of species and maintain the productive capacities of the ecosystem.

(2) Establishing links by rivers and roads

Links often follow natural or existing land or water features such as ridgelines, stream valleys, rivers, canals, utility corridors, and others. Although each link is unique, most connect recreational, natural, and cultural areas. Some links are designed for people to use for recreation and nonmotorized transportation, while others are designed for wildlife, biodiversity, and scenic beauty. The width and functions of links in planning area is shown in Table 2. The main corridor along the main layout of the planning, the main corridor along the rain runoff, high pressure corridors, community center green belt layout[3]. At the same time, in order to ensure the connectivity and accessibility of the corridor, three corridors are arranged along the road.

Grade of the links	Width	Function
Main links	90m-120m	Can be capable of absorbing and retention of runoff from the entire region in strong precipitation, while provide habitat for egrets and other birds and frogs, finally realize the symbiosis of man and nature. Can also be combined with community garden and leisure agriculture.
Secondary links	30m-90m	Can be able to absorb runoff in the middle intensity precipitation.
Three level links	20m-30m	Can absorb runoff in the low intensity precipitation.

Table 2—Grade of the links

(3) Using small sites to form ecological nodes

Sites are small natural habitat and recreation site that is independent of a large natural area. It is a supplement to the hubs and acts as a stepping stone. Sites in this planning are the center green of the community, small gardens by the street, the landscape squares and so on. They are evenly distributed in various communities, combined with the community center service facilities, to improve the living environment of the community, at the same time, provide leisure and entertainment venues for community residents.

Figure 7 —Structure of GI

3.4.2 GI PRIORITY PROTECTION SYSTEM

According to the hubs, links and sites that have been identified, we determine the different evaluation factors, and give all kinds of evaluation factor to a certain weight value, then score them(Tab.3). On this basis we can get grading system of the hubs,links and sites. Based on these results, all kinds of elements with high scores can be extracted, then obtain the GI priority protection system, with strict protection all of the elements; various elements of low scores can be implemented within the appropriate development and construction.

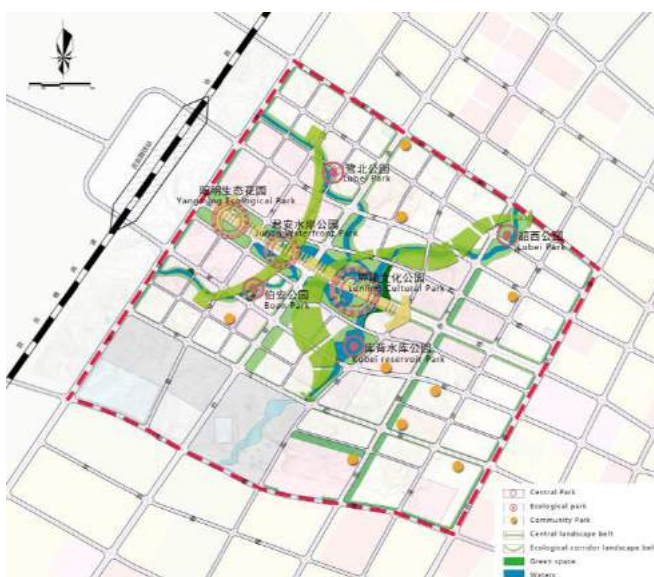

Element	Evaluation factor	Weight
Hubs	Proportion of internal natural areas	6
	Flow length	4
	Vegetation coverage , Number of vegetation types	3
	Distance to main road, Distance to nearest hub, Wetland, Abandoned land	2
	Bio-diversity, Terrain, Soil type number, River connection	1
Links	Connect to the high level hubs.	8
	The average value of Mountain Block and Water Block, The number of connection breaks	4
	The grade of the road, the total number of species, Peripheral buffer suitability	2
	Total area,Stream length, Distance from the nearest main road and secondary road, Biological integrity,Wetland	1
	Peripheral buffer suitability	8
Sites	Distance to the hubs	6
	Part of the area of mature and natural vegetation	4
	The total number of species	3
	Total area,Stream length, Distance from the nearest main road and secondary road, Biological integrity,Wetland	1
	Peripheral buffer suitability	8

Table 3 –Evaluation factor and weight[4]

3.4.3 GREEN SPACE SYSTEM PLANNING STRUCTURE

The green space system planning of this district is based on the GI priority system, taking the per capita green space index and all kinds of green spaces accessibility as the condition. It emphasizes on the accessibility and closeness to nature, and pays attention to the integrity, systematicness and ecological of urban green spaces, so as to improve the urban living environment quality and create green leisure spaces. According to the Ji'an city overall planning layout and planning objectives, we determine the green space system structure of the planning area as “one axis, seven hearts, four corridors, multiple points”(Fig.8).

One axis: that is the central green landscape axis from east to west, and has important position in building the green space pattern of high speed rail portal area.

Seven hearts: include Yangming Ecological Park, Junan Waterfront Park, Luling Cultural Park, Lubei Park, Shaoxi Park, Boan Park, and Kubei Reservoir Park that are located in the green landscape belt.

Four Corridors: combined with water systems, wedge shaped infiltration, to ensure the integration of urban land and the surrounding ecological green spaces.

Figure 8 - Green space system planning structure

pollution caused by vehicle exhaust; to bring natural elements into the streets; to provide opportunities for the low impact traffic systems.

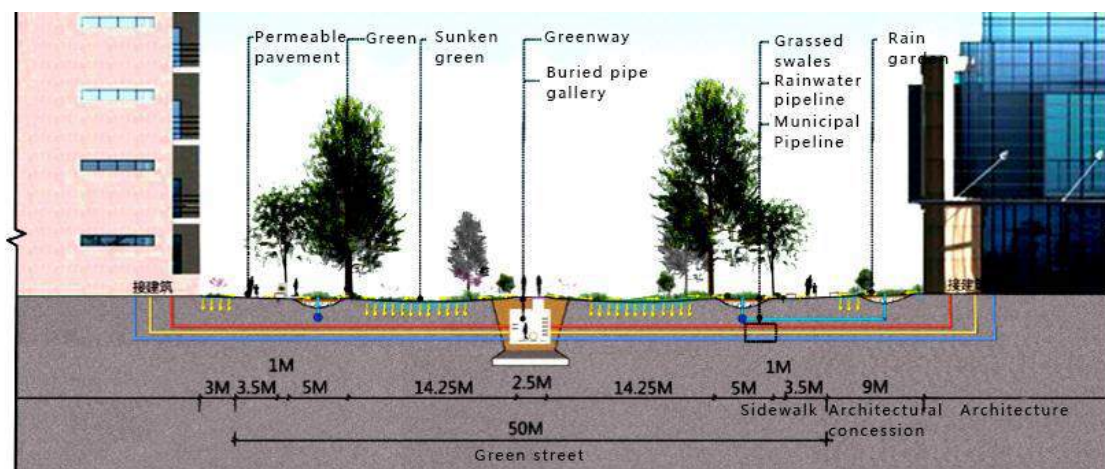

Figure 11 - The Connection of Regional Green Space System

The artificial wetland is an artificial design and manufacture. As a green infrastructure, it can bring a variety of benefits such as natural wetlands like. They can be used as economic and efficient measures for flood control and city stormwater management, also as a wild animal habitat, and can enhance the landscape aesthetic taste, provide recreational facilities. The planning makes a number of stormwater runoff planning to be the adjustable artificial wetlands. In the water season they can be used to store rainwater, and in the dry season they can be used as green spaces for the residents to play (Fig.12).

Figure 12 - Seasonal rainfall water level and green space

4 CONCLUSIONS

Green infrastructure has functions with complex characteristics, includes two aspects in summary: one is to serve people, by protecting and connecting the scattered green space to provide social services such as leisure, health and aesthetic; one is the service to the system of nature, through biological and habitat protection, keeping the connection of natural areas to maintain biodiversity, and avoid habitat fragmentation.

The function of green space, the structure of green space and the actual effect of planning are the key points of urban green space system planning. In the background of Rapid City, strengthen the concept that city green space is the city infrastructure, by GIS and other scientific analysis methods, identify elements that constitute the network of green infrastructure. On the basis, further improving the urban green space system planning, can provide a powerful guarantee for the scientificity of green space function, the rationality of the structure arrangement and the effectiveness of the planning, to further promote the construction of the smart city and sponge city.

Because of the limited space, the author believes that the following two aspects can be discussed: first, the construction of citizen participation mechanism. GI involves a wide range of aspects, and involves a lot of the general public interest, but the current public participation mechanism is not perfect. We can further

discuss in the follow-up study; two is the limitations of the scale. About green infrastructure of district scale, the main contradiction is not the connectivity, but should consider the fairness of GI elements (such as city park) in space. On this basis, further optimize the research results.

ID 1353 | GREEN INFRASTRUCTURE IN LIMINAL STREETSIDE SPACES: CASES FROM EUROPEAN CITY CORES

Ken Tamminga¹

¹Penn State University

krt1@psu.edu ; krtamminga@gmail.com

1 INTRODUCTION

Human interactions ranging from everyday socialization to celebratory gathering and insurgency are all more or less accommodated along the streets of contemporary Western cities. In the denser quarters of European cities, in particular, the street is the setting along which much of the civic life of urban dwellers is played out. As the pedestrian moves laterally from the roadway curb outwards, a narrow ribbon of quasipublic/private space that emerges from adjacent buildings is usually encountered. In the city core and inner ring suburbs, this transition zone harbours stoops, landings, areaways, pavement gaps at foundation walls, facades, sills and lintels, handrails, stairwells, and other niches that present urban dwellers with tight-but-sufficient opportunity for streetside horticulture and related accoutrements. It is this underappreciated transition zone, and the recreational and expressive activities associated with growing plants in it, that is addressed below. I use the term convivial greenstreet to convey an assemblage of features and patterns in a supportive context (street, built form). This setting is enacted by gardeners (residents, merchants, employees) who cultivate plants to a degree sufficient to elicit some sensory appreciation on the part of passers-by and, now and then, to prompt social engagement between cultivators, neighbours, and passers-by who share the street's frontage.

"Convivial greenstreet" as used here is a conceptual umbrella term for a range of greenstreet types that all have in common an emphasis on informal private and quasi-public installations. The ideal convivial greenstreet (hereinafter: CG) accommodates processes and patterns of socially inclusive, uncommodified, and culturally diverse horticulture that is situated in physically interstitial and socially liminal streetside niches in the tight quarters of contemporary cities (Steven, 2007). A proposed—and still evolving—typology with a focus on residential types is provided in Section 3, below.

The convivial greenstreet may be framed within the generally analogous rubric posed by critical urbanists, including Dovey (2008) and Miles (2000). Both scholars trace various kinds of citizen ornamentation and place-making as ways to reclaim urban space and ascertain local identities. Miles (2000, p.203) writes, "An understanding of the architectural everyday contributes to sustainability by emphasizing the specifics of locality...sustainable solutions to urban problems will be found outside the dominant structures of development." And Dovey (2008, p. 175) seems to anticipate a role for CGs in his call for "new ways of

putting roots in place which resist the totalizing retreat in space or time and the paralyzing view that freedom is found in enclosure.” The quotidian, open, free-spirited cultivation occurring along the more robust convivial greenstreets may also be viewed as gentle kind of emancipatory ‘play’, reminiscent of the Situationist’s unitary urbanism (Pinder, 2004; Sadler, 1998). However, whether any forms are directly antagonistic of the hegemony of the corporatized city is beyond this paper’s scope. But that CGs may in some small way counteract the banal aspects of urban society seems apparent, as demonstrated later in the paper. Finally, as a mostly benign phenomenon that can contribute to local and civil society, I suggest ways that planners and urban designers can provide professional and moral support.

This paper builds on an initial examination of such streets in Tamminga (2014) that focused on conceptual reification and situating of the CG phenomenon in the theoretical literature. It observed that:

“In contrast to the generic public streetscape, [the convivial greenstreet] tended to be smaller-scale, walkable, and spatially intimate streets in and around the city core—linear spaces imbued with foliage, flower and fruit, and visibly well-tended. In such places it was readily apparent that pedestrians slowed their pace, curious over a plant or a bit of intriguing green infrastructure, or pausing when met by a waft of fragrance or a serendipitous butterfly. At routine times of day, when inhabitants, shopkeepers, and visitors crossed paths, friendly greetings were expressed. Children actually played in the streets after school. It seemed that both the horticultural activity and the objects of horticulture were serving as pretext for a sort of civic gezelligheid (Dutch) or gemütlichkeit (German)—both terms translate imprecisely as a warm and sociable togetherness. Certain streets in certain cities felt especially verdant, affable, and alive. Some of the more notable examples hinted at a locally expressive kind of neighbourhood sustainability—both in terms of the physicality of the space (ecology, materiality), and in terms of the planterly discourses (verbal, sensory, semiotic) in which sustainability values and practices might be shared and reinforced ... Three key facets of the places observed—the social (conviviality), the material/ecological (greenstreet flora and its infrastructure), and the spatial (street volume)—are captured in the phrase “convivial greenstreet.” ...When sufficiently intense, the greenstreet is the active spatial context for a material culture of personalized-yet-interactive horticulture that expresses, demarcates, instructs, appropriates and contests.”

The notion of conviviality is an important variable in this conceptual framework. In his seminal critique of industrial society, Ivan Illich (1973, p. 12) criticizes the rise of professionalization, making an appeal to “enlarge the range of each person’s competence, control, and initiative, limited only by other individuals’ claims to an equal range of power and freedom.” Illich would have appreciated the role of CG gardeners on the urban scene. While urbanists debate the ideal of conviviality (e.g., Purdy, 2014), others assert that conviviality in the city is “the very nourishment of civil society itself” (Peattie, 1998, p. 250) and “the essence of urbanity” (Shaftoe, 2008, p. 5). Nowicka and Vertovec (2014, p. 352) observe that even conflicts over “everyday issues such as gardens...are modes of civil interaction.” And the renowned urbanist Jane Jacobs (1961, p. 30) wrote, “Sidewalks, their bordering uses, and their users, are active participants in the drama of civilization.” At the scale of the metropolis, Lees (2004, p. 3) writes, “This century, even more than the last, will be an urban one in which the city is the measure of the civility and sustainability of society.” More than just tolerant civility, however, place-based conviviality in the city connotes a kind of inclusive multi-community neighbourliness that embraces difference and exchange. Drawing on my initial work (2014, p. 4), I note that,

“conviviality and community in this context are not the same things. Communities have members and non-members, with members often making decisions about in- and exclusions. On the other hand, conviviality is contingent and dynamic and sometimes eventfully inclusive of visitors drawn to pause along their way. All the while, the greenstreet performs double duty as a public corridor that also accommodates the passage of others. Yet at its core conviviality draws on community for its cohesion. The spatio-physical environment and adjacent land use activities provide the continuity within which the convivial mood ebbs and flows, peaking now and then during daily events of personal engagement with the greenstreet materiality or inter-personal and inter-community interactions along the street.”

As the scholarship and praxis of urban green infrastructure (GI) develops, the range of green infrastructure components continues to expand to include newly identified tendrils and shards—such as CGs—that contribute to the health and well-being of urban dwellers. The European Commission (2016) contrasts GI with single-purpose, traditional grey infrastructure by noting that “green spaces can perform a variety of very useful functions, often simultaneously and at a fraction of the cost. One of the key attractions of green infrastructure is this multi-functionality.” While the Commission asserts that GI is a “planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services,” it also acknowledges the contributions of informal environs, stating that GI “includes semi-natural spaces such as parks, private gardens, and hedges” and places that “can be enhanced by individual gestures such as collecting rain water or leaving parts of a garden untouched.” Focusing on the city, the Commission states that “green infrastructure can and should be an integral part of urban areas too—particularly in densely populated areas” that “can significantly enhance the health and well-being of urban residents, improving social cohesion and the quality of the living environment.”

AESOP 2017’s conference track #5 on Green Infrastructure echoes the Commission’s stance: “Green infrastructure should be designed and managed as multifunctional resource capable of delivering a wide range of benefits to humans and ecosystems, such as...biodiversity conservation...enhancing identity, cultural values, and resilience.” The work of the Commission and the exploration of GI through the forum of AESOP ‘17 help suggest that the collective impact of CGs in cities where they are emerging as a distinct GI form is likely to be meaningful in ecological, social and cultural terms, across the breadth of the contemporary urban core. In commenting on accessibility to urban horticulture, Maltby and Nandan (2017) note that “there is substantial research on the positive impact on people’s mental state of having living plants be a part of their environment. In addition to the psychological and aesthetic benefits, more plants in our concrete environment will also provide crucial ecosystem services, such as mitigating air pollution and heat island effect, improving stormwater management, and potentially increasing bio-diversity.” The relationships between urban environmental quality and human health and well-being are supported by research in environmental psychology, urbanism, and urban ecology, including the work of Hartig et al. (2003), Kaplan (2001), Kuo (2011), Matsuoka & Kaplan (2008), Saümel et al. (2016), Thwaites et al. (2013), and Ulrich et al. (2006), among others.

2 METHODOLOGY

Informed by relevant methodologies used in urban landscape analysis and urban ethnography (Foxley, 2010; Krase, 2014; Kusenbach, 2003; Nuvolati, 2014; Ramsden, 2014; Tilley, 2010), the lion’s share of data collection activities comprised walking along, and documenting observations within, pre-targeted streets in select European cities (Table 1). My initial research focused on cities in the Netherlands, Rhineland area of German, and Belgium—where it is readily apparent that horticultural proclivities and urban living have co-mingled. Since then other European cities have been, and continue to be, added to the list. Selection criteria included urban spatial density, socio-economic diversity, land use (primarily medium-density residential and commercial) and walkability. Most readily identified CGs were found in historic urban cores, but notable cases do occur in contemporary inner ring suburbs in cities like Amsterdam and Cologne.

Country / City	Neighbourhood / Quarter	Dates
Netherlands		
Amsterdam	Jordaan, Grachtengordel-West	July 2011, Oct. 2014
Delft	Binnenstad, Centrum-oost	July 2011, Oct. 2014
Leiden	Binnenstad-Zuid/Noord, Stationsdistrict	July 2011, Oct. 2014
Leeuwarden	Centrum	July 2011, Oct. 2014
Katwijk	Katwijk aan Zee	Oct. 2014
Germany		
Cologne	Ehrenfeld, Altstadt-Süd, Süß	May, 2013, Sept. 2014
Bonn	Lindenthal, Neustadt-Süd	May, 2013, Sept. 2014
Frankford	Altstadt, Zentrum, Südstadt	May, 2013, Sept. 2014
Aachen	Innenstadt	May 2013
Aachen	Aachen-Mitte	Sept. 2014
Andernach	city centre	Oct. 2014
Rostock	Stadt-mitte, Südstadt	June 2016
Denmark		
Copenhagen	Christianshavn, Indre By, Vesterbro	Aug. 2010, June 2016
Belgium		
Brussels	Saint-Gilles, Forest, Ixelles	Aug. 2011, Sept. 2014
Ghent	Centrum, Patershol	Sept. 2014
France		
Paris	Le Marais, Quartier d'Amerique Montmartre, Quartier Latin	Oct. 2014
Spain		
Barcelona	Gràcia, Eixample, Barceloneta, Horta, Ciutat Vella	June 2016
Lisbon, Prague, Budapest		pending, summer 2017

Table 1 - Research Locales

To select likely neighbourhoods, municipal websites were accessed and key informants (e.g. local planners and urban designers) were asked to provide direction. Virtual walkabouts on Google Street View reinforced the long list of potential greenstreets prior to travelling to each city. Once in situ, target neighbourhoods were crisscrossed by foot to locate those streets exhibiting relatively high densities of greenstreet artefacts. Selected streets were then inventoried for CG features through field notes, site measurement, and photo-documentation (Tamminga, 2014).

The number and type of convivial greenstreets examined to date vary widely from city to city. Typically, all cities visited contained examples of at least partially-formed CGs. Certain remarkable neighbourhoods, such as Binnenstad in Delft and the Hoefstraat area of Leiden (both in the Netherlands), exhibited street clusters where well-formed and fully functional CGs were close to becoming the convention. In other cities, neighbourhoods such as the very compact traditional communities of Gràcia and Barceloneta in Barcelona displayed only one or two horticultural components: façade-mounted floral baskets and sill planters in an architectonic streetscape otherwise devoid of greenery. Overall, the majority of the cities investigated had at least 2 to 3 cases of streetscapes that showed sufficient diversity and intensity of horticultural installations to be considered CGs, based the typology shown in Section 3 below.

Building heights and building height-to-street width ratios were estimated to give a sense of the spatial volumes that might accommodate streetside gardening. Vegetation apparently cultivated by residents and commercial employees (that is, not municipal workers) were assigned to basic plant form categories, along with container type and position and installation technology. Supportive accoutrements such as pottery, art, and bird houses, and private-sector accommodations that seemed available for pedestrian use such as benches and bicycle rails were noted. Any temporary accompanying installations that seemed integral to the identity or functioning of the CG were noted—for example, signs, notes and graffiti that suggested semiotic intents such as territorial marking, sponsorship, and interpretive messages for passers-by. Public streetscape installations (e.g. street trees, lighting and banners) were also documented. Case study streets were classified as to land use, and any indicator of socio-economic and cultural characteristics were noted. Both during and after inventorying, activities and social interactions along the street that appeared to be associated with streetside horticultural were observed and noted.

All data on streets displaying significant CG characteristics were then compiled and sorted to develop the typologies presented in the following section. Analysis of the steadily growing corpus of CG photos, maps, and field notes, as well as tie-in with literature in several disciplines, has continued to date.

3 TYPOLOGY AND CONCEPTUALIZATION

Field investigations and analysis of photo-documentation indicate 4 main types of convivial greenstreet in the cities visited. Note that it is quite possible that more categories will emerge as other European cities are studied (Prague, Budapest and Lisbon are scheduled for summer 2017). For each of the types shown in Table 2, land use, number of storeys along street frontage, building height-to-street width ratio, key actors along the street, and cadence, or rhythm, of horticultural and associated convivial activity is noted.

Type 1 Residential emerged as the most common and diverse type of CGs in the cities studied. This was expected for several reasons: i) by definition streetside horticulture installations are private or quasiprivate ii) residents are the most likely agents to engage in such activities on the daily basis required to grow plants successfully, and iii) horticultural diversity tends to mirror the diversity of cultures and sub-cultures common in the core sectors of European cities, while plants and their orchestration serve as an effective medium for individual expression.

As noted previously, residential sector convivial greenstreets are characterized by compact urban conditions with a dearth of private yard garden plots; thus, the only available space for gardening is within a narrow horizontal and vertical corridor along the street frontage where traffic activity is either inherently moderate or otherwise controlled by permit or regulation. Consistently, the richest examples of residential CGs were to be found on streets with 'human-scale' spatial volumes: narrow streets and 2–4 storey attached dwellings.

The exemplar of Trompetstraat in the Binnenstad quarter of Delft, the Netherlands, is shown in Figures 1 and 2. While this street dates back to the 1600s, there are some modern-era residential infill units that fit their context well. Referring to the keyed 'anatomy' in Figure 2, the street itself is narrow [A], and clad in permeable brick pavers. Only permitted vehicles allowed. The building height-to-street width ratio is about 1.5:1, with a human-scaled 2–2.5 stories of building frontage. Potted perennials on the stoop [B] and annuals sprouting from gaps along the foundation [C] mark the visually-important transition from horizontal to vertical. A domestic artefact doubles as a planter [D], and the adjacent entryway is framed by a well-tended vine [E]. Further into the vignette, a homeowner's bench [F] is offered to neighbours and passers-by.

CG type	Adjacent land use	Building height/ street width; # storeys	Key interacting agents/actors	CG activity cadence
<u>Type 1. Residential</u>				
Type 1a.	entirely Residential	2:1–1:2 2–4 storeys	resident–resident; resident–passers-by	home day-time, pre- workday, noon, evening
Type 1b.	mostly Residential; some small-scale Commercial and Institutional	2:1–1:2 2; 3–4 storeys	resident–resident; resident–merchant; resident–passers-by	overlapped business hours, home day-time
<u>Type 2. Mixed Commercial</u>				
Type 2a.	smaller-scale Commercial; interspersed Residential	2:1–1:3 3–5 storeys	merchants–passers-by merchant–resident passers-by–passers-by	business hours; minor pre/post-business
Type 2b.	larger-scale Commercial and Institutional	varies	passers-by–passers-by employee–passers-by	business hours, festivals
<u>Type 3. Celebratory</u>	varies	varies	varies: participants, consumers	varies; reflects celebration / ritual itinerary

Table 2 - Typological Framework (adapted from Tamminga, 2014)

Another potted plant [G] and a deciduous shrub [H] mark a front door. Sconce-hung potted geraniums, large [I] and small [J], add interest to facades. A simple but period-appropriate lamp [K] complements the plantings and contributes, along with the "eyes on the street" (Jacobs, 1961) that typify CGs, to enhanced night-time security. A ledge along the upper cornice of one residence provides a high perch for more flowers [L], drawing the eye upward and forward. Doorways [M] along greenstreets vie with plants in terms of colour and gracious materiality as they, too, are subject to the aesthetic impulses of residents.

As with most narrow CGs in the Netherlands, Denmark, Belgium and Germany, bicyclists [N] and pedestrians co-inhabit the street with little difficulty, while low landings [F, G] provide a plinth for pedestrians or sitters when needed. When a rare side yard does occur [O], a tree is often allowed to overtop and shade the street—in this case a linden. Overall, the individual parts work with the spatial volume and bounding facades as a whole to create a harmonious setting that appeals to the senses and invites neighbourliness. Part of the success of the street must be attributable to community cohesiveness—parents and children engage in life on the street. Residents have their own Trompetstraat Facebook page, and colourful street graphics reminding inhabitants of events or services are posted at key points.

Although it is difficult to capture the entirety of the assemblage of greenstreet elements—much less its full ambience—in singular photographs, the Trompetstraat images do provide a useful cataloguing of what comprises archetypal Type 1a and 1b greenstreets. Compared to Type 2 and 3 greenstreets, Type 1 streets embrace a much larger range of horticultural forms and artefacts:

Figure 1 - Scene Along Trompetstraat, Delft, the Netherlands

Figure 2 - Anatomy of a Type 1a Street, Trompetstraat, Delft, the Netherlands

at least 11 sub-classes of CG elements were identified during field work, ranging from doorstep/stoop potted plants to trellised dwarf fruit trees to façade-mounted scone planters to the ubiquitous

spontaneous-then-tended plants associated with interstitial gaps along the street. Such gaps often persist from historic street or infrastructure misalignments, providing opportunities for animated and engaging 'greenshards' planted and tended by adjacent residents. An excellent case is that of the Sustainable Quarters Contracts program in Saint-Gilles on the southwest perimeter of Brussels (Commune de Saint-Gilles, 2016). Figure 3 shows one of its collaborations along Chaussée de Forest.

Figure 3 - 'Greenshard' Along Type 1b Street, Chaussée de Forest, Saint-Gilles, Belgium

Residential installations, in fact, far exceeded Type 2 Mixed Commercial installations (discussed below) in terms of expressiveness, ingenuity, and diversity of form and patterns. Interestingly, there were cases in most cities where residents and merchants alike appeared to have at least the implicit permission of local authorities to remove several sidewalk pavers along their foundation wall to allow excavation, followed by backfilling with growing media and plant installation (Figure 4). Or perhaps some of these installations are evidence of a mild-mannered form of the public space insurgency discussed by Hou (2010).

Socio-economically, it is not the case that CGs are necessarily associated with enclaves of affluent urbanites, as might be expected. In fact, robust greenstreets were found in a wide variety of social and cultural contexts. There were, however, links evident between sub-communities and the kind of horticultural taking place on the street—whether artistically expressive or politically or ecologically dogmatic. Figure 5 shows an edible micro-ecology installation on an eye-height windowsill in the Altstadt neighbourhood of Bonn, Germany. The little signs loosely translate as, “Edible wild plants from the countryside.” In fact, edible plants are common to almost every Type 1 CG in the western European cities visited: tomatoes, peppers, gourds, vine fruits, and more are offered free-for-the-picking. Another good example is the slot rowhouse complex along Rodelijvekensstraat in Ghent, Belgium (Figure 6), an ornamental and culinary plant smorgasbord communally cultivated by the mixed Turkish–student community.

Figure 4 - Removed Paver with Fruit Tree Espalier, Altstadt Süd, Cologne, Germany

Figure 5 - Streetside Edibles, Altstadt, Bonn, Germany

Still, the vast majority of greenstreet installations serve to simply brighten up the street frontage and provide an outlet for outdoor gardening.

Clearly, the daily tending of flowers and vines—sometimes unapologetically overlapping on public rights-of-way—contributes to the quotidian life of the street. I often observed resident plant-tenders chatting with neighbours who were taking their dogs for a walk. It seemed to me then that the public acts of streetside cultivation and dog-walking alike were as much pretences to socialize as they were about simply accomplishing the tasks at hand.

Figure 6 - Slot Street Along Rodelijvekensstraat, Ghent, Belgium

For reasons that have yet to be closely examined, certain residential streets exhibit much more horticultural activity than others, and certain neighbourhoods accommodate a higher density of greenstreets than others. It may be that horticulturally-inclined cultural groups tend to live in close proximity. Or it is possible that some streets harbour one or several trend-setting gardener-activists, after which ‘communities of practice’ develop (Wenger, 1998). Anecdotally, when I asked several residents along greenstreets in Amsterdam and Leiden about their horticultural learning, they were quick to acknowledge the valued presence of a local master gardener. At the larger scale, The Netherlands, northern Belgium, and western Germany are the three countries where there appears to be a strong correlation between regional horticultural tradition and translation to, or reinterpretation of, urban CGs.

Type 2 Mixed Commercial greenstreets are of two sub-types. Type 2a greenstreets tend to be associated with smaller and specialty retail, green grocers, and restaurant establishments in finer-grained commercial

'main street' located in close proximity to core area and inner ring residential districts. Streetscape spatial volumes are moderately larger scale than Type 1, with open volumes associated with wider commercial arterial streets. A key Type 2a variable is that vehicular traffic is in some way moderated; wide sidewalks, bump-out planters, and various regulatory traffic restrictions result in less pedestrian/traffic interaction. This situation, in turn, presents two-fold opportunity: merchants find space along the frontage and out to the curb line to install plants, benches and related paraphernalia, and pedestrians feel sufficiently buffered from traffic to enjoy the installations tended by store personnel. Overlapping jurisdictions are quite common, and seem to be either ignored or tolerated by local authorities, or actively embraced through partnerships and support programs.

Figure 7 shows an example in the Cologne inner ring suburb of Ehrenfeld, where commercial streetside gardening is encouraged through the Engaged in Ehrenfeld program (eva eV, 2017). Such initiatives involve non-profit/municipal partnerships that provide infrastructure, plants, and materials (soil, mulch, etc.) that are installed and maintained by adjacent proprietors and their employees. In other cases, there is simply agreement that maintenance of public installations is the responsibility of the adjacent storeowner.

Installations are often customized, taking on the local flair and perhaps even personalities of their caretakers.

While marketing tactics are likely also at play, in comparison with formal streetscapes and corporate installations, Type 2a greenstreets impart a sense of authenticity and convivial generosity.

Type 2b greenstreets are associated with larger-scale urban developments along major arterials.

Traffic impacts and the coarse-grained pattern of businesses along the frontage often combine to undermine the intents of streetside gardening. Large hotels and restaurants are frequent contributors, often installing rather formal and costly installations in the context of streetside cafés operated along the sidewalk by permit.

An aura of corporatist control can permeate Type 2b environs, although clients and passers-by alike seem to tolerate the lack of colloquial charm while they appreciate the shade, screening and sensory qualities afforded by the plant assemblages.

Type 3 Celebratory greenstreets are less common than Type 1 and 2 versions. Typically, they include plant installations associated with holidays or special events. A good example is the maibaum ("May tree") tradition in some western German cities, during which 4 to 8 meter tall birches are harvested and distributed as part of May Day activities. At night, the trees are clandestinely strapped by secret admirers

to building facades or utility posts near the residence of the focus of their affection. The trees are often festooned with colourful streamers and red paper heart cutouts. On some streets in Bonn and Cologne, the number and density of maibaum are such that they have a major, albeit short-lived, visual impact on the street. Conviviality often ensues as suitors, families, and friends take to the streets to celebrate the coming of spring and the possibility of new relationships.

Figure 7 - Type 2a Installation, Venloerstrasse, Ehrenfeld, Germany

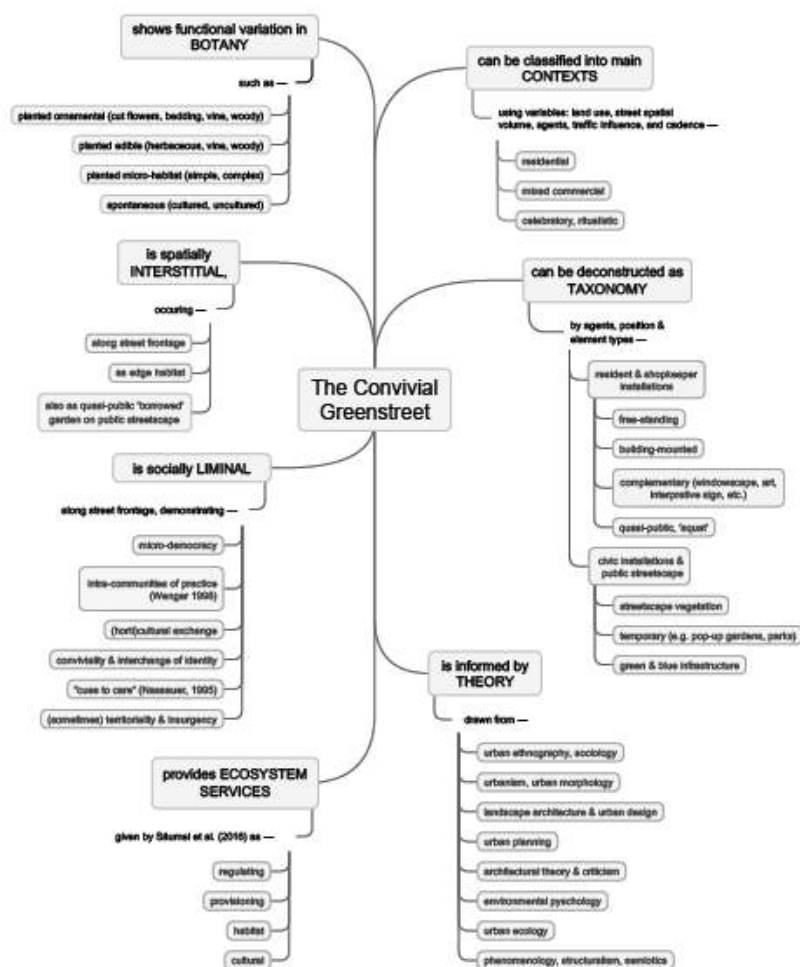

Figure 8 - Concept Map

With a working typology in place, and having conducted wide-ranging field studies and several cycles of literature review, it is now possible to construct a conceptual model that frames the essential components of both the idea and the physical reality of the convivial greenstreet. The Figure 8 concept map above shows multiple perspectives from which CGs can be considered. These include spatio-physical contexts, interstitial and liminal characteristics, functional variation in botany, taxonomic structure, ecosystem services provided, and paths by which the convivial greenstreet notion can be informed by the literature. As more cities have yet to be studied, the model should not be considered exhaustive.

4 CONCLUSION AND RECOMMENDATIONS

Convivial greenstreets of all kinds, and the myriad of elements and activities that go into their collective making, contribute to the vitality and inclusiveness in these European cities. We have seen that CGs are at their most expressive, diverse and genuine in the spatially constrained residential precincts in and around the urban core. In these contexts, the ostensible lack of gardening space becomes the impetus to plant and tend, rather than an excuse not to. While underlying sociological or anthropological questions remain, the careful cataloguing of greenstreet materiality and phenomena in the field since 2010 across 16 cities in 6 countries has resulted in a working typology and a corpus of many hundreds of streetside particularities that, taken together, help to build a picture of this small but special part of the urban morphology of contemporary European cities. In 2014 (p. 18), I wrote that, "Streetside gardening is at its core a bridging system, a lingua franca between the diverse actors along the street. From that standpoint, greenstreets are a hopeful phenomenon—a desire that city dwellers have to emerge; to freely engage their neighbors and the diverse life of the street; to both confront and embrace its possibilities and complexities." Further and ongoing studies since then have helped affirm this stance.

My hope is that this paper will prompt AESOP '17 attendees to take up further convivial greenstreet questions as scholars, or to advocate for greenstreets as practitioners in their own places. If we have some consensus that convivial greenstreets are a largely positive force in the civil realm, then there's much work to do to ensure that they flourish and develop. As an outgrowth from what has become a longitudinal research project, I would suggest 3 frames of actions for urban policy-makers and designers to consider, as follows:

1. Walk. Become personally acquainted with convivial greenstreets—even just their nascent forms—in your own cities. Be on the street during the active times when horticulture (and GC culture) is taking place, both on weekdays and weekends. Observe, photograph, draw, map and otherwise document the phenomenon where it occurs.
2. Converse. Ask questions, both on the street and in the public forum. Listen to and acknowledge the benefits of streetside gardening and its myriad micro-installations, as well as contributions being made to the larger life of the city. Initiate conversation and gather stories from residents, merchants and visitors who are willing to share. Assure them that policy-makers and designers are ready to accommodate and support their beneficial greenstreet activities, whether ongoing or contemplated.
3. Support. Share your applicable knowledge, or leverage the knowledge of colleagues, in support of convivial greenstreets. Initiate programs, such as Bonn's *Lehrpfad Stadtökologie* ("city ecology educational trail") program that collaborates with communities on a range of greenstreet installations. Advocate for streetside gardeners who are trying to strike the sometimes precarious balance between free expression and responsible citizenry. Work with neighborhood leaders, master gardeners, and plant nursery suppliers to encourage sustainable, inspiring, and culturally diverse CG networks. Conduct workshops. Build intra-and inter-neighborhood communities of practice. Finally, ensure space for streetside gardening; if policies and codes are counter-productive or outdated, revise them. Provide accessible reference material as to best-practices that are tailored to local, evolving situations. Encourage respectful, inclusive creativity and healthy productivity through the act of planting and tending.

ID 1369 | GREEN INFRASTRUCTURES: A FRAMEWORK TO APPLY A MULTISCALAR AND TRANSECTORAL APPROACH IN PLANNING

Luisa Pedrazzini¹

¹Regione Lombardia Environment

luisa_pedrazzini@regione.lombardia.it

1 TAILORING THE EU GREEN INFRASTRUCTURE STRATEGY

According to EU strategy green infrastructure is: “a strategically planned network of natural and semi-natural areas with other environmental features designed and managed to deliver a wide range of ecosystem services. [...] On land, GI is present in rural and urban settings” (EC, 2013b:3) therefore, it is recognised and referred to a multifunctional network of healthy ecosystems, serving the interests of both people and nature (Figure1).

Referring to planning instruments this drives to assume that a green infrastructure (GI) strategy should favour a better integration between territorial/urban planning and design with sectorial planning and other instruments and policies with spatial impact by the mean of the multifunctional nature of GI.

Figure 1 – Components of a Green Infrastructure (EC 2013b:8)

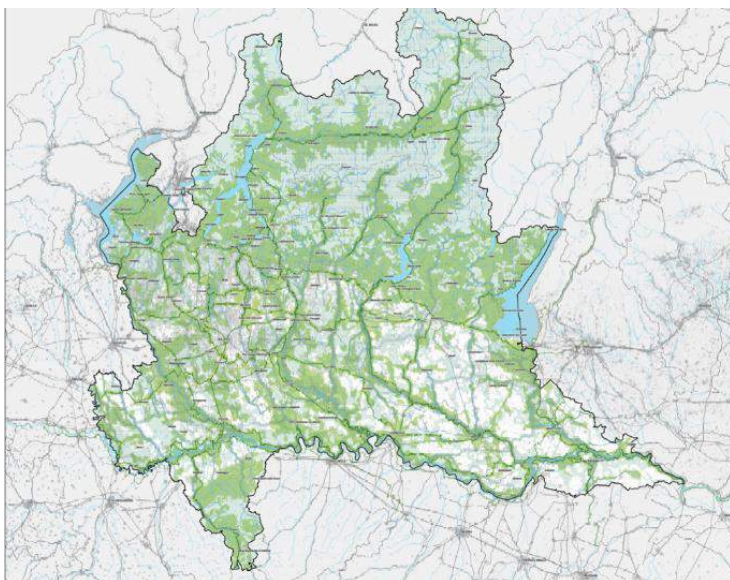

In order to foster the improvement of approaches and tools towards its implementation, the planning experience currently under way in Lombardy Region (IT) related to the new Regional Landscape Plan (RLP) is a good example that assumes concretely the role and potential of green infrastructures in spatial planning with a multi-scalar approach. The RLP fully undertakes the principles of the European Landscape Convention (ELC), where: “Landscape” means an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors” (COE, 2000), recognizing the importance of environmental and ecological components in landscape planning, and improving the integration between cultural and environmental aspects. Moreover, according to the ELC, the plan pays great attention to “landscapes that might be considered outstanding as well as every day or degraded landscapes” (COE, 2000) considering that this typology of landscape covers a large part of Lombardy, corresponding to the metropolitan region of Milan.

The new plan proposes a strong integration between cultural asset (historical), natural (ecological, environmental) and agricultural components, adapting different protection or enhancement rules according to the wide range of diversity characterizing the regional landscape (Regione Lombardia, 2015; Pedrazzini, 2016). A very wide ranking of landscapes and environmental mosaic composes this ten million inhabitants region: from the metropolitan region of Milan, characterized by high anthropic and environmental pressure (up to 7,000 inhabitants/km² in Milan), to the southern valuable agriculture plain and to the northern alpine region with its wilderness and high ecological value. According to this diversity and complexity in term of natural and cultural asset, anthropic pressure and environmental risks, the RLP sketches the main regional strategy and targets that should be further developed and applied at different level of governmental competence, with specific and tailored aims and operative solutions according to the local specificity and by favouring a citizens’ participative approach.

2 A MULTI-SCALAR NETWORK FOR AN INTEGRATED AND EMPOWERED PLANNING

In order to give concreteness to the integration between environmental, ecological, agricultural and cultural aspects the main RLP project consists in designing and implementing the Regional Green Network (RGN) as the fundamental green infrastructure for a balanced regional development (figure 2). This is coherent and fully assumes the concept of multi-functionality of a Green Infrastructure, particularly important in a region with a very intense anthropic feature as in Lombardy. Due to the comprehensive character of the regional Landscape plan, the RGN represents a strategic project, in accordance with the cross-sectoral and cross-scale application as defined by the European Green Infrastructure strategy, particularly

considering that “the implementation of green infrastructure would benefit from integrated spatial planning early in the planning process” (EC, 2016:150).

The proposed RGN is founded on the existing Regional Ecological Network (REN), composed of sites and networks of ecological importance and characterised by biodiversity (Natura 2000 sites, Sites of Community importance, Ramsar Sites, regional and national parks, etc.).

Figure 2 – Regional Landscape Plan: proposal of the RGI (RL and DASTU)

To the REN other components such as agricultural, cultural, historical and places of leisure are added providing and ensuring the accessibility to the regional green infrastructure by citizens. The added value of the RGN system is to allow a real comprehensive and integrated planning approach to the diverse elements of the natural, cultural and rural systems favouring the access and use of RGN by soft mobility and transport network such as pedestrian, cycle paths and public transport.

About the spatial planning dimension of the RGN, it works at different levels in term of contents, targets and governmental relationships. The network is designed by the RLP, appointing the main objectives at regional level as a multifunctional infrastructure; later are delivered to the different levels of administrative and spatial competences the task to improve and develop specific contents, subsequently the related Green infrastructure by the mean of the provincial and urban planning instruments will be planned.

Referring to the contents, the RGN is designed assuming the main landscape and environmental asset characterising the region (eg.: agriculture, lakeshores, peri-urban agriculture, forests, historical and irrigation canals, historical paths, green tranquil areas, spring water, etc.), finding out the main focal points where the environmental network and the landscape cornerstone elements converge (Figure 3).

According to the diverse territorial specificities, these elements could be open areas where the presence of ancient monasteries or historical rural settlements is combined with precious agricultural areas and wetlands, rural historical paths and irrigation canals, and where the RGN provides the integration of green and blue networks. This allows combining in a durable e strategic perspective the diversity and richness of a territory where the natural characterization was enriched during the time by the humankind, carrying out a spatial structure where natural and anthropic elements established a good integrated and working well system, identified in a typical landscape feature.

The RGN works proactively orienting its construction with linking sites of environmental importance to other elements of landscape and cultural importance in a unique network.

The RLP establishes by the RGN the main regional priorities in the environmental context and the focal points of the network. Strategic regional knots, cornerstones and areas (e.g.: main rivers, lakes, paths,

eco-museums, etc.) are planned, giving to other administrative levels specific competencies and tasks to improve the system based in the regional ecological backbone network. Starting from the RGN network, provinces and municipalities will improve secondary networks and implement territorial development according to the RGN structure by the mean of their planning instruments.

To complement this approach the RGN works on areas, knots and part of the network under risk for anthropic pressure or intercepting derelict areas needing to be recovered as recognised of priority importance by the RLP.

Figure 3 – Regional Landscape Plan: proposal of the RGI – Detail (RL and DASTU)

As an example, in the metropolitan region of Milan, these sites are along the rivers or in the southern periurban fringe of the city that is particularly subject to settlement pressure but where is still present an important agricultural and environmental asset. Infact the metropolitan region is characterized by dense and sprawled urban settlements, residual open space, marginal agriculture, but also by valuable ancient rural settlements, ancient monasteries and the lasting countryside.

Further, residual spaces with important biodiversity, a valuable agriculture production and a tradition of rural activities still exist in this area. The RGN can help to put in value and give a specific perspective to urban agriculture, attention to the periurban landscape and reevaluate derelict peripheral areas within an integrated green network strategy.

This way the RGN responds to both the principles of conservation (with protection) and restoration (with recovering), allowing to enhance the territorial capital of a rich despite unbalanced region. The RGN acts in a more extended way compared to that proposed by the European Environmental Agency (EEA, 2014:19) where the RGN works mainly on the habitats and ecosystems.

Starting from the general objective of the landscape improvement as main target of the regional plan, the related aim is to recognize the RGN as a natural and semi-natural structure characterized by multifunctional functions.

It is designed and recognised as a multifunctional resource, capable of delivering a wide range of benefits to citizens and nature. It can contribute to climate mitigation, providing ecosystem services, biodiversity protection, renewable energy, enhancing identity, cultural values and resilience.

The plan of the RGN should establish at regional scale the governance rules and the main contents, aims and strategy for its implementation, giving to the decision makers at different scale of planning the responsibility (town and country planning) to develop and implement contents of the RGN at the different territorial scales. This is by the application of the principle of subsidiarity, in order to improve the role and responsibility of decision makers more close to citizens, with a multi-scalar and learning process and for improving active citizens' participation to the decision making process.

Further, in the plan it is very important to improve the role of a RGN in order to provide a framework useful to connect and coordinate at regional scale different policy domains such as agriculture, forestry, nature, energy, culture, tourism, and disaster prevention. In planning policies, the RGN should be useful to promote concrete and fruitful relationships between built up, periurban and rural areas, giving a framework in which connections and relationships include proactive protection and carefully transformation policies.

3 A LEARNING BASED PROCESS

The importance of this project is that RLP intends to develop the RGN as a green infrastructure with the contents of a GI strategy as a fundamental element in a comprehensive planning instrument. This can improve a strategy directly influencing sectorial planning/policies and territorial planning, in fact in Italy landscape planning is directly referred to a constitutional competence and then it is hierarchically higher and more powerful compared to other planning instruments. Then the Regional Landscape Plan can assume the role of a meta-coordinator of diverse but convergent strategies environmentally oriented (climate adaptation, sustainable energy, biodiversity, land taking, etc.).

A second issue that gives relevance to RGN project is because it allows a sort of extension to the concept of Green Infrastructure strategy, being the RGN tailored and adapted according to specific contents and feature of the diverse territories, and then giving a comprehensive value to the concept of multi-functionality of the RGN.

A third point of interest is referred to the structure of the RGN that implies a strong awareness of the diverse governmental competencies involved in its planning and management. It is created at regional level and contains the main strategic objectives but it is strictly linked to the further level of planning for its successfully implementation, then part of the contents and design have to be completed for its further improvement by other level of planning and management in a sort of vertical horizontal cross-disciplinary coordination.

As in the case of GI, they can work at different level: from the EU (with the GI strategy) to national and regional level with building up the main backbone network structure sketching the principal feature of a more extensive physical structure.

Local or town/city scale	Regional and national scale	EU level	Descriptor
Natural and semi-natural ecosystems, such as pastures, woodland, forest (no intensive plantations), ponds, bogs, rivers and floodplains, coastal wetlands, lagoons, beaches, marine habitats	Extensive agricultural and forest landscapes, large marsh and bog areas, rivers and floodplains, shorelines/coastal zones	Freshwater systems, major river basins, mountain ranges, regional sea basins	Core areas – outside protected areas
Local nature reserves, water protection areas, landscape protection areas, Natura 2000 sites	Regional and National Parks and wilderness zones (includes Natura 2000 sites)	Ecological Networks with cross-border areas, incl. Natura 2000 network	Core areas/protected areas
Restored areas which were before fragmented or degraded natural areas, brownfield land or disused quarries, transitional ecosystems due to land abandonment or regeneration processes	Restored ecosystem types	Restored Landscape systems covering a substantial part of agricultural/forestry areas and industrialised sites, including cross-border areas	Restoration zones
High nature value farmland and multi-use forests (such as watershed forests), protection forests (against avalanches, mudslides, stonefall, forest fires), natural buffers such as protection shorelines with barrier beaches and salt marshes	Extensive agricultural landscapes, sustainable forest management on regional and national level, functional riparian systems	Transboundary landscape features on river basin or mountain range level, sustainable coastal and marine management zones related to the respective sea basin	Sustainable use zones
Street trees and avenues, city forests/woodlands, high-quality green public spaces and business parks/precincts, green roofs and vertical gardens, allotments and orchards, storm ponds and sustainable urban drainage systems, city reserves incl. Natura 2000	Greenways, green belts, metropolitan park systems	Metropolitan areas with substantial share of high quality green areas in Europe, including coherent approaches in cross-border urban zones	Green urban and peri-urban areas
Hedgerows, stone walls, small woodlands, ponds, wildlife strips, riparian over vegetation, transitional ecosystems between cropland, grassland and forests	Multi-functional, sustainably managed agricultural landscapes, riparian systems	Supra-regional corridors, substantial share of structure-rich agricultural, forestry or natural landscapes	Natural connectivity features
Eco-ducts, green bridges, animal tunnels (e.g. for amphibians), fish passes, road verges, ecological powerline corridor management	De-fragmented landscapes, improved areas along transport and energy networks, migration corridors, river continuum	European-wide or transnational de-fragmentation actions	Artificial connectivity features

Figure 4 – Physical features of Green Infrastructure in relation to scale and function (EC, 2016:156)

Particularly, at regional level have to be fixed the main strategic green hubs and linear elements of the network, constituting the cornerstones of the strategy in order to further improve a coherent network of GI at local level and further carry out operative measures (projects) springing up a virtuous circle (Figure 4).

In the case of a strong anthropic region like Lombardy a GI have to be tailored according to the specific territorial feature, taking in account and valorizing specificities of the complex mosaic composing it. The RGN and the subsequent Provincial Green Network and Local Green Network have to interact positively to work out efficient solutions against the risk of further fragmentation of the territory and ecosystems. In

positive, the diverse green networks can to improve relationships between the natural and anthropic systems in order to ensure efficient ecosystem services.

In the European Commission communication Green Infrastructure – Enhancing Europe's Natural Capital (EC, 2013a), GI is defined as a tool for providing ecological, economic and social benefits through natural solutions, helping people to understand the advantages nature offers human society and to mobilise investments that sustain and enhance these benefits (Figure 5).

Being the GI a spatial concept providing services at different scales it could assume the character of a governance instrument that allows coordination and integration of policies. In a very antropized region like Lombardy the most important resource will be even more an efficient and reliable territorial system and the RGN can help to go behind the typical conflict between grey and green infrastructures, focusing on the quality of landscape and environment as a key issue for the durable economic attractiveness of a region.

ID 1392 | POLITICAL CONFLICT ON SPATIAL PRACTICE AT URBAN PARKS IN TURKEY: CASES OF ANKARA AND İSTANBUL

Yasemin İlkay¹

¹Van Yüzüncü Yıl University, Turkey
yasemin.ilgay@gmail.com

1 INTRODUCTION: WHAT IS 'POLITICAL' AT URBAN PARKS?

Urban parks are defined as 'green', 'open' and 'public' spaces where citizens recreate themselves; interact with nature and each other. Furthermore, (as lived spaces) parks provide a backcloth for spatial practices and (re)produce urban everyday life via framing daily rhythms and behaviours within their physical boundaries. Nonetheless, urban parks (as conceived spaces) are regulated via official decisions of the state, especially by the hand of local governments, which implies the spatial policy of the party in power and capital accumulation process rather than use value of inhabitants and spatial quality of natural-built environment.

Indeed, spatial policy is fragile particularly in the countries like Turkey, since it is extremely influenced by the political-economic shifts. Moreover, neo-liberal spatial policies stretched the limits and definitions of public and private spaces; which led to both deformation of open-green areas and privatization of public spaces.

We can follow a disruption and displacement process within urban public spaces and green areas especially in the cases of Ankara and İstanbul, two great cities of Turkey. As an essential example, Ankara was conceived and re-designed delicately in 1920s as the capital of newly-established nation-state which has both a spatial and political essence in the planning history of Turkey. The re-creation of Ankara served for not only creating new publics with their (public) spaces but also constituting the examples of modern city planning in new Turkish Republic (i.e. Gençlik Park [meaning Youth Park, one of many examples constructed in several other Turkish cities in early-republican period] and Güvenpark [the name of the park means 'safety', 'trust'; it was designed with a symbolic-political content and formed as a part of both the master plan of the city (Jansen Plan) and micro design of the city-centre]). However, public space pattern of the city has been gradually disrupted in the following decades. Rather than staying in and practicing publicness, citizens tend to pass through open public spaces, which is partly a result of incremental and arbitrary approaches to the design and construction. Moreover, the political-symbolic displacement process –during the reproduction of open public spaces and urban greenery– led to a decrease in the socio-spatial quality of such spaces. On the contrary to the first era of early-republican period, dysfunctional and poor-quality public spaces have been constructed and reproduced through plans, codes and projects of decision makers hand in hand with market mechanisms though their recreational and public potentials via urban daily experience.

Parallel to the displacement process witnessed in the capital city, disruption and deformation were observed in quality and quantity of green areas in several locations, particularly in metropolitan cities. As the most critical case, the attempt to reconstruct Topçu Kışlası –one of the military barracks from Ottoman Period– in Taksim Square, İstanbul, by demolishing Gezi Park [in 2013] led to several struggles spreading all over the country. This contradiction appeared as a breaking point in both political and spatial history of Turkey. Nevertheless, the JDP (Justice and Development Party) Government has continued to interfere public spaces and green areas after June Resistance at Gezi Park (in İstanbul), such as construction of a mosque in Validebağ Grove in İstanbul, construction of the new house of president and Ankapark in AOÇ (Atatürk Orman Çiftliği – Atatürk Forest Farm), and destruction of almost 6000 trees in Yırca Village, in Soma, despite the legal rejection of the construction permit, which may be seen as 'sickness' (as caricatured in Fig. 1.). These attempts also resulted in conflicts, indicating the symbolic tension between the two faces of the public: the inhabitants (the 'public' as users) and the government (the formal 'public' in the role of state who has the right and responsibility to shape physical forms of public spaces and green areas), which implies the political dimension of the issue.

Figure 1 - A cartoon criticizing the green policy of JDP, Behiç Ak, 22.11.2014, Cumhuriyet
Source: http://www.cumhuriyet.com.tr/cizim/147115/Behic_Ak_Kim_Kime_Dum_Duma.html

The cartoon (in figure 1) criticizes the recent attempts of central government in Turkey; the translations are (from left to right, up to down): (1) "They were constructing a building in Validebağ Grove"; (2) "They were determined to cut the trees in Gezi Park"; (3) "A law was enacted to cut the olive trees"; (4) "Hundred thousands of trees were cut for the construction of bridge and airport in İstanbul"; (5) "They are going to construct buildings on the open spaces for gathering during earthquakes"; (6) "Oh my god! The state has officially got sick!" The recent spatial policy of JDP's government on environment and green is criticized in the cartoon, arguing that the state has got sick. Spatial policies interfere not only our physical environments but also via spatial projects they influence our daily lives, rhythms, rituals, construction process of self-identities and social bonds. The mentioned cases above indicate a turning point to a new era in the green policy of Turkish governments and also imply a potential field of political-symbolic struggle through urban space. Considering this turning point, "how urban parks function via reproduction of space recently" occurs as a critical question. Such spaces promise spatial practices linked to a pure use value rather than exchange value, so "how can urban parks survive within urban spatial pattern as 'a natural' and 'an open public space' within this mode of production"?

Although (open) public spaces, especially urban parks, are on the basis of our daily experience and self-reproduction process; in Turkish case, they have turned out to be places where we pass through and seem to be at the mercy of the decision makers or to be constructed through market mechanisms, which lead to arbitrarily developed open public spaces. However, they have great social, political and professional potentials. The recent attempt to demolish Gezi Park (and the struggles over it since June 2013) is a good example of both of these situations in Turkey. The opposition rose against not only the spatial intervention to our organization of public spaces but also to the undemocratic intervention to our everyday life and rhythms.

This transformation and struggle will be critical in following years in Turkey. This very recent struggle indicates the tension between users and (technically or politically) designers of these spaces. This study bulldozes the conflictual nature of urban parks in Turkish case within examples of reproduction of such spaces especially in Ankara (the capital city of Turkey) and in some other cases in İstanbul (the largest metropolis of the country) through the analysis of 'reproduction mechanisms', 'meaning shifts' and 'spatial-historical phases'. These examples would both demonstrate a framework for the main question of the study: how has neoliberalism shifted the boundaries of symbolic/political content of Turkish urban parks; and would indicate the political-spatial potentials rested in this shift such as the case of Gezi Resistance during June 2013.

2 HISTORICAL PHASES FOR REPRODUCTION OF URBAN PARKS IN TURKEY

Most of the largest parks in Ankara were created in 1920s after the declaration the capital of new nation state: Turkish Republic. Urban parks did not occur until Republican Period (Oğuz, 2000). In the Ottoman Era, palace gardens existed under the ownership of the Sultan; society recreated themselves in the orchards (bağlar) and private gardens. Therefore, large urban parks in Ankara are products of 'Republican project to construct a modern society' (Oğuz, 2000: 165): [i.e. Gençlik (Youth) Park (see Fig. 2.) is the first planned urban park to supply the public recreation need in Ankara (Uludağ Sökmen, 1998a, 1998b; Oğuz, 2000)].

Figure 2 – Gençlik Park, 1953

Source: Gürkaynak Alpayeski's Personal archive, in 'Ankara Resimleri Meraklıları Platformu'[Facebook group]

The first dominant theme related to phases for urban parks, which indicates a transition process, is a revenge on socio-spatial inheritance of Ottoman Empire (İlkay, 2016). In the second half of 19th century, the industrial revolution and capitalist mode of production influenced the legal-institutional framework and spatial organisation in Ottoman cities as well. Ottoman Empire was open to capitalist relations; the new city centres were organised around banks, insurance firms, hotels, and office blocks rather than market places located around Bedesten [a covered Turkish bazaar]. The city centre was expanded with train stations, docks, harbours, post offices; and state buildings settled among this pattern as a result of rising bureaucracy in the empire. In addition to spatial re-organization of the centre, new transportation modes (such as cars, trams, ferries, suburban trains) evolved beyond pedestrianized patterns, which also led to urban sprawl, suburbanization and shifts in both societal stratification and types of landuse. Such a sudden urban transformation awoke the lack of legal-institutional organization and a necessity of planning. In 1836 and 1837, Van Moltke prepared the first plan of the Empire for İstanbul. In 1848, Ebnîye Nizamnamesi (the Code of Structures) was legislated for İstanbul (Tekeli, 1998). This legislation aimed to regulate land expropriation, construction permits, width of streets, and height of buildings (Çalışkan, 1990; cited in Müftüoğlu, 2008). Moreover, as one of the first institutional regulations in the empire, in 1855, Şehreminliği / Şehremaneti (a kind of municipal authority) was established for the city of İstanbul (Tekeli, 1998, Kayasü, 2005); 'şehir' means 'urban' and 'emin' means 'trustworthy' in Turkish, which indicates a role attributed to a mayor or institution as the guard of the city (Cengizkan, 2002) and implies the roots of the conflict between ownership and possession of urban space in Turkish cases. In 1882, the first development law of Ottoman Empire, Ebnîye Kanunu (the Law of Structures) was enacted. Construction was forbidden in recreation areas and urban parks were constructed in İstanbul in several locations such as Gülhane, Sultanahmet, Fatih and Üsküdar-Doğanlar, which was a positive dimension of the new law (Müftüoğlu, 2008). The first urban green area in Ankara was Millet Bahçesi –Garden of Nation (see Fig. 3.). This space, located in Ulus (the old city centre), was the only urban green (before Republican Era), consisting of a small pond with wooden theatre building. In addition to this garden, vineyards in districts of Ankara such as Çankaya, Etilik and Keçiören were used as recreational needs by the citizens of the city (Çalışkan, 1990; cited in Müftüoğlu, 2008).

Figure 3 – Millet Bahçesi (Garden of Nation), Ulus
Source: http://www.ergir.com/2012/Ankara_Palas.htm

Spatial and institutional regulations continued till the beginning of 20th century in the empire, however these attempts were not enough to organize a holistic, planned beautification and development for cities; the macroform was not considered in these limited regulations, which was the most lacking issue in the Empire's spatial policy at that time. Moreover, these spatial re-organization attempts were condemned to be unsuccessful since a new political and spatial organization was forthcoming in this land. Şengül (2003) labels the urbanisation period after the establishment of nation state in Turkey as 'urbanisation of state' during the years between 1923 and 1950. Within this period, Ankara was declared as the capital city, which was attempted to be developed as a spatial project of the extension of the newly established nation state ideals.

This era indicates a rejection of the spatial-institutional inheritance of the Ottoman Empire and relatively a holistic spatial policy towards not only urban green areas but also all of the urban segments. The lack of central political-spatial organization and organic urban pattern (inherited from the Empire) complicated the control of central nation state, therefore the spatial transformations had to be organized at first nation state scale and then the city had to be re-organized as political-spatial node of the modernist project of the state (Şengül, 2003, Tekeli, 1998). Ankara, as the capital city, was selected as the model for this transformation, which was a challenge (Cengizkan, 2002).

Various legislations were enacted as a part of the new spatial policy (Cengizkan, 2002; Kayasü, 2005). Ankara Şehreminliği (The Directory of Development) was established in 1924 (Müftüoğlu, 2008), which was equipped with a great spatial authority (Tekeli, 1998). As the first activity, Lörcher, a German architect, was assigned to prepare a report (with three plans attached to it) on the inventory of spatial and social needs of Ankara (Cengizkan, 2002; Cengizkan, 2004). Lörcher Plan, which constituted the basis of Jansen Plan –the first official plan of Ankara approved in 1928– organized both the new neighbourhood as Yenışehir [recently Kızılay Square (which later turned out to be the new centre of the city in 1950s)] and the pattern of public spaces and green areas reproducing the public sphere within this neighbourhood and the whole city. The square with Güvenpark, attached to it, was designed as the node of this pattern through a holistic and organized planning attempt (Cengizkan, 2002).

Figure 4 – Güvenpark, Yenisehir (New City)

Source: Gürkaynak Alpayseski's Personal archive, in Ankara Resimleri Meraklıları Platformu [Facebook group page]

Güvenpark was also attached to Kızılay Square, and both were designed to be the symbol of the new republic and the public space of the bourgeoisie (see Fig. 4.). Located at the intersection of two main streets, Kızılay Square was planned to provide a new kind of public life via spatial elements such as Havuzbaşı and Güvenpark (Batuman, 2000; Batuman, 2002). Moreover, AOÇ (Atatürk Orman Çiftliği – Atatürk Forest Farm) was conceived in 1925, on a 150 000 da area, by the demand of Mustafa Kemal Atatürk, the founder of the nation state. With this multifunctional farm, a large area would turn out to be a huge urban green space in the very centre of both Ankara and the middle Anatolia (see Fig. 5). This space would provide space for both agricultural activities and recreational facilities for the citizens; and in addition to these functions, the daily needs of the citizens for milk, beer, cheese, oil, and yoghurt would be met via the production in this farm (Müftüoğlu, 2008).

Figure 5 – A Drawing of Atatürk Forest Farm (AOÇ), 1936

Source: <http://www.kuzeyormanlari.org/2014/08/21/ataturk-orman-ciftligi-arazisinin-ucte-ikisi-gitti/>

Jansen Plan was sensitive to both protecting the natural layout of the city and creating a spatial structure of urban greenery. Within a holistic approach, valleys and brooks were planned to be protected and strengthened via green belts and the continuity of urban green spaces was proposed (Müftüoğlu, 2008). Furthermore, green areas were planned to meet citizens' recreational and social needs (Değirmencioğlu, 1997). Gençlik Park (Youth Park) was located at the city centre, Ulus, consisting of a huge water

component, which covered 1/3 of the total area (Kayasü, 2005); this space was realized in 1946, such a huge water element was a dream at that time at the heart of an Anatolian city (Uludağ Sökmen, 1998.b.). Güvenpark was conceived to be a 'square park' attached to Kızılay Park (see Fig. 6) as a component of the green space system defined in Jansen plan (Memlük, 2009). Kızılay Square consisting of Güvenpark was designed as a spatial strategy to create a public sphere with its spatial necessities (Batuman, 2000 & 2002). Atatürk Boulevard was playing an essential role as an axis connecting critical open and public spaces such as parliament, Güvenpark, Kızılay Square and Zafer Park (means 'Triumph Park' in English). This pattern created a public-recreational axis [north-south skeleton of public sphere in Yenişehir] (Batuman, 2002) reaching to Gençlik Park in Ulus. The parks on this axis [Gençlik Park, Kızılay Park, Güvenpark and Zafer Park] were meeting the recreational needs of the citizens (Memlük, 2009). In this period, youth parks, culture parks, and urban forests were constructed in several cities by the demand of Atatürk to provide public places for citizens to socialize and educate oneself on the new public domain of the nation state. These urban green areas were designed as squares and public gardens in several cities (such as Adana, Afyon, Ankara, Antalya, Bolu, Bursa, Çanakkale, Gaziantep, İstanbul, İzmir, Samsun and Trabzon) between 1923 and 1945. These spaces were used as tools and stages to publicise the reforms of new period – i.e. Atatürk presented the new Turkish alphabet in Sarayburnu Park in İstanbul, on August, 9th, 1928 (Gündüz, 2002). Summarising during the urbanisation of state period open and green spaces were used as not only recreational places but also representational spaces forming the social-political perceptions of citizens.

Figure 6 – Kızılay Square and Güvenpark, 1942, postcard

By 1950s, modernization in agricultural techniques led to massive population movements from rural areas to cities in Turkey. In fact, Ankara had experienced population growth after its declaration as the capital which resulted in difficulties to implement holistic plans and provide a regular urban development. Moreover, this era witnessed some other political-economic shifts. The rest of the world was passing through a process of Welfare state after the Second World War and Turkish economy was opened to wider capitalist relations by the help of Democrat Party after the transition period to multi-party regime. Şengül (2003) names this chaotic era as 'the urbanisation of working class'. Squatter settlements spread all over the large cities in the form of 'slum belts; informal sectors and authentic transportation modes (like 'dolmuş') appeared in the daily life of cities as a result of lacking systems of the state and control mechanisms with lacking infrastructure (Tekeli, 1998). New comers (coming from rural areas turned out to be workers from being farmers) encountered and conflicted at and through urban space with the urban inhabitants which had political and spatial consequences (Şengül, 2003). The first spatial transformation related to our issue was that, Kızılay (earlier Yenişehir as a housing neighbourhood) turned out to be a commercial centre by 1952 (Batuman, 2002). The public spaces of this area, especially Güvenpark, attracted the ambition of working classes who could not access there before, this occurred as both a political/symbolic and a spatial-social demand (İlkay, 2008). During this period, differentiated social groups and classes could encounter at Kızılay, which was a city centre and a square with an urban park, these

encounters developed differentiated narratives and symbols over the space which formed the political and symbolic content of the space (Batuman, 2002). The first and largest designed public space of the capital city turned out to be a political stage and an issue which was subjected to struggles [for a detailed narrative of this political-spatial shift, see: İlkay, 2007 and İlkay, 2008].

Şengül (2003) defines a third era in Turkish urbanization and planning history by 1980s as: 'Urbanization of capital'. In 1970s welfare state declined in leading economies of the world which resulted in a shift from redistributive spatial policies to growth oriented neoliberal spatial policies as well. Moreover, identity politics shone out and replaced distributional politics. By 1980s all of these changes influenced the urban green policy in Turkey in three dimensions: (1) use value has replaced with exchange value more deeply which limited the creation and reproduction of urban space; (2) such an approach led to a decrease in the spatial quality and a fragmentation of mechanisms and processes of reproducing urban space; (3) as a result of rise in identity politics, the space reproduction turned out to be more sensitive to representational politics and dynamics, which opened a path to increase in symbolic-political struggles on urban green areas and therefore the public character of the urban green areas precluded the natural dimension and open space character of such spaces (İlkay, 2016). These themes dominate the reproduction mechanisms for urban parks in Turkey, by 1980s, which will be discussed within examples in the next sub-section of the paper.

3 SYMBOLIC STRUGGLES (ON SPATIAL PRACTICE) AT URBAN PARKS

The economic-political context of Turkey brought a shift to exchange value from use value parallel to the world economies. This shift has been deepened in subsequent decades; 2002 is a turning point for Turkish politics, when the Justice and Development Party (JDP) grabbed the power. 'Deregulation' and 'liberalization' have framed Turkish planning and development structure by 2002, which catalysed private sector in urban spatial reproduction processes via legal and institutional rearrangements (Balaban, 2008). This facilitation decreased the quality and quantity of urban green areas (i.e. Fig. 7), which have hardly met the needs of increasing urban populations and developed lands. However, the official sources claim the opposite, which makes it difficult to document the exact transformation of amounts and quality of urban green spaces (İlkay, 2016). Nonetheless, in-depth interviews (conducted during the writer's PhD thesis [İlkay, 2016]) demonstrated that citizens perceive an 'impoverishment' of green and open spaces in Ankara.

Figure 7 – The decrease in green areas in Istanbul
Source: <http://wowturkey.com/forum/viewtopic.php?t=136028&start=160>

The planning system has been gradually fragmented; separate institutions conflicted in the same segment or thematic space of the cities and they had to interfere at a location with respect to various legal texts (Duyguler, 2012). This resulted in a chaos, which grow this impoverishment up. In the cases of Ankara, the metropolitan municipality seems to either conflict or harmonize with the district municipalities, this leads to a duality in the manner to interfere the local spaces and to transfer funds for construction of urban parks. The discussions among municipalities or the juridical struggles between metropolitan municipality and the chamber of architects and planner imply the changing definition of urban green areas. The cases indicate that, the natural character and basic motivation for urban green areas have been withdrawn so

that the parks seem to be conceived as either 'symbolic spaces' or stages for political demonstrations. Figure 8 demonstrates an announcement of the opening ceremony of an urban park, which is attached to urban transformation project area; however in fact such an ceremony seems to perform two political motivations: (1) to give a stage to the existing prime minister to explain his party's propaganda for the forthcoming elections in June 2015 and (2) to legitimate the urban transformation processes via a ceremony of drawing lots for the possible inhabitants of the newly developed housing area (see Fig. 8) (Ilkay, 2016).

Figure 8 – The announcement of Ankara Metropolitan Municipality for the opening ceremony of Hatip Çayı Park on 23.05.2015

In Turkish metropolitan cities, such a content for spatial development was not an issue of 2000s, rather it rooted from earlier. By 1990s, a new political era began with the local elections in 1994. Islamic municipal politicians captured the power of several cities; Refah (Welfare) Party won the elections at the prominent cities such as Ankara, and İstanbul which had been castles and models of spatial modernization project of newly established Turkish Republic since 1923 (Doğan, 2007). Between 1997 and 2002 the Islamic local governments performed several populist spatial implementations at Kızılay Square and Güvenpark such as İftar tents, free public transportation during Bayrams (religious festivals), concerts of popular singers, and delivering plastic balls after victory of national football team. Batuman (2002) discusses the symbolic function of such tents with free public transportation as providing the conservative poor populations (who are living in the peripheries of the city) to reach city centre both bodily and symbolically since they would be visible at urban open public spaces and green areas with their Islamic identity and cultural values. This was a reciprocal desire among the mayors, local politicians and the communities who gave charge to them (Batuman, 2002).

Doğan (2007) defines 'Islamist' as not a rise of spirituality, rather it is an ideology or legitimizing tool on the political stance of the Islamist Politics and it is framed through a set of systematic attempts to regulate both the state and the society. Refah (Welfare) Party [RP] continued their success in the next parliamentary elections in 1995, as becoming one of the prominent actors in the parliament after elections. This success influenced the symbolic struggles occurring in the urban space via spatial projects, symbols and limitations on spatial practice. Doğan (2007) examines the Islamist Municipal Governments in the case of Kayseri, one of the large cities of Turkey, located at Middle Anatolia. He argues the Kayseri case as a significant example of reproducing urban space as a part of their great representational project which serves for empowering the societal-political impact of the Islamist movement within public sphere. Şükrü Karatepe, the mayor, practiced a strategy called 'White City Kayseri' via reconstructing certain public spaces by reorganizing with Islamic motifs between years 1994-1998. These motifs would emphasize the conservative values while deleting the previous symbols and structures. Seljuk motifs and spatialisation symbols dominated such an attempt (Doğan, 2007).

Figure 9 – The decrease in green areas in İstanbul
Source: 'The Park, The Penguin, and The Gas', Öztürkmen (2014)

Related to this issue, one of the recent similar trials is the attempt to construct Topçu Military Post at Taksim Square. This case is critical since not only it is a top-down intervention; but also, this specific intervention occurred with a potent to create counteraction on both symbolic content of spaces and freedom of everyday urban lives (see Fig. 9). Gezi Park in Taksim Square was attempted to be demolished by the party in power, towards the end of May in 2013. The JDP government aimed to re-vitalize Topçu Military Post as a part of pedestrianisation project conceived at the historical and political square of the city. This spatial intervention was certain to be a political attempt, which comprises a symbolic displacement process and an attack to the collective memory of the citizens in İstanbul, and Taksim Square. The government insisted on this spatial project though the counter-views rose; without any legal permit to reconstruct the military post, the trees were begun to be cut off and the police responded harshly to the ones who reject this illegal reconstruction. When the police's intervention got more violent towards activists, and inhabitants of the park –who were trying to protect the space, as the police burnt the tents of the inhabitants, the other cities also began to rebel against both this project and violent activities of the police. Figure 10 demonstrates the harsh struggles among policemen and protestors in Ankara, Kızılay, with reference to the events in İstanbul (İlkay, 2016).

Figure 10 – Kızılay District and Yüksel Street (one of the significant pedestrianized paths), Ankara Policemen are located at Güvenpark, in Kızılay while the protestors are struggling with them along the boulevard (photos by Hüseyin Aldırmaz)

This struggle was not solely against the destruction of a couple of trees; but also, it rooted from a reaction towards intervention on undemocratic re-organization of both our public spaces and daily rituals and rhythms. This conflict indicates the tension among the users and designers of the same space; also, it implies a struggle field on urban everyday spatial practice. Protests continued several days via severe struggles, death and injuries, polemics, all of which has influenced our political-societal atmosphere since then. However, Gezi Park, as a living site and environment showed us a potent to re-create our own urban daily life spaces and practices.

Figure 11. Protestors created their own daily spaces and practices after capturing the park, Gezi Park, İstanbul, 14.06.2013, (Personal Archive)

The protestors with the inhabitants of İstanbul, and out comers all together occupied the park, set their own daily life, rituals, and spaces such as library, forums, music, eating and drinking patterns (without paying money) and spatial-political discussions, activities (see Fig. 11). Although this democratic and communal atmosphere was destroyed with gas bombs and other interventions on the evening of 15th June [by demolishing tents, all the spatial setting, posters, stands, activity nodes], this spatial practice has been a symbol and a model of counter actions towards undemocratic spatial projects and interventions (İlkay, 2016).

Gezi Park event and June Resistance has echoed since then; several park forums and NGOs were created after this model struggle [Such as: Anıtpark Forumu, Atatürk Orman Çiftliği Halk Meclisi, Ayrancı Forumu, Çayyolu Üç Fidan Parkı Forumu, Çayyolu Atapark Forumu, Çayyolu Türkkonut Halk Meclisi, Eryaman Forumu, Ethem Sarısülük Parkı Forumu, Güvenpark Forumu, Seğmenler Parkı Forumu, Yüzüncü Yıl Forumu and Tuzluca Dayanışması (Ankara forumları hayallerindeki Ankara'yı konuştu, Sol, 29.09.2013: <http://haber.sol.org.tr/kent-gundemleri/ankara-forumlari-hayallerindeki-ankarayi-konustu-haberi-80334>)].

However, on the other hand severe interventions and undemocratic spatial projects also continued.

Government, with the help of private sector and certain local governments, has attempted to transform certain green spaces such as constructing a mosque in Validebağ Groove in İstanbul, which is a great breathing space among housing neighbourhoods; constructing the Presidential Palace and an entertainment park in Atatürk Forest Farm, which is both an inheritance of the founder of Turkish Republic and one of the largest and oldest urban green spaces of Ankara (see Fig. 12.); cutting almost 6000 trees in Yırca Village, in Soma, though there is a legal rejection of the construction permit (İlkay, 2016). Also, a recent attempt has threatened the existence and atmosphere of Roma Park in Cihangir, İstanbul, by destructing the most of the space for the construction of social entities although the site has also an archaeological potential.

Figure 12 – Destruction of Atatürk Forest Farm via Construction of the Presidential Palace, 2014
Source: <http://kentinsesi.tv/?m=2014&paged=3>

4 CONCLUSION

All these attempts led to conflicts, implying the symbolic contradiction among the two sides who define the physical boundaries and spatial practice of such spaces: the inhabitants (users) and the government (who has the right to define physical boundaries of public spaces). Urban parks and other public spaces are critical sites to be seen therefore easily turn out to be representational spaces. The form and content of the symbols and political hegemony depends on usually the party in power and relations among top to down and from bottom up societal movements; however, parks which are regarded as purely natural spaces usually function as political sites –scenes and subjects.

Examining the historical phases and transformation of political/symbolic content of urban parks in Turkey (in the cases of Ankara and İstanbul), three essential shifts draw attention: (1) Recent attempts of spatial transformation of urban parks and green spaces usually imply both a rejection a destruction of especially the spatial values and practices of early republican era, the spatial inputs created by Mustafa Kemal Atatürk and his colleagues. Atatürk Forest Farm and Gençlik Park in Ankara, and Gezi Park in İstanbul are essential examples. This turns out to be a demolition process of previous political symbols and an attempt to be seen and applying pressure through space on the opposition. (2) As exchange value has been emphasized, the quality and quantity of urban green areas have been reduced. The green policy and approach has been shifted from a relatively more sensitive conception of nature to a more aggressive approach towards nature and urban space. (3) The holistic reproduction processes and planning tools have been left aside and fragmented institutional structure and planning attempts got on the stage. But all these negative aspects did not delete the importance of urban parks. Rather, urban parks gained significance as representational spaces and turned out to be critical castles of the struggles on spatial practice at urban green areas. Acknowledgements: Special thanks to Prof. Dr. Ali Cengizkan, who supported all dimensions of the study, and contributed to the process of shaping the boundaries of the research.

1 BACKGROUND

Munich (Figure 1) is a growing city and is one of the most competitive metropolitan areas in Germany (Figure 2), characterised by a dense concentration of functions developed through complex and dynamic ecological, social and economic networks acting at city, region and global levels. The increase of landscape consumption due to settlement and traffic is accordingly above average and accounted for 6% between 2004 and 2010. The population of the City of Munich, currently about 1.5 Mio., is expected to grow by approximately 230,000 inhabitants until 2030. With around 7% the expected population growth between 2010 and 2030 is nowhere else as high in Germany; the actual number of population for the whole region is around 5,5 Mio.

Figure 1 – Englischer Garten, Munich (Stefanie Grüber, 2013)

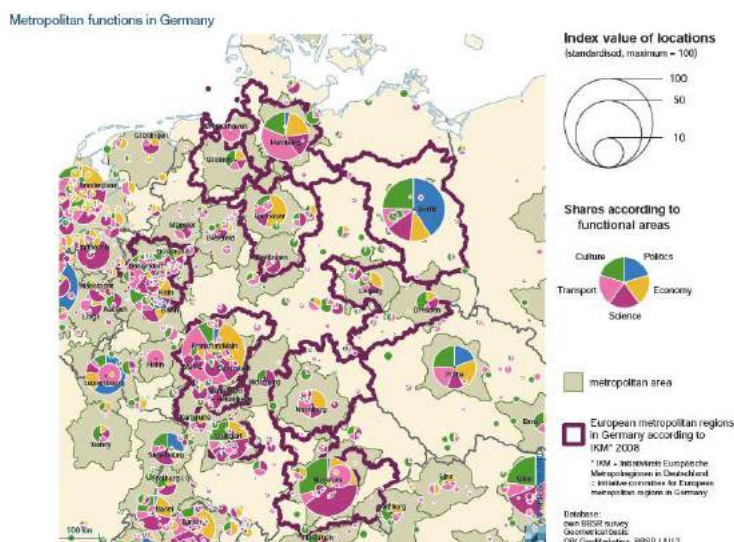

Figure 2 – Metropolitan functions in Germany (BBSR, 2010)

Within the city, the population density is one of the highest in Germany, with 47 residents per hectare. 39% of the residents are foreigners or Germans with a migration background. Population growth and urban development are increasing putting pressure on the urban green spaces. On the other hand, those trends reclaim the development of connected green blue infrastructure for recreation and other social benefits. Moreover, on-going social and environmental changes, such as the diversity of cultures and lifestyles, and the growing requirements for a healthy and resilient city already influence the space development of Munich at various levels, posing several intertwined challenges to the different stakeholders.

2 LANDSCAPES IN FLUX

Munich is situated in the Alpine foreland of Bavaria, in southern Germany. The subsurface is composed of Neocene and Quaternary formations made up of loose alluvial, fine- to coarse-grained sediments. Today's landscape is known as the Munich gravel plain, which comprises sander terraces formed during the Pleistocene glacial periods, as well as the modern floodplain of the Isar river (Bauer et al., 2006).

Extensive grassy heathlands and deciduous oak woodlands have formed over time, but today intensive agricultural lands and other human settlements have largely replaced them. The Isar river (Figure 3) - whose floodplain represents the most important green corridor of Munich - comes to the surface only in the northern part of the city, where extensive marshlands can be found. Former west-east railway networks also represent valuable urban ecological linear systems for ecological connectivity. Natural protected areas - protected by law - urban parks and public open spaces are directly managed either by the municipality or the Bavarian state (Oppermann and Pauleit, 2005; Pauleit, 2005). Around 11% of the region belongs to the Natura 2000, the largest coordinated network of protected areas in the world, listed under both The Birds (Directive 2009/147/EC of the European Parliament and of the Council of 30 November 2009 on the conservation of wild birds) and the Habitats (Council Directive 92/43/EEC on the Conservation of natural habitats and of wild fauna and flora) directives. A green belt, comprising almost 335 km², surrounding the city of Munich is of great importance for biodiversity, ground water recharge, and recreation, as well as for climate mitigation functions.

Figure 3 – The Isar river (www.muenchen.de)

3 THE GREEN INFRASTRUCTURE APPROACH

Through the adoption of four planning and design principles – multifunctionality, connectivity, green-in-grey integration and social inclusion – Urban Green Infrastructure (UGI) can help to maintain and enhance quality of life in urban areas. Multifunctionality is concerned with the provision of several ecological, socio-cultural, and economic benefits, intertwining different functions of urban green space. Connectivity includes both ecological and social connectivity. Integration recognizes the potential of a more holistic approach by linking green and grey infrastructures, while socially inclusive planning is concerned with equity and environmental justice in planning and design processes. Thus, the green infrastructure approach is based on several main principles to promote social cohesion, biodiversity, climate change mitigation and adaptation, physical and mental health and well-being, and green economy (Andreucci, 2017; Hansen et al., 2016).

Urban Green Infrastructure implementation processes are open to all and incorporate the knowledge and needs of diverse parties, with special emphasis on including affected and vulnerable social groups and disadvantaged people. Consequently, Urban Green Infrastructure is seeking to balance the interests of different stakeholders in order to reach a higher level of accessibility to green space services and benefits.

Complementary to the functional issues of the UGI, there are also aspects to take in consideration, which comprises the urban and architectural quality of the surroundings of the green open spaces and the aesthetics of both.

The aesthetical and three-dimensional qualities of dwellings und open space systems are especially important in the periurban situations, because they are often anonymous, sometimes even degraded, places lacking clear characteristics. The public space represents in those contexts the “medium” able to structure and define the citizens’ mental map, facilitating orientation and identification within the daily and ordinary living spaces.

4 PERSPECTIVE MUNICH - “COMPACT – URBAN – GREEN”

The Perspective Munich “Compact – Urban – Green” urban development concept was established by the city council in 1998 and since then continuously updated. A main principle “City in Balance” has also been launched in 2015, with four strategic guidelines and ten action areas of urban development. “Foresight and cooperative management”, “Open atmosphere and attractive appearance”, “High quality and characteristic urban spaces”, “Caring and committed urban society” - the strategic guidelines - are cross section-oriented, tailoring relevant action plans to future challenges. Thematic guidelines contain specialized objectives on almost all the important urban development issues, such as welfare, mobility, education, health, business, cityscape, and ecology. Together with the strategic guidelines, objectives provide input and define future urban development goals. Strategies are implemented and turned into programmes,

actions and projects, where both risks and opportunities - focussed on individual city districts – are carefully evaluated across disciplines. Projects, actions and programmes are finally articulated following the guidelines (Perspective Munich, 2015).

4.1 MUNICH NORTHERN REGIONS

The regions between the rivers Isar and Amper, differently from southern Munich, which enjoys environmental quality and a recognized role in recreation and touristic activities, deserves specific attention needing to be conceptually re-thought. The on-going hybridizations of functions is generating a vivid debate about ecological and environmental concerns, as well as social bottom-up initiatives towards inclusiveness. The move of the Munich airport from München-Riem to its new location - 35 km north of the city centre - and its forthcoming enlargement represent, in particular, major threats for those fragile and valuable lands, having boosted anthropic growth towards the periurban north-east.

Specifically, in view of its potential for large settlements, Munich northeast becomes a strategic location, mid- to long-term, as an emerging new housing and commercial location. Coupling new building and transport infrastructure construction with landscape protection and with local demand for recreational opportunities represent a crucial concern.

With this respect, Green Infrastructure should be considered the most suitable approach in order to foster new connections among existing fragmented natural and semi-natural areas, and to provide opportunities for inclusive urban and peri-urban landscapes.

Prerequisite for any sustainable urban development is certainly the upgrading of the mobility infrastructure. Inter-connecting the old and new neighbourhoods requires improving both the road network and the public transportation - building the S8 tunnel, extending the U4, and/or the tram – and with this respect the risk of soil sealing is to be taken carefully into account (Perspective Munich, 2015).

In other northern areas, between Kunstareal and Olympiapark, the planned restructuring of the areas around the Olympic park and the Dachauer Straße offers an unusual opportunity to re-organise a large city district. This plan includes the development of the so-called “creative quarter”, a new city neighbourhood in which a new concept of living and working creatively will be implemented. Other programs envisage the reorganisation and the up-grading of the existing neighbourhoods’ openspace and green areas around the Olympic park, as well as the further development of sportive, recreational and cultural opportunities, all extremely appreciated by the population and visitors alike (Perspective Munich, 2015).

Between Milbertshofen and Freimann, the re-qualification and re-use of the former barracks and commercial areas - Bayernkaserne and Funkkaserne - into new city districts are also emerging in Munich’s north. With the extension of the Research and Innovation Centre (FIZ) by BMW, Munich technological pole will be further strengthened. This will require innovative mobility and social policies, effective beyond district limits. Apart from specific education facilities, like the BildungsLokal in Hasenberg, new education and sport services - giving encouragement for requalification and offering attractive opportunities for recreation - would also need to be implemented. Sports are of great importance for integration, as well. Further topics already included in the programming activities are securing the existing and developing new commercial areas, while preserving the landscape, especially the heathlands, in cooperation with the neighbouring municipalities (Perspective Munich, 2015). Effective and innovative governance, consequently, represents a major challenge.

The action area of Allach-Untermenzing, also in the north of Munich, is defined by close interrelation among the issues of housing and commercial areas development, on one side, and the instances of landscape and nature protection, on the other. By re-functioning commercial into housing areas, potential areas for large settlements are emerging. The demographic growth and the change in population mix is already urging new urban open spaces. Major requests include the up-grading of social, technical and traffic infrastructural networks and the requalification of the existing natural elements and systems of the area, their importance with regard to the urban climate mitigation and adaptation, and their functions as important recreation areas. A relevant concern is also the socially critical merging of new and existing settlements and communities. A vital impulse for Allach could also possibly come from the planned new district centre at the Oertelplatz (Perspective Munich, 2015)

5 OPEN SPACE DEVELOPMENT STRATEGY MUNICH 2030

The metropolitan region of Munich offers in general a high quality of life. Besides the urban setting with its cultural values, this is also because of its natural and semi-natural landscapes, offering a variety of recreational destinations (Figure 4). Together with riverine landscapes (Isar, Amper and other rivers), urban parks, castles and other existing green spaces, Munich green belt structures the green network layer of the Open Space Development Strategy Munich 2030 - Freiraum München 2030 (Figure 5).

The focus of the urban landscape and green planning - leveraging on both formal and informal instruments - is above all the quality of life in the dense city of Munich. This translates into well-equipped spaces for leisure and recreation, attractive city landscapes, conscious uses of the natural resources, as well as protective measures to preserve urban biodiversity (Freiraum München 2030, 2015).

The green belt of the outskirts of Munich, in particular, fulfils an important balancing function for the city climate and serves the citizens and visitors of Munich as an important recreation area. These functions are to be maintained and strengthened. Then comes securing the agricultural usefulness (Figure 6) and linking of the green areas (greenways) in cooperation with the neighbouring municipalities. A further challenge exists in improving the styling of the city districts on the outskirts, particularly in the revaluation of urban construction quality and public areas (Perspective Munich, 2015).

The strategy Open Space Development Strategy Munich 2030 presents, in particular, three guiding themes: (i) Open space and "slow down": escaping hecticness and cautious staging of specific characteristics are key issues; (ii) Open space and "densification": re-densification of urban structures implies also revitalization and renewal of open space qualities, (multi-dimensional spaces); (iii) Open space and "transformation": systematic connections of city and nature, water management, urban cooling, landscape recycling, food landscapes and incremental value generation, through the implementation of aesthetic and spatial strategies.

The "park miles" are core elements of the future Munich open space development. Green corridors, that connect existing parks with the open landscape; especially at the city fringe, the park miles have great importance. They reduce also visitor pressure from natural protected areas. Among others, this strategy involves the following measures: connecting people and the environment; activating actions, programs and initiatives; stimulating participation at all level; and cooperating, especially in governance, in order to realize full potential.

Figure 4 – Overlooking Munich landscape (Fritz Auweck, 2016)

Figure 5 – Freiraum München 2030 (City of Munich, 2015)

Figure 6 – Northern periurban Munich (Maria Beatrice Andreucci, 2017)

6 CONCLUDING REMARKS

In Munich dense areas, several issues and sometimes conflicting interests need to be thought in one place together: biodiversity and climate change adaptation, agriculture and recreation, transport and quality, design quality and do-it-yourself. Multiple and overlapping uses as well as temporary one at a time reclaim new strategies and tactics of cooperation amongst different stakeholders.

Munich development in coming years will show a special dynamics in the selected area by way of larger restructuring (commercial to living space) and densification (living and commercial space) activities, accompanied by substantial potentials for improving the quality of urban development. Next to energy-efficient urban redevelopment in existent buildings and new construction this includes the extension of the greenway system and the renewal of existing parks, which will contribute to better interlinking of existing and new settlement structures. There are furthermore potentials for improving the living quality on heavy traffic streets, such as Mittlerer Ring, particularly through nature-based solutions with regard to noise protection. A further goal is the maintenance and promotion of social stability in the districts through the need-based development of the social infrastructure (e.g., day care centres and schools) as well as measures for integration and education. Therefore, as stated by the Department of Urban Planning and Building Regulation of the City of Munich (2015) “the development of interdisciplinary goals and a common planning understanding for those areas as well as the accompanying integrated view and approach are of great importance” for sustainable and inclusive Munich long-term development.

ABSTRACT: The Trama Verde e Azul, blue and green network, or simply TVA, is one of the main territorial structuring dimensions of regional/metropolitan planning adopted for the Belo Horizonte Metropolitan Region - RMBH, Southeast Brazil. Developed as a result of a bottom up participatory planning process and inspired by international as well as local green infrastructure and river restoration programs, the TVA proposal seeks to articulate nature, culture and urbanization, through the combination of a series conservation units, open spaces, community facilities and other environmental and cultural assets, all connected by a water system of rivers, streams and lakes, and focusing on planning strategies for land use control, organic and family agriculture, ecologic tourism and ecosystem service delivery programs, among others. This paper discusses the extent to which these metropolitan planning strategies may lead to social and environment transformation towards justice, focusing on TVA implementation,

highlighting zoning categories, design criteria and other planning and community involvement programs being collectively built through a rich but very contentious combination of statutory instruments and negotiation strategies involving stakeholders, public officials, planners and policy makers.

KEYWORDS: Metropolitan Planning, Green infrastructures, Green-blue network, Belo Horizonte.

1 FOREWORD

The Federal University of Minas Gerais (UFMG) has carried out, for eight years now, an innovative experience of metropolitan planning in Belo Horizonte, Brazil, involving a significant number of faculty members, students and some independent consultants in a bottom-up participatory process that has included public officials and civil society representatives of the 34 municipalities that integrate the metropolitan region. Belo Horizonte Metropolitan Region (RMBH for the corresponding Portuguese acronym), is located in the Brazilian Southeast and is the third largest in population in the country, having 5. 873. 841 inhabitants according to 2016 latest census estimates (Figure 1).

Figure 1 – Belo Horizonte Metropolitan Region in Minas Gerais State and Brazil, UFMG (2017)

This activity started as an extension project in 2009 when the University was invited by the State Government to lead, under consulting basis, the formulation of the Integrated Development Master Plan (PDDI as for its Portuguese acronym) with funds provided by the Metropolitan Development Fund¹ and authorized by the Metropolitan Development Council. Within a period of 18 months, a team of 50 faculty and 80 graduate and undergraduate students in Architecture, Geography, Economics, Social Sciences, Education, Planning, Engineering, and other related fields, developed the PDDI for the RMBH based on collected data, mapping and transdisciplinary thematic studies, but mainly on the results of a series of participatory activities such as workshops, seminars, open meetings and public hearings.

Coming from a very authoritarian, technocratic and comprehensive top-down metropolitan planning tradition, this experience has meant a shift from social reform to mobilization and social learning processes, according to Friedman's theoretical framework (1987) which have been central to bridge gaps between technical knowledge and everyday practices, aiming at the achievement of more accurate understanding of local processes, the strengthening of collective actions and the supporting of policies and

¹ This fund is the result of annual voluntary contributions of the 34 municipal members plus an equal total amount provided by the State of Minas Gerais. The Metropolitan Development Council, comprised by seven municipal representatives, five from the state executive sector, two from civil society and two from the state legislative power, is the organism that decides on priorities and the use of this funding. A complete view of RMBH's metropolitan governance structure (Arranjo Metropolitano) can be obtained in www.rmbh.org.br or and authorized by the Metropolitan Development Council. Within a period of 18 months, a team of 50 faculty and 80 graduate and undergraduate students in Architecture, Geography, Economics, Social Sciences, Education, Planning, Engineering, and other related fields, developed the PDDI for the RMBH based on www.agenciarmbh.mg.gov.br

programs that are oriented to social engagement and transformation other than to the reinforcement of status quo, hegemonic priorities and socio-spatial exclusion.

PDDI was officially launched in 2011 and starting in October 2013, the Metropolitan Macro-Zoning ordinance (MZ as for its acronym in Portuguese) was also developed under similar methodological arrangements, involving around 90 UFMG faculty and students. The MZ is considered one of the main strategies to implement the spatial restructuring of the metropolitan territory proposed by PDDI, along with infrastructure and housing investments. Currently, the same team is working on reviewing and updating eleven of the 34 RMBH's Municipal Master Plans (PDM as for the acronym in Portuguese) to match PDDI's guidelines and MZ criteria.

The participatory process for the Metropolitan Plan lasted almost two years, and accounted for around 3000 participations and 610 institutions and civil society organizations. The following Macro-Zoning development lasted 15 months and accounted for 1120 participations. Both processes involved a series of activities, which were initially geographically and thematically organized, and were progressively disciplinarily integrated both at the local and regional scales. Theatre sketches on metropolitan issues, collective mapping, a project newsletter and an internet site with permanent on-line access to all work-in-process information were some of the innovative strategies used to mobilize and involve local residents and stakeholders.

This paper discusses the planning strategies developed by the Metropolitan Macro-Zoning Project aimed to materialize the proposed PDDI spatial structure guidelines on the regions' territory. It focuses on the implementation of the Blue and Green Network (Trama Verde e Azul in Portuguese or simply TVA as for its acronym) and describes the zoning categories, the design criteria and other planning and community involvement programs that were collectively built through a rich but also very contentious combination of statutory instruments and negotiation strategies involving stakeholders, public officials, planners and policy makers within a common participatory platform meant to articulate different scales as well as metropolitan interests and local needs.

Figure 2 – MZ participatory process scheme and activities, UFMG (2013)

2 RESHAPING THE METROPOLITAN SPATIAL STRUCTURE: CENTRALITIES, MOBILITY NETWORK, METROPOLITAN INTEREST ZONES AND THE BLUE AND GREEN NETWORK - TVA

TVA was initially conceived as a background element of RMBH spatial restructuring scheme proposed by PDDI which also included a main roads and transportation system, a hierarchical network of urban centralities and specific zones and areas of special metropolitan interests, assigned for environmental and cultural heritage protection, water supply resources, food production, improved mobility and economic

development. This proposed new spatial structure has been basically meant to face historical social, economic, and environmental problems caused by the existing one-centred radial spatial structure, too much concentrated in Belo Horizonte and surrounded by extended unequipped peripheries: a spatial translation of an unbalanced and unfair distribution between costs and benefits of urban development (Figure 3). During the MZ development process, the TVA idea gained momentum from both technical and public support, becoming one of the main guidelines for the metropolitan spatial structure implementation strategy.

Figure 3 – PDDI spatial restructuring scheme for RMBH, UFMG (2011)

Aiming at an alternative planning strategy for the Region, Metropolitan Interest Zones (ZIM as for the acronym in Portuguese) were collectively designed throughout the Macro-Zoning project process, having their boundaries and contents justified by public functions of common interests oriented by the following main PDDI's guidelines: (1) develop existing and new urban centralities, (2) enhance economic development axis, (3) increase density in selected areas for housing and mixed uses and control urban sprawl, reducing pressure over environmentally sensitive areas and food production regions, (4) protect water supply resources and conservation areas; (5) favour the provision of affordable and social housing, open spaces and community facilities in the centralities, (6) avoid the aggravation of social spatial segregation and (7) develop strategies for the implementation the blue and green network, TVA.

This way, under an integrated participatory planning approach, involving local stake holders in the decision making process, three very strong taboos in Brazilian planning tradition have been somehow broken. The first refers to the historical split between urban development and environmental protection, seen as two incompatible motivations that usually result in conflicting regulations and policies coming from different rationalities as already highlighted in Costa (2008). The second has to do with the use of zoning ordinances limited to urban areas, leaving the rural ones unregulated, even though Federal Law 10.257/2001, also known as The City Statute, has established the obligation for Master Plans to cover the entire municipal territory¹

The third has to do with what Fernandes (2005) among other authors call municipal autonomy at all costs that result in the lack of continuity and conflicting rules within similar environmental constraints or urban dynamics throughout different municipal boundaries, especially in metropolitan areas submitted to conurbation.

The ZIMs were subdivided into three different types according to their main characteristics and planning objectives: (1) socioeconomic development zones related to centralities and main highways and transportation axis, (2) water management zones, corresponding to water catchment areas for metropolitan supply purposes and (3) landscape protection sites and mining territories. On top of theses ZIMs, another zoning layer called Special Metropolitan Guideline Zones (ZDEM as for the acronym in Portuguese) has been proposed to address specific issues under specific policies such as central city requalification, slum upgrading, illegal settlement regularization, infrastructure upgrading, mining area rehabilitation and TVA implementation. Besides, Areas of Metropolitan Interests (AIM as for the Portuguese acronym) have also been identified throughout the whole remaining territory outside the ZIMs as privileged places for the implementation of PDDI programs, designed to encourage, for example, organic and family agriculture, ecologic tourism and payment for eco systemic service delivery (Figure 4).

¹ A research project sponsored by Ministério das Cidades, the Brazilian Federal Authority for urban development planning and policies, in 2011 evaluated, from a critical perspective, the series of recent Municipal Master Plans developed after Federal Law 10257/2001, Brazilian main reference for urban planning also known as The City Statute.

Figure 4. Zones and Areas of Metropolitan Interest, UFMG (2015)

Each ZIM has been internally divided into sub zones with respect to specific urban and environmental dynamics, resulting in different requirements for density limits, minimum lot sizes, minimum pervious surface area, height and bulk ratios and other subdivision, land use and design criteria (Figure 5).

Specifically about the control of maximum building limits per lot surface area, another vicious aspect of Brazilian zoning tradition has been broken: the mistaken merging of two originally separated rights over urban land, which are property rights and building rights, being the second the result of a discretionary act by local government according to common public interests, environmental and infrastructure carrying capacity, among other planning requirements, as a materialization of the social function of urban property as established by the 1988 Brazilian Federal Constitution¹

Figure 5. RMBH Macro-zoning sub-zones, UFMG (2016).

This way, according to the MZ final negotiated proposal, the general building potential for all zones was assigned as 1.0 (equal to the plot surface area) being any variation above this value subjected to planning conditions and/or payment of development rights, up to a maximum amount established for each zone. A

¹ The concept of social function of urban property, conceived as a submission of private property rights to common interests and community priorities, has been regulated by The City Statute in 2001, which assigned Municipal Master Plans to locally determine where and how within the municipal territory it shall be materialized.

similar reasoning was agreed to support for the percentage of social housing and provision of public spaces required for new development projects which, according to their characteristics, are also supposed to be submitted to environmental impact analysis and planning permits through an integrated metropolitan process.

The MZ experience has showed us that, even though the use of more sophisticated and complex instruments in planning regulation and management has been a prevailing trend to face old and new urban environmental issues, bringing social practices and regulation closer to each other seem to be a much more promising way to achieve more effective planning instruments. Avoiding marked oriented zoning ordinances which have traditionally aggravated social spatial segregation in Brazilian urban areas is a way, as Rolnik (1999) points out, of putting down invisible walls between formal and informal ways of accessing urban land, housing and a healthy environment for all.

3 TVA: AN INSPIRING CONCEPT

Over the course of planning history, many utopian models have included green spatial structures as key elements to organize urban spaces. Understanding their evolution has not only helped us realize how society's relationship with the environment has changed but it also has also inspired the search for new strategies for articulating nature, culture and urban development, as in the present TVA case study.

The origins of planned urban green facilities date back from the 18th and 19th centuries when public parks and gardens were created in reaction to the poor environmental conditions in industrial revolution cities both for recreation and aesthetic purposes (TUNER, 1998). Ebenezer Howard's garden city concept is at the base of English New Towns by Parker and Unwin, where a chain of green open spaces, parks and protected farm land formed the so called green belts involving urban areas, also as an attempt to control growth. The proposal of connecting urban parks developed by Olmstead and Vaux launched the idea of corridors integrating open spaces for natural resource protection, social use and circulation, as well as for landscape structuring, being the Boston Emerald Necklace (1895) an emblematic example.

This idea of a system of green areas and public open spaces connected by linear elements such as vegetated roads and water ways has progressively evolved to what became the green structure model from the late 20th

Green web is also a late 20 century, conceived as a strategy for territorial land use planning and environmental management (FABOS and RYAN, 2004). This approach is based on three main components: natural corridors and ecologically significant systems, parks and green axis connecting recreation areas on land or water, cultural and historic heritage assets.

th century concept that proposes the integration of open spaces by vegetated roads and infrastructure buffer zones, bikeways, bridges, waterways, parks, coast lines and all kinds of green corridors. They merge ecological and social functions, providing new green use possibilities and connecting the existing ones to enhance biodiversity and community life. The notion of green infrastructure also refers to these systems but is more commonly applied to small scale interventions such as urban green road and sidewalk side spaces, river restoration banks, flood control devices such as detention reservoirs, bio ditches and infiltration pits¹

According to Quintas (2014) the term Urban Green Structure has first been nationally used in Portuguese planning in a central government document published in 1992 by DGOT, which is the General Authority for Territorial Management, and then, in the Lisbon Green Plan, developed in the 1993 and published in 1997. Aimed primarily at supporting the review of the Municipal Master Plan – PDM (as for the acronym in Portuguese), this plan proposed a system of open spaces, green areas and surface water bodies, encompassing both urban and rural areas, involved by a system of natural occurrences related to the

¹ For more elements on the evolution of the concept of green infrastructure, see also Thomas (2010) and Quintas (2014).

concept of *continuum naturalis* defined by Cabral (1980) and later expressed by the 1987 National Environmental Law¹.

It resulted in a sequence of continuous and discontinuous portions of the territory recognized by their own identity given the cultural and landscape values of both urban and natural environments (TELLES, 1993). Although the “web” concept, formed by vegetated surfaces (the green dimension) interwoven by water lines and bodies (the blue dimension), is not explicit in this plan, streams and run off related morphological elements (water headboards and splitters, slopes and flood plains) are the key elements of the proposed structure merged to a cultural dimension that encompassed landscape unities and urban ensembles recognized by their *genius loci*² and areas identified as suitable for urban growth and rural activities.

Although this plan was not at that time entirely incorporated in the 1994 PDM, its main elements were present in the 2007 PDM which has been reviewed in 2012, as well as in the Lisbon Metropolitan Region Territorial Management Plan adopted in 2001 and also reviewed in 2012. It showed a deliberate attempt to articulate territorial scales (metropolitan, municipal and neighbourhood) as well as planning and project strategies to implement the proposed green structure, including design criteria and guidelines for specific site interventions. and areas identified as suitable for urban growth and rural activities.

Belo Horizonte’s TVA also relates to this systemic notion of a spatial structure based on a hierarchized network of connections among green areas and water bodies, urban as well as rural, more or less anthropized, protected or still to be valued and recognized. However, there is much more to it than just ecological and functional purposes. It departs from the notion of nature as part of the process of production and appropriation of urban space and as one of the main territorial axis of PDDI’s metropolitan spatial restructuring proposal, and it derives from the effort to “articulate adequate conditions of attraction and reproduction of the hegemonic productive capital – mining, property development, advanced services – with actions that reinforce, protect, and give visibility to small scale collaborative local and micro-regional activities – agriculture, crafts, services, among others (MONTE-MÓR et al, 2017).

Two other relevant planning experiences are also important to mention here as inspiring references to TVA. The first is the DRENURBS project, which has been carried out in Belo Horizonte municipality for 15 years now. It focuses on urban creek recovery through integrated interventions that include removing informal settlements from flood prone areas, housing the removed population in social housing projects as close as possible, providing sewer, drainage, solid waste disposal and mobility solutions taking the whole watershed into consideration and improving recreation opportunity and environmental management by the implementation of urban parks, erosion and sediment control devices and green corridors. In spite of its limited reach (only five of the eighteen priority catchment basins have been so far retrofitted) and recent reduction of its political support and financing capacity, it had a great impact as demonstration of alternative and more comprehensive sanitation solutions as compared to the traditional rectification and channelling of stream beds³.

The second inspiration for TVA is the French concept of *trame verte et bleue* which stands for green and blue infrastructure, a network of land and water ecological continuities identified by regional ecological studies and planning documents produced by the French government, local authorities and groups of authorities and applying to the whole country territory. It includes ecological continuities, core areas of biodiversity, ecological corridors, watercourses and wetlands and contributes to improving the conservation status of natural habitats and species and achieving good environmental status for water bodies (<http://www.trameverteetbleue.fr/>). These principles have been increasingly adopted in European regional environmental development and recovery plans, particularly in places experiencing severe degradation such as former decaying mining areas (MONTE-MÓR et al, 2017).

¹ National Law 11/87, later modified by National Law 13/2002, or “Lei de Bases do Ambiente”, is the main reference in Portugal for environmental protection in planning practice.

² It refers to a phenomenological approach to the environment and the interaction between place and identity as proposed by Schultz (1981).

³ Belo Horizonte’s 2011 Urban Drainage Plan has analyzed the 98 municipal watersheds and indicated the priorities for intervention in 16 of them, based on sanitary conditions, population and flood hazard vulnerability. For more information on the Drenurbs Program, its outcomes and recent pitfalls see Costa et al, 2012 and Araújo and Pinheiro, 2015.

Searching to move forward, Belo Horizonte Metropolitan Region TVA was conceived to be gradually formed by the interweaving of many complementary existing and proposed elements which can be gathered by their common nature as the following: (i) green infrastructure such as parks and other conservation areas, remaining forests and agricultural land, natural monuments, geological heritage sites, ecological corridors and other potential green areas to be protected; (ii) blue infrastructure of surface water bodies and underground water reserves, flood plains, wetlands and other relevant water resources, including the existing metropolitan water supply watersheds; (iii) cultural and natural heritage assets such as museums, cultural facilities, historical and cultural ensembles, libraries, places related to non material heritage practices (iv) places related to ecological tourism and cultural policies; (v) areas of urban ecological agriculture and small scale processing of food and crafts, among several other communal uses of the metropolitan territory; (vi) alternative networks of mobility such as bicycle and walking tracks, small roads, train corridors, pedestrian oriented roads systems, among other forms of connections.

The proposal, still to be further developed, embraces a set of principles and a general physical structure to be detailed, adapted and adopted by public as well as private social agents that produce and use the metropolitan space, establishing an increasing network of natural and built environmental collective values that articulate nature, culture and urban development (Figure 6).

As highlighted by Monte-Mór et. al. (2017), the TVA

“broadens the meanings of the proposed territorial restructuring associating the production of abstract space with the appropriation of social spaces at metropolitan level. As such, the political and institutional articulations to make it happen are still to be invented, but will certainly influence metropolitan and local policies. It constitutes a utopia of the future, bringing nature and culture as central to the process of production of space, recognized as a source of learning, to be appropriated and transformed by society through everyday life”.

Figure 6. The TVA general scheme and elements, UFMG (2015).

4 EXPLORING IMPLEMENTATION STRATEGIES

As a view and a planning framework, a structural guidance for a future ideal scenario to be constantly searched but never necessarily completed, TVA is considered a long-term project, which requires different levels of participation and engagement, collaboration and governance. It should also count on regulatory command-and-control types of instruments as well as induced and voluntary initiatives, coming both from the public and private sectors, as well as from civil society. As far as the necessary financing, investments should come from Federal, State and Municipal government levels, but also from the private sector, civil society institutions and public-private partnership to ensure the required funds, to implement the proposed

green structure and promote a diversity of associated economic activities and, at the same time, to create opportunities for work and income generation.

The following are some implementation strategies that are already available or possible to be developed within the Brazilian regulatory framework and planning tradition (Figure 7). Many of them have been incorporated to the legislative project that is currently being discussed and negotiated to become the Macro-Zoning State Law to which all Municipal Master Plans to the 34 metropolitan members will have to conform.

- i. Statutory requirements related to specific planning regulations and permits for new subdivisions and development projects such as compulsory provision of open public space, buffer zones, green areas and public facilities;
- ii. Mitigation and compensation measures originated from environmental permit processes of new development projects and activities subjected to Environmental Impact Analysis: creation of conservation areas, maintenance of green spaces, adoption of environmental control devices such as green rooftops, rain water capture and reuse, infiltration pits and run off detention reservoirs;
- iii. Metropolitan and municipal zoning design criteria: TVA is part of all Metropolitan Interest Zones – ZIMs which have specific parametric requirements, some specifically designed to allow for parcel based incremental green infrastructure implementation: green setbacks, minimum impervious ratio and minimum tree coverage ratio are some of them;
- iv. PDDI policies and programs, especially those designed to Metropolitan Interests Zones - ZIMs and Metropolitan Interest Areas - AIMs conceived to promote small scale and family based agriculture production, agro ecologic agricultural practices, urban agriculture, food security, eco systemic service delivery payment and ecologic tourism activities;
- v. Degraded mining area recovery complying to environmental legal requirements and having a social use as public facilities, parks and recreation areas, whenever possible;
- vi. Cultural and landscape heritage protection, including environmental features as part of buffer zones and surroundings to the core listed assets;
- vii. Public-private partnerships, guaranteed the public use of open spaces resulting from planning gains negotiated as part of each development project;
- viii. Adoption of TVA concepts at different planning scales, such as the municipal level, water basin committee level, among other planning instruments and governance frameworks.

Figure 7: Examples of implementation strategies for TVA, UFMG (2016).

Besides the formal regulatory schemes and planning instruments already mentioned, which are fundamental to the continuous process of construction of the TVA, other strategies shall be added and experimented, as suggested by Cabral (2015), arisen from the articulation of the proposed structure (a political planning view) to the opportunities for action (through social mobilization, policies, plans and projects) provided by metropolitan governance within a permanent and systemic institutional design for collaborative planning.

5 FINAL REMARKS

This paper meant to discuss the extent to which metropolitan planning strategies may lead to social and environmental transformation towards justice, focusing on TVA implementation, through a rich but very contentious combination of statutory instruments and negotiation strategies involving stakeholders, public officials, planners and policy makers.

As part of a long term extension project led by the Federal University of Minas Gerais, short term political interests within four-year governmental office periods could be reduced in favour of more community involvement and a collectively built structural view for RMBH, emphasising process rather than product as a result of a metropolitan planning experience.

While the PDDI centralities network and the Macro-Zoning criteria attempt to combine land use planning with reduction of socio spatial disparities, the TVA web emphasizes a different but complementary logic that seeks to articulate nature, culture and urbanization. The discussion involved seems an important way of developing a broader comprehension of metropolitan citizenship, a concept widely applied during the participatory process, as a sense of place, a feeling of belonging to a large articulated territory, in which nature and urbanization can be conceived and experienced together. The virtual horizon orienting this planning conceptions is one in which the metropolitan area could be restructured through both TVA elements combining nature and urbanization as lived spaces, and the proposal of reinforcing a network of centralities articulated by a multimodal mobility network. The two seek to put together principles of social and economic equity, urbanity and environmental and cultural justice.

Of course such proposal represents a contra hegemonic project in a highly contested terrain, related to real estate market and land property, mining and industrial capital interest, among others which see nature – mainly land and water - primarily as an economic asset to be explored. But it is interesting to notice that during the participatory workshops where the TVA was discussed, there was widespread acceptance, even a sort of enchantment with the idea, by the participants. Although it may sound naïve, it is important to emphasize that it is only through social engagement, recognition of conflicts and mutual learning between faculty, professionals and the population that such ideas can be made possible.

ID 1509 | UTILIZING SPATIAL AND LANDSCAPE PLANNING TO PROMOTE ECOLOGICAL CONSERVATION ON UNIVERSITY CAMPUSES

Daniel Orenstein¹; David Troupin²; Ella Segal¹; Gili Hakima-Koniak¹; Jennifer Holzer¹

¹Technion - Israel Institute of Technology; ²Haifa University

danielO@ar.technion.ac.il ; davidtroupin@gmail.com ; israel.pistaciella@gmail.com ; israel.koniak@gmail.com ; israel.holzer.jen@gmail.com

ABSTRACT: Universities globally have committed themselves to behaving as responsible citizens in addressing global ecological challenges through physical planning and management of their campuses. At the Technion – Israel Institute of Technology, a comprehensive, two-year planning effort was made to revise the vision and physical plans of the main university campus in Haifa to meet emerging 21st century challenges facing the academic community. Defining and addressing ecological challenges was integral to this effort and an ecological advisory team worked closely with campus planners to envision an ecologically sustainable campus. This paper reflects upon this process, from its first stages of problem definition and goal setting, through a multifaceted ecological survey and the integration of architectural and urban planning students into the planning process, to production of the final statutory zoning plan and strategic master plan. The study highlights the particular challenges of a campus that sits on the interface between urban and natural ecosystems and one that demands rapid development with a concurrent desire to preserve ecological integrity. Conclusions highlight the universality of the ecological responsibilities and challenges that universities face, suggest general strategies for exploiting the planning process towards ecological sustainability goals, and advocate for the integration of students into campus design activities.

1. INTRODUCTION

The role of the university, as often defined in terms of its responsibilities towards larger society, is to prepare students to be socially responsible global citizens (Harkavy, 2006), to produce knowledge for addressing global social, economic and ecological (i.e. sustainability) challenges (Alshuwaihat and

Abubakar, 2008; Finlay and Massey, 2012), and to act as a socially-responsible institution (Alshuwaikhat and Abubakar, 2008; Viebahn, 2002). As teaching and research institutions, the knowledge produced within university campuses should be applied for the benefit of humankind. As such, since the 1990s, universities have looked inward to their own campuses in order to reshape them as exemplary models for sustainability, particularly within the environmental realm (Alshuwaikhat and Abubakar, 2008; Finlay and Massey, 2012). Among the many sustainability criteria are the institution's commitment towards distinctly ecological priorities of preserving biodiversity and ecosystem integrity. However, the relative emphasis of ecological priorities varies greatly from being a central facet of university objectives to, more often, a relatively minor element.

Even among environmental considerations, ecological priorities are relatively minor. The Association for the Advancement of Sustainability in Higher Education's Sustainability Tracking, Assessment & Rating System (STARS) awards an institution's efforts conserving endangered species or environmentally sensitive areas, or general environmentally sustainable grounds management (Association for the Advancement of Sustainability in Higher Education, 2014). But while these ecological considerations are explicit in the STARS criteria, they are only a few of over 60 criteria that include all aspects of sustainability, from educational curriculum and research, to campus and community engagement, to university operations, and planning and administration (AASHE2014). As such, the university sustainability literature that focuses on biodiversity is only a small part of the overall oeuvre. In comparison, much of the literature focuses on ecosystem flows, including carbon and water cycles as expressed in energy use, architecture, and transportation. Representative of this phenomenon is the University of Massachusetts, Amherst, which dedicated a revision of its master plan to sustainability issues, which dealt almost exclusively with energy use and greenhouse gas emissions. Biodiversity, when mentioned, is in reference to the role of vegetation in carbon sequestration. The program includes additional foci including food and waste management and a management focus on runoff water including creation of wetlands and ponds for multiple benefits, including biodiversity (Pavlova-Gillham et al., 2015).

The current research deals exclusively with the ecological aspects of campus design. Ecological, in this sense, focuses on biota and ecosystem processes on campus, and in particular, the protection of biodiversity, the long-term provision of ecosystem services and positive intervention in ecosystem processes (e.g. ecological integrity). There are three reasons why universities should be particularly concerned with ecological challenges. The first, as noted above, is their stated commitment to good citizenship and global and regional sustainability. The second is the plethora of scientific knowledge and a fitting venue for its application, making it efficient for university faculty to "act locally". Finally, university campuses occupy a significant amount of land in multiple ecosystem types, and therefore their physical planning can have a profound impact on ecological characteristics of their region. For example, the University of Michigan has historically occupied between 8 and 10% of the total land area of Ann Arbor, Michigan (Brinkman, 1981).

University campuses vary widely with regard to their physical locations vis-à-vis cities, with some being distinctly urban with few open spaces, while others are located along a gradient between the built and the non-built environment, encompassing natural and semi-natural ecosystems (e.g. Cornell University, 2008). The sheer spatial size of campuses and their population leads some planners (e.g. Sasaki, 2009) to compare them to, and plan them as, small cities. Additionally, many universities possess satellite properties that serve as nature reserves, botanical gardens, and biological field stations. These satellite properties, while crucial for fulfilling the universities' ecological goals and responsibilities, do not face the same planning dilemmas as the central campuses with their multiple, often competing, development goals. The present work addresses the main core campus of universities, where most of the research, education and administration takes place.

This paper documents efforts to integrate ecological considerations into an urban university campus, the Technion – Israel Institute of Technology. We describe a two-year process in which an ecological advisory team worked in parallel to a larger multi-disciplinary planning process of the university's physical environment. As noted, the paper addresses a somewhat neglected consideration – ecology, in terms of biodiversity and ecosystem integrity, which is generally subsumed within the larger university sustainability literature. We suggest that the process of physical planning affords a novel and productive opportunity to integrate ecological considerations into the priorities and objectives of the university, although the process also reveals the challenges in prioritizing ecological considerations.

2. ECOLOGY AND THE TECHNION PLANNING PROCESS

The Technion – Israel Institute of Technology was founded in 1924 and the Faculty for Architecture (later Architecture and Town Planning) was among its first departments. The university campus was located in the Hadar neighborhood of Haifa, and was moved in 1954 to a 130-hectare piece of land on a steep hillside adjacent to Haifa's Neve Sha'anani neighborhood. According to aerial photographs, the land on which the Technion was built consisted primarily of heavily grazed, Mediterranean chaparral – shrubs and annual plants – that was later forested with Stone pines and Aleppo pines (*Pinus pinea* and *Pinus halepensis*, respectively), which were popular forestry trees through most of Israel's history (Fig. 1 and 2; Tal, 2013). The topography of the campus influenced the architectural designs. Three wadis (dry riverbeds that run only following winter rains) run through the campus from south to north, two of which are on the borders of the campus and one running through the center. Early plans of the campus envisioned the central wadi as a green stripe and pedestrian pathway through the campus, and building was avoided in this area (Fig. 3). Between 1965 and 2012, four additional campus master plans were utilized. The most recent plan allowed for 50 hectares of built space. Today, the southern (upslope) portion of the campus consists of a planted pine woods, while a 2 hectare plot in the northern area of the campus is designated, since 1982, as an ecological garden.

In 2012, the institution commissioned a new master plan, and turned to its Building and Maintenance Division and to the Faculty of Architecture and Town Planning to complete the task. The new planning committee was headed by architects, landscape architects, and planners, and was supplemented with a wide range of subject-area advisors, including faculty experts in transportation, ecology, environmental psychology, education and others. Technion graduate students were also integrated into the planning staff as both advisors and research assistants. The committee had three objectives: a strategic master plan for creating the vision of the Technion, a statutory, zoning land-use plan, and a plan for real-time project interventions (Assif et al., 2015).

The strategic master plan is a vision statement that aims to “enhance [the campus’] unique spatial characteristics as a home base for its faculty, staff, students and visitors, and to lead the campus towards better integration in its urban and natural contexts” (Assif et al., 2015; p.13). It requires (and received) the approval of the institution's Board of Governors. The zoning code is a statutory document that requires approval by city and regional planning committees and that designates permitted land uses within the Technion. The intervention and involvement plan “takes immediate action to reflect and fulfill components of the strategic plan in real time (Assif et al., 2015; p.13).

In recognition of the planning committee's emphasis on ecological sustainability (which was, as yet, only vaguely defined), the committee provided support and resources to support a multi-phase ecological assessment of the campus in order to receive ecologically-sound recommendations.

3. THE ECOLOGICAL ASSESSMENT OF THE TECHNION CAMPUS

The ecological assessment team divided its work into four parts: 1) review of ecological planning on university campuses (grey literature review of university planning documents) and defining the “ecological campus” concept based on ecological principles, and examples and precedents from other universities; 2) assessment of the biodiversity and ecosystem services found in the Technion campus, and assessment of the potential for their conservation and improvement; 3) review of administrative structures for supporting ecological planning, and 4) development of an ecological vision for the Technion campus, including guidelines and recommendations on how to integrate this vision into the masterplan and actual development of the campus.

3.1 REVIEW OF ECOLOGICAL PLANNING ON UNIVERSITY CAMPUSES: COMPACT, CONNECTED, CONSERVED

There was little available in the English-language academic literature with regard to particular ecological guidelines in campus planning and development¹. There is, however, abundant material within the grey literature, including reports and planning documents from university campuses that have emphasized the importance of ecological conservation and provide guidelines for campus planning and management. Therefore, we relied mainly on grey literature (reports and planning documents from university campuses) and websites that were dedicated to these issues. Our objective was to glean the main ecological principles that have been integrated into such plans and gain a clear view of the "state of the art". Our starting point was several reviews and ranking of universities published in online news websites². We expanded the information obtained from these sources through an internet search for several relevant keyword combinations (campus* + ecolog* + plan* + university*). The master plans of some universities were readily available, while other institutions had websites presenting plan essentials and related activities.

Our review of university precedents for ecological planning revealed three main principles that were common in many universities as reflected in their planning documents: (1) compact development (Fig. 4) – concentrating development in existing core areas; giving precedence to renovation of existing structures; prioritizing development in areas with existing infrastructure; (2) connectivity of open spaces and natural habitats (Fig. 5) – this often includes a classification or hierarchical division of the campus into units based on multiple criteria such as land cover, hydrology, topography, and land use; and (3) conservation of high quality and key natural habitats (Fig. 6) – this can include conservation of large areas as preserves or reserves, undertaking ecological reclamation and restoration projects, and taking steps to improve the ecological value of habitats, also in the developed areas (e.g., vegetation soil and water restoration, prioritizing native species in gardening and landscaping, monitoring and treating invasive species, avoiding the use of pesticides and herbicides. These three themes are exemplified in the University of Wisconsin (UW), Eau Claire Master Plan whose vision headings are “connected and engaged,” “green and open,” and “compact and integrated” (Campus Master Planning Team, 2011). It is important to note that in most cases, including UW Eau Claire, that while these three themes are consistent with ecological objectives, ecology is not the primary focus of the themes, but rather they are associated to social, transportation and educational goals (see below).

3.1.1 COMPACT

Due to the severe impact of urban development on biodiversity (Hansen et al., 2005; McKinney, 2002), compact urban development is recommended across the planning and ecology literature in order to slow the impact of urban development and conserve open spaces for their ecological value. Compact and high-density development is recommended in many campus master plans as serving multiple economic, social and environmental goals. The most common of these is creation of walkable and public-transit oriented campus centers, but also include efficient use of infrastructures, catalyzing social and scholarly interactions, defining a clear campus boundary and identity, and preservation of open spaces elsewhere in the campus (Campus Master Planning Team, 2011; Cornell University, 2008; Sasaki, 2009; University of Idaho, 2000). Most of these campus plans refer to a compact academic center, while the built environment (research parks, athletic complexes, residential areas) extend beyond this center, suggesting that ecological considerations are not the primary driver of compact development.

3.1.2 CONNECTED

Connectivity between habitats is a predominant theme of the conservation ecology and planning literature (Pulliam and Johnson, 2002; Zipperer et al., 2000). Networks of open spaces are discussed in some university planning documents in terms of ecologically connectivity (Sasaki, 2009). But more often they are promoted for sense of place, integrative design with the built environment, aesthetics, providing coherence

¹ Curiously, the largest proportion of this small literature comes from Chinese case studies. These sources have English-language abstracts, but are rarely available in English-language journals.

² <http://grist.org/article/2009-08-20-top-20-green-colleges/full>; <http://collegestats.org/2009/10/the-nations-greenest-universities-top-10-eco-friendly-colleges>; <http://www.princetonreview.com/green-guide.aspx>

and green connectivity between the built environment, and their role as a social and recreational venue in the natural environment (Brook McIlroy Planning & Urban Design, 2003; Campus Master Planning Team, 2011; Carol R Johnson Associates Inc, 2012; Cornell University, 2008; Sasaki, 2009; The University of Warwick, 2007; UMass Amherst Campus Planning Division, 2012; University of Idaho, 2000). These plans often note the ecological relevance of open space connectivity for ecological reasons, though they give far less attention to the ecology per se than to the other justifications.

Another aspect of ecological connectivity concerns the connection of a campus to prominent features of the natural environment, including rivers and other water bodies, university ecological reserves (see below) and natural landscapes. The Master Plan for the University of Wisconsin, Eau Claire, for example aims to use campus planning to better integrate and connect the campus to The Chippewa River and Little Niagara Creek (Campus Master Planning Team, 2011).

3.1.3 CONSERVED

The third guideline, conservation of open spaces of high ecological value, is touted for multiple reasons, including, but not limited to, the goal of preserving biodiversity and important habitats. The preservation and expansion of green infrastructures is a very prominent theme among campus planning documents (e.g. Campus Master Planning Team, 2011; Sasaki, 2009; University of Idaho, 2000), although here, too, the emphasis is on human uses of green spaces and then only sometimes (and briefly) in connection to biodiversity or habitat conservation. Prominent reasons for preserving and expanding green spaces on campuses include providing recreational spaces for the campus community, emphasizing connectivity between built spaces, strengthening the connection between the campus and local communities and enhancing the cultural relevance of the institution (Sasaki, 2009; Skidmore Owings & Merrill LLP, 2008). Water bodies, including wetlands, riparian areas and waterfronts, sometimes receive mention for their biodiversity value and potential for restoration (e.g. The University of Warwick, 2007). In addition to physical planning, campus master plans emphasize the importance of landscape planning and its role in obtaining ecological objectives. Tree plantings are a commonplace recommendation. Some campus master plans are accompanied by a landscape vision and detailed operational instructions, such as that of University of Tennessee, Knoxville (a urban campus), which promotes the use of native plants for purposes of biodiversity enhancement and ecological health (Carol R Johnson Associates Inc, 2012). Native plants are also suggested for water conservation (e.g. University of Utah).

3.2 BIODIVERSITY AND ECOSYSTEM SERVICES SURVEY OF THE TECHNION CAMPUS

We conducted two biodiversity surveys in the Technion campus, one for the fall season (August-September 2014) and one for the spring season (March-May 2015). Each survey assessed the species richness of five taxonomic groups in randomly selected locations throughout the Technion campus. In order to select the sites for the survey we superimposed the map of the Technion with a 30 x 30 meter grid and selected randomly 31 cells. These cells represented the range of land cover types found in the Technion – including entirely undeveloped areas (no structures or paved surfaces) onto areas with partial to nearly complete artificial cover (90-100% structures, paved roads etc.). In both seasons the surveyors visited and surveyed the same sites. The five groups were: medium-sized and large mammals (using trap cameras), bat (using bat detectors), plants, butterflies and birds (the latter three through direct observation).

The main findings of these surveys were that the Technion Woods, a forested plot in the southern, up-slope campus is unique in comparison to the rest of the campus, including species not found elsewhere in the campus such as wild boars (*Sus scrofa*), golden jackals (*Canis aureus*), rock hyrax (*Procavia capensis*), chukar partridge (*Alectoris chukar*), and a red-listed (endangered) plant species Myrtle (*Myrtus communis*). We concluded that the presence of these species only in this area is a result of its being a part of a large tract of natural and semi-natural areas found to the south of the Technion that lay on the fringes of Haifa's developed area (i.e., the rural-urban interface). Overall, the species richness found in the Technion was representative of urban areas and similar to that found in a biodiversity survey conducted in Haifa in 2012.

An ecosystem service assessment of the Technion campus was conducted in 2014-2015. The assessment consisted of the three steps: (1) A team of expert assessors conducted preliminary fieldwork to determine the presence and quantity of the various ES in the built and forested areas of campus. The team adopted the ES outlined by the Israel National Ecosystem Assessment (INEA) for reference; (2) 27 interviews with representatives of the various campus stakeholder groups (e.g. faculty, students, administrators, visitors) aimed at defining “high priority” ES, and; (3) a matrix of high priority ES was developed and analyzed in terms of value and connection to underlying ecosystem processes. The team analyzed the provision of high priority ES as affected by different campus development plans relative to the current state.

High priority ES, as defined in the stakeholder interviews were primarily cultural services. Among them, relaxation was the most commonly noted, with “existence value and biodiversity” receiving the second most attention. An additional unique benefit that emerged in the interviews is the importance of nature in giving a campus “prestige and status”, as the natural components of the campus are seen to attract both donors and students. This finding would later play an important role in connecting tree cover to the overall image of the campus that planners chose to develop. The only regulating ES that received considerable attention, and thus considerable weight when assessing the services, was the air quality improvement. No provisioning services were noted by the interviewees. The research team used the ES inventory to assess how different campus development scenarios would increase or decrease the provision of these services, thereby affecting wellbeing of the campus community.

3.3 ADMINISTRATIVE STRUCTURE

Since we were considered not only with the ecological principles needed to protect and embellish biodiversity and ecosystem integrity on campus, but also with the administrative means for implementing ecological recommendations, we also queried the literature and selected universities regarding the administrative structure of institutions who have implemented sustainability programs. We reviewed available literature and conducted interviews with staff at eight American universities to learn about the administrative processes by which these universities initiated and incorporated sustainability into their decision-making processes. Ecological priorities are included under the broader umbrella of “sustainability” objectives. While we found many campuses that emphasized carbon, water and waste policies, very few explicitly noted ecological objectives, and among them ecology (wildlife conservation or ecological integrity) was rarely a primary objective. We also investigated the administrative structure of the Technion to identify key personnel who might be willing, able, and empowered to help us turn a conversation about sustainability into action.

Most campuses that prioritize environmental sustainability have dedicated sustainability offices on campus. A sustainability office works closely with ground and maintenance on campus, usually directed by an administrative committee. Committees are divided into subunits, each with a specific sustainability focus, e.g. water, food, buildings, transportation, etc. Each of these schools has a written sustainability plan, either incorporated into a master plan or as a standalone document. Campuses also make significant efforts to publicize their environmental efforts and educate the campus community.

4. DEVELOPMENT OF AN ECOLOGICAL VISION FOR THE TECHNION CAMPUS – GUIDELINES AND RECOMMENDATIONS

The ecological advisory team concluded its work by formulating guidelines and recommendations to the planning team. The recommendations were based on the two prior stages – the lessons learned from other universities and the findings of the surveys conducted in the Technion. These recommendations were divided into three:

- a. Recommendations in accordance with the three presiding themes of ecological campus planning: compact development, connectivity of open spaces, and conservation of high ecological quality land. In this regard, it was recommended that the southern forest patch (The Technion Woods) and the ecological garden serve as the primary open spaces on campus and that building be avoided in these areas. Moreover, the central wadi would serve as a green belt connecting the

two areas. These recommendations were indeed adopted and reflected in the campus statutory zoning plan (Fig. 7).

- b. Recommendations that are based on intensity of land use – low intensity (the Technion Woods and the Ecological Garden), interstitial spaces, and the built environment. For primarily open/natural areas, the advisors recommended a management policy emphasizing both biodiversity potential and cultural ecosystem services. The team recommended thinning the forest in accordance with the advice of biodiversity surveyors to encourage the growth of annual plants and shrubs, thereby increasing diversity of plants and animals, as well as developing a low-impact infrastructure for human use (pathways, picnic areas, educational signage) and a longterm socio-ecological research platform (Mirtl et al., 2013). Interstitial spaces between buildings and in the central campus emphasize ecological gardening. Landscaping, in which the use of native species are emphasized, has been emphasized as a crucial mechanism for university campuses to conserve and enhance biodiversity (Kermath, 2007). We developed two simple rules of thumb for campus gardeners which would be easily remembered and which reflect the overall findings of the biodiversity survey. First, we recommended managing gardens to increase habitat availability for birds, bees, butterflies and bats. Second, we recommended that all plant choices for campus gardens fit at least two of three criteria: (1) Be a local species to Mount Carmel; (2) Be an aesthetically pleasing species, and (3) Be a species that can provide habitat for a target species from the taxa noted above¹. Finally, recommendations for buildings and their immediate surroundings included the development of green roofs and walls and the placement of nesting boxes and bird feeders.
- c. Recommendations for specific projects for increasing the potential for campus biodiversity and for cultural ecosystem services. These recommendations were diverse and included the restoration of the central campus wadi, the establishment of the forest education and research site, improving access to the Ecological Garden, employing a professional gardening team for the campus that also had experience in ecological gardening, and coordinating ecological goals with those of transportation, education and energy. Indeed most of the recommendations here have synergies with other campus goals including resource conservation, strengthening the physical image of campus, integrating students and staff from different faculties and more.

5. ECOLOGICAL CAMPUS PLANNING IN THE CLASSROOM

Scholars note the importance of connecting the content of university courses with the sustainability goals of the institution, as well as preparing a cadre of young adults who are intellectually equipped to address global environmental challenges (Alshuwaikhat and Abubakar, 2008; Kermath, 2007; Koester et al., 2006). A curriculum that emphasizes sustainability is considered a crucial component of an overall university sustainability plan. Further, the natural physical space of universities provides opportunities for outdoor education, and in particular for ecological education. This pedagogical resource is noted generally in campus planning documents (e.g. Cornell University, 2008) and more specifically in others, such as the development of outdoor classrooms for ecological education (Campus Master Planning Team, 2011). Kermath (2007) cites the use of the physical planning process as an excellent mechanism for educating landscape architects and planners about ecologically sustainable landscape planning.

Even prior to the beginning of the campus planning process at the Technion, the physical campus was used as a focal study object for ecology courses for landscape architecture students. Each year, graduate students in this mandatory course were required to assess the ecological challenges of the broader region (e.g. habitat degradation and loss, invasive species proliferation, species extinctions) and then propose a design intervention in the university that would address their selected challenge. Students were allowed to focus at any scale they selected, from campuswide to a single building or small patch of ground. They chose challenges as diverse as habitat preservation for both common and endangered species, restoration of campus streams, and increasing the ecological literacy of students and campus visitors. They were directed to the Landscape Architecture Foundation “Landscape Performance Series”² projects

¹ These criteria allow for the possibility of use of exotic species if, and only if, they provide habitat for other species of interest. We allow for this possibility due to the fact that butterfly surveys of the campus found that the diversity of that taxon was low, even for an urban environment. The butterfly surveyor suggested using (exotic, though not invasive) plants to attract particular native species of butterflies.

² <https://landscapeperformance.org/>

that received accolades for addressing ecological challenges through design for inspiration and ideas. While the students' work was intended for purely for educational purposes, when the course instructor was approached to act as ecological advisor to campus planning, he was uniquely equipped with a reservoir of student-inspired ideas for implementation. Further, several students were recruited to work on the plans, as well. As a result, several ideas directly inspired by students found their way into both the master and the statutory plans. In this way, successive generations of students acquired theoretical experience in campus planning, while learning about the potential for university campuses to serve as exemplars of ecological conservation in the urban environment.

6. DISCUSSION

In this work we show that spatial and master planning of campuses can be an effective mechanism for advancing the ecological goals of the institution, particularly when ecological goals are synergistic with a suite of other goals, including connectivity, creating spaces for learning and social activity, and creating an outdoor environment that reflects the university's cultural identity.

Many of the recommendations above were integrated into each of the three planning products at the Technion Campus (The strategic master plan, the new zoning code and the active intervention plan). The presence of multiple ecological concerns and objectives in the master plan document suggests that, with some initiative, ecological objectives can be raised and pursued with the support of the plan, which has been approved by the institution's board of governors.

University campuses are often considered small cities (Alshuwaikhat and Abubakar, 2008; Finlay and Massey, 2012), although they can be divided into the larger environment in which they are nested, whether it be urban, agricultural or natural (undeveloped) or some combination thereof. Reconciling the place of the Technion in a heterogeneous environment was a central feature of the planning process. The most significant contributions of the ecological assessment to the outputs of the planning process were (1) the inclusion of the Technion Woods, the Ecological Garden and the central wadi into an "Ecological-Historic Corridor" in the statutory zoning plan, and (2) the definition of the image of the Technion as a "ForestCity" with its emphasis on the significance of tree cover in the strategic master plan.

Kermath (2007) noted that the simultaneous emphasis on cultural and natural heritage on university campuses can have a synergistic impact on both social wellbeing and ecological conservation. The Technion campus image, as described in the master plan, is one of a city within a forest and the plan is enthusiastic in its endorsement of the value of forest cover and its benefits for both academic life and the environment. Alongside this image is the fact that the campus itself is nestled in the midst of a city and hosts a large population of students, staff and visitors. Rather than emphasize the potential conflict between these two images (city and forest), the master plan adopts the "ForestCity" image as a new and unique concept tailored for the Technion campus. As a ForestCity, the Technion plans aim to preserve a central greenspace and enhance the tree and plant cover throughout the campus – in the preserved areas, the interstitial spaces and integrated into the buildings themselves.

Nearly a decade ago, Alshuwaikhat and Abubakar (2008) noted that most universities, despite environmental proclamations and commitments, approached sustainability in an ad-hoc and limited way, often focusing on a limited number of environmental parameters (this point is re-emphasized by Finlay and Massey, 2012, and others). Our analysis suggests that ecological conservation receives only limited attention in most university plans, and then usually in relation to other social, economic or environmental objectives. Most plans focus primarily on energy, water and waste cycles with the objectives of conserving resources and reducing waste (Finlay and Massey, 2012). These are perceived by planners and consultants as "low-hanging fruit" that are economically beneficial in addition to their environmental benefits, and are therefore common first steps since they can be justified financially. We suggest this is positive and desirable, but it does not allow for realizing the full potential of university campuses to be positive actors in ecological conservation. Arguably, universities that address energy, water and waste flows are addressing ecological systems from an ecosystem perspective, considering their local to global scale impact with regard to greenhouse gas emissions, and energy and water consumption. Some university plans discuss landscaping in terms of hydrological flows or [generalized] habitat creation or protection. However, very few of the outline plans we reviewed here addressed species- and habitat-level

ecological conservation considerations as recommended in the ecocity model (Finlay and Massey, 2012) and has been attempted in the Technion plans.

Sustainability, in the broad sense, also receives prominent attention within the master plan. As is common in most of the university planning documents reviewed here, the Technion plan expresses commitment to environmental management of resources, including energy efficiency, waste reduction, and water conservation. However, as a result of the active participation of an ecological advisory team and the positive reception to its recommendations by the planning team, ecological conservation also plays a significant role in sustainability goals. As such, the master plan directs “increased emphasis on the harmonic relationship between the campus community and the unique ecology of Mount Carmel” (Assif et al., 2015; p.86), and sets as a planning goal “preserving and nurturing the unique natural environment in which the campus is situated” (Assif et al., 2015; p.87)

The strategic decision to develop the campus image as a “ForestCity” ensures the maintenance of green landscapes within the campus, but does not alone assure ecological objectives beyond those associated with green infrastructures, such as cultural ecosystem services, carbon sequestration, shade, etc. Biodiversity must be addressed through specific directives regarding habitat creation and restoration and species choices for gardening and forestry. While ecological conservation is one of many considerations driving planning objectives at the Technion, ecological considerations received greater emphasis in its strategic and statutory zoning plans than is typical of the university planning documents reviewed here, and certainly more than they had in past Technion planning documents. This was made possible through collaboration between planners and an ecological advisory team, through the sponsorship of biodiversity and ecosystem service assessments, and through extensive discussion, coordination and integration of ecological considerations final planning documents. The integration of students into the planning process via academic courses created a win-win situation, provided planners and ecological advisors with ideas, models, and research, while providing students with hands-on experience and the gratification of seeing some of their analyses and ideas work their way into final planning documents.

ID 1541 | PARTICIPATIVE APPROACH FOR DEVELOPING NATIONAL LEVEL GREEN INFRASTRUCTURE POLICY: A REFLECTION ON SLOVENIAN SPATIAL DEVELOPMENT STRATEGY

Nadja Penko Seidl¹; Mojca Golobic¹

¹University of Ljubljana, Biotechnical Faculty

nadja.penko@bf.uni-lj.si ; mojca.golobic@bf.uni-lj.si

1 INTRODUCTION

This paper addresses three issues:

1. First, the contents (outcomes), as well as the process of the development of Slovenian spatial development strategy 2030 (SPRS 2030) will be presented. SPRS is the strategic national planning document, which was adopted in 2004 and is currently in the process of revision.
2. Second, green infrastructure planning within the SPRS will be discussed.
3. And third, the findings from the evaluation study, explicitly analyzing the vertical and horizontal integration potential will be presented.

2 THE REVISION OF SLOVENIAN SPATIAL DEVELOPMENT STRATEGY

Slovenian spatial development strategy is a national strategic planning document. The strategy was adopted in 2004 and it's currently under the process of revision. The whole process follows the policy development cycle and can be divided in three basic steps: (1) first, spatial policy is adopted/developed, (2) second, measures and projects are implemented, and (3) third, the implementation of measures and projects is evaluated.

Figure 1 – Three basic steps of SPRS development (Source: Miklavčič et al., 2016, pp. 13)

After SPRS was adopted in 2004, several studies and evaluation reports have been prepared from to evaluate spatial development and the implementation of SPRS: Zero report on the status of spatial planning (Černe and Kušar, 2005), An analysis of current situation, development trends and guidelines for Slovenia spatial development (Pogačnik et al., 2011), SPRS 2030 - An analysis of the implementation of SPRS programmes and measures (Golobič et al., 2014). In 2016 Report on spatial development of Slovenia (Miklavčič et al., 2016) was prepared as a synthesis of all aforementioned reports. It also serves as expert groundwork for the preparation of new spatial development strategy.

The evaluation of spatial development on the basis of selected indexes has shown, the decline of implementation from the strategy's goals. According to SPRS 2030 - An analysis of implementation ... (Golobič et al., 2014) one of the main reasons for the gap between the goals and their implementation was weak vertical and horizontal integration, i.e. the ability of the spatial policy to coordinate other policies influencing the spatial development and weak control over local planning. The necessity that the document

would be accepted as their own among the stakeholders was recognized as an important improvement in this context.

Therefore, the revision of SPRS has been planned as a participatory process, where various sectoral policies and other public interests will be tuned. Different stakeholders are included in the preparatory process, and public debate is encouraged, to ensure that the new SPRS will be adopted as a document, which will be recognized as their own among different stakeholders.

2.1 SPRS 2030 TIMELINE AND PUBLIC PARTICIPATION

Although the Ministry of the environment and spatial planning has initiated the revision of SPRS already in 2013, the first activities have been launched in 2015, when baselines and process plan of the SPRS 2030 have been introduced. Inter-sectoral working group was formed and the first public consultation on the baselines of the SPRS 2030 was organized, followed by the on-line public conference. Later that year, the draft of SPRS 2030 goals and vision has been prepared. In the period from July 2015 to September 2017 several public conferences for different stakeholders and inter-sectoral meetings are being organized. Four thematic groups have been formed, where experts from different fields have been gathered to discuss four main topics: (1) functional urban areas, (2) possibilities for low-carbon society, (3) countryside and green infrastructure, and (4) mountain and border areas.

The results from all four thematic groups will be synthesized in “Spatial development model of Slovenia”, which will be developed in 2017. Later in 2017 and in the beginning of 2018, the draft version of SPRS 2030 will be put into public consultation and sectoral reconciliation. After that, the final document will be revised and adopted.

Figure 2 – The SPRS preparation process and public participation (Source: Prenova Strategije ...)

2.2 SPRS 2030 VISION, GOALS AND FOUR MAIN TOPICS

As it was discussed in previous subchapter, the whole process of SPRS 2030 revision is planned as participatory, where different stakeholders, public bodies, as well as general public are encouraged to cooperate within the process to achieve the common goal: spatial strategy, where various interests will be reconciliated and tuned in order to achieve resilient/sustainable spatial development.

The vision of spatial development is based on the values towards which the Slovenian society is oriented: solidarity, tolerance, cooperation, safety, peace, quality of life, innovative society, trust, knowledge, skills, identity, democracy, equality and efficiency. Slovenia in 2030 is a safe country, which ensures well-being and contentment of its citizens in healthy environment. People are closely connected to nature, cities are green and the process of suburbanization is controlled. Countryside is well-connected with cities, public services are accessible and its traditional cultural landscape is preserved. Natural resources are used sustainably, the country aims towards food and energy self-sufficiency. Citizens are proud on their country and they participate spatial planning policy development and implementation.

The strategy itself is based on the vision and five goals, which have been set in the beginning of SPRS 2030 development:

1. Rational and efficient spatial development.
2. Competitiveness of Slovenian towns.
3. High quality of life in towns and in countryside.
4. Slovenia's spatial identity.
5. Resilience (Vision and goals of the ..., 2016).

Each of the five main goals is divided into more specific sub-goals, which will be further elaborated in the strategy.

In the current strategy (SPRS 2004) guidelines for spatial development are presented within three main chapters: (1) settlement structure/pattern, (2) infrastructure, and (3) landscape, whereas in the revised strategy (SPRS 2030), a slightly different organization of topics is being introduced. Spatial development vision and goals are being elaborated/discussed/implemented within four main topics:

1. Functional urban areas,
2. Possibilities for low-carbon society,
3. Countryside and green infrastructure, and
4. Mountain and border areas.

For each of these topics, a thematic group with stakeholders from different fields has been formed. Four groups of researchers who are experts in the various fields of planning (e.g. spatial, regional and urban planning, landscape architecture, geography, agriculture, forestry) were developing the expert groundwork for each topic, whereas the Ministry of the environment and spatial planning led the whole process. Several meetings with the ministry as well as workshops with stakeholders have been organized. Stakeholders received the material in advance and have been asked to actively participate on the workshops where several questions have been discussed. All the comments and recommendations from the workshops have been discussed and on the basis of these recommendations the reports have been supplemented. A need for a joint workshop has been recognized after the first round of workshops, since especially the topics (1) Functional urban areas, (3a) Countryside and (4) Mountain and border areas have been recognized as overlapping and intertwining. For the purposes of the second workshop, six types of areas have been determined and discussed:

- Urban areas (1),
- Suburban countryside areas (1+3a),
- Suburban border areas (1+4),
- Border countryside areas on lower altitudes (3a+4),
- Border countryside areas on higher altitudes (3a+4), and
- Mountain areas (4).

One of the main emphases of the workshop was the discussion on SPRS 2030 goals and the means/measures for achieving these goals within abovementioned areas as well as within different fields/topics (e.g. (2) low-carbon society, (3b) green infrastructure). The latter have been discussed separately, whereas the goals and measures for their implementation do not necessarily follow the abovementioned typology. The results from each group as well as the results from joint workshop will serve as the expert groundwork for the strategy.

3 GREEN INFRASTRUCTURE (GI) PLANNING

3.1 THEORETICAL BACKGROUND FOR GI DEVELOPMENT

According to Dige et al. (2014, 8), green infrastructure is defined as: "... a tool for providing ecological, economic and social benefits through natural solutions, helping us to understand the advantages nature offers human society and to mobilise investments that sustain and enhance these benefits." Naumann et al. (2011, 1) understand GI as: "...the network of natural and semi-natural areas, features and green spaces in rural and urban, and terrestrial, freshwater, coastal and marine areas, which together enhance ecosystem health and resilience, contribute to biodiversity conservation and benefit human populations through the maintenance and enhancement of ecosystem services. Green infrastructure can be

strengthened through strategic and co-ordinated initiatives that focus on maintaining, restoring, improving and connecting existing areas and features as well as creating new areas and features.”

On the basis of the above mentioned definitions, the main characteristics of GI and the objectives, which guided the development of GI concept within SPRS 2030 have been defined:

1. GI should not be considered just the result of a planning process but also as the process itself. GI planning is a strategic approach to conservation planning (McDonald et al., 2005), combining the planning methodologies from ecological planning (Ndubisi, 2002) with the key principles of landscape ecology (Ahern, 2007). The knowledge of ecological systems' structure and functioning is derived from landscape ecology, whereas ecological planning methods enable planning and management of landscape changes in a way that various functions of GI are preserved and/or enhanced.
2. GI is a system of interlinked elements and processes, which provide various functions on different levels. Three basic elements of GI can be identified: (a) hubs as the core areas, interlinked with (b) corridors and (c) stepping stones. GI is a dynamic system, where constant flows of energy and material among and within its elements maintains equilibrium of the whole system.
3. Three principles guide the development of GI: (a) heterogeneity among and within its elements, (b) connectivity among different elements of the whole system and (c) multifunctionality of its elements as well as the system as a whole.
4. GI is hierarchical system and all sub-systems need to be in balance in order to the system as a whole functions well. Different functions are emphasized on different levels and within different spatial contexts. On the international (continental) level, GI has a key role in providing ecosystem and ecological functions, whereas on urban level, social and cultural functions are emphasized.
5. Regarding the (wider) spatial context, four different strategies can be applied in GI planning: (a) protective, (b) defensive, (c) offensive and (d) opportunistic (Ahern, 1995). In GI planning several strategies are usually combined in order to achieve the consistency of system.

3.2 GREEN INFRASTRUCTURE CONCEPT WITHIN SPRS 2030

As it was already discussed in the previous chapter, green infrastructure has been recognized as one of the main topics in the SPRS 2030. Although Slovenia is characterized by well-preserved natural environment, deviations from goals, set in the SPRS 2004 often result in negative impact on green infrastructure. Urban sprawl, non-rational land use for industrial zones and adjacent infrastructure, and also forest overgrowth have been recognized to have the biggest negative impact on green infrastructure.

The necessity to address the issue of green infrastructure on the national level, as well as to interlink the national GI concept within international environment, and, to set the guidelines for the development of GI on regional and urban level, has resulted in the inclusion of GI into one of the four main topics of SPRS 2030.

Considering the theoretical background of GI planning and the Slovenian spatial context, the concept of GI planning within SPRS 2030 was based on objectives from the chapter 3.1.

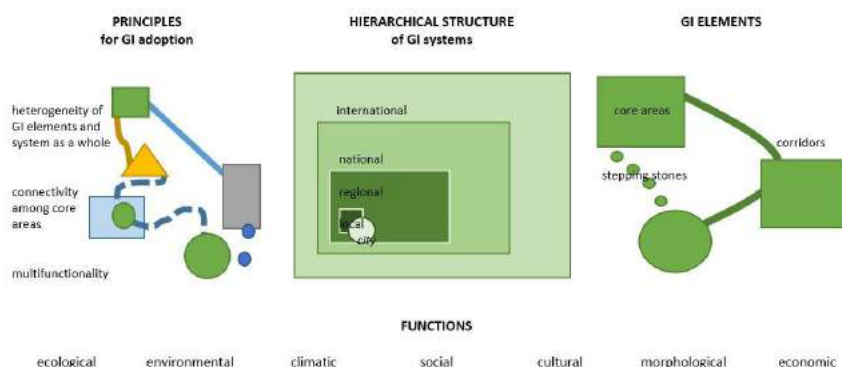

Figure 3 – Different aspects considered in GI planning for SPRS 2030

3.2.1 THE DEVELOPMENT OF GI ON NATIONAL LEVEL

Since SPRS 2030 is a national planning document, GI concept has been based on national level. The connections to international, European level have also been considered, since almost whole Slovene territory is considered as a conservation area within European GI network, while it provides ecosystem services and represents an important habitat area within Europe.

Therefore GI concept on national level (Figure 4) has been developed on two main hubs, which are both a part of important naturally preserved areas in European context: Alpine and Dinaric area. Four main watercourses: Sava, Drava, Mura and Soča are the most important corridors, which interconnect national GI system with neighboring countries, and, stepping stones between two core areas should be defined to enable key ecosystem functions on European level (e.g. migration of big mammals).

Elements, which form a backbone of GI on the national level, the measures for their selection/inclusion, and functions of proposed elements have been proposed and discussed on the final joint workshop with stakeholders.

Furthermore, guidelines for the development of GI on regional and local levels have been set, as well as guidelines for the development of urban GI.

River corridors	Rivers Sava, Drava, Mura and Soča	Corridors	xx	x	x	x	x	xx	0
Landscape of national importance	Areas which overlay with above mentioned elements; stepping stones within intensively cultivated/densely populated landscape	Core areas/stepping stones: cultural landscape	0	0	0	x	xx	xx	x
Outstanding landscapes									
Forests with important ecological function	All	Core areas: managed natural landscape	xx	xx	xx	xx	x	0	0
Forests with important social function									
Conservation forests			xx	xx	x	0	0	0	0
Forest reserves									
Agricultural land	High nature value farmlands; agricultural land of lower quality and not within larger agricultural complexes	Core areas/stepping stones: cultural landscape	x	0	0	x	x	x	x
National nature conservation areas	Landscape and regional parks which serve as stepping stones and corridors	Core areas: managed natural and cultural landscape	x	x	0	x	x	x	x
Biosphere reserves	Areas within intensively cultivated landscape, stepping stones	Core areas/corridors: biosphere reserves	x	x	0	0	0	0	0
Habitats of large carnivores	Partly included as Natura 2000 areas; migrations	Core areas and corridors	x	x	0	0	0	0	0
* The importance of each function for the national level GI system as a whole is evaluated on 5-stage scale; value 1 means that the function is of no/minor importance on the national level and value 5 means that the function is of major importance on the national level.									
** The importance of individual elements' function is evaluated on three stage scale: xx – function of great importance, x – function of medium importance, 0 – function of minor or no importance.									
E – economic, S – social, P – physical (reference to Figure 6)									

Table 1 – GI elements, functions and measures for inclusion of elements into national GI system (Source: Penko Seidl et al., 2017)

4 STRATEGIC (EX-ANTE) EVALUATION OF SPRS

Strategic evaluation has been commissioned in spring 2016 in parallel to the process of SPRS 2030 development with the aim to support its coherence, relevance and effectiveness in terms of achieving territorial cohesion. The concept of territorial cohesion (Camagni 2007, EATIA 2011) has been chosen as a reference for SPRS 2030 as well as its strategic evaluation (Figure 6). As space is a limited natural resource, the only possibility for an increased efficiency of its use (without overusing and degrading it) is in its multifunctionality, which in parallel brings synergistic effect to its users and increases territorial cohesion (territorial identity, efficiency and quality). The priority should therefore be given to projects and measures according to their overlapping and synergistic function.

The interim report of the strategic evaluation (November 2016) focused on intervention logic of spatial development policy. The findings from the previous research (Pogačnik et al., 2011, Zavodnik Lamovšek et al., 2014, Golobič et al., 2014) indicated that the results of spatial development diverged from the set objectives of spatial policy. The gap between the formal consistence of different sectoral documents with spatial objectives and actual outcomes, indicate serious shortcomings in policy implementation. One of the main reasons is inappropriate intervention logic of the spatial policy. While its objectives underline interdisciplinary and trans-sectorial approaches, the policy measures predominantly rely on normative and top-down implementation. These are too weak in the circumstances of complicated administrative processes, unclear and often changing competences of different administrations and low level of trust among the stakeholders. The new vision, as formulated within SPRS 2050 (Bartol et al., 2016), recognized this problem and promotes change towards more participative and communicative approaches to spatial management. However, the process of SPRS 2030 preparation until now did not succeed to showcase such approach. Despite its declared participativeness, supported by a large number of organized events

and involved persons, the actual stakeholders' contribution and level of commitment is questionable. The competence and formal (political, administrative) power and responsibility of involved representatives was low, and the process was too loosely organized to achieve the communicative process. The evaluation team proposed to adopt a more structured process, which would require (1) for each sector to indicate own priorities, (2) to identify overlapping issues between the spatial and every other relevant sector (as synergistic or conflicting), and (3) to develop the proposals for projects and measures, which would support the synergistic and resolve the conflicting issues. To enable this process and improve the spatial policy implementation, a few measures need to be enforced: electronic evidence on land use and related regimes, land management (financial) instruments, intersectoral body with clear responsibilities and regional planning.

As regards green infrastructure, the multifunctionality and territorial cohesion concept are of key importance. The hierarchy and priority as well as guidelines for planning and management should be defined according to principal and overlapping functions of GI: economic - E, social - S or physical - P (see Table 1); and their contributions to territorial cohesion; i.e. territorial identity (Ti), effectiveness (Te) or quality (Tq). As can be concluded from Table 1; the elements most contributing to territorial cohesion (TC) are: nature conservation areas/national, landscape and regional parks and high nature value farmlands; (contributing to all elements of TC), Natura 2000 and forests with important ecological function (contributing to Tq) and landscapes of national importance (contributing to Ti).

Figure 6 – The concept of territorial cohesion

5 CONCLUSIONS

Three issues have been addressed and discussed in this paper:

1. The process of preparation of Slovenian spatial development strategy,
2. The role of green infrastructure planning within SPRS, and
3. The strategic evaluation of the process as well as the document.

Spatial development in Slovenia since the adoption of SPRS 2004 diverged from the set objectives of spatial policy. According to the strategic evaluation for the policy revision, the main reasons is inappropriate intervention logic of the spatial policy. While its objectives underline interdisciplinary and trans-sectorial approaches, the policy measures predominantly rely on normative and top-down implementation. Accordingly, different stakeholders did not accept the strategy as their own development opportunity. The new vision, as formulated within SPRS 2050 (Bartol et al., 2016), recognized this problem and promotes change towards more participative and communicative approaches to spatial management. Therefore, the process of SPRS revision has been set as a participatory one, where different stakeholders are included in the preparation of the document. But the inclusion of various stakeholders into the process often means the collision of diverse value systems and consequently diverse ends and means for their achievement. Reconciliation of all these interests and appetites has proved to be a challenging process. According to findings of strategic evaluation of the SPRS 2030, this shift was not completely successful. Despite a large number of organized events and involved persons, the actual stakeholders' contribution

and level of commitment is questionable. A more structured process would be required, consisting of the following steps (1) for each sector to indicate own priorities, (2) to identify overlapping issues between the spatial and every other relevant sector (as synergistic or conflicting), and (3) to develop the proposals for projects and measures, which would support the synergistic and resolve the conflicting issues.

The deviation from goals, set in SPRS 2004 has resulted also in negative impacts on natural environment. The development of green infrastructure concept on national level is an attempt to strategically plan and manage (generally well preserved) natural environment in order to implement various functions. The concept was based on the interconnection of different types of naturally preserved areas, which create a backbone of national green infrastructure, provide opportunities for inclusion into international GI system, as well as set guidelines to establish GI on regional and local level.

ID 1550 | MODELING ECOLOGICAL NETWORKS AND LAND VALUE FOR THE PRIORITIZATION OF NATURAL AREAS CONSERVATION

Laurent Martinez¹

¹IRSTEA Grenoble, UMR PACTE

laurent.martinez@irstea.fr

1 INTRODUCTION

The strategy promoting Green Infrastructure (GI) from European institutions (2013) considers the spatial structuration of (semi) natural areas as a network and resulting environmental features impacting populations. The strength of the GI's approach lies in the effort to integrate the ecological and social values of natural areas in combination with other land development (Laforteza et al. 2013): this strategy encourage an integrated approach of space planning at different scales and promote the multiple services associated with natural areas. From a conservation biologist perspective, it is not a new idea, since it is based on environmental continuity, ecological networks and landscape connectivity. Yet, considering natural landscape as a network that offers a structural frame for the development of the biodiversity of tomorrow (and secure some ESS for our societies) forces to rethink our spatial planning approaches.

Landscapes are seen in this paper as a dynamic and structured spaces with a social dimension where management and planning play a key role. Physically, landscapes are composed of artificialized components (Grey infrastructure) and natural components (Green infrastructures) in interaction.

In France, planning process is historically a top-down process based on technical and professional expertise. After several decades of planning at national scale, French government tends to give more decisional power to regional and local scales (i.e., decentralization). Multiple guidance documents of soft planning such as SCOT (Schéma de Cohérence Territoriale/ territorial coherence program), present a mix between national, regional strategies and the translation of European directives about environment and socio-economy. Town planning regulations are now framed by this soft planning, but local collectivities still have to adapt it, dealing with all the contextual and operational components. Their task is to spatially, legally and institutionally define and regulate urbanistic rules at the finest scale (hard planning; Purkarthofer, 2016). Moreover, the planning process is gently opening to democratic participation with mitigate successes. We will focus on a problem coming from the difficulties to take account of the different values of natural areas. These values correspond to different estimations of natural areas in ecological or socio-economical terms.

Findings some tools that could shed light on the importance of the identified stakes are requested, especially in urban areas with high levels of artificialization and under sprawl dynamic. Several tools have already been developed to assess values of natural areas or values of landscapes but they are poorly transferred together to operational field because of their focus on a single value. From conservation

biology field, Beier et al. (2011) made a first step to a better cohesion between planning institutions and spatial sciences, highlighting the main technical and organizational points that have to be monitored in order to build a coherent connectivity map at regional scale. But more than a protocol to build a common tool, a common framework between sciences and planning is lacking to take account of all kind of values associated with natural areas.

The awareness of these different values can be seen through the spread of environment concept (70's), biodiversity concept (90's and 2016) and ecosystem services (ESS) concept (70's and reborn in 2005). Santolini et al. (2016) highlight that "The ESS framework could [also] be a useful interface between science and decision-making". Mobilizing ESS concepts, GI's approach could be the needed hall where science and operational planning meet again. A framework, based on both scientific knowledge and "good practices", that is claiming to consider the different values of nature at any scales of planning. In urban contexts such as metropolitan areas, GI's approach encourages the participation of new stakeholders to the decision making process. It can also lead to be construed as a guidance to limit urban sprawl and promote urban regeneration.

If in one hand the planning processes become more complex, with more stakes to deal with, in another hand it's aiming to a better integration of the social, economic and environmental components in space. It is slowly shifting from a discontinuous process approach to a continuous one. As a consequence, this context brings scientists to work on several questions about the value of natural attributes as a (dis)service set and about the value of landscapes.

This fresh started Phd project aims first to discuss about technical and methodological contributions identified as useful to clarify some central stakes into future planning and decision making. Our research object deals with the valuation of natural areas through two different prisms: ecology and socio-economic. The main research question of the project can be stated as:

How can the values of (semi-)natural areas be captured, discussed and prioritized into the planning process?

Our final objective is to propose a method allowing decision makers to perceive and assess different values of natural areas. Yet, a part of this research work also aims to understand the relations between the different values associated with natural areas. Our study case will take place in the Grenoble-Alpes Metropole area, a region in France with several degrees of urbanity and a large panel of natural characteristics.

The first section of this paper presents how ecologists assess the ecological value of a landscape through the analyze of an ecological network with connectivity measures. The second section presents econometric methods to capture socio-economical values of a landscape and a method to capture people perceptions of natural attributes in their environment. The last section presents briefly the working prospects of this Phd project.

2 ECOLOGICAL NETWORKS AND LANDSCAPE CONNECTIVITY

Ecological networks aim at reconnecting fragmented natural areas in landscapes, with different degrees of urbanization. As landscapes are dynamic objects, connectivity is not stable over time. In the following paragraph, we will give a brief definition of landscape connectivity, introduce some modeling approaches and give an outlook of the proposed methods to build our ecological network.

2.1 WHAT IS LANDSCAPE CONNECTIVITY?

Connectivity is the extent to which movements of genes, propagules (pollen and seeds), individuals, and populations are facilitated by the structure and composition of the landscape (Rudnick et al. 2012). It depends both on the distribution of particular habitats in space, on the permeability of the matrix (non-habitats) which is composed of habitats non-suited for a species and on the presence on barriers like cliff, highways, high-speed railway lines or rivers which often are linear object. Assessing connectivity is a

species centered approach (Pearson et al., 1996), based on the requirements for species to survive at the population level.

Connectivity can be split in two main components:

- i. Functional connectivity (or realized connectivity) describing the states of genes, individuals or populations flows in the landscape. Ecological surveys and monitoring can be deployed to capture this functional connectivity for some species.
- ii. Structural connectivity describing the physical landscape: topography, hydrology, type, size and organization of habitats. In conservation planning, the “continuum concept” is mobilized to build ecological corridors between two focal conservation areas. This concept aims to physically link the same types of habitat and is a perfect example of structural connectivity.

These two components are linked, but a “good” structural connectivity does not induce a “good” functional connectivity (Taylor, 2006), whether for the target species or for the others species sharing the same habitat. Some physically disconnected habitat can also present a good functional connectivity for some flying species, like birds, or species with high dispersal capabilities.

When data about the distribution and the realized movements within and between populations is scarce or missing, the structural approach can be a first step to integrate the management of natural areas in decision making (Urban and Keitt, 2001). A potential tool to theoretically assess connectivity is graph theory, which can be defined as an idealized representation of networks pattern (Dragicevic and Sinclair, 2013). This method has been widely mobilized to implement ecological corridors in landscapes. The “Trame Verte et Bleue” program in France is based on graph theory, serving as a high level vision of landscape connectivity in urbanism documents. To go beyond the limits of structural connectivity, in a « learning by doing » process (Kato and Ahern, 2008) and improved by consecutive steps of adaptative planning, Functional connectivity can be assessed by monitoring the distribution and dynamics of species populations.

An alternative to the adaptive planning is to improve modeling of the functional connectivity of ecological networks: the structural networks are enhanced with ecological data related to one or several species. We chose to mobilize this approach also called potential connectivity by conservation professionals.

2.2 MODELLING APPROACH AND METRICS

There are several ways to model the landscape connectivity and most of them use GIS software in order to spatialize the data. Spatial patterns indices, nearest neighbor distance, buffer radius or graph theory are used to evaluate potential connectivity (Calabrese and Fagan, 2004). The strengths of graph theory approach in modeling connectivity are highlighted by Rayfield et al., (2011):

- i. The possibility to characterize connectivity at large scales with many habitat patches
- ii. The ability to balance data requirements with information content
- iii. The possibility to incorporate ecological data, like species biology requirements or dispersal capabilities to build the graph

In other words, by adding the modeling of species-specific dispersal in the graph building, we can assess a potential connectivity of landscape.

To build our ecological network, we chose to mobilize the Graph theory. In this method, we consider habitat patches (nodes) are considered to provide all environmental and natural resources that a focal species needs to realize their entire cycle of life. Those nodes are connected by potentials corridors (edges) which are generated between habitat patches.

In a first step, habitats for individual species are identified at a chosen time. We will mobilize minimum habitat area and habitat quality data for every species in order to identify the potential nodes. In a second step, the species median dispersal distance will be approximated via trait based predictions (Whitmee and Orme, 2013; Mimet et al., 2016). These predictions only exist for terrestrial mammals on which our model will focus. To build the edges of our graph, we selected two main methods which are based on dispersal species-specific distance and on a simplified landscape grid, usually built from land use and/or land cover

maps, crossed with topographic models. Each cell has a resistance to movement value, or a probability of dispersion to an adjacent cell.

- i. The multiple least-cost paths method is based on the idea that a species will use the shortest way between two habitats in terms of movement costs. This approach is based on species dispersal distance, its capacities to perceive environment and on the landscape resistance to movement. Least-cost method can be used to delineate corridors in more or less elaborate ways for every focal species identified as pertinent at a given scale.
- ii. The circuit theory method supposes a more random walk of individuals in the landscape (probability to disperse from a cell to another in the landscape grid). If it can help to delineate corridors spatially, its main strength is that this method allows us to build current density maps with multiple pathways between habitats patches and inform us about existing dispersal bottlenecks in an identified corridor or in the landscape. This method was proven effective for gene flows (Mc Rae and Beier, 2007). Those bottlenecks are labeled of high priority in order to keep or enhance connectivity for a given species.

Beyond the difficulties to select connectivity metrics, building permeability or the resistance grid is the critical part of the modeling. The resistance value of each cell is a proxy of the real crossing cost for a particular species. Moreover, as it is difficult to assess the pertinence of a resistance value through a component of the landscape for a given species, the values are generally “expert estimates” or extrapolated from field survey (e.g. GPS tracking).

However, it is fundamental to understand the limitation of modeling and metrics used in order to assess connectivity (Kindlmann and Burel, 2008). These connectivity metrics depend on the focal species, landscape/time scales, and spatial neighborhood. Pascual-Hortal and Saura (2006) proposed to test simple metrics under scales and landscape complexity changes. The most common way to assess landscape connectivity is to use a set of different metrics, informing us on element, component and network scales (Rayfield et al. 2016).

All those methods are currently used mostly for a single species and can be mobilized for operational work on fine scale. The choice to work with some focal species and not others seems to be a strong bias to legitimate a corridor planning to preserve biodiversity at large scale.

2.3 MULTISPECIES APPROACH

Optimally, we have to take into account every species present in a landscape. Currently, multispecies approaches are still in development. We present here some approach to deal with this issue.

A common way to take account of several species is to build several species-specific networks. Poodat (2013) suggests to represent the connectivity outcomes seen as different alternatives, then to let the decision makers to fix planning prioritization choices.

In a case of a located arrangement, like a structure to cross a highway, Mimet et al. (2016) propose to mobilize multivariate representations and to choose the location that can concern the most of the species. As an alternative, some authors propose to create some cluster of species with the same ecological characteristics (dispersal capabilities, preferred habitat types kind and minimum habitat area) in order to build virtual model species. This approach by cluster can also work at broad scales as demonstrated by Correa Ayram et al. (2017) who have built three virtual species from forest areas in order to obtain three scales of landscape connectivity. The last way is to build a multispecies ecological network is to study the connectivity of an umbrella species habitat. Theoretically, an umbrella species is supposed to live in an ecological network overlaying several others species specifics networks. Yet this approach has encountered many critics from operational fields: professionals highlighting a problem of network viability as the optimum habitat quality cannot be the same for a lot of species due to resources and niches competition.

2.4 RESEARCH OUTLOOK

In this first part, we presented several approaches used to build ecological networks in conservation planning. From a planning perspective, a linear corridor identified at regional scale, either by habitat continuum or by least-cost paths method can be stated at local scale by mobilizing circuit theory approach. If the data is accurate enough and mobilizing graph theory approach (Crombette, 2016), urban corridors can be designed in highly artificialized areas, in order to enhance ordinary biodiversity. To fulfill this purpose, it does not always require connecting two or more natural spaces nodes. A current density map based on several species characteristics could give us an estimation of the importance of an area in terms of connectivity. At last, this current density map could inform us on some areas with high medium or low value of connectivity, opening preferably some areas to urbanization for conservation purpose.

These methods offer some ways to preserve biodiversity by taking account of the different flows present in (semi)natural landscapes. Yet this ecological valuation of natural areas only represents a dimension of the landscapes value and brings some more questions in a planning perspective. Decision makers also need to take account of other parts of natural landscapes value, through different valuation methods in order to answer questions.

Do the areas of high connectivity value match with high socio-economical values of natural landscape perceived by people? Locating and detecting potential conflictual areas between ecological and socio-economical stakes looks like a prerequisite to state a consistent development strategy. We will present the methods we chose to capture the socio-economical values of natural landscape in the next part.

3 PERCEIVED NATURAL AMENITIES

The fragmentation of landscape has ecological impacts, but has also direct and indirect impacts on society. People can set a positive or negative value of some landscape's attribute depending on their perception of the environment, their personal sensitivity and practices.

In economy, two kind of approach coexist to evaluate the implicit prices of the landscape attributes. The first one is based on revealed preferences from the market condition (e.g. hedonic pricing method), every compartments that can be observed from real market of a good or service. The second one is based on stated preference (e.g. contingent valuation method). Both approaches are well described in literature, but hedonic pricing method offers us two advantages. First, this method is spatially explicit, and can be integrated under GIS software. Second, some reference close to our case study on periurban landscapes are already available (Cavailhes et al., 2007). We plan to mobilize this method in order to capture the impact of natural amenities on property prices or rents.

3.1 NATURAL AMENITIES AND HEDONIC PRICING

Hedonic pricing (Rosen, 1974) is an econometric method based on revealed preference theory. It is built in order to analyze people's choice from empirical data. Applied to real estate field, this method supposes that a (real or rental) property is a composite good divisible into a set of characteristics but sold as one. Those characteristics co-determine the property price and can be embedded (dwelling area, age of housing, etc.) or extrinsic, like neighborhood factors spatially localized (commuting costs, accessibility or proximity to amenities or services).

An amenity is originally an economical term used to describe a non-produced public good that have no explicit price. The presence of characteristic set of amenities (e.g. proximity and accessibility to schools, health services, urban parks, natural areas, etc.) can attract some people whose work may not be the main purpose to select a location (Chen et al., 2008). It can be identified as a driver of development at regional (Ullman, 1954) or city scale (Clark et al. 2002). Natural amenities are more specific and can be define as "[...] elements of the environment (e.g., climate, water bodies, coastlines, mountains, and forests) that attract people" (Kovacs et al., 2017). We will adopt a more generalist definition proposed by Schaeffer and Dissart (personal communication): A natural amenity for a group of people or firms is a (bundle of) place-based biophysical attribute(s) that generate(s) localized benefits valued by most members of this group.

Amenities are heterogeneously distributed in the landscape and scarce in a given context: lakes or trees in highly artificialized areas, health services in rural areas etc. The literature on natural amenities does not show a clear result between natural characteristics of landscape and property price (Brossard et al., 2011): it is all context and data dependent. Moreover, impacts from a bundle of natural amenities on property prices can be constant, or depend on distances between amenities and property location. These inconsistent results could be explained by the quality of environmental data used in modeling process. Natural areas of landscapes are mostly simplified into ground cover layers, without taking account of the use of spaces. Brossard et al. (Ibid.) proposed to cross ground cover data with the legal status of plots to overcome this issue. It is an approach that may offer a representation closer to the real accessibility to some areas. It could also bring a better estimation of "future ground cover changes" (e.g. private woods/farmland that could be opened or closed to urbanization). Inconsistent results could also come from a spatial modeling issue as the study area extent can also capture several effects that an amenity can have on real estate market at different scales. We will see in next part how to go beyond this limit.

3.2 MODELLING ISSUES

In practice, a spatial regression model is built in order to explain the price of the property, or the rent (explained variable), by a set of characteristics (explanatory variables). Assuming the market is in equilibrium, we can estimate the marginal price of a characteristic impacting the property price, referred as the willingness to pay of the good owner. The selection of the characteristics is a critical issue for the interpretation of the model and exposes it to critics. In order to build the model, two approaches can be mobilized: a machine learning approach where characteristics are selected from empirical data or an approach by choice where characteristics are selected on the base of their importance in case context, or in the literature. To sum it up, the categories of explanatory variables mainly used in hedonic pricing literature are structural variables (e.g. dwelling area, number of rooms, parcel size ...), neighborhood variable (e.g. income, travel time to work, distance to road/railroad/golf course ...) and natural amenities from open spaces (e.g. distance to nearest forest/park, forest density, shape of the patch...).

In order to get a robust estimate of the marginal price of a characteristic, it is essential to reduce all kind of correlation (spatial and a-spatial) between the variables of the model. Yet, some limits of statistical analysis of spatial data reside in the difficulties to get rid of it, even if some methods allow us to go through these issues

In one hand, endogeneity between variables can create interpretation biases and inconsistency of coefficients. It is the case when two or more characteristic can be explained by another one omitted in the regression, or by a characteristic that we can't capture. E.g., the neighborhood prestige can be hard to measure by itself, but it plays a major role into real estate market through a "between us" effect. The price of property depends on the location of amenity and inversely, so it is not possible to compartmentalize the pure effect of each variable. Endogeneity can also be observed through the correlation between a characteristic and the error term of the model. A way to take account of heterogeneity consists in using instrumental variables correlated to endogenous characteristics and independent to model residuals.

In another hand, the spatial dimension of the model bring a spatial correlation issue that we have to take into account, otherwise the regression coefficients are biased and cannot be mobilized to estimate a marginal price (Le Gallo, 2002). Spatial autocorrelation is based on the first law in geography: "Everything is related to everything else, but closer things more so" (Tobler, 1970). To detect the spatial structure of the data, we have to analyse if a characteristic is randomly distributed in space, or clustered (high values in a contiguous area, low values in another) or "chess like distributed" (high values area surrounded by low values area and inversely).

Several spatial models already exist and are exposed and discussed in Gelfand et al. (2010) or Anselin et al. (2013). Yet, according to these issues, the data "quality" have to be tested in order to select which spatial models can be applied (Anselin, 2002) to calculate consistent marginal prices. To sum it up, the hedonic pricing approach can help us to capture a monetary value of natural amenities through real estate prices. But several technical and data related complications can lead to misinterpret the results.

3.3 LOCAL KNOWLEDGE

Even if we can identify which natural amenities are preferred through a will to pay to benefit from it, we are far to be able to capture the resident local knowledge of the environment. Human and social sciences developed several methods to capture it, but results are usually hard to capture, qualitative, vague, and hard to incorporate in planning processes (Rentanen and Kahila, 2009). Still this local knowledge has been identified as fundamental to build and legitimate a planning decision in the eyes of the public (Douglass and Friedmann, 1998). We did not delve enough to present different approaches to capture local knowledge, we will focus on a single concept that could be mobilized in our study.

The concept of Public participation GIS (PPGIS) could be an approach mobilizing people through a map-based participation tools permitting to capture the local knowledge of environment and the value of landscape for people. This map could be overlaid and compared with results from ecological and econometric models. This PPGIS concept has been criticized because of the complexity of GIS interaction, unable to mobilize non expert people and thus far from people experiences of environment exhaustiveness (Poplin, 2012). But development of user friendly SIG tools and open source technologies allow more and more people to express their perceptions and their value.

Methods like softGIS developed in Aalto University (Finland) take account of the needs of planners in operationalizing terms (Rantanen and Kahila, 2009; Kytä et al., 2013): testing the representativeness of the people answering to a survey program, feeding back the users on the results, questioning the complementarity between technical and local knowledge and thus their weight in decisional process etc. Data from local knowledges captured via a softGIS approach could even be incorporated in hedonic pricing approach (Czembrowski et al. 2016). In this last approach, the local knowledge is used in order to improve the quality of environmental data mobilized in the hedonic pricing model.

Yet, in order to capture a 'social' value of landscape from residents perceptions, several other approaches have still to be considered.

4 WORKING PROSPECTS

At a later stage, the doctoral work will focus on the discussion about convergences and contradictions between the selected values associated with natural areas (cf. section 2 and 3.). Both a force and a limit of our project is to propose methods spatially-explicit methods. The interest of spacialization is to offer a medium support between different kinds of values (ecological, economic or social) and a critic of this approach is that non spacialized values are not taken into account.

Our final goal aims to discuss and propose technical advices in spatial specific contexts to shed light on the prioritization choice of a value over another under urbanization pressure and sprawling process. Some prioritization tools have been jointly developed between scientists and planning actors and can take a lot of forms. We already identified two kinds of tools that can be used in order to shed light on prioritization of land use for nature conservation, both based on GIS approach. Moilanen et al. (2005) have developed the Zonation software, a tool based on a weighted prioritization process. Strength of the weighted approach is to propose a prioritization but a drawback of this approach is a lack of local flexibility since this weight is based on a global choice of prioritization. Another way to support decision is to mobilize GIS-Based Multiple-Criteria Decision Analysis, a modeling process often considered as a complex black box by decision-makers (Greene et al., 2011). Consequently, those tools do not challenge the discussion prior to decisional process and thus are not widely mobilized. Ultimately, the researcher can inform and supplement the planning process, mobilizing and crossing different methods and technique, but also have to bring support tools that can be mobilized. The choice to use it does not only depend on the tools accuracy, but also of their acceptability by decision makers.

ID 1591 | ACHIEVING SPATIAL QUALITY IN INTEGRATED PLANNING: AN EVALUATION OF THE DUTCH 'ROOM FOR THE RIVER' PROGRAM USING QUALITATIVE COMPARATIVE ANALYSIS

Stefan Verweij¹; Jelte van den Broek¹; Tim Busscher¹; Margo van den Brink¹

¹University of Groningen

s.verweij@rug.nl ; t.busscher@rug.nl

ABSTRACT: In line with recent trends towards area-oriented planning, flood risk management has seen a shift from a water control strategy towards a water accommodation strategy. In the Netherlands, this resulted in the policy program Room for the River. The projects in this policy program are expected to achieve two key objectives: first, the accommodation of higher flood levels, i.e., water safety, and second, improving the spatial quality of the riverine areas. Whilst research has shown that the program is successful with respect to increasing water safety, less is known about its second objective. This paper thus has two aims: (1) assessing the extent to which the program has been able to achieve spatial quality and (2) identifying the conditions that explain this. To these aims, archival and survey data were collected, and analyzed using Qualitative Comparative Analysis (QCA). The analysis shows that there are various combinations of conditions for achieving spatial quality. We conclude that these different combinations entail different strategies, and that by means of those, the program management has been successful in achieving spatial quality in the Room for the River program.

KEYWORDS: Area-Oriented Planning; Program Theory Evaluation; Project Evaluation; Project Management and Organization; Qualitative Comparative Analysis; Room for the River; Spatial Quality

ACKNOWLEDGEMENT

This research was commissioned by Rijkswaterstaat, as part of the long-term research cooperation between Rijkswaterstaat and the University of Groningen. The content of this paper does not necessarily represent the views of Rijkswaterstaat and are thus the researchers' responsibility. We want to thank Regina Havinga, Milou Joosten, Hermine der Nederlanden, and Marije Hamersma for their support and feedback in the research process.

1 INTRODUCTION

Recently, flood risk management in the Netherlands has seen a strategic reorientation from controlling the water, by constructing and maintaining flood defenses such as dams and dikes, towards a strategy that stresses the accommodation of the water (Jong & Van den Brink, 2013; Meyer, 2009; Wiering & Arts, 2006). This reorientation is characterized, first, by an increasing importance of spatial planning in flood risk management (Jong & Van den Brink, 2013; Van Buuren, Edelenbos, & Klijn, 2010; Wiering & Immink, 2006): when possible, spatial planning solutions are preferred over technical solutions (Van Buuren, Edelenbos, et al., 2010). Second, in the new strategy, the physical water system conditions the water management and not the other way around (Van Buuren, Edelenbos, et al., 2010). Thus, water management has become increasingly area-oriented; flood risk management is now planned conjunctively with other spatial policy objectives such as transport, nature, and agriculture (Van Buuren, Edelenbos, et al., 2010; Wiering & Driessen, 2001; Wiering & Immink, 2006). This trend towards area-oriented planning can be observed in other fields as well, such as transport infrastructure planning (Heeres, Tillema, & Arts, 2012).

The proliferation of area-oriented planning is visible in the Dutch € 2.362 billion policy program 'Room for the River' (Rijke et al., 2012). In this program, Rijkswaterstaat¹, provinces, municipalities, and regional

¹ Rijkswaterstaat is the executive agency of the Dutch Ministry of Infrastructure and the Environment. It is responsible for the design, construction, management, and maintenance of the main infrastructure facilities, including the waterway network and systems (Rijkswaterstaat, 2012).

water authorities (i.e., water boards) are cooperating in the implementation of 34 projects (Ministerie van Infrastructuur en Milieu, Ministerie van Economische Zaken, & Ministerie van Binnenlandse Zaken en Koninkrijksrelaties, 2016; Ruimte voor de Rivier, 2016c). The objective of the policy program is twofold: first, the accommodation of higher flood levels, i.e., water safety, and second, improving the spatial quality of the riverine areas. Although the program's midterm evaluations concluded that this dual objective proved effective in terms of the achievement of integrated solutions that address both water safety and spatial quality (Hulsker et al., 2011; Van Twist et al., 2011), the evaluations also stressed that the projects still had to be implemented. Currently, the program is close to completion. As part of its final evaluation, this paper presents the evaluation of the program's instruments that were deployed to achieve spatial quality. Given the program's status as an international frontrunner in integrated planning and water management (Zevenbergen et al., 2013), this evaluation bears relevance to the international academic community as well.

The program's dual objective can be seen as the incarnation of the area-oriented planning approach in Dutch flood risk management. Whereas recent research on area-oriented planning has indicated that the approach is taking root (Heeres, 2017), scholars have also warned that it is demanding and easily abandoned when policymakers are confronted with the high (transaction) costs that come with it (Hijdra, 2017). Generally, when complexity in spatial planning increases – e.g., in terms of multiple objectives and the inter-sectoral and inter-organizational cooperation required to achieve those – under time and budget pressures, the tendency to simplify and revert to old routines increases (Salet, Bertolini, & Giezen, 2013; Verweij, Teisman, & Gerrits, 2017). This was also reflected upon in the midterm evaluation of the Room for the River program: “the water safety objective is strongly supported and it is endorsed by the national politicians, but the spatial quality objective is generally seen increasingly as a luxury that is costly and mainly focused on new nature in the river areas, whereas simultaneously budgets are cut on new nature in other areas” (Van Twist et al., 2011, p. 15).¹ Therefore, this paper has two aims: (1) to assess the extent to which the Room for the River program has been able to achieve the spatial quality objective, and (2) to identify the conditions that explain this.

To these aims, we collected archival and survey data and analyzed it using Qualitative Comparative Analysis (QCA) (Rihoux & Ragin, 2009; Schneider & Wagemann, 2012). Specifically, we applied QCA in its capacity as a method to evaluate the program theory of Room for the River (cf. Varone, Rihoux, & Marx, 2006). QCA has recently been introduced in the fields of spatial planning (Verweij et al., 2013) and water management (e.g., Huntjens et al., 2011). QCA is well-suited to comparatively analyze a medium-n of cases and to identify combinations of conditions for explaining a certain outcome of interest. Moreover, QCA systematizes and formalizes the comparative process, thereby increasing the rigor and transparency of the comparison.

This paper is further structured as follows. In the next section, the background of the Room for the River program is provided, including results of its midterm evaluations (Section 2). In Section 3, the program theory is elaborated, focusing on the program's instruments that were deployed to achieve spatial quality. Next, the data and method are explained in Section 4. The analysis and results of the QCA are presented in Section 5. In Section 6, conclusions are drawn and the results are discussed.

2 THE ‘ROOM FOR THE RIVER’ PROGRAM

2.1 BACKGROUND OF THE PROGRAM

After a flooding and two near-dike breaches in 1993 and 1995, the Dutch national government decided to increase the flood safety levels of the country's main rivers: the Rhine, the Meuse, and their branches including the Waal and the IJssel (see Zevenbergen et al., 2013). Figure 1 provides an overview of the rivers and their average discharges. The expected increase in river discharges, partly due to climate change, caused a shift in focus from dike reinforcements towards creating room for the rivers. This was accompanied by a growing awareness of the economic, ecological, and landscape value of the river areas, resulting in an increasing focus on spatial quality. This led to the introduction of the Room for the River program (Ruimte voor de Rivier, 2007).

¹ This quote is translated from Dutch.

Figure 1: Map of the partition of Rhine and Meuse water among the various branches of their delta 2000-2011 (source: Maximilian Dörrbecker, Wikipedia)

The program was given a legal basis with the so-called 'Spatial Planning Key Decision' (in Dutch: Planologische Kernbeslissing; PKB) in 2007 (Ruimte voor de Rivier, 2007). The PKB enabled the government to formulate an integrated policy approach on the level of a whole river area, so as to take into account the different spatial functions and processes within it conjunctively (Ruimte voor de Rivier, 2007). The PKB is structured around two objectives. The first objective is to improve the protection of the river basins against floods. Specifically, the aim is to accomplish a minimum discharge capability of 16,000 m³/s for the Rhine at Lobith. The required discharge from the Rhine into the IJssel is 250 m³/s (Ruimte voor de Rivier, 2007). The PKB's secondary objective is to improve the spatial quality in the river areas. Following the so-called 'National Spatial Strategy' (in Dutch: Nota Ruimte) (see Priemus, 2007), the Room for the River program aims to maintain the unique character of the particular river basin, focusing on ecological, cultural-historical, economical, and aesthetic values (Ruimte voor de Rivier, 2007). The program has a budget of € 2.362 billion (Ministerie van Infrastructuur en Milieu et al., 2016) and consists of 34 projects. In the program, these projects are coined 'measures' and they can be found along the river Rhine and the Rhine's branches the Waal, IJssel, and Nederrijn. This is shown in Figure 2 (Ruimte voor de Rivier, 2016c). The measures include, amongst others, floodplain excavations, dike relocations, and 'depoldering' (Ruimte voor de Rivier, 2007, 2016a), as shown in Figure 3. Currently, 26 projects have been completed (Ruimte voor de Rivier, 2016a).

Figure 2: The measures (projects) in the 'Room for the River' program (source: Ruimte voor de Rivier, 2016c)

The program is coordinated by the 'Program Directorate Room for the River' (in Dutch: Programma Directie Ruimte voor de Rivier; PDR), which is part of Rijkswaterstaat.3 Within the PDR, the 'Cluster

Spatial Quality' (in Dutch: Cluster Ruimtelijke Kwaliteit; Cluster RK) is responsible for the coordination of the program's second objective, focusing on directing, facilitating, and monitoring the different projects in achieving spatial quality. The Cluster is supported by the so-called 'Quality Team' (Q-team), which has an advisory role (Collignon-Havinga et al., 2009; Klijn et al., 2013).

The program followed a decentralized approach: the individual projects are managed by various appointed governmental bodies. These include municipalities, provinces, water boards, and Rijkswaterstaat. Each individual project is developed in a planning phase and a realization phase. The Cluster RK and the Q-team visit and advise the projects during both phases. The Cluster RK furthermore assesses the projects at key moments in their development, i.e., after the development of a design that marks the end of the planning phase and at the end of the realization phase (Collignon-Havinga et al., 2009; Feddes & Hinz, 2013).

How we are making room for the river

Figure 3: The different types of measures in the 'Room for the River' program (source: Ruimte voor de Rivier, 2016b)

2.2 PREVIOUS EVALUATIONS OF THE PROGRAM

During the implementation of the Room for the River program, several midterm evaluations were conducted, focusing on how spatial quality was included in the different projects. In 2011, Van Twist et al. (2011) evaluated the program's general progress regarding the PKB-objectives, also giving attention to the instruments used to achieve them. They concluded that, in general, the involved persons were satisfied with the multi-level organizational structure of the program, where the central and strategical steering of the PDR was combined with the decentral implementation of projects. Swift implementation was enabled by taking account of future project phases, appointing the Q-team, and by the facilitating role of the PDR. Furthermore, the combination of binding administrative agreements with informal meetings supported projects in remaining on track.

In addition to the general evaluation by Van Twist et al. (2011), Hulsker and colleagues (2011) specifically reviewed the planning phase and its results regarding spatial quality. The decentralized implementation of the projects accommodated an integrated approach in which water safety and spatial quality were combined, although the evaluators were critical on the extent to which this integration was sufficiently captured in the administrative agreements. Ensuring spatial quality was facilitated by combining formal and informal instruments, focusing on both the content and the process of the projects. Instrumental was the development of an integral design created by an interdisciplinary team, with an important role for the landscape architect. The design is a content- focused instrument, which received less public resistance

when local stakeholders were involved in its development process. It was further concluded that the project-based implementation approach might have decreased the coherence between the projects on the program level of the whole river area.

The third midterm evaluation focused on the realization phase (Feddes & Hinz, 2013). It was found that achieving spatial quality was subject to various frictions, inter alia in translating the design and spatial quality requirements into realization contracts, especially so when the implementing agency also created parts of the design. It was further concluded that designers and landscape architects can play an important role after the planning phase in safeguarding spatial quality during implementation. It was finally observed that the design was legally secured, binding the implementer to the spatial quality requirements. Instead of focusing on the legal requirements, though, the Cluster RK often applied a more informal strategy for safeguarding spatial quality where they tried to communicate the integral meaning and value of the projects.

3 THE PROGRAM THEORY OF 'ROOM FOR THE RIVER'

Public programs or policies are based on (often implicit) assumptions about the outcome to be achieved by the policy and the conditions and actions required to that end (Varone et al., 2006). A policy or program, such as Room for the River, can be understood as a theory in the sense that:

"...It describes a cause-and-effect sequence in which certain program activities (administrative outputs) are the instigating causes and the social benefits (policy outcomes) are the effects that they eventually produce. (...) The model of causality of a public policy is always a normative representation of the 'operation' of society and the State. Proof of its validity comes through implementing and evaluating the effects of public policies" (Varone et al., 2006, p. 219).

Program theory evaluation is a form of realistic evaluation (Astbury & Leeuw, 2010; Blamey & Mackenzie, 2007; Pattyn & Verweij, 2014). In realistic evaluation, policy programs are presented as CMO-configurations: a program consists of Mechanisms (M) which are intended to produce an Outcome of interest (O) in a certain Context (C). In the present evaluation, we apply QCA as a method for realistic evaluation (cf. Befani, Ledermann, & Sager, 2007; Befani & Sager, 2006). This requires that the program theory is operationalized in terms of an Outcome (Section 3.1) and C/M-conditions (Section 3.2) that potentially produce this outcome. In the present evaluation, the instruments deployed by the Room for the River program represent the M-conditions.

3.1 OUTCOME: SPATIAL QUALITY

In the Room for the River program, spatial quality is defined in three dimensions: use value, experience value, and future value (Ruimte voor de Rivier, 2015; Terra Incognita, Bureau Strooming, SAB, & Alterra, 2009).¹ Use value refers to the utility, efficiency, and effectiveness of a physical structure and its surrounding space, experience value refers to the perception and experience of it, and future value refers to the robustness and sustainability of the structures and the space (Hooimeijer, Kroon, & Luttik, 2001). This conceptual triplet is derived from ancient Roman author and architect Vitruvius, who said that structures should exhibit three qualities; they should be useful (*utilitas*), beautiful (*venustas*), and solid or robust (*firmitas*) (Hooimeijer et al., 2001). In the program, area- oriented planning has been an important point of departure to increase spatial quality along these dimensions. That is, by integrating water safety with other spatial policy objectives including economy, nature, and recreation, the use, experience, and future values are believed to increase (Ruimte voor de Rivier, 2015). The 'Vitruvius Triplet' was translated by the Q-team into the coherence between hydraulic effectiveness, ecological robustness, and cultural meaning and aesthetics (see Klijn et al., 2013).

The spatial quality was assessed by the PDR at two moments in the projects: spatial quality at the end of the planning phase – which we abbreviate in this paper as SQ_PLAN – and spatial quality at the end of the realization phase for the PKB-objective as a whole – which we abbreviate in this paper as SQ_PKB (see

¹ In Dutch: gebruikskwaliteit, belevingskwaliteit, and toekomstkwaliteit.

also Table 3). For the planning phase, the spatial quality is expressed in the design of the spatial plan, i.e., the quality of the design. This was assessed in the program in terms of sufficiency (see Table 3). For the realization phase, the spatial quality is found in the “concrete result” of a project (Klijn et al., 2013, p. 291), that is, whether the intended plan was realized. It concerns the relative improvement of spatial quality compared to the baseline situation prior to the initiation of the program (see Table 3).

Various instruments were deployed in order to achieve spatial quality. These instruments were deployed in a certain project context. Together, the instruments and context are, in QCA-terms, the ‘explanatory conditions’ for spatial quality. Figure 4 provides an overview of the conditions in the Room for the River program theory. The conditions are further elaborated in Section 3.2 and subsequently operationalized in Section 4 (Table 3).

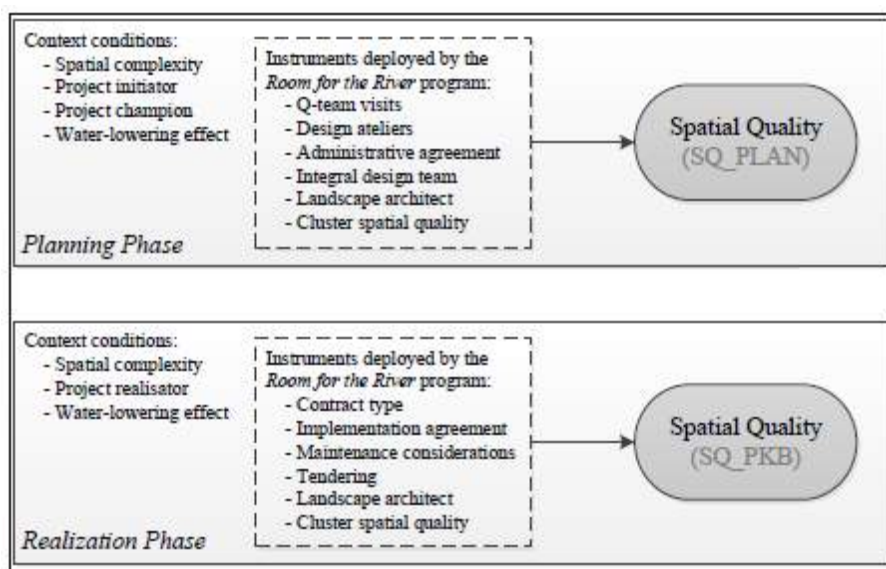

Figure 4: The explanatory conditions in the ‘Room for the River’ program

3.2 EXPLANATORY CONDITIONS: CONTEXT AND INSTRUMENTS

The projects in the Room for the River program are developed in two phases: a planning phase and a realization phase. In the planning phase, spatial designs are developed that are aimed at improving spatial quality. In the realization phase, the spatial designs are implemented and the projects are constructed. In the two phases, different instruments are deployed, under different context conditions, to achieve these goals. Because spatial quality achieved in the designs might not materialize in the “concrete result” (Klijn et al., 2013, p. 291) of the project at the end of the realization phase, separate analyses will be conducted for the two phases (see Section 5).

3.2.1 EXPLANATORY CONDITIONS: PLANNING PHASE

The first context condition is Spatial Complexity (PLAN_SC). In area-oriented planning approaches, spatial quality is expected to increase through the integration of different spatial policy objectives related to, e.g., water, transport, nature, and agriculture (Heeres, 2017; Van Buuren, Edelenbos, et al., 2010). This integration is expected to lead to synergy gains. However, it also increases complexity as different spatial functions may impose different, possibly conflicting, demands on the spatial design (Verweij et al., 2013). Hence, integrated approaches are more complex than solutions that only involve the embedding of flood risk measures in the existing landscape (Rijkswaterstaat, 2007). In the Room for the River program, three general types of measures are distinguished (see Figure 3):

- Technical measures, e.g., strengthening dikes.
- Measures within the banks, i.e., the ‘wet area’ inside the banks that is not protected against floods (in Dutch: buitendijkse maatregelen), e.g., lowering floodplains.

- Measures beyond the banks, i.e., measures in the area behind the dike where residential areas can be found (in Dutch: binnendijkse maatregelen), e.g., dike relocation and depoldering.

Whereas the measures within the banks generally have a more technical nature, the measures beyond the banks mostly concern complex integrated area-based planning projects, involving multiple spatial functions and often implying the realization of a new water concept. In fact, the measures beyond the banks represent the reorientation from the water control strategy towards the water accommodation strategy (Alberts, 2009). For instance, the dike relocation at Lent, as part of the project *Ruimte voor de Waal* (see Appendix 1), involved the demolition of existing structures including dwellings (Projectgroep Dijkteruglegging Lent, 2007). This increased the impact and complexity of the project in terms of, inter alia, political sensitivity, but it also offered opportunities to redesign the area in such a way that spatial functions are conjunctively addressed, allowing for synergy gains (Van Buuren, Edelenbos, et al., 2010; Verweij et al., 2013). In the present evaluation, we take the type of measure as a proxy for spatial complexity (see Table 3). The expectation is that more complex measures lead to higher spatial quality in the spatial design.

The second context condition is the Project Initiator (PLAN_INI). The project initiator is formally responsible for completing the project (Rijke et al., 2012). In the Netherlands, a broad distinction is made between general, territorial governments (in Dutch: algemeen bestuur) and functional governments (in Dutch: functioneel bestuur) (Raad voor het Openbaar Bestuur, 2015). The projects in the program can be initiated by either of them. The functional governments concern the water authority at the local level (i.e., a so-called water board) or Rijkswaterstaat at the national level, both of which have a strong orientation towards water safety. The mandate of Rijkswaterstaat, though still primarily focused on water safety, is somewhat broader since it is involved in determining the goals of Dutch water management on the strategic level (Ministerie van Infrastructuur en Milieu & Ministerie van Economische Zaken, 2015). The general, territorial governments in the program concern the local municipalities and the regional provinces. The municipal and provincial governments are charged with integrally balancing the various interests, of which water safety is only one amongst others (Unie van Waterschappen et al., 2011). Whereas the municipal governments are concerned with balancing interests on the local level, the provinces act as ‘area directors’ (in Dutch: gebiedsregisseur) on the regional level, allowing them to orchestrate the integration of different spatial policy objectives on the level of a whole river area. Hence, the expectation is that when general, territorial governments – and provinces above all – are initiating the project, this will contribute to higher spatial quality.

The third context condition is the Project Champion (PLAN_CHAMP). Project champions are persons outside the initiator’s project team, who “do not have to do what they do to aid the project; they go well beyond their expected and traditional job responsibilities” (Pinto & Slevin, 1989). They can be local champions (e.g., Raadgever et al., 2016), such as an alderman who encourages a project team to increase spatial quality, or persons from national governments such as Rijkswaterstaat. Project champions can play an important role in successfully developing projects (Pinto & Slevin, 1989). In the United Kingdom, for example, project champions were key in the promotion of environmental restoration in river management (Adams, Perrow, & Carpenter, 2004) or sustainable urban drainage systems (Alexander et al., 2016). Traditionally, water management is a technocratic discipline dominated by engineers (Van Buuren, Edelenbos, et al., 2010); a project champion who focuses on spatial design considerations can then, so is the expectation, contribute to higher spatial quality, as opposed to a situation where a project champion is absent.

The fourth context condition is the Water Lowering Effect of a project (PLAN_WAT). This condition reflects the program’s water safety ambitions. Water safety can be understood as the primary and initial objective of the program and spatial quality is the secondary objective that conditions the measures that are chosen in the project (*Ruimte voor de Rivier*, 2007; Groenendijk et al., 2016; Hulsker et al., 2011). Initially, as prescribed in the PKB (see Section 2.1), the projects were required to develop three alternative measures: one with a maximum water lowering effect, one with a maximum improvement of spatial quality, and one with the lowest costs (Hulsker et al., 2011). This, however, was at odds with the integrated approach of combining the objectives of water safety and spatial quality. In the end, most projects have been able to develop a more integrated approach in their planning phases after all; the midterm evaluation showed that this resulted in effective solutions with spatial quality (Hulsker et al., 2011). Altogether, as the two objectives are supposed to be interlinked, the expectation is that the water lowering effect of a project can

influence the degree of spatial quality realized in the spatial plans, but whether this influence was actually positive or negative is not clear. The QCA-analysis can shed light on this.

The first instrument condition is the influence of the Q-Team (PLAN_QT). The Q-team is an advisory team, which was chaired by the State Advisor for the Landscape (in Dutch: Rijksadviseur voor het Landschap), and which consisted of five specialists with different disciplinary backgrounds: landscape architecture, urban planning, river engineering, ecology, and physical geography (Klijn et al., 2013; Q-team, 2012). The Q-team was tasked with producing “independent recommendation[s] on enhancing spatial quality; i.e., on request as well as unasked, and unrestrained by formal governmental or institutional opinions. (...). The Q-team was commissioned to coach the planners and designers, to peer review the designs and plans, and to report to the minister about the spatial quality achieved” (Klijn et al., 2013, p. 289). Of particular importance were the visits of the team to the projects, where suggestions to further improve spatial quality were provided (Collignon-Havinga et al., 2009). Previous evaluations of the Room for the River program indicated that the Q-team contributed to increasing the spatial quality in the project designs (Hulsker et al., 2011; Van Twist et al., 2011).

However, for the planning phase, no explicit expectation can be formulated about the relationship between the number of visits by the team and spatial quality (SQ_PLAN). That is, on the one hand, more visits are supposed to increase spatial quality. On the other hand, however, a high number of visits could also indicate an initial low spatial quality requiring additional efforts of the Q-team. The QCA-analysis may shed light on which is actually the case. For the realization phase (SQ_PKB), for which spatial quality is measured relatively (see Table 3), the expectation is that a higher number of visits increases spatial quality.

The second instrument condition is the Design Ateliers (PLAN_DES). Design ateliers are a form of interactive planning where different participants co-design the projects (Heeres et al., 2016). Such co-design processes have the potential to improve the quality of spatial planning outcomes (see e.g., Enserink & Monnikhof, 2003; Lamers et al., 2010). In general, stakeholder involvement can also reduce resistance to the project and increase stakeholder satisfaction (see e.g., Roth & Warner, 2007; Verweij et al., 2013). Design ateliers can play an important role in this (Van Buuren, Klijn, & Edelenbos, 2012). The previous midterm evaluation of the Room for the River program in fact indicated that sufficient and timely participation in several projects “has led to a significantly better spatial quality” (Hulsker et al., 2011, p. 47; see also Van Twist et al., 2011, p. 14).¹ In the abovementioned Ruimte voor de Waal project, for instance, the design process resulted in “improvements to the quality of the area as well as to the technical functioning of the channel in terms of water safety” (Heeres et al., 2016, p. 424). A recent evaluation of three major water safety policy programs in the Netherlands (including Room for the River) likewise concluded that (local) participation can increase support and improve spatial planning designs (Groenendijk et al., 2016). The expectation thus is that when the design ateliers were well-timed and sufficiently organized, this resulted in a more interactive, inclusive process approach where local knowledge is mobilized leading to improved spatial quality.

The third instrument condition is the concretization of the spatial quality objective in an Administrative Agreement between the public partners (PLAN_AGR). The “administrative agreements about the division of tasks and cooperation must ensure rapid and effective implementation of measures” (Van Stokkom, Smits, & Leuven, 2005, p. 81). The partners include Rijkswaterstaat and, normally, regional governments such as water boards and provinces. For each project, an administrative agreement is signed which outlines the framework within which the project is to be developed. This agreement is an important instrument for securing spatial quality in the projects (Collignon-Havinga et al., 2009). Previous midterm evaluations indicated that the dual objective of the Room for the River program was recorded well in the project agreements, but the integrated approach towards achieving the dual objective was not (Hulsker et al., 2011; Van Twist et al., 2011). As said above, initially the projects were required by the PKB to develop three alternative measures, which was at odds with the integrated approach of combining the objectives of water safety and spatial quality. Hence, the expectation is that it is not so much important that the spatial quality objective is stated in the agreement; what is important is that spatial quality is specified beyond the general notion that it has to be taken into account. If this is the case, this is expected to provide extra impetus for achieving spatial quality.

¹ This quote is translated from Dutch.

The fourth instrument condition is the Integral Design Team (PLAN_INT). Traditionally, designers are the top-down mechanistic experts in charge of developing a technical design focused on the optimization of territorial solutions, which in the present study would imply a strong focus on optimizing the design for water safety; the designers work rather independently and become ad-hoc involved only when their expertise is required at a certain stage in the planning process (Heeres et al., 2016; Vos, 2014). However, creative and innovative solutions are more likely to emerge in multidisciplinary teams where various competences, knowledge, and skills are combined through interactive processes of knowledge sharing and creation (Alves et al., 2007; Fong, 2003). The multidisciplinary is important because “spaces and places do not have singular identities but can have multiple identities” (Heeres et al., 2016, p. 413), including those related to water safety and spatial quality, and multidisciplinary allows for observing and combining these in an integrated planning solution (Heeres et al., 2016; Klijn et al., 2013). In the Room for the River program, multiple disciplines were involved in the design for the projects. The integral design team consists of a spatial designer, a river expert, an ecologist, a geologist, a cultural historian, and a cost expert (Hulsker et al., 2011). The expectation is that, by involving multiple disciplines, synergies can be achieved resulting in designs with higher spatial quality.

The fifth instrument condition is the role of the Landscape Architect (PLAN_LAND). The landscape architect played an important role in the planning phase (Klijn et al., 2013). From a more traditional architectural perspective, “spatial design is often understood as a product, with a strong focus on the content of plans and designs” (Heeres et al., 2016, p. 412). In that capacity, landscape architects in Room for the River are involved in creating a specific spatial quality plan. In these instances, the landscape architect was only asked by the project team to deliver a specific product rather autonomously. From a spatial planning perspective, designs are “a way to manage a wider creative process of arriving at decisions and action” (Heeres et al., 2016, p. 412). In that capacity, the landscape architects, as members of the integral design teams and with input from the design ateliers (cf. Van Buuren et al., 2012), were not only asked to deliver a product but played an important role in the interactive planning process as well. The expectation is that the landscape architect in the second capacity can contribute more to the realization of spatial quality in the planning phase.

The sixth instrument condition is the involvement of the Cluster Spatial Quality of the Room for the River program in the individual projects (PLAN_CLUS). The Cluster RK is responsible for the coordination of the program’s spatial quality objective and facilitates the projects herein. To this purpose, it uses various resources, ranging from more formal assessments of plans to a helpdesk where projects can go to for questions and assistance (Collignon-Havinga et al., 2009; Hulsker et al., 2011). The midterm evaluation indicated that the Cluster’s role as a facilitator, “without sitting on the designer’s seat”, was influential in achieving spatial quality (Hulsker et al., 2011).¹ The expectation thus is that the more closely the Cluster was involved in a project as facilitator and guardian of spatial quality, the higher the achieved quality of the project design.

3.2.2 EXPLANATORY CONDITIONS: REALIZATION PHASE

The three context conditions in the realization phase are Spatial Complexity (REAL_SC), the Project Realisator (REAL_REA), and the Water Lowering Effect of a project (REAL_WAT). For these conditions, the same program theory applies as detailed for spatial complexity, project initiator, and water lowering effect in the planning phase (see Section 3.2.1). Regarding spatial complexity, the chosen measures designed in the planning phase (e.g., strengthening dikes, lowering floodplains, or depoldering) are also the measures that have actually been realized at the end of the realization phase (see Tables 1 and 2). However, with respect to the project realisator, i.e., the administrative body responsible for acquiring permits, tendering, and the contracting of private parties for the realization of the plans (Rijke et al., 2012), this is not necessarily the same administrative body that also acted as project initiator.² Regarding the water lowering effect, it should be mentioned that the actual effect realized at the end of the realization phase can be higher or lower than the prospected effect at the end of the planning phase.³

¹ This quote is translated from Dutch.

² Compare the data for the conditions PLAN_INI and REAL_REA in Tables 1 and 2.

³ Compare the data for the conditions PLAN_WAT and REAL_WAT in Tables 1 and 2.

The first instrument condition is the Contract Type (REAL_CON). Contracts are formal arrangements that legally bind the implementation actors. In the Room for the River program, four contract types have been used (Feddes & Hinz, 2013):

- Traditional 'RAW' contracts, where the project realisor specifies the technical design including the "underlying calculation of materials needed and construction time" (Lenferink, Tillema, & Arts, 2013, p. 617) to be implemented by the private contractor (Feddes & Hinz, 2013).
- Engineering and Construct (E&C) contracts, where the contractor is now responsible for working out the technical and logistic details of the design (Feddes & Hinz, 2013; Lenferink et al., 2013).
- Design and Construct (D&C) contracts, where the contractor becomes responsible for the whole design and not just the working out of the details of the design (Feddes & Hinz, 2013; Lenferink et al., 2013).
- Plan, Design, and Construct (PD&C) contracts, where the private contractor, in addition to the design, is now also responsible for the spatial planning process (PIANOo & Unie van Waterschappen, 2016; Ruimte voor de Rivier, 2015).

The PD&C contract is the most inclusive one in that it integrates different phases of project construction into a single agreement. It allows the private contractor to (partially) parallelize and align the processes of planning, design, and construction, allowing for faster, more efficient, and higher quality project realization (Lenferink et al., 2013; PIANOo & Unie van Waterschappen, 2016; Ruimte voor de Rivier, 2015). In terms of inclusiveness, the D&C contract comes second, followed by the E&C, and the RAW contracts. The expectation is that the more inclusive the contract, the higher the quality that can be achieved.

The second instrument condition is the concretization of the spatial quality objective in a Realization Agreement between public partners (REAL_AGR). The realization agreement outlines the framework of ambitions, collaboration, and responsibilities within which the project is to be implemented. Specifically, it describes "the quality, budget, time, market approach, project control methodology, and risk distribution between [the] region and Rijkswaterstaat" (Rijke et al., 2012, p. 374). This agreement is an important instrument for the successful implementation of the program's projects (Groenendijk et al., 2016). The midterm evaluation of the realization phase identified as a success factor the degree to which the spatial quality objective is specified in this agreement beyond a general reference to the design resulting from the planning phase (the so-called 'SNIP-3' document), that is, whether or not a "brief description is included of what is essential for the spatial quality of the plan" (Feddes & Hinz, 2013, p. 34).¹ The expectation thus is that it is not so much important whether the spatial quality objective is referred to or not in the realization agreement (because it always is); what is important is that spatial quality is specified beyond the general notion that it is important. If this is the case, this is expected to provide extra impetus for achieving spatial quality as it implies that spatial quality is more strongly safeguarded.

The third instrument condition is the inclusion of Maintenance Considerations in the realization phase (REAL_MAIN). The early consideration of maintenance issues is important to prevent high maintenance costs after project realization (e.g., Van Vuren, Paarlberg, & Havinga, 2015), to ensure that plans are realistic and that designs are of a good quality (Rijke et al., 2012), and to ensure that spatial quality after project realization conforms to the preferences of the local communities – e.g., some people prefer wilder landscapes whilst others prefer well-kept landscapes (Buijs, 2009). In the Room for the River program, maintenance plans were drafted in the so-called 'SNIP-3' document (see above) at the end of the planning phase, which plays an important role in anchoring spatial quality (Van Herk et al., 2015). In some projects, these plans were updated during the realization phase to ensure the continued focus on spatial quality. The previous midterm evaluation indicated that spatial quality is easily lost out of sight, especially when projects transition from one phase to the next (Hulsker et al., 2011). It is therefore expected that when the maintenance plans were updated during the realization phase, this contributes to a better safeguarding of spatial quality.

The fourth instrument condition is the extent to which spatial quality was included in the Tender Document of the project (REAL_TEN). The tendering documents play an important role in anchoring spatial quality (Feddes & Hinz, 2013; Van Herk et al., 2015). In the projects, "spatial quality was a selection criterion in tender procedures and was detailed in accompanying ambition documents" (Van Herk et al., 2015, p. 93). However, the projects differed in the extent to which this criterion was anchored in the tender documents

¹ This quote is translated from Dutch.

(Feddes & Hinz, 2013). For instance, the extent to which private contractors are rewarded for including spatial quality depends on whether or not spatial quality was a so-called 'EMVI-criterion' (Ruimte voor de Rivier, 2015), i.e., 'Economically Most Advantageous Tender' (see Rijkswaterstaat, 2016).¹ In the project Ruimte voor de Waal, for instance, spatial quality was an EMVI-criterion (see Table 2), which made it an explicit requirement for the project design by the private contractor (Brouwer, Schouten, & De Vries, 2017). The expectation is that when spatial quality requirements are more explicitly included in the documents, this has a positive influence on the realization of spatial quality.

The fifth and sixth instrument conditions are the role of the Landscape Architect (REAL_LAND) and the role of the Cluster Spatial Quality (REAL_CLUS). For these conditions, the same program theory applies as detailed for the equivalent PLAN_LAND and PLAN_CLUS conditions in the planning phase (see Section 3.2.1). For both conditions, the expectation is that closer involvement of the landscape architect or Cluster RK implies that spatial design consideration are taken into account more during the realization phase. This is of particular importance since in the realization phase, financial considerations often start to dominate the process (see e.g., Verweij, 2015a).

4 DATA AND METHOD

The QCA-approach for this evaluation consisted of five steps (Rihoux & Lobe, 2009; e.g., Verweij, 2015b). In the first step, the cases were selected. The Room for the River program consists of 34 projects. Currently, 26 projects have been completed; 8 projects are still being realized (Ruimte voor de Rivier, 2016a). Initially, 23 projects were selected for this evaluation because these were completed and because Rijkswaterstaat had archival data available for these projects (see Appendix 1). For the final analyses, only those projects were selected for which data on all the conditions were available (see Tables 1 and 2). This means that for the planning phase, 20 projects were analyzed (see Table 1) and for the realization phase, 19 projects were analyzed (see Table 2).²

In the second step, the data were collected. The first data source is written documents from the archives of the Room for the River program. The data were collected by one of the researchers, in the period September 2016 to April 2017. Access to the data was provided by Rijkswaterstaat. The collection of the data and the construction of the conditions (see Section 3) evolved iteratively (cf. Berg-Schlösser et al., 2009; Rihoux & Lobe, 2009). That is, the collection of documents and the regular meetings between the researchers and the program managers from Rijkswaterstaat who commissioned the present evaluation, progressively provided insights into the program's theory, and this, in turn, informed the researchers about the data that needed to be collected. The second data source is questionnaires. Since the archives did not provide data on all the conditions, a small survey was sent out to project managers to collect additional data. The relevant project managers for the survey were identified by the program managers from Rijkswaterstaat. The survey data were collected in the period April 2017 to May 2017. After all the data were collected, two data matrices were constructed: one for the planning phase (i.e., Table 1) and one for the realization phase (i.e., Table 2).

In the third step, the cases were calibrated. Calibration is the process of transforming the raw project data from the data matrices (Tables 1 and 2) into scores between 0 and 1 by clustering similar cases per condition (Ragin, 2008; Schneider & Wagemann, 2012). Basically, per condition, cases are ranked from high to low, after which (program) theory and/or cluster analysis are/is used to group the cases: projects within a group are considered similar cases and projects from different groups are considered dissimilar cases. The quantification that occurs here serves to ensure a systematic and transparent comparison. For instance, spatial quality after the realization phase (SQ_PKB) was assessed by the 'Program Directorate Room for the River' with a five-value scale: worsened, not improved, barely improved, improved, and strongly improved (see Table 3). This five-value scale was calibrated into 0.0 (worsened), 0.3 (not improved), 0.6 (barely improved), 0.8 (improved), and 1.0 (strongly improved). The middle value of 'barely

¹ In Dutch: Economisch Meest Voordelige Inschrijving.

² Note that the projects' names as publicly known and communicated about (see Ministerie van Infrastructuur en Milieu, Ministerie van Economische Zaken, & Ministerie van Binnenlandse Zaken en Koninkrijksrelaties, 2016; Ruimte voor de Rivier, 2016a) are sometimes different from how they are internally administrated, managed, and monitored by Rijkswaterstaat (see Appendix 1). For the case names of the projects, we adopted the names as internally administrated by Rijkswaterstaat. For clarification purposes, we also provide the project labels under which they are known in the public policy documents (see Appendix 1).

improved' is calibrated as 0.6, expressing that it is still more positive than negative, but not overly positive.¹ The calibration rules for all the conditions are provided in Table 3. The calibration process resulted in the calibrated data matrix provided as Appendix 2.

In the fourth step, the calibrated data matrix (Appendix 2) was transformed into so-called 'truth tables' (see Appendices 3 to 6) using the QCA-package in R (Duşa, 2007, 2016). A truth table sorts the empirical cases over the logically possible configurations; it is the core of the QCA-analysis (Schneider & Wagemann, 2012). Each row in the truth table presents one logically possible configuration. The number of truth table rows is determined by the formula 2^k , where k stands for the number of explanatory conditions included in the analysis. First, each of the 20 or 19 cases was assigned to one of the truth table rows. Then, based on the cases in the truth table row, the truth table row was assigned a score on the outcome. Each row in the truth table can thus be read as a statement of sufficiency: when the row was associated with spatial quality, that particular configuration was considered sufficient for the outcome to be produced (Rihoux & Ragin, 2009; Schneider & Wagemann, 2012).

The fifth step was the truth table minimization using the QCA-package in R (Duşa, 2007, 2016). This involved the pairwise comparison of truth table rows that agreed on the outcome and differed in but one of their conditions (Schneider & Wagemann, 2012). The condition in which two truth table rows differed was logically redundant: whether the condition was present (i.e., a score of 1.0) or absent (i.e., a score of 0.0), the outcome was produced irrespectively. This fifth step resulted in minimized solution formulae that show which combinations of necessary and/or sufficient conditions are related to the achievement of spatial quality (see Tables 4 to 7 in Section 5). A condition is necessary when it has to be present for the outcome to occur. Necessary conditions are identified in a separate analysis prior to the truth table minimization (Schneider & Wagemann, 2010).

It should be stated that the third to fifth steps have been an iterative process, as is normal in QCA (Berg-Schlosser et al., 2009; Rihoux & Lobe, 2009). For instance, if a truth table contained cases that agreed on all the conditions (i.e., are in the same truth table row) but contradicted on the outcome, then this so-called 'contradiction' had to be resolved (Schneider & Wagemann, 2010). This was done by, inter alia, recalibration, removing conditions from the analysis, or excluding the contradictions from the truth table minimization (Rihoux & De Meur, 2009).

Case label	Conditions:										Outcome
	Context Conditions				Instrument Conditions

Table 2: The data matrix for the realization phase
Marked cells indicate missing data. Cases with missing data are not included in the analyses.

Condition	Raw data	Our calibration	Explanation of our calibration
Outcomes			
Spatial Quality in planning phase (SQ_PLAN)	Archival data; data from assessments by the PDR. No standardized scale was used by the PDR to assess the spatial quality after the planning phase. The data are largely qualitative descriptions.	0.0 = insufficient 1.0 = sufficient	In the absence of a standardized scale and because the data are qualitative, we only broadly distinguished between two categories: insufficient and sufficient. Cases were coded as 0.0 or 1.0 based on the PDR's qualitative descriptions.
Spatial Quality in realization phase (SQ_REAL)	Archival data; data from assessments by the PDR. The PDR assessed the overall spatial quality (of the projects as a whole) relative to the PKB-objective. The PDR used a five-value qualitative scale: strongly improved, improved, barely improved, not improved, and worsened (see Table 2).	0.0 = worsened 0.3 = not improved 0.6 = barely improved 0.8 = improved 1.0 = strongly improved	The cross-over point is set at 0.6, because 'barely improved' still indicates a positive score, but not overly positive. Because the program's objective is to increase spatial quality, the category 'not improved' is calibrated into a negative score. Projects that were assessed with scores in-between two qualitative categories (i.e., Cases 03, 08, and 20; see Table 2) were calibrated by averaging their quantitative scores (see Appendix 2).
Conditions planning phase			
Spatial Complexity (PLAN_SC)	Archival data; data from the public website of the program. ¹⁴ Nine different measures can be found across the projects. These are shown in Figure 3.	0.0 = technical measures 0.7 = <i>huidendijkse</i> measures 1.0 = <i>hennendijkse</i> measures	The measures beyond the banks (in Dutch: <i>hennendijkse maatregelen</i>) are most complex and calibrated as 1.0. These measures are: depoldering, dike relocation, and high water channel. Technical measures do not concern the involvement of multiple spatial functions and are hence calibrated as 0.0. These measures are: dike strengthening, lowering groynes/ <i>langsduimen</i> , removing obstacles, and deepening summer beds. The measures within the banks (in Dutch: <i>huidendijkse maatregelen</i>) are more complex than technical measures, because different functions become involved, but less complex and less politically sensitive than the measures beyond the banks, because usually the current water safety concept is maintained. They are calibrated as 0.7. These measures are: lowering floodplains and water retention. In the case of multiple measures (i.e., Case 04; see e.g., Table 1), the most complex measure is used for the calibration.
Project Initiator (PLAN_INIT)	Archival data; data from the administrative agreements. In principle, only one administrative body acts as the project initiator. There are four possible initiators: water boards, Rijkswaterstaat, municipalities, and provinces.	0.0 = water boards 0.3 = Rijkswaterstaat 0.7 = municipality 1.0 = province	General territorial governments (i.e., provinces and municipalities) are more area-oriented than functional governments (i.e., Rijkswaterstaat and water boards). Provinces are most area-oriented and hence calibrated as 1.0. The functional governments are less area-oriented. Of the two, the water boards have a narrower mandate than Rijkswaterstaat and are hence calibrated as 0.0. In one project there were two initiators (i.e., Case 16; see Table 1); this case was calibrated by averaging the quantitative scores.
Project Champion (PLAN_CHAMP)	Survey data. Project managers were asked whether or not a project champion was present and how important s/he was (on a scale from 1 to 10) for achieving spatial quality in the spatial design.	0.0 = project champion absent 1.0 = project champion present	When a project champion was present, this is calibrated as 1.0. When a project champion was absent, or when project managers indicated that the champion was unimportant (score of 5/10 or lower), this is calibrated as 0.0.
Water Lowering Effect (PLAN_WAT)	Archival data; data from the 'Spatial Planning Key Decision' document. The water lowering effect is measured as the aimed water level reduction in centimeters.	0.0 = ≤ 8.8 cm 0.3 = 8.9 to 17.5 cm 0.7 = 17.6 to 26.2 cm 1.0 = ≥ 26.3 cm	In the absence of a standardized scale or theoretical expectations about the water lowering effect on spatial quality, we performed a cluster analysis with the Touloum threshold-setter (Cronquist, 2016). When multiple values were provided within a project for different locations (Cases 02, 03, 08, and 16; see Table 1), the water lowering effect was averaged. We tested for multiple thresholds, indicating 17.5 cm as the cross-over point.
Q-Team (PLAN_QT)	Archival data; data from Q-team reports. The condition is measured as the number of visits as documented in the final report of the Q-team after the planning phase.	0.0 = ≤ 3.5 visits 0.3 = 3.6 to 6 visits 0.7 = 6.1 to 8.5 visits 1.0 = ≥ 8.6 visits	In the absence of a standardized scale of precise theoretical expectations on the number of visits for achieving high spatial quality, we performed a cluster analysis with the Touloum threshold-setter (Cronquist, 2016). When a single visit included multiple projects (i.e., Cases 02&03, Cases 09-12, and Cases 14&15; see Table 1), these visits were counted for each project. We tested multiple thresholds, indicating 6 visits as the cross-over point. Because the cross-over point indicates ambiguity, ¹⁵ Case 06 and 16 with 6 visits were further examined using the survey data; this showed that the importance of the Q-team for spatial quality was low in Case 06 (score of 1/10) and high in Case 16 (score of 7/10). Hence, Case 06 is calibrated as 0.3 and Case 16 as 0.7.
Design Ateliers (PLAN_DES)	Survey data. Project managers were asked how many design ateliers were organized, how important the ateliers were (on a scale from 1 to 10) for achieving spatial quality in the spatial design, and whether or not the number of organized ateliers was sufficient.	0.0 = no ateliers 0.7 = few but sufficient (1 to 3) ateliers 1.0 = many ateliers (≥ 6)	In the absence of any standard or minimum number of design ateliers and because the project managers used various and different ways (both qualitative and quantitative) in response to the survey question, we broadly distinguished between three categories. For projects with only a few ateliers (1 to 3 ateliers) the project managers consistently indicated this was 'sufficient' and these cases are hence calibrated above the cross-over point. Cases with 6 or more ateliers are calibrated as 1.0 because there is a clear gap between cases with 3 ateliers and cases with 6 ateliers.
Administrative Agreement (PLAN_AGR)	Archival data; data from the administrative agreements. In the administrative agreement, the spatial quality objective was either generally mentioned ('no' specification) or it was specified.	0.0 = general notion spatial quality 1.0 = spatial quality specified	Cases where spatial quality was concretely specified are calibrated as 1.0. Cases where spatial quality was only generally referenced are calibrated as 0.0.
Integral Design Team (PLAN_INT)	Survey data. Project managers were asked which of the six disciplines were involved in the projects.	N/A	Because in all the projects (nearly) all disciplines were involved, this condition is not included in the analysis (no variation).
Landscape Architect (PLAN_LAND)	Survey data. Project managers were asked in which way the landscape architect was involved in the project, how satisfied they were with the architect's involvement, and the extent to which they were an integral member of the project team (on a scale from 1 to 10, where 10 indicates maximal process-oriented involvement).	0.0 = landscape architect focused on planning product 1.0 = landscape architect focused on planning process	Because some respondents (Cases 20 and 23) assessed the role of the landscape architect qualitatively (see Table 1), we only broadly distinguish between two categories. Cases with a score of 6.0 or higher are calibrated as 1.0 because this indicates that the role of the landscape architect is more process-oriented than product-oriented. The respondents' answers to other (qualitative) questions on the role of the landscape architect further corroborate this calibration.
Cluster Spatial Quality (PLAN_CLUS)	Survey data. Project managers were asked about the extent to which the Cluster Spatial Quality contributed to achieving spatial quality in the spatial design (on a scale from 1 to 10). Additional questions focused on the specific instruments.	0.0 = limited or negative contribution 1.0 = important	Because some respondents (Cases 06, 09-12, and 20) provided a qualitative assessment of the involvement of the Cluster Spatial Quality (see Table 1), we only broadly distinguish between two categories. Cases where the involvement was scored 6.0 or higher are calibrated as 1.0, because this
	deployed by the Cluster, i.e., the formal assessments, the helpdesk function, and the spatial quality manual.	contribution	indicates an important contribution rather than a limited or negative contribution of the Cluster. Data for Case 08 were ambiguous (see Table 1), but the case was calibrated as 0.0 as the data did not clearly indicate importance of the Cluster.
Conditions realization phase			
Spatial Complexity (REAL_SC)	Same as PLAN_SC (see above).	Same as the calibration of PLAN_SC	Same as the calibration of PLAN_SC (see above).
Project Realizator (REAL_REAL)	Archival data; data from the realization agreements. In principle, only one administrative body acts as the project realizator. There are four possible realizers: water boards, Rijkswaterstaat, municipalities, and provinces.	Same as the calibration of PLAN_INIT	Same as the calibration of PLAN_INIT (see above).
Water Lowering Effect (REAL_WAT)	Archival data; data from the 'Room for the River' progress report (2016a). The water lowering effect is measured as the realized water level reduction in centimeters.	0.0 = ≤ 10.2 cm 0.3 = 10.3 to 20.5 cm 0.7 = 20.6 to 30.8 cm 1.0 = ≥ 30.9 cm	Similar to the calibration of REAL_WAT. When multiple values were provided within a project for different locations (Cases 02, 03, 06, and 16; see Table 2), the water lowering effect was averaged. We tested for multiple thresholds, indicating 20.5 cm as the cross-over point.

Contract Type (REAL_CON)	Archival data. Four different contract types are present amongst the projects: RAW, E&C, D&C, and PD&C.	0.0 = RAW 0.3 = E&C 0.7 = D&C 1.0 = PD&C	The PD&C contract is the most inclusive one, followed by the D&C contract. These are hence calibrated as 1.0 and 0.7, respectively. The E&C and RAW contracts are non-inclusive contract types, but the first is more inclusive than the latter. They are hence calibrated 0.3 and 0.0, respectively.
Realization Agreement (REAL_AGR)	Archival data; data from the realization agreements. In the realization agreements, the spatial quality objective was either generally mentioned ('no' specification) or it was specified.	Same as the calibration of PLAN_AGR	Same as the calibration of PLAN_AGR (see above). This condition was in the end not included in the analysis.
Maintenance Considerations (REAL_MADN)	Survey data. Project managers were asked whether or not the maintenance plan of the project was updated during the realization phase.	0.0 = maintenance plan not updated 1.0 = maintenance plan updated	When the maintenance plan of a project was updated, this is calibrated as 1.0. When this was not the case, this is calibrated as 0.0.
Tender Document (REAL_TEN)	Survey data. Project managers were asked to what extent spatial quality was included in the tender documents as criterion and whether or not it was an <i>EMVI</i> -criterion.	0.0 = not included 1.0 = included	When spatial quality was explicitly included in the tender documents as an <i>EMVI</i> -criterion – or as a hard requirement otherwise – this is calibrated as 1.0. When this was not the case, this is calibrated as 0.0.
Landscape Architect (REAL_LAND)	Survey data. Project managers were asked whether or not and in which way the landscape architect was involved in the project, how strong his/her influence was in achieving spatial quality (on a scale from 1 to 10), and how good his/her relationship was with the private contractor (on a scale from 1 to 10).	0.0 = no or limited involvement of landscape architect 1.0 = close or influential involvement of landscape architect	Because respondents varied in the way they answered the survey questions, we only broadly distinguish between two categories. When the landscape architect was not involved or only in a very limited way ('at distance' from the project), this is calibrated as 0.0. When the landscape architect was closely involved or influential, this is calibrated as 1.0.
Cluster Spatial	Survey data. Project managers were asked about how close the	0.0 = not involved.	Because some respondents (Cases 14, 15, and 20) provided qualitative
Quality (REAL_CLUS)	Cluster Spatial Quality was involved with the project and the extent to which the Cluster was influential in achieving spatial quality in the project (both on a scale from 1 to 10). Additional questions focused on the specific instruments deployed by the cluster, i.e., the helpdesk function and the program-wide meetings.	not influential 1.0 = involved, influential	assessments (see Table 2), we only broadly distinguished between two categories. The quantitative scores on involvement and influence were averaged. Subsequently, cases with a score of 6.0 or higher are calibrated as 1.0.

Table 3: Operationalization and calibration of the outcomes and the conditions

5 ANALYSIS AND RESULTS

We first tested for necessity and found no single necessary conditions. The condition with the highest consistency score for necessity was the absence of REAL_WAT for the realization phase, with a consistency of 0.806. This does not meet the required 0.9 consistency threshold for necessity (Schneider & Wagemann, 2012). For the analysis of sufficiency, we performed truth table analyses.

For the planning phase, the truth table would consist of a total of 512 (i.e., 29) logically possible configurations, because there are in total 9 conditions (4 context and 5 instrument conditions). For the realization phase, the truth table would consist of 256 (i.e., 28) logically possible configurations, because there are in total 8 conditions (3 context and 5 instrument conditions). Because only a medium-n of cases is available for the analyses of both phases, this produced many so-called logical remainders. A logical remainder is a truth table row for which no or not enough empirical evidence (i.e., cases) is at hand (Schneider & Wagemann, 2012). These logical remainders are problematic, because the analysis of the truth table entails the pairwise comparison of truth table rows that agree on the outcome and differ in only one of their conditions (with many empty truth table rows, a very few pairwise comparisons can be made). Therefore, we performed separate analyses for the context and instrument conditions, for the planning and realization phases respectively. We thus conducted four analyses. The results of the analyses are shown in Tables 4 to 7.

For all the analyses, we have provided the complex solutions, as shown in the tables below. In the tables, the black circles (•) represent the presence of a condition and white circles (O) represent the negation of a condition. Blank cells represent irrelevant (redundant) conditions. In generating the complex solutions, no logical remainders are included in the minimization of the truth tables (Schneider & Wagemann, 2012). Hence, we have not made any assumptions about logical remainders, i.e., empty truth table rows.

For the analysis of the context conditions in the planning phase (Table 4), the truth table consists of 16 configurations (24) of which 9 are empirically present (see Appendix 3). The consistency cut-off point ("Incl.") was set at 0.538 because all the cases in Configurations 16, 13, and 15 have the outcome (see Appendix 3); the other configurations are either contradictions or only cover cases that have the non-outcome.

For the analysis of the instrument conditions in the planning phase (Table 5), the truth table consists of 32 configurations (25) of which 12 are empirically present (see Appendix 4). The consistency cut-off point ("Incl.") was set at 0.769 because all the cases in Configurations 15, 16, 32, and 2 have the outcome (see Appendix 4); the other configurations are either contradictions or only cover cases that have the non-outcome.

For the analysis of the context conditions in the realization phase (Table 6), the truth table consists of 8 configurations (23) of which 5 are empirically present (see Appendix 5). The consistency cut-off point

("Incl.") was set at 0.846 because all the configurations have the outcome. Only one configuration constitutes a contradiction (i.e., Configuration 1) that is caused by Case 03. This is only a minor contradiction, as this case has a raw score on the outcome of 0.4. In that case, the spatial quality was improved locally, but it had worsened regionally (see Table 2). Moreover, the other 4 cases in that configuration do have the outcome. Hence, all configurations were included in the minimization of the truth table.

For the analysis of the instrument conditions in the realization phase (Table 7), the truth table consists of 32 configurations (25) of which 12 are empirically present (see Appendix 6). The consistency cut-off point ("Incl.") was set at 0.850 because all configurations have the outcome; only Configuration 18 constitutes a contradiction, which is caused by Case 03, and was hence not included in the minimization of the truth table.

6 CONCLUSIONS AND DISCUSSION

At the outset of this paper, we aimed (1) to assess the extent to which the Room for the River program has been able to achieve the spatial quality objective, and (2) to identify the necessary and/or sufficient conditions for achieving spatial quality. In Section 6.1 we address the first aim and in Section 6.2 we address the second aim.

6.1 HAS THE ROOM FOR THE RIVER PROGRAM ACHIEVED ITS SPATIAL QUALITY OBJECTIVE?

Using the advisory reports of the Q-team as input, the projects were assessed by the Cluster Spatial Quality of the Room for the River program after their planning phase and after their realization phase for the PKB-objective as a whole. The results indicate that at the end of the planning phase, 12 of the 23 projects (52%) still performed insufficiently (see Table 1). It should be noted that for the four Nederrijn projects (Cases 09-12), no clear final assessments were available. However, the available qualitative reports listed various improvement measures¹, indicating that the spatial quality was still insufficient at that point.

For the evaluation of the program's performance after the realization phase relative to the PKB-objective as a whole, the projects were assessed on a five-value scale (see Table 3). With the exception perhaps of the project Langsdammen Waal (Case 03) where, although it was improved locally, spatial quality had worsened on the regional level, there are no projects where spatial quality has worsened or not improved compared to the situation before the Room for the River program (see Table 2). Of the 23 projects, 20 projects have seen an 'improvement' (3 projects; 13%) or 'strong improvement' (17 projects; 74%). Whereas the previous midterm assessments of the program (Feddes & Hinz, 2013; Hulsker et al., 2011; Rijke et al., 2012; Van Twist et al., 2011) concluded that the Room for the River program enhanced spatial quality, the present evaluation confirms this on the basis of a larger set of projects that now also have been finalized.

6.2 WHAT ARE THE NECESSARY/SUFFICIENT CONDITIONS FOR ACHIEVING SPATIAL QUALITY?

Based on the results of the analysis, we conclude that there are no necessary conditions for achieving spatial quality. Based on the truth table analyses, we also conclude that there are no sufficient conditions, i.e., conditions that by themselves produce spatial quality: as can be observed from the results (Tables 4 to 7), at least two conditions are required to produce spatial quality in any situation. In the remainder of this section, we will discuss the results.

6.2.1 PLANNING PHASE: IMPORTANT CONDITIONS AND EFFECTIVE STRATEGIES

Table 4 indicates that two configurations of context conditions can explain the achievement of a high spatial quality: a high spatial complexity together with a territorial government as project initiator and the presence of a project champion (Path 1), or a high spatial complexity, again with a territorial government as project initiator but now combined with a low water lowering effect (Path 2). These results indicate the importance of a high Spatial Complexity – i.e., measures within the banks (i.e., lowering floodplains and water retention) or measures beyond the banks (i.e., depoldering, dike relocation, and high water channels) – for the achievement of spatial quality in the planning phase (see Table 4). This is in support of the theoretical expectation that a higher complexity may allow different spatial functions to be addressed conjunctively, resulting in synergy gains (Heeres, 2017; Van Buuren, Edelenbos, et al., 2010; Verweij et al., 2013). The results also indicate the importance of having territorial governments – i.e., a municipality or a province – as Project Initiators. This is in support of the expectation that territorial governments may be more concerned with balancing different spatial interests than water boards or Rijkswaterstaat, who are more focused on realizing the water safety objective (see Section 3.2). Interestingly, the results show that

¹ These are the so-called 'Besluit Nederrijn3: Toets Ruimtelijke Kwaliteit' documents.

a Project Champion can indeed play an important role in achieving spatial quality (Path 1) – which is in support of the theoretical expectations (see Section 3.2) – but is not required by necessity (Path 2). In fact, in projects with a low Water Lowering Effect (Path 2), a project champion may help in promoting spatial quality (Case 16), but is not required (Cases 13 and 17). This could indicate that in projects with a low water lowering effect, there may be more latitude, that is, room to develop spatial solutions that maximize spatial quality, thus making the presence of a project champion who fights for safeguarding or promoting spatial quality less needed.

Table 5 shows that spatial quality can be achieved by means of three configurations of instrument conditions. The first strategy is to basically go ‘all-in’ and to maximize efforts to increase spatial quality (Path 3). Through a close involvement of the Cluster Spatial Quality, the landscape architect, and the Q-team¹, and through organizing design ateliers, and specifying spatial quality in the administrative agreement, a high spatial quality can indeed be achieved. We coin this strategy the going-all-in strategy. This strategy is effective, but may be less efficient in terms of the resources (time, budget, personnel) it requires. The results indicate two other strategies that are also effective and may be more efficient as well. In the second strategy, the efforts are focused on the role of the Cluster Spatial Quality. The Cluster operates on the program management level. Hence, we coin this strategy the program-as-guardian strategy (Path 1). Through a strong involvement of the Cluster Spatial Quality as a facilitator and guardian of spatial quality, less resources need to be devoted to the Q-team, design ateliers, spatial quality in the administrative agreement, and the involvement of the landscape architect. An alternative explanation of this strategy is that, when little energy is devoted in a project to achieving spatial quality by means of those project management instruments, it is required that the Cluster Spatial Quality steps in to steer the project in the right direction. The third strategy mirrors the program-as-guardian strategy. We coin it the project-as-driver strategy (Path 2). Here, the steering by the program management is less dominant, and the motor block for achieving spatial quality is formed by the projects themselves through organizing many design ateliers, explicating spatial quality in the administrative agreement, and a close involvement of the landscape architect.

It will be interesting to further study the types of program management present in the different strategies (cf. Buijs & Edelenbos, 2012; Busscher, 2014; Van Buuren, Buijs, & Teisman, 2010). Although this will require additional qualitative data collection and analysis, the program-as-guardian strategy seems to imply a type of program management in which the program monitors the projects and intervenes in the projects’ scopes when progress towards spatial quality is hampered. Conversely, in the project-as-driver strategy, a much more facilitative type of program management seems to be in place. In this strategy, the role of the program does not seem to be to enforce projects to achieve spatial quality, but to enable and empower them in their ambitions to strive for spatial quality. Finally, the going-all-in strategy seems to implicate a program management that is pro-actively stimulating the projects to work towards improving spatial quality. In this strategy, the program seems to function more as a partner. Hence, it seems to adopt a type of program management somewhere in between the other two strategy types.

The results further indicate that with regard to the Q-Team, a low number of visits seems to be associated with the achievement of a high spatial quality (Paths 1 and 2). Whereas the previous evaluations of the Room for the River program indicated that the Q-team contributed to increasing the spatial quality in the project designs (Hulsker et al., 2011; Van Twist et al., 2011), we argued that a high number of visits could actually indicate a low initial spatial quality requiring additional efforts of the Q-team (see Section 3.2.1). Inversely, our results indicate that a low number of visits may be associated with a high initial spatial quality. Although follow-up analyses into the relationship between the involvement of the Q-team and the spatial quality in the realization phase are required to shed more light on this finding, our analysis does show – in contrast to the previous midterm evaluations that were based on fewer cases with less formalized research approaches – that many Q-team visits does not necessarily lead to high spatial quality in the planning phase. The Q-team does not seem to have been the core instrument around which the success of the Room for the River program revolved. In fact, our results indicate that the Design Ateliers, the Administrative Agreement, and the Landscape Architect are more important instruments for achieving spatial quality (Paths 2 and 3). The importance of these project-level instruments was also found in the previous midterm evaluations (Hulsker et al., 2011; Van Twist et al., 2011). It is also in support of

¹ The condition PLAN_QT is indicated as redundant in Path 3. However, the raw data show that for both Cases 04 and 16, the Q-team paid six visits to the projects, which is very close the cross-over point (see Table 3). Moreover, in Case 16, the survey respondent also assessed the Q-team’s role in the planning phase as important with a score of 7/10 (see Table 3).

theoretical expectations about the importance of co-design and the involvement of multiple disciplines in spatial planning for achieving spatial quality (Heeres et al., 2016). Finally, the results indicate that the Cluster Spatial Quality indeed played an important role in achieving spatial quality in the planning phase (Paths 1 and 3), but that its efforts are less so required in projects where strong efforts are practiced by the projects themselves (i.e., the project-as-driver strategy; Path 2).

6.2.2 REALIZATION PHASE: IMPORTANT CONDITIONS AND EFFECTIVE STRATEGIES

Table 6 indicates multiple configurations of context conditions that can explain the achievement of a high final spatial quality: a functional government as project realisor combined with a low water lowering effect (Path 1), a territorial government as project realisor combined with a high water lowering effect (Path 2), a high spatial complexity combined with a functional government as project realisor (Path 3), or a high spatial complexity combined with a high water lowering effect (Path 4). The results indicate the variety of contexts within which projects have been realized; there do not seem to be unambiguous relationships between any of the conditions and the achievement of spatial quality. In different configurations, Spatial Complexity, the Project Realisor, and the Water Lowering Effect contribute to the achievement of spatial quality in different capacities. Interestingly though, projects with a low water lowering effect are often realized by a functional government (Path 1 and also partly Path 3) – i.e., a water board or Rijkswaterstaat – whereas projects with a high water lowering effect are often realized by territorial governments (Path 2 and also partly Path 4) – i.e., a municipality of province. This is perhaps counterintuitive in the sense that it may have had been expected that the functional governments are more focused on water safety and would hence be the realisor for the projects with a high water lowering effect (see Section 3.2). Although this would require additional qualitative data collection and analysis, an explanation of this result could actually be that in those projects where a high water lowering effect has been achieved, the goals of the water board or Rijkswaterstaat with respect to water safety have been satisfied, after which a municipality or province was then given the lead (or provided the latitude), within the scope set by the water lowering effect, to maximize spatial quality.

Table 7 shows that spatial quality in the realization phase can be achieved by means of nine configurations of instrument conditions. These results are puzzling in the sense that the sheer number of possible paths towards the achievement of spatial quality makes it difficult to draw clear and unambiguous conclusions. Taking into account as well the somewhat puzzling results of the analysis of the context conditions, a follow-up analysis may be required in which the number of conditions is decreased and in which the context and instrument conditions are combined in one comparative analysis (see Schneider & Wagemann, 2006). Still, some observations can be made. First of all, Paths 4 and 8 may again be characterized as going-all-in strategies. In those cases, the strategy was to nearly go 'all-in' and to maximize efforts to increase spatial quality with respect to deploying 4 out of 5 instruments. In particular, inclusive contracts – i.e., D&C or PD&C contracts – combined with the specification of spatial quality in the realization agreement and the updating of the maintenance plans, supplemented with either the close involvement of the landscape architect (Path 4) or of the Cluster Spatial Quality (Path 8), proved effective for achieving spatial quality. At least equally interesting is that in three cases, represented by Path 5, quite the opposite seems to have occurred. There, contracts were non-inclusive, spatial quality was not included in the tender documents as a criterion, and the landscape architect and the Cluster were not closely involved. With this strategy, which we tentatively coin the remote strategy, spatial quality was hardly safeguarded, but it was achieved nevertheless. This path perhaps points towards the importance of organizing for spatial quality in the planning phase, laying the fertile ground for the realization phase. It might be that in these cases, spatial quality had already been so well developed – both in terms of content (what is to be realized) as well as process (how will this be realized) – that spatial quality did not need specific attention anymore in the realization phase of the project. It also points to deviant cases that may be selected for further case study research (see Schneider & Rohlfing, 2016). The remaining configurations (Paths 1-3, Path 6-7, and Path 9) showcase various particular strategies. Two subsets of strategies may be distinguished here. One is what may be coined the limited-steering strategy. This strategy is represented by Paths 1, 2, and 6. In those cases, there was limited steering on the safeguarding or promotion of spatial quality and the steering that occurred was focused on updating the maintenance plans to ensure that maintenance considerations would be taken into account early in the realization process. The other strategy, represented by the remaining Paths 3, 7, and 9, may be coined the contract-steering strategy. In those cases, steering was less limited (although not 'all-in') and focused on

the specification of spatial quality in tender documents and/or on project realization through inclusive contracts.

The results indicate that the various instruments applied in the Room for the River program's realization phase – i.e., Contract Type, the inclusion of Maintenance Considerations, the Tender Documents, the involvement of the Landscape Architect, and the involvement of the Cluster Spatial Quality – have contributed to achievement of spatial quality in different capacities. First, more inclusive contracts can indeed contribute to higher spatial quality (cf. Lenferink et al., 2013) but not necessarily so. Follow-up analyses may further delve into the question of whether and in what ways more inclusive contracts indeed stimulate a higher spatial quality. That is, it may well be that it is not so much the contract type per se that is important, but rather what is actually determined as the project scope in the contract, and the way contracts are managed and implemented (Verweij, 2015a). Second and likewise, updating the maintenance plans and the specification of spatial quality in the tender documents can indeed contribute to spatial quality, but much will depend on how the private contractors actually act upon what was agreed in the plans and documents. With respect to the involvement of the landscape architect, thirdly, it is noticeable that his/her role has been less prominent compared to the planning phase. In the planning phase, s/he was closely involved in fourteen of the projects and in the realization phase in just five of the projects. Finally, the results indicate that the Cluster Spatial Quality can indeed play an important role in achieving spatial quality in the realization phase (in particular Paths 8 and 9), but that its efforts are generally not required (Paths 2-4) or that projects even benefit from a remote role of the Cluster (Paths 1, 5-7).

6.3 IN CONCLUSION

Based on the results of the analysis, we have concluded that the Room for the River program has been successful in achieving spatial quality and we have identified different strategies that are effective to that end. On the basis of our research, we can also conclude that integrated area-based planning is indeed further developing in the Dutch river policy domain. In contrast to previous warnings about high transaction costs (Hijdra, 2017) and the tendency to simplify and revert to old routines when complexity increases (Salet et al., 2013; Verweij et al., 2017), we observed that in the context of the Room for the River program, spatial quality is no longer only seen “as a luxury that is costly and mainly focused on new nature in the river areas” (Van Twist et al., 2011, p. 15). Rather, various practical strategies have been developed for realizing the secondary objective of the Room for the River program in concrete water planning practices. Given the program's status as an international frontrunner in integrated planning and water management (Zevenbergen et al., 2013), these strategies may prove valuable for planning practices in other countries as well. As a final remark, we note that the analyses presented in this paper will be supplemented by in-depth case studies of projects that are representative of many of the paths identified through the QCA. These case studies will enable us to delve deeper into the intricate relationships between the conditions that constitute the paths towards the achievement of spatial quality.

ID 1643 | EVALUATING NEIGHBOURHOOD SUSTAINABILITY ASSESSMENT METHODOLOGY AS A LOCALIZATION TOOL FOR GLOBAL TARGETS

Simge Özdal-Oktay¹

¹Cankaya University

sozdal@cankaya.edu.tr

ABSTRACT: In the last two decades, global sustainable development concerns have become more decisive on urban development strategies. This new order also created two major sub-processes. While the first one mainly covers the interpretation of major scale sustainable development goals into sub-national strategies, the second one includes providing a successful sustainability monitoring mechanism in coherence with national obligations for global sustainability targets. Sustainability assessment methodology (SAM) have gained importance by standing at the intersection of these two sub-processes. SAM tools have been developed in different geographies for monitoring and supporting sustainable development principles throughout the design and implementation processes. In this context, this paper presents a framework for the utilization of these methodologies in the localization of global sustainability targets through the case of Turkey. For this purpose, criteria of eight existing Neighbourhood Sustainability Assessment Tools (NSAT) were compared for obtaining a combined matrix. In the first stage, provided

matrix evaluated in terms of global sustainability targets and Turkey's national obligations. For providing a local framework and discussing the coherence between national sustainable development strategies and sectoral priorities. Analytic Hierarchy Process (AHP) was used as a simple prioritization technique and applied to decision makers, academicians, activists and project executors from different sectors. The applied framework brings a new perspective and provides an initial guideline for localization of global sustainability goals over discussions on Turkey.

Keywords: Sustainability Assessment, Neighbourhood, Sustainable Development, Localization

1 INTRODUCTION

In parallel with the increasing importance of sustainable development policies, the need for process monitoring and assessment increased as well, and the most important impact of this approach on communities is the recognition of the essential role of local values and policies in the implementation process of global principles. Combining these two approaches in 2002 Local Action 21, nations focused on the effective implementation of sustainability including monitoring and continuity. In this process, it is crucial to choose the right tools that compatible with local characteristics (Kusakabe, 2013). New generation sustainability assessment methodologies (SAMs) provide alternative options that applicable in different geographies and offer a comprehensive tool at various scales for assessing sustainability performance from decision making to post-implementation periods (Adinyira, Oteng-seifah, & Adjei-kumi, 2007; Alberti, 1996; Bebbington, 2009; Böhringer & Jochem, 2007; Shen, Jorge Ochoa, Shah, & Zhang, 2010). Due to these performance-based methodologies mainly used at building scale neighbourhood sustainability assessment methodologies (NSAMs) have taken its place among the common assessment tools. On the other hand, applications of urban scale SAMs could not spread as much as other methodologies as a result of the long and multi-staged assessment process.

Several studies have been conducted with the emphasis on the role of neighbourhoods in the comprehensive sustainable development process. Besides the common debates on negative impacts of urban sprawl, and rapid suburbanization, weakened ties in community – environment relations, and context-specific development practices became the new focus of these studies, and NSAMs were evaluated as a tool to reinforce the links between society, environment, economy, and politics by defining local obligations and necessities for sustainability through measurable criteria sets (Adinyira et al., 2007; Berardi, 2013; Pope, Annandale, & Morrison-Saunders, 2004; Sharifi & Murayama, 2014). Recently, neighbourhood scale methodologies spread to the world as an effective tool for comprehensive sustainability (Sharifi, 2013). In this study, eight successful examples of NSAMs introduced and comparatively analysed according to the context-specific criteria sets.

2 NEIGHBOURHOOD SUSTAINABILITY ASSESSMENT

Although global sustainability goals successfully degraded to the neighbourhood design principles, applications are hardly achieving the long-term targets, mainly as a result of different local characteristics. NSAMs propose a new local methodology for translating these principles to a measurable, context-specific criteria sets. Each of these methodologies involves a set of category, criteria, and indicator. Each criterion has a specific weighting that given in accordance with local priorities (Oktay & Özdede, 2009; Poveda & Lipsett, 2011; Sharifi, 2013). In the last decade, many countries developed a national assessment methodology at the neighbourhood scale. LEED-ND (United States) BREEAM Communities (United Kingdom), DGNB NUD (Germany), Green Star Communities (Australia), QSAS Neighbourhoods (Qatar), Pearl Communities (Abu Dhabi) and Green Mark for Districts (Singapore) provide the best examples by representing different geographies from the earth.

LEED-ND

US Green Building Council (USGBC) developed the first green building assessment methodology in 1998 for new constructions. With LEED-ND assessment tool, USGBC aimed to certify newly developing mixed-use neighbourhoods and single-use infill for promoting sustainable, healthy, affordable and environment-

friendly settlements. Many professionals and entrepreneurs from various sectors included in the development process of the methodology. New Urbanism and Smart Growth as leading urban planning approaches in the US have reflected in the criteria sets along with the basic principles of existing LEED methodologies. The methodology covers 12 prerequisites, 44 criteria under 3 main, 1 additional and 1 bonus categories, which are Smart Location and Linkage (SLL), Neighbourhood Pattern and Design (NPD), Green Infrastructure and Buildings (GIB), Innovation and Design Process (IDP) and Regional Priority Credit (RPC). First, two of the three main categories promote urban design principles of the two leading approaches, such as housing and jobs proximity, compact development or transit facilities (CNU, NRDC, & USGBC, 2011).

BREEAM COMMUNITIES

Building Research Establishment Environmental Assessment Method (BREEAM) Communities has been introduced in 2011 for supporting design processes including decision-making and implementation. Although the methodology is partially adaptable to different contexts and spread to many parts of the world in a few years, United Kingdom territory defined as the main target for applications and criteria developed according to the local context of this territory (BRE Global Limited 2014).

Assessment process defined starting from the master planning, and it only covers new developments and renewal areas/brownfield developments. The methodology includes 41 criteria under 6 categories that Governance (GO), Social and Economic Wellbeing (SE), Resources and Energy (RE), Land use and Ecology (LE), Transport and Movement (TM) and Innovation (Inn) (BRE Global Limited, 2014).

CASBEE UD

CASBEE for Urban Development (CASBEE UD) requested by Urban Renaissance Headquarters and has been developed in 2006 by Japan Sustainable Building Consortium (JSBC) as against to global warming and the heat island effect. There are two approaches in the evaluation process, Environmental Quality in Urban Development (QUD) and Load Reduction in Urban Development (LRUD). QUD consists of 3 categories, QUD1 Natural Environment (microclimates and ecosystems), QUD2 Service functions for the designated area, and QUD3 Contribution to the local community (history, culture, scenery, and revitalization). These 3 categories later separated into 15 criteria and 35 sub-criteria. Similarly, the second approach, LRUD includes 3 main categories, LRUD1 Environmental impact on microclimates, facade, and landscape, LRUD2 Social infrastructure, and LRUD3 Management of the local environment. These categories later separated into 16 criteria and 43 sub-criteria (IBEC, 2007).

DGNB NUD

DGNB New Urban Districts (NUD) introduced by German Sustainable Building Council (DGNB) in 2011 for a comprehensive evaluation of environmental, and economic performance. The methodology developed with an efficient participation of the public and private sectors, academia, and entrepreneurs. The process provides both an assessment and a design tool for new developments primarily in Germany and Scandinavian countries (Anders, 2013; Mansfeldt, Pedersen, Sørensen, & Jensen, 2012). The methodology focuses on quality categories, Environmental Quality (ENV), Economic Quality (ECO), Sociocultural and Functional Quality (SOC), Technical Quality (TEC), and Process Quality (PRO). These categories later separated into 14 sub-categories and 45 criteria. Mix-use development defined as the basic requirement for all projects in the assessment process. Accordingly, the system defines minimum 10%, maximum 90% housing development for the site to be assessed (Anders, 2013).

GREEN STAR COMMUNITIES

Green Star Communities developed by Green Building Council of Australia (GBCA) in collaboration with different sectors and introduced in 2012 as a neighbourhood sustainability assessment methodology to provide a guideline for local administrations in line with the sustainable planning objective. In terms of similar climatic conditions, applications focus on new and infill developments in Australia, New Zealand,

and South Africa (GBCA & AECOM 2012). In the development process, the methodology has evaluated in terms of the national framework and as a rating tool for providing a comprehensive approach. 6 main categories, which include “Governance, Design, Liveability, Economic Prosperity, Environment, and Innovation”, were determined in accordance with the national development strategies, “enhancing livability, economic prosperity, environmental responsibility, design excellence and strong governance”. These categories later separated into 38 criteria. In the certification process, a great importance has given to the commitment to the Green Star Communities’ principles. Accordingly, certified neighbourhoods have to achieve necessary criteria and receive a certificate once in every five years (GBCA & AECOM, 2012).

GSAS/QSAS NEIGHBOURHOODS

GSAS/QSAS Neighbourhoods developed by Global Sustainability Assessment System (GSAS) and Qatar Sustainability Assessment System (QSAS) developed by Gulf Organisation for Research and Development (GULF), for assessing the environmental performance of a project, testing building, and infrastructure system and ensuring project’s commitment to the smart growth and sustainable urban planning principles. The methodology developed along with the master plan and development plans and defined as applicable to both new developments and existing neighbourhoods. The main categories involve “urban connectivity, site, energy, water, material, and indoor environment”. The rating ratio defined from -1 to 3 (GSAS/QSAS Technical Committee & GORD, 2013).

PEARL COMMUNITY RATING SYSTEM (PCRS)

PCRS developed by Estimada in 2010 in the context of The United Arab Emirates along with the Vision 2030, which requires at least minimum level certification for all new developments. The methodology developed for rating development projects through the lifecycle. The main categories were identified as “integrated development process, natural systems, livable communities, precious water, resourceful energy, stewarding materials, and innovating practice”. These main categories were later separated into 64 criteria. The first stage of the assessment process “Pearl Design Rating” developed for increasing the vitality of real estate market. In the second stage, “Pearl Construction Rating” measures the improvement and the achievement of the project. The last stage defined as “Pearl Operational Rating” which can be applicable only the occupancy rate of the area reached to 80%, and two years after the application is completed (UPC & Estimada, 2010).

GREEN MARK FOR DISTRICTS

The NSAM developed by Building and Construction Authority (BCA) of Singapore in 2009 for ensuring and monitoring environmentally sensitive master planning. In parallel with the 2030 vision of the country, the main objective introduced as providing a new platform for participatory planning and future partnerships and leading high performance in sustainability. The main categories involve “energy efficiency, water management, material and waste management, environmental quality and protection, and green building and other green features”. These 5 categories later separated into 24 criteria. The highest importance has given to the environmental quality and protection category and the highest possible score for the area is limited with 185 points (BCA, 2013).

2.1 COMPARATIVE ANALYSIS OF EXISTING METHODOLOGIES

Previous studies reveal that the main target of these methods is to achieve globally accepted sustainability principles at local scales, on the other hand, the achievement depends on the localizing these principles in terms of local context (Berardi, 2013; Nguyen & Altan, 2011; Sharifi & Murayama, 2014). National strategies and geographical features are the main constituents of differences. Hence, their origin could be based on different planning approaches. For instance, CASBEE UD and BREEAM Communities are based on Urban Renaissance in UK and Japan, LEED ND, Green Star Communities and QSAS Neighbourhoods follows Smart Growth and New Urbanism principles in the USA. Accordingly, LEED ND emphasized urban design and physical improvement in the criteria sets, BREEAM Communities, CASBEE

UD and DGNB NUD focused on the social dimensions, such as equality in land use and participation. Australia, Qatar, Singapore and Abu Dhabi gave importance to climate and energy issues in Green Star Communities, QSAS Neighbourhoods, Green Mark for Districts and Pearl Communities as a result of their geographical position (Ozdal Oktay, 2015).

When the categories and criteria of all these methodologies compared in accordance with the overlaps, meaning resemblances, and differences in criteria and indicators, for a clear and integrated criteria set, the provided matrix constitute from 9 main categories and 64 criteria. The main categories include “location and site selection, natural environment protection, land use management and urban design, social integration and participation, sustainable building, sustainable infrastructure, economic integration, governance and innovation” (Ozdal Oktay 2015). Examination of NSAMs in accordance with defined categories and criteria reveals that most of the criteria related to “location and site selection” covered by LEED-ND in parallel with US’ national mitigation strategies on urban sprawl. The largest number of criteria related to natural environment included by the CASBEE UD. 16% of DGNB NUD criteria defined under the land use management and design category. BREAAAM Communities and Green Star Communities give great importance to social criteria. While LEED-ND focuses on sustainable building category, CASBEE UD promotes sustainable infrastructure in the assessment process. Along with the role of the central government in Abu Dhabi, Pearl assessment methodology included the highest number of criteria under the governance category. Innovation related criteria were not covered in CASBEE, DGNB, and QSAS. Each NSAM defined the size of the application according to different measures, such as population, the number of buildings or the area of the application site. While CASBEE and Green Mark defined no upper limits, QSAS Neighbourhoods doesn’t require both upper and lower limits for the application (see Table 1) (Ozdal Oktay, 2015).

Prioritization of defined categories and criteria is very important for emphasis of the local needs and the priorities and adaptability of the universal sustainability principles. It also allows for adaptation of existing methodologies into different local conditions, such as BREEAM Communities. In this framework, each category and criterion are assigned a weight according to the predetermined national standards (LEED), calculated impact values (DGNB), and expert opinions and evaluations (CASBEE, BREEAM, DGNB, Green Star, Pearl, and Green Mark). As values can be defined directly by the experts, several prioritization methodologies can be used, especially when the number of the participants is high. Analytic Hierarchy Process (AHP) is one of the most common methodologies by offering simple and effective evaluation process (Bhatt, Bhatt, & Patel, 2010; Rosa, 2013; Saaty, 1980, 2008).

3 FRAMEWORK DEVELOPMENT FOR TURKEY

Adapting an existing methodology or weighing categories and related criteria obtained from multiple selected SAMs in accordance with the local priorities of the application area is one of the widely accepted methods in developing a context-specific NSAM (Ozdal Oktay, 2015).

3.1 THE AHP METHODOLOGY

The Analytical Hierarchy Process (AHP) introduced by Thomas Saaty in 1980 for providing a simple, flexible and powerful tool for complex decision making and prioritization (Rosa, 2013; Saaty, 2008). The methodology enables to obtain the optimum results in a transparent and a relatively objective manner by including multiple category and sub-criteria, and reflecting both qualitative and quantitative factors (Saaty, 1980, 2008; VillarinhoRosa & Haddad, 2013). AHP provides an effective measurement for pairwise comparisons based on expert opinions and uses expert opinions to obtain a hierarchy (Saaty, 2008). To be able to structure the hierarchy AHP requires the definition of the problem, a collection of related data, and identification of alternatives, categories, and sub-criteria. (Saaty 1980; Saaty 2008; VillarinhoRosa & Haddad 2013). Once the comparison matrix has been built, the relative importance is calculated for each criterion according to 1 to 9 numerical scale (see Table 2), then the results are normalized by making the sum of the values on each column equal to 1, and averaging the values on each row (Saaty 1980).

Numerical Scale	Interpretation
1	Equally important
3	Slightly more important
5	More important
7	Strongly more important
9	Absolutely more important
2,4,6, and 8 are intermediate values	

Table 2 - Numerical scale for the relative importance

To combine individual evaluations in a group, final values are aggregated by calculation of the geometric mean. The result gives the global score of each category and criteria (Saaty 1980). The AHP incorporates the calculation of the Consistency Index (CI) and Consistency Ratio (CR) for calculation of the possible inconsistencies in the expert evaluations. CR value is obtained from the CI/RI equation. RI represents the Random Index when comparison values for each category and criterion are completely random. Accordingly, if CR value is smaller than 0.1, the results are considered as consistent and a reliable result can be expected from the AHP (Saaty 1980; Saaty 2008; Rosa 2013; Bhatt et al. 2010).

3.2 LOCALIZATION OF THE EXISTING NSA CATEGORIES THROUGH AHP

The government of Turkey committed to use Agenda 21 and Millennium Development Goals as a guideline for its national sustainable development process. In the 2014 development report, the biggest achievement was defined as the elimination of extreme poverty and improvement in the community health. On the other hand, improvements are still not enough for reducing the gender inequality, especially in education, and achieving the comprehensive sustainability. According to the national statistics, the inequality ratios are increasing each year. Since 1996, 7th Development Plan, sustainable development is the part of national strategies. However, the scope is extended in 2014 with the 10th Development Plan. In this context, for the first time sustainability was discussed separately in “liveable spaces and sustainable environment” chapter. Although there are several LEED and BREEAM certificated luxury housing projects in Turkey, there is no application at the neighbourhood scale. Additionally, since 2007 three national building SAM has been developed by Environment Friendly Green Building Association, Mimar Sinan Fine Arts University and Turkish Standards Institution. Nevertheless, none of these methodologies has been applied yet (Ozdal Oktay, 2015).

In order to establish a local, neighbourhood scale framework for Turkey, categories of eight successful NSAMs combined in a matrix, and afterward AHP principles tested on each of them. To be able to build the hierarchy the goal defined as Sustainable Neighbourhood Development and pairwise comparison matrices generated from the 9 categories obtained. In the data collection stage, questionnaire based on the AHP was sent to 23 institutions. Particular attention was paid to select participants from different regions of Turkey. 40 expert opinions were received from government institutions, the private sector, academia, and NGOs. Maximum CR value calculated as 0,0012 which is smaller than 0,1. Therefore, the results accepted as consistent and reliable. Pairwise comparisons applied to categories separately. The maximum normalized score calculated as 1,00, and this score received by two categories involving “location and site selection and natural environment protection”.

Goal: Sustainable neighbourhood Development	
Categories	Global Weights
Location and Site Selection	1,00
Natural Environment Protection	1,00
Land use Management and Design	0,69
Sustainable Infrastructure	0,69
Social Integration and Participation	0,65
Governance	0,50
Sustainable Building	0,50
Economic Integration	0,40
Innovation	0,24

Table 3 – Given Global Weights of the Existing Categories

As a result of the AHP questionnaire, the three sectors of four has given the highest priority to the “natural environment and protection” category. The private sector weighed the “location and site selection”

category at the highest level. On the contrary of other three sectors, the academia has evaluated land use management and design category at the 7th row. “Social integration and participation” weighed differently by each sector. In relation to the national priorities on gender equality especially in education, the criteria under this category should be enhanced by defining prerequisites. According to the national agenda, besides the inequalities, energy production, greenhouse gasses emissions, and the earthquake risk at the centre of the current development strategies. Therefore, related criteria under “land use and design, and economic integration” should be defined as prerequisites. This approach will also help to build a framework that promotes local needs and national priorities (Ozdağ Oktay, 2015).

Figure 3 - Distribution of the indicators

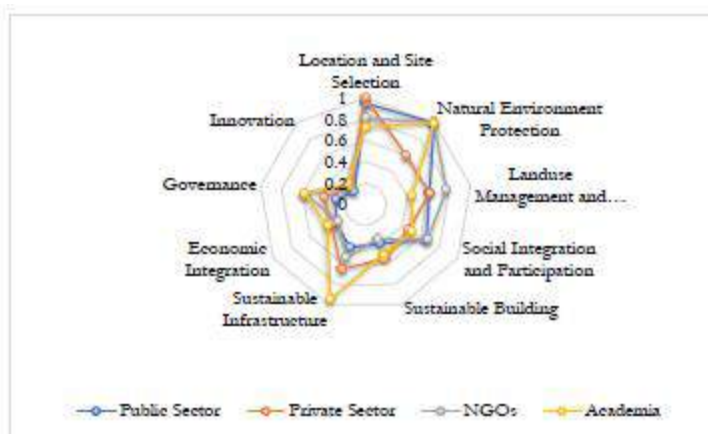

Figure 4 – Sectoral Distribution of the Global Weights

4 CONCLUSION

The prioritization of the categories of eight existing NSAMs will provide a simple framework for structuring a local methodology in combination with the national obligations and local priorities. This suggested methodology is a part of the larger study that involves not only categories but only related sub-criteria. The matrix obtained from the comparative analysis of selected NSAMs can be extended diversified as well as the number of the participants. On the other hand, it is important to keep the framework solid and in relation to the projected scale. Also, AHP provides an effective and easily applicable tool for complex issues and enables to a great number of participants.

Based on the results of this study common principles of neighbourhood sustainability can be easily localized in consideration with different local aspects and national context, and by applying effective prioritization tools.

ID 1686 | WHICH STANDARDS FOR PUBLIC OPEN SPACE? A NEW CONCEPTION FOR THE 21ST CENTURY CITY

Yodan Rofo¹; Marco Cremaschi²

¹Ben-Gurion University of the Negev; ²SciencesPo, Paris
yrofe@bgu.ac.il ; marco.cremaschi@sciencespo.fr

1 INTRODUCTION

What all historical centres have in common is that they are built along streets, and streets make up most of their public space. Streets make up between 25 and 35% of the land area of these urban centres. It is not too difficult to see the impact of modern ideas of city planning on the urban fabric. Watch whatever city on google maps and shift outwards to almost any new development begun in the latter half of the 20th century. All these areas are characterized by having fewer streets; greater distances between intersections; mid to low building coverage; either high or low rise buildings and density; but always extensive open spaces, mostly green areas.

Cities are made of buildings and the spaces between them, both private and public (Marshall, 2004). Planners and policy makers have invested more in the design and regulation of the built up areas, standards mandating parks and gardens being a notable though limited exception to the rule. The recent critique of contemporary urbanism, has stressed the need of interconnecting again the two separate halves.

In this paper we deal with the problem of what should we demand from public open space (POS) in the cities of the 21st century. In particular, we address the question of the balance between streets, public parks and gardens. Eventually, we ask the question of how much POS is needed and what are the best ways to supply it? Until fairly recently, “orthodox” planning culture would have answered unanimously in favour of more parks and gardens, a trait severely criticized by Jacobs in the following quote:

In orthodox city planning, neighborhood open spaces are venerated in an amazingly uncritical fashion, much as savages venerate magical fetishes... Walk with a planner through a dispirited neighborhood and though it be already scabby with deserted parks and tired landscaping festooned with old kleenex, he will envision a future of More Open Space (Jacobs, 1961, p. 96) .

Why this? And why has planning given up on streets as social spaces and relegated them to movement and access functions only?

In order to answer these questions, we first address the notion of open space and in particular of public open space (POS), sketching rapidly the intertwined elaboration of measures, forms, and needs. Dealing in particular with the UK, Italian and other European cases, we show that standards, far from being a plain policy tool, result from a complex web of policy assumptions.

Secondly, we propose an analytical framework to understand how standards rely, in different countries either on political justifications or technical measures. In fact, they are a non-neutral policy tool, often

justified by social, ecological and health reasons as well as technical knowledge. Any change of standards is in fact related to corresponding changes of a multi-layered policy and knowledge structure.

Thirdly, we dissect the consequences of POS standards, showing how they contribute to the creation of non-urban development and make it next to impossible to build dense, lively urban places. Further, we address the dilemma arising from the still ill-considered contrast between space and density, and between urban and metropolitan form. We are concerned in particular with the impact of POS standards on the possibility to achieve functioning urban neighbourhoods and projects.

In the conclusions, we suggest that time has come to allow our standards of POS to reflect the recent evolution of street standards recognizing them as an essential part of the public space. This move will reduce the need for public land in new development, while providing for a diversity of allocations and density as well as dynamic change. Even more important, it will require and incentivise the design of streets as real social space, adapting them to new urban and metropolitan contexts.

2 THE EVOLUTION OF PUBLIC OPEN SPACE STANDARDS

Urban streets and green areas are old love and hate affairs of cities, the story of modern cities being one of eradicating and controlling the wild life of streets (Winter, 2013) and setting aside vegetated areas as parks.

Historians are trying to reconstruct the complex origins of guidelines, unravelling the fascinating social and conflictual construction of the plainest technical rules. It is worth noting that green areas were initially meant as amenities or functional spaces, while environmental reserves and complex forms like the suburban green belt developed in parallel. An increased awareness of the benefits of parks arose from the opening of the private gardens of enlightened rulers or aristocrats: the first public park was established in Munich in 1792 (Brantz and Dümpelmann eds., 2011), and was followed by frequent commissions in other cities.

Since the beginning of the park movement in the 19th century, the provision of parks and playgrounds was seen as a clean, healthy and righteous alternative social space to city streets (Schmidt, 2008). One should not underestimate the circulation of these models; for instance, Olmsted and Eliot started the Boston Park system (the 'Emerald Necklace') during the late 19th century. It is noteworthy to remember, however, that Olmsted designed parks and parkways, as well as urban and suburban neighbourhoods, at the same time.

However, the two traditions of thought related to streets and parks have often crossed paths, and have been reframed, igniting new waves of policies and propelling the transfer of models (the "city beautiful" and the "garden city" being just two examples of the international circulation of models). The notion of 'open space' is in fact the offspring of this couple, whose ties seemed quite apparent until not long ago. The notion of the importance of open space likely dates back to the 'Select committee on public trails in London' (Turner, 1992) that arose in 1833 with a concern for "the exercise and amusement of the middle and humbler classes."

In the modern planning movement, beginning with the garden city, and increasingly throughout the 20th century the street was considered a physical, social, and moral danger (Hall, 2014; Miller, 1990). In a very real sense, after the mass entry of motorized vehicles into cities in the 1920s, streets definitely became more dangerous, particularly for children. Howard, Frank Lloyd Wright, Le Corbusier and many others attempted to reconcile man, nature, and machine, either disguising development as nature or surrounding it by nature. The latter dissolved the city in a bucolic park occupying only 15 percent of the land (Fishman, 1991, pp. 163– 263), strongly advocating the abolition of urban streets, and the complete separation of pedestrian and vehicular movement.

The English and Italian cases offer some interesting parallels, having been reconstructed by historians, which might resonate with other national experiences. The first, interestingly designs a four step progress which somehow anticipates a general trend from quantitative to qualitative approaches (Maruani and Amit-Cohen, 2007). In particular, the London Plans (1929, 1943-44 and mostly that of 1976) have been landmark moments of change:

- An initial standard was proposed by Unwin building upon the patronizing attitude toward the lower class, which were supposed to adopt and benefit from the same healthy lifestyle of the nobility¹;
- During WW2, the Abercrombie plan fostered a more systematic approach introducing the notion of the network of open space, a reformulation of the green belt; standards were reduced², yet it introduced a concern for the unequal distribution of POS in different areas;
- Later, social scientists were involved in introducing a richer view of the qualitative dimensions of accessibility, appropriation and feelings though with scant practical effect (Turner, 2012; Burton and Veal, 1971).
- Finally, a typology of green areas replaced the POS standard since the mid-seventies, each one corresponding to a catchment area³.

A negotiation between planning authorities and applicants will define the precise amount, location, type and design of green areas. However, the share depends on the number of dwellings or the extent of site (300 dwellings or 15 hectares being usually the threshold). The outcome will depend also on the specific characteristics of the site and its context. In contemporary development projects, a comparatively higher density of people will become rapidly incompatible with the standard, although it is often recommended by policy guidelines.

In the Italian case, the fascist government introduced a modern planning law in 1942, and standards were introduced after WW2. Similarly to the French case, the state was bound to provide for open space and public buildings, but no standard was introduced. Only in 1967, a national law mandated each local plan to ensure that a certain amount of land was made available for public use. The original concerns derive from an unusual actor: it laid in the social concerns and political demands promoted by the early women movement in the 1950s (Renzoni, 2014).

Standards were thus conceived as direct obligations of municipalities to set land aside for public use, being the minimum ratio between the space allocated to facilities of public and social interest, and the sum of zoned uses (residential, production, etc.). They were meant to provide for green areas and for other public services, notably schools, parking lots and social services⁴.

The norm entitles each perspective inhabitant to a minimum of 9 sq.m. of green areas, and as much for all the rest (18 sq.m. per capita in total), that the municipal plan must provide. In theory, that land should be in the same planning zone, and should be acquired by the city in the immediate period following the approval of the plan, which recently has been limited to five years.

A similar standard has been later introduced in Spain too (Càceres 2003). However the law does not bound the state to a fixed standard, as in France (Aja 1997), though the local plans can introduce quantitative prescriptions. The government aims at providing 10 sq.m. of gardens and parks per inhabitant., sporting facilities or forests being included in a second target of 25 sq.m. per capita.

In a slightly different way, the German city of Hamburg determines the provision of green areas and parks as a ratio which is derived from global directives, landscape programmes, or local assessments. Eventually, requirements per capita come down to 6 sq.m. of green areas in close proximity to dwellings (up to 500 m. walking distance), plus 7 sq.m. of principal parkland (13 sq.m. in total).

All of these design guidelines, through the various subsequent reformulations, seem inadequate to cover increasingly varied development models. In fact, they roughly converge in quantitative terms only in the case of medium density of between 100-150 inhabitants/hectare. Applying the two models, either preserving 10-15% of green areas or calculating 10-15 sq.m. per capita, we get more or less the same results (Table 1) in cities with a density of about 140-150 inhabitant/ha (the case of Manhattan). For lower

¹ As early as 1925, the National Playing Field Association, delving upon contemporary literature on US cities (Turner, 1992). Later in 1929, Raymond Unwin reused it for the Greater London Planning Committee, which eventually implied an earlier formulation of the Green Belt. The resulting standard postulates 7 acres of open space for 1000 people (28 sq.m. per capita), mostly being private, and ¼ POS (7 sq.m.) (Turner, 1992).

² Approximately, 16 sq.m. per capita (4 acres of open space per 1000 population).

³ A regional park of 400 ha is thus suggested for an area of a radius of 8 km (the size of metropolis); a district park of 60 ha for an area of a radius of 3.2 km of (the size of a city); and so on.

⁴ In particular, the minimum standard of public space included 9 sq.m./p of gardens and parks, 2.5 of parking lots, 4.5 for schools and 2 for general equipment.

density (cities like Hamburg or London, for instance) or higher density (Paris or Hong Kong) standards tend to diverge and produce incompatible results.

Density inhab./ ha	Standards	
	13% of Land Outcome in sq.m./per capita*	9 sq.m. per capita Outcome in % POS of total
25	52	2
50	26	5
100	13	9
150	9	14
200	7	18
250	5	23

Table 1: Density and standards

Density is thus the crucial cleavage in applying POS standards. In recent years, despite the growing awareness of the importance of city streets to the liveability of urban environments, the research on public health and urban planning still tends to highlight the importance of public parks and gardens for health and well-being (Barton, 2009; Fan et al., 2011; Serag El Din et al., 2013). Thus there is still a conflict between those who advocate for more green open space, and those that advocate for more lively urban public space (Hebbert, 2008). Even more so, the issue of urban POS per capita remains controversial either from a normative or a technical approach. An often quoted WHO standard suggest a minimum of 9 sq.m. of green open space per capita. Developed countries tend to adopt a much higher standard of 20 sq.m. per capita. Of late, environmental experts fostering the balance between carbon dioxide with oxygen production suggested raising the standard to 40 sq.m. of urban green space in high quality and 140 sq.m. suburban forest area per capita or about 50% of a neighbourhoods surface area, but this includes both public and private areas (Szulczewska et al., 2014).

3 PUBLIC OPEN SPACE IN CODES AND GUIDELINES

In POS, public means that all these spaces can be used for individual and collective purposes by respecting a set of codes, which are both cultural and regulatory. Codes however are publicly debated and publicly enforced rules. Often, such complex codes are a better guaranty of open and free use than the mere condition of being a public property. The worldwide spread of quantitative standards has been justified for their clarity as a measuring tools and their easiness of implementation (Gold, 1973; Hill and Alterman, 1977).

A national system of planning regulates POS according to different dimensions, namely a normative, technical and regulatory dimension. Two ideal types are shown in Table 1. The first ideal type conceives POS as spatial objects; whose ideal distribution depends on a catchment area defined by pedestrian mobility; and practically negotiated with developers. The second ideal type conceives POS as legal attributes; whose size depends on the number of present or future users, with only secondary attention to spatial positioning; and is enforced by a central agency in control of local authorities. Even if many combinations are possible, the British and Italian planning systems can epitomise the two types (Table 2).

	Type A	Type B
Normative	Performative: The dimensions and quality of working POS units (parks, gardens, small open space)	Legal: Individual needs or a collective right to POS
Technical	Scalar: A typology of POS units made to fit the geographical scale	Linear: A quantitative requirement per capita, sometimes articulated in functional subsets
Regulatory	Discretionary: The control is meant to regulate markets, and directed towards private developers	Mandatory: The control is meant to regulate government, and directed towards lower tiers of governments

Table 2: POS in Planning systems

The normative level designates POS and prescribes how to recognise and name them. The English case interestingly classifies different objects, i.e. parks or streets, according to specific sets of qualities, extension being just the first; this is an apparent culture led activities, where different cultures of planning or sensibilities are likely to emerge across time or countries; not surprisingly, cultural attitudes towards planned objects are subject to revisions, and change has in effect occurred several times. For instance, the London Plan classifies parks according to width and geographical scale (Regional, Metropolitan, district or local); and green area according to size and form (Small Open Spaces, Pocket Parks, Linear Open Spaces). In the Italian system, on the contrary, no previous definition of POS is provided, the discussion is being left to evolve according to changing sensibility (particularly apparent at a local scale).

Eventually, normative assumptions lead to technical statements. These are typical planning tools linking land to people through either binding or indicative relations. However, planners deal with POS in many different ways, the main difference being whether their technical estimation is based upon the aggregate appraisal of urban space (a share of total surface); or the requirements (or rights) of individuals. Planning relates these objects to the actual or future population, indicating a ratio according to either quantitative or qualitative threshold; these normative statements vary enormously, depending in part on asserted policies, in part on discretionary arrangements between actors.

Finally, as far as regulation is concerned, planning law and codes can make stronger or weaker obligations to which either public or private actors have to comply. These obligations depend on the style of regulation, the administrative language and multilevel negotiations among layers of government. These technical approaches reflect divergent political concerns and policy origins. It is not difficult to impute to the English case a concern with the control of land, the dysfunctionality of the markets, and thus economic values and developers' options. On the contrary, it is possible in the Italian case to retrieve an assessment of human needs, resulting from a political claim for a basic right, and the aim of controlling the population at the same time, and reducing local governments' freedom of decision in the second case.

4 WHAT THE STANDARDS DO TO THE CITY?

So if access to public and open space is important, the question remains: how much open space? The response, historically, has been to establish minimum standards of POS per person, in a similar way to the space standards imposed on residential buildings in order to insure reasonable living standards. However, these standards vary widely from place to place. The influential World Health Organization (WHO) recommends a minimum of 9 sq.m. of green space per capita, and that all residents live within a 15 minute walk to a green space (UN-Habitat, 2015a). This space allocation has to be added up to the allocation for public services (such as schools, kindergartens etc.) and the necessary streets to allow for access to buildings. The application of this standard, puts practical limits on the gross density of urban development, if it is applied equally across all neighborhoods of the city (Figure 1). This is because as the density increases, the percent required for public land use exceeds 60%, which means that net density rises, limiting the building typology to high-rise building (Alexander, 1993).

There is much research on the importance of urban density for city economic and social liveability (De Nadai et al., 2016; J. M. Jacobs, 1961), transportation sustainability (Ewing & Cervero, 2010; Kenworthy & Newman, 1999), and not least the overall expansion of cities over arable and useful land (Angel, Parent, Civco, & Blei, 2011). One can see from the graph in figure 1, that different open space standards have significant impact on the feasibility of urban density, and on the urban fabric itself. With a 9 sq.m. per person standard, it is not feasible to build at a density higher than about 105 dwelling units to the hectare. While a standard of 3 sq.m. to the hectare will allow a density reaching 200 units to the hectare.

The consequences of high POS standards are that they limit our ability to reach high urban densities with low and mid-rise buildings and force us to build either high rise buildings or at a mid-low density. Both of these typologies make it difficult to create walkable, vibrant cities. Public transport is also less viable, and urban sprawl and automobile dependence are increased. Low densities also make it harder to create mixed use areas. Therefore, existing POS standards contribute to sprawl and diminish the sustainability of urban areas.

Figure 1– The relationship between Gross density and public land using different sq.m./p standards

The calculations assume: a neighbourhood development of 10,000 units and a mean household size of 3.1 persons/hh. The street area is progressively calculated from 20% at the lowest density to 30% at the highest.

4.1 SOME OTHER PROBLEMS WITH PUBLIC OPEN SPACES

Moreover, in research comparing POS quality and use in neighbourhoods in Israel (Feierstein & Rofe, 2010; Rofè, Zarchin, & Feierstein, 2012), we found that in lower density neighbourhoods, there was over provision of public space, because the regulations for the accessibility to POS, and their minimum size, were governing the size and location of POS. Thus, neighbourhoods already enjoying a large allocation of private open space, were also enjoying POS allocation that reached between 15-30 sq.m. per person. Furthermore, our study showed that the green POS in the neighbourhoods were used much less than civic POS, located close to commercial and service areas. POS were mostly used by adults accompanying toddlers to playgrounds, and even children stop using them when they begin to go out into the neighbourhood on their own. Finally, in a survey of neighbourhood residents we found that spending time in the neighbourhood park is the activity less enjoyed outdoors, relative to walking along the neighbourhood's streets, which was the second preferred activity after sitting in one's own private open space.

5 A NEW FLEXIBLE STANDARD INCLUDING STREETS

It seems that the standards cause an inflation of POS. A comparison between areas of traditional urbanism (Nice), modern urban planning (Ashdod in Israel), New Urbanism (Poundbury, UK) and contemporary informal housing area (Santo Amaro in Recife, Brazil) has shown that while traditional and informal urbanism have a rate of 4-5 sq.m. of public space per person, modern urbanism has four times as much at about 19 sq.m./person, and the new-urban development an incredible 65 sq.m./person (Schocken & Ludermir Bernardino, n.d.). This is similar to findings with regard to distance between major streets (Porta, Romice, Maxwell, Russell, & Baird, 2014). In both cases these are the results of modern planning standards that are still mandated. We seem to be at a conundrum. POS are important for health and well-being, as well as the environmental functioning of the city, but it seems that when they are mandated, they are actually over-supplied, little used, and become a burden on the community's resources.

The reason for the conundrum, is that we have become oblivious to the major resource of POS in the city. Even in modern planned cities, streets constitute the largest extent of public space. They are necessary, because they provide access to private property. We know that they are the place where most encounters occur in public space. But in order for encounters to happen, there has to be co-presence and awareness of each other in public space. Gehl and Gemzoe calculated that the average density in public space in Copenhagen remained roughly 12 sq.m./person (Gehl & Gemzoe, 2003), thus as space for pedestrian activity became available, more people came to use it. As we saw historic and informal cities have a POS to population ratio between 3-6 sq.m. per person (at the urban quarter level). Thus, in order to create lively

streets it seems that between a quarter and half of the population living in its vicinity needs to be outside in it at any one time, which seems a rather high number. In reality, we know also that most pedestrian movement occurs on major streets (Hillier, Penn, Hanson, Grajewski, & Xu, 1993; Jiang, 2009; Lerman, Rofè, & Omer, 2014), and that these main streets are also responsible for the majority of social and economical life of the city (Carmona, 2014). Boulevards and main streets function better as human spaces when more than 50%, and often about 70% of their section is felt to be a “pedestrian realm” – an area where pedestrians feel unthreatened by cars, even if cars are allowed within it (Allan B. Jacobs, Macdonald, & Rofe, 2003; Rofe, Yerushalmi, Margalith, & Windsor, 2015). This means that a large investment in streets is in order to make them functioning public space. But this investment will not be possible if that space is not considered as part of the needed provision of POS in an urban area, thus allowing a corresponding reduction in the amount of parks and gardens for which land needs to be allocated.

What would happen if we begin to actually take seriously the fact that streets are an important part of public space, and begin to count them as part of the space required by the POS standard? Provided, of course, that they are designed in such a way as to allow between 60-70% of street space to be pedestrian oriented and therefore potentially public space. Indeed, in the UN-Habitat, Global Public Space Toolkit (2015b), the first three principles are:

1. Adequate space for streets and an efficient street network (30% of land area)
2. High density (a minimum of 15,000 p/sq.km. which translates to 150 p/hect. or roughly 50 du/hect.)
3. Mixed land use (40% of the floor space for economic uses)

Thus, it is possible that 40-60% of the area of all streets will be designed and managed as a pedestrian realm. While in narrow and local streets the pedestrian realm occurs almost automatically, wide and major streets have to be designed as boulevards and green corridors (Bosselmann, Macdonald, & Kronmeyer, 1999; Mehaffy, Porta, Rofe, & Salingeros, 2010). This will result in natural traffic calming and therefore a reduction in number and severity of accidents, and the ability to meet the POS standards, without losing the possibility to achieve high density.

As can be seen in figure 2 below, taking into account the streets as part of the public space needed to satisfy the standard allows us to achieve even 15 sq.m per person while still arriving at a density of about 100 du/hect. (or about 300 people/hect.). At a standard of 3 sq.m. per person we can achieve a density of 200 du/hect. While still maintaining public land beneath 40% of the area of the development. Between these two extremes we can reach a diversity of allocations, according to the type of development required, and the urban context. Peripheral areas may have a larger ratio of public space per inhabitant, while central and dense areas may be planned to a lower space standard (but probably higher quality and complexity). Obviously, when applying the standard, one will have to make sure that the streets are indeed designed in such a way as to enable them to become a social space, and that will give the city, and developers an incentive to do so, because it will enable them to increase density, and to allocate less land to public uses, and more to private, income producing land.

Figure 2– The relationship between Gross density and public land proposed standards taking into account streets as part of POS.

Indeed, as cities grow and consolidate they reduce the ratio of population to public land available, and transform the land from public open space to mostly streets. Thus the standard could be seen as capturing both the spatial change in cities from centre to periphery, as well as the temporal dimension of growth, densification and consolidation. An area that starts with 15 sq.m. per person or higher, as it grows, adds height to the buildings, and people to homes, it usually will not increase in the quantity of streets and public spaces it has – therefore the ratio of POS per person will become lower, and the density higher. Thus, this variable standard will allow once again cities to grow naturally, without attempting to add public space as they densify. Thus this system also merges the two regulations systems discussed above (Table 2). It allows for a variability in POS allocation per inhabitant, according to the context and cultural preferences, while maintaining the viability of the urban system as a whole by controlling the overall proportion allotted to public space.

6 CONCLUSION

A consensus position since the 19th century is that, of all the unbuilt parts, public open space (POS) is a fundamental component of a city. We remind readers that POS is the sum of two key components of the unbuilt part of a city: first, all kinds of streets and secondly green areas. Though early industrial developments heavily ignored environmental concerns for the sake of profit and control, green areas have been on the front stage of cultural debates due to their social and formal implications.

The need for open space has often been claimed for different reasons. In the modernist approach of the city as a 'living machine', built and unbuilt parts are disconnected: in the unbuilt side, streets were demoted to traffic corridors, in order to support increasing mobility. Car mobility in particular has led to dematerializing streets into the notion of networks, and confined them to the realm of engineering rather than place-making.

Parks have however resisted the reduction to functional machines. Most of the research has concentrated on the profound social and pedagogical implications of green areas. Only recently, parks have been reinvigorated by the international concern with public health, the environment and urban sustainability, and recently urban metabolism.

On the other hand, the metropolitan restructuring of cities leads to a re-conceptualisation of urban tools, like parks and streets. The new geographical scale changes also the appreciation of age old issues, in particular: the lack of natural space; density; and the role of networks in interconnecting both artificial and non-artificial spaces. Recently, green networks have been called upon to play an increasingly important role in fostering a sustainable model of urban development (we deal with the greening at the metropolitan scale in a forthcoming paper). Researchers and advocates call for increased allocations of green spaces in the city, not always distinguishing between the metropolitan scale – where the mean amount of POS per capita is often measured, and the standards based on these means that operate at the level of urban neighbourhood or project.

In parallel, there has been a re-evaluation of the importance of streets to urban public space (Gehl, 1987; Hebbert, 2005; Jacobs, Macdonald, & Rofè, 2003; Murrain, 2002). This has led to substantial changes in policy and guidelines. There are also signs that policy makers' attitudes are changing, as underlined by UN-Habitat director J. Clos in preparation of the recent Habitat III conference.

However, there seems to be still a disconnection between these two streams of thought, seeking to create an urbanism adequate to the challenges of the 21st century. We suggest that the time has come to reconsider streets as an essential part of the public space network that is needed to satisfy the policy standard for POS, and to unify the standards for both streets and public space provision. This move allows moderating the need for public land in new development, while providing for a diversity of allocations and density as well as dynamic change. Even more important, it requires designing streets as real social space, and adapting them to new urban and metropolitan contexts.

Does it mean that POS standards will change? The answer is no unless both the normative and regulative dimensions are taken into account. As shown by a recent body of comparative research, national planning systems are quite different from each other (European Commission, 1997; Newman and Herschel, 2002), reflecting national traditions and legal and political frameworks. Planning cultures are even more diverse,

and they interfere consistently with the normative side of planning (Sanyal, 2005). Structuring issues and circulating ideas (Healey and Upton, 2010) have been constantly part of an ongoing discussion between reformers and policy-makers. All planning systems have addressed the question of how much open space is required in a given situation: but the answer depends as much on the political side as on the technical one.

ID 1693 | OILANDSCAPES. THE RECONVERSION OF FOSSIL FUELS MESHES AS "GREEN ENERGY BACKBONES" FOR THE TERRITORIAL RESTRUCTURING OF THE THIRD INDUSTRIAL REVOLUTION

Alberto Verde¹; Alessandro Massarente¹

¹University of Ferrara, Department of Architecture

alberto.verde@unife.it ; alessandro.massarente@unife.it

ABSTRACT: Fossil fuels industry has always been carrier of huge spatial transformations: first of all, because the extraction of carbon-fossil resources requires the investment of huge amounts of funds to deploy a widespread infrastructural network, and secondly, because the associated industrialization process deeply contributed in the definition of new urban morphologies and settlements. We could affirm that fossil fuels and industrial revolutions represent two sides of the same coin. Since the end of XVIII century, the two industrial revolutions have been dominated by a fossil fuels' monopoly in terms of energetic production, firstly driven by coal-based activities and later by oil. As already known, hydrocarbon resources are not equally and democratically distributed in the subsoil, and this has created over the centuries some vertical dependences between fossil fuels suppliers and consumers, which completely redefined the geo-political equilibrium among countries. One of the most remarkable effects of this unbalanced distribution of fossil resources in the subsoil had been, especially during the first industrial revolution, the territorial attractiveness of hydrocarbon-rich territories for the settlement of huge heavy industry sites. The consequent high concentration of employment reshaped the territorial hierarchies among population, countryside, urban areas and infrastructures. The aim of the first part of the paper is to investigate about the role that fossil fuels industry played in the definition of territorial hierarchies during the first and the second industrial revolutions. The analysis will be led through a comparative study of some GIS cartographies of two renowned European territories: the "Ruhr region" and the "central Veneto region". In the second part of the paper, we will focus in a more proactive way on the "oil mesh of the North-Eastern Po valley" and wonder about how fossil fuels infrastructures could be "deengineered", albeit maintaining their energy production identity, and imagined as "green infrastructures", so becoming those landscape articulators which can foster the dialogue across territorial, urban and architectural scales thanks to their new socio-ecological role. The "scenario building" (Viganò, 2012 and Sijmons, 2014) will root its beliefs, assumptions and constraints around the vision of the "energetic transition towards the third industrial revolution" which, as advocated by the American economist J. Rifkin (2011), envisages a massive shift towards new renewable and territorially distributed forms of energy production.

1 A COMPARATIVE ANALYSIS OF TWO POLYCENTRIC MODELS: THE RUHR AND THE CENTRAL VENETO REGIONS

1.1 INDUSTRIALIZATION PROCESS

Not by chance one of the most important industrial development processes, tightly dependent on coal mining activities, settled up in Ruhr region. The reasons date back to Carboniferous era, something like 320 million years ago, when the equator passed right by this region. The process of petrification and coal formation of hermetically-sealed and compressed coastal forests in the marshy lowlands required million of years and was concentrated along an East- West area which went from the Ruhr region to Belgium, passing through southern Netherlands, perpendicularly to the river Rhine. At the beginning of the XIX century, the Ruhr region was still an agricultural area, characterized by small, handicrafts and semi-rural towns of about 8'000 inhabitants. Between 1840 and 1860, a revolutionary technical innovation in deep coal mining, which allowed digging up to 600 m deep and catching bituminous coal, kicked off a wide territorial industrialization process which lasted for almost a century (fig.1). The main industrialization trends can be summarized as follows (Reulecke, 1984 and Hötter, 1988):

- the first period (1840-1860) is characterised by the opening of new deep mining sites all over the "Hellweg strip", a sub-region comprised between the rivers Emscher and Ruhr which is crossed by the homonymous medieval trading route. New collieries and iron plants were settled up in rural contexts close to coal mining sites and to the existing small, semi-rural villages along the Hellweg trading route (Duisburg, Essen, Dortmund), contributing to their rapid urban growth;
- the second industrial development era (1860-1890) can be considered as the "golden age" of the productive Ruhr region because the enthralling power of industrialization moved North, towards the river Emscher, and led to the opening of several coal open pits in the middle of almost uninhabited territories (Oberhausen, Gelsenkirchen, Herne);
- only in the 1960s, after the end of the Second World War and the necessity to reconstruct the economy of a devastated country, the "Ruhrgebiet" witnessed another important industrial development era in its Northern part, towards the river Lippe. While coal industry was starting to collapse, the cooperation between petroleum and chemistry boosted the settlement of some huge petrochemical industrial complexes on the banks of the river Lippe. This industrialization stage never reached the envisioned amplitude because of the oil crisis at the beginning of the 1970s.

It is interesting to notice that while the Ruhr region faced the apex and the crisis of an economy based on a concentrated industrialization over a century, Veneto region was not touched by any massive industrial revolution (fig.2). Indeed, according to Roverato (2008) and Bagnasco (1977), a long, soft and dispersed industrialization process, opposite to the rapid industrial concentration occurred on the occasion of the "industrial triangle" (Milan-Turin-Genoa) and based on the consolidation of some SME industrial districts operating around smaller urban centres, began to take root in the region from the end of the XIX century. This phenomenon gave rise to what Bagnasco calls "the third Italy", so as to highlight an alternative territorial development model which differs from the usual dichotomy between the North-Western Italy's industrialization and the backwardness of the South. The richness of the spontaneous and diffuse SME industrial pattern around small urban centres was not perceived by the politics of the time to the point that Veneto, until the 1960s, was considered an agricultural and underdeveloped region, "the South of the North Italy" (Roverato, 2008), so as to enact special laws to boost the economic development of depressed areas.

Only two concentrated industrial episodes around the most important urban centres of the region had been experienced in Veneto, namely:

- Porto Marghera, where refining and petrochemical activities were settled from 1920s taking advantage of the logistic harbour which allowed to accommodate oil tankers coming from Italian colonies in North-Eastern Africa;
- the industrial platform in the South-eastern outskirts of Padua, where an inland port and a highly diversified industrial production settled up.

During the 1950s, these two big industrial poles deeply contributed in the consolidation of that fragile, dispersed and decentralized industrialization thanks to sectorial productive synergies and to the accumulation and sharing of experiences, knowledge and human capital. But it is with the crisis of big

industrial productive sites from the middle of the 1970s that the decentralized industrialization model affirmed itself as the predominant model of the region and became visible to the most through a pervasive cohabitation of industrial landscapes with rural ones.

1.2 INDUSTRIALIZATION AND RAILWAY INFRASTRUCTURES

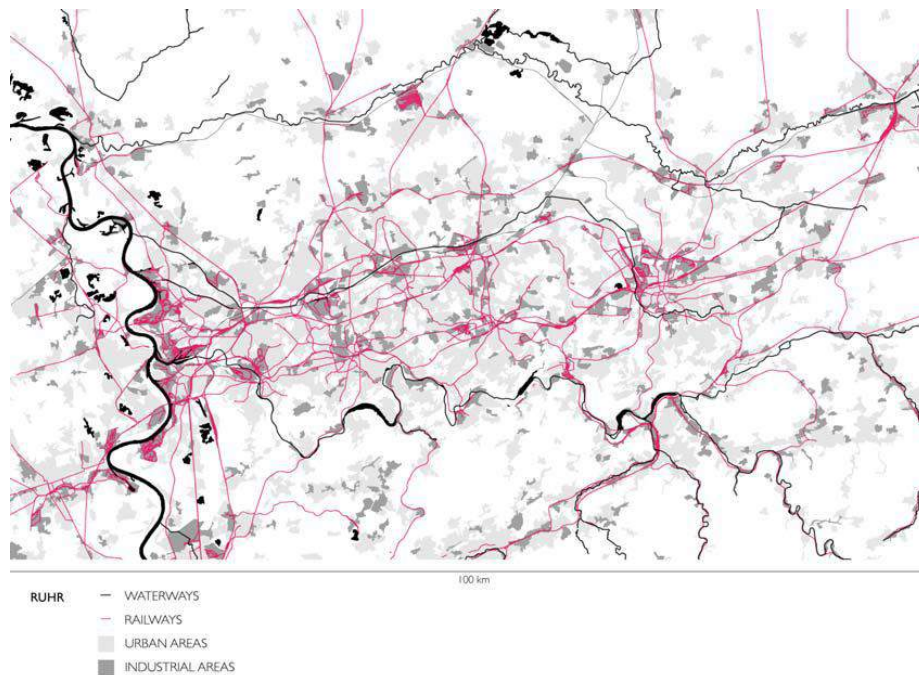

Figure 3 – The railway infrastructures of the Ruhr region (elaborated by the author, source: DIVA-GIS metadata)

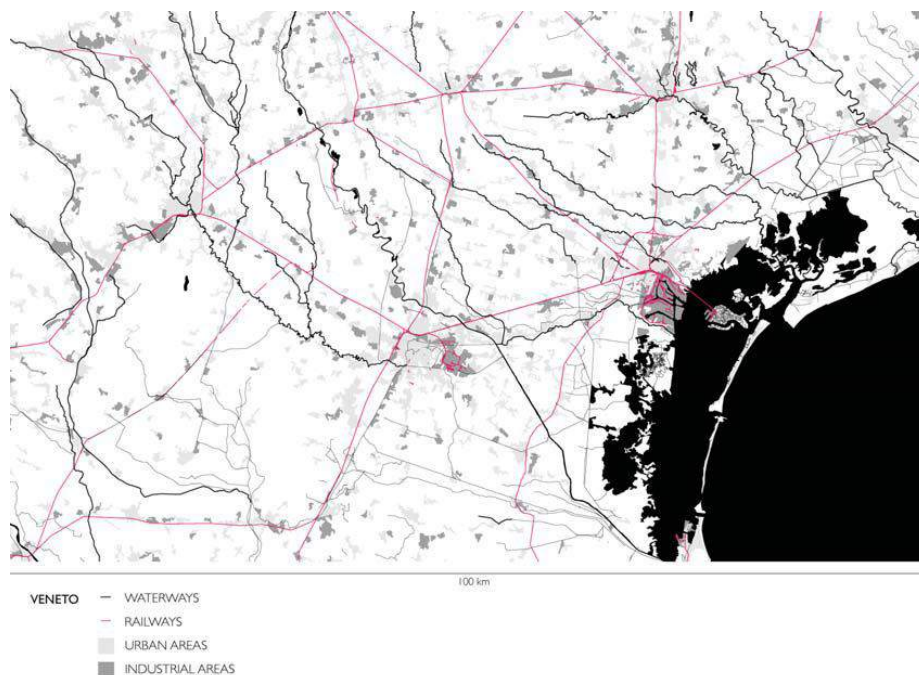

Figure 4 – The railway infrastructures of the central Veneto region (elaborated by the author, source: DIVA-GIS metadata)

With the lack of a regional railway infrastructure planning, private company owners built a profit-oriented railway network for goods and raw materials transport purposes, so as to connect coal mining sites to heavy industrial plants or to logistic harbours along the river Rhine (Reulecke, 1984). If during the first regional industrialization period railway infrastructures reinforced the role of the existing urban poles along the Hellweg trading route, during the second one a principal East- West oriented railway axis parallel to river Emscher became the principal backbone along which the sparsely inhabited territories settled up their

urban and industrial growth (fig.3). Only at the beginning of the XX century, with the nationalization of the existing railway network, railways began to be used even for passenger transport (Hötter, 1988). This circumstance contributed in the diffusion of the “garden city” model as the principal miners’ dwellings model, so connecting residential areas with working sites, recreational areas and city centres by public transports. It is remarkable how the tardive industrial development along the river Lippe completely lacks of a dense railway network such as the one in the Southern Ruhr region.

If we look at the central Veneto region, the railway infrastructural development had a completely different course. In fact, the railway network in Northern Italy was implemented at the end of the XX century, and Veneto was far to be interested by any massive and concentrated industrialization process. Thus, the railway mesh that crosses the central Veneto region is completely independent from any industrial relationship, but it is rather the result of a general infrastructural planning for passenger accessibility, goods supplying and even military purposes (fig.4).

1.3 INDUSTRIALIZATION AND ROAD INFRASTRUCTURES

The motorway infrastructural network in the Ruhr region started to be developed since the 1920s, with the proposal of creating an East-West 3-lane motorway connecting Duisburg with Dortmund and with the implementation of the Reich Autobahn, parallel to river Emscher (Reulecke, 1984). Nevertheless, only the tardive industrial development occurred during the 1960s along the river Lippe had a direct relationship with the road network. In terms of regional accessibility, the dense Ruhr agglomeration is well served by 3 national East-West motorway axes, but, on the contrary, North-South connections are insufficient (fig.5).

What is outstanding from a first look at central Veneto region is, on one side, the scarcity in national motorway axis and, on the other one, the fine “isotropy” of the secondary road level, based on the Roman agricultural orthogonal grid (fig.6). The widespread capillarity of the local road network allows low dense territories to be used in an extensive way, being very well connected to decentralized production areas. This very peculiar type of road system, together with the decentralization of the industrial production on a vast territory, created the conditions for the settlement of some mixed commercial and industrial “agglutinations” (Savino, 1998) along important local road axis, the so called “strade mercato” (market roads).

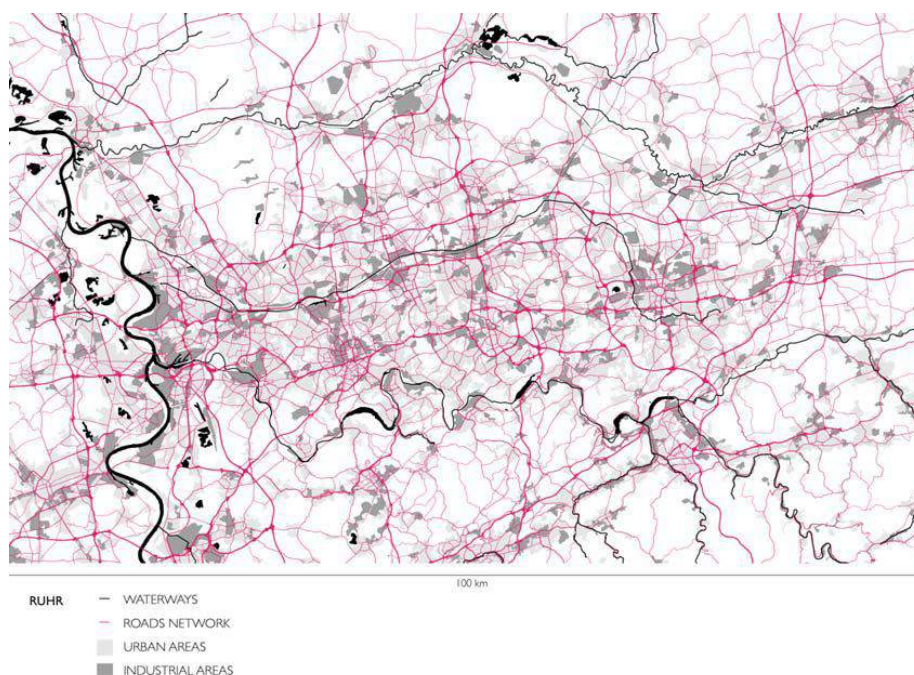

Figure 5 – The road infrastructures of the Ruhr region (elaborated by the author, source: DIVA-GIS metadata)

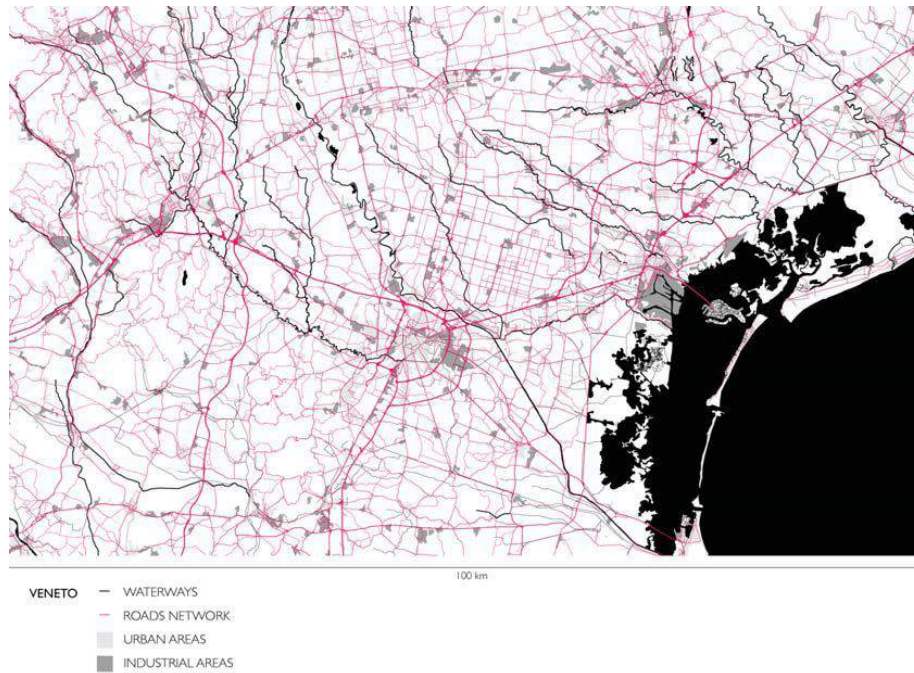

Figure 6 – The road infrastructures of the central Veneto region (elaborated by the author, source: DIVA-GIS metadata)

1.4 POLYCENTRISM

The comparative analysis of the two case studies under the lens of their polycentric territorial structure reveals how the two models work in a completely different way. The massive industrialization of the Ruhr area led to a significant wave of migration from rural areas. Two main trends characterized urban areas' expansion according to their geographical situation:

- along the Hellweg trading route, the already existing urban centres (Essen, Bochum, Dortmund) had a remarkable radial expansion until industrial boundaries in the outskirts;
- moving North, towards the river Emscher, the lack of former consolidated semi-rural settlements encouraged a linear development of urban areas parallel (Oberhausen) or perpendicular (Gelsenkirchen) to railway infrastructures.

At the beginning of the XX century, the political and territorial fragmentation began to raise the issue about how to manage a regional growth which lacked of a unitary structure and development strategy. The “polycentric” model prevailed over the “metropolitan” one because of the presence of several medium cities presenting similar growth rates, high urban densities and no hierarchical dependences towards only one major urban centre (Reulecke, 1984).

In the following decades up to 1980s, the continuous urban growth of the polycentric urban system made the administrative boundaries no more recognizable. Urban areas merged in a densely builtup area, which enclosed industrial, commercial and administrative clusters together with some fragments of agricultural and natural landscapes (fig.7).

The polycentric territorial development of the central Veneto region is based on completely different assumptions. According to Indovina (1990), at the very beginning of the light and diffuse industrialization process at the end of the XIX century, central Vento was affected by an internal relocation process of local people in the same region thanks to some economic improvements, but no massive migratory phenomenon was registered. This consequent rural settlement model is called “campagna costruita” (built countryside) by Indovina (1990) and is based on the social role of the “family” as the minimal organisational unit, which compensates the lack of public facilities. During the 1970s, in parallel with the crisis of the major productive sites and the affirmation of the industrial decentralization, a process of social substitution in the rural context took place. In fact, the urban middle class started to move towards small rural villages to get closer to the decentralized workplaces and to search for better living conditions which

best corresponded with their imaginary lifestyle. The consistency of population who sought for living in decentralized territories was elevated, so that Indovina (1990) defines this stage as “urbanizzazione diffusa” (diffuse urbanization), a preliminary step towards the “città diffusa” (diffuse city), which is characterized, during the 1990s, by the decentralization of urban, commercial and public facilities.

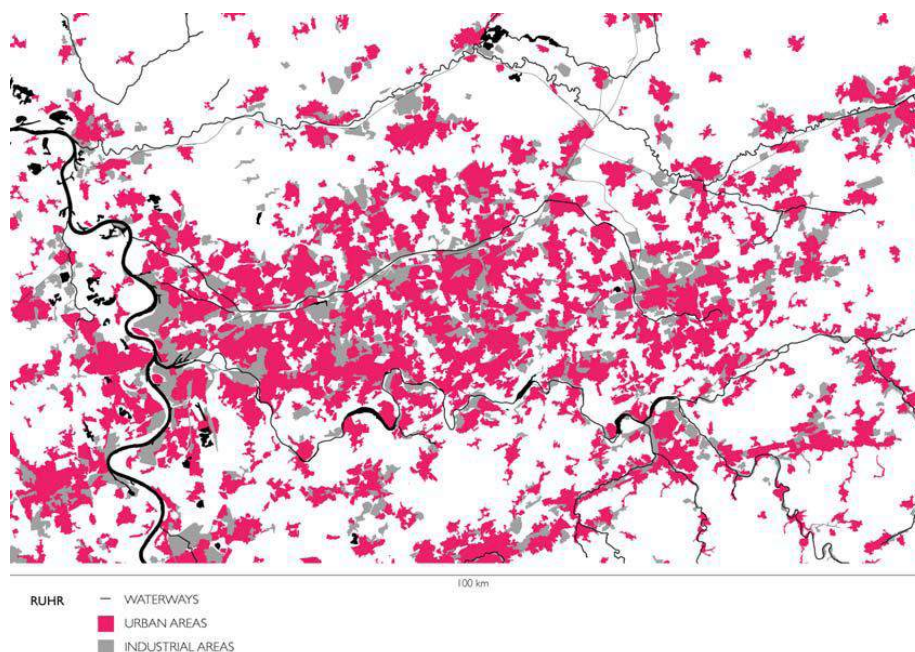

Figure 7 – The polycentric structure of the Ruhr region
(elaborated by the author, according to Corine Land Cover 2012 metadata)

Figure 8 – The polycentric structure of the central Veneto region
(elaborated by the author, according to Corine Land Cover 2012 metadata)

The “città diffusa” looks like a territory constituted by a diffuse polycentric structure of medium and small urban centres immersed in an agricultural continuum where few major cities punctuate the territory, but don’t play the strongly hierarchical role of “metropolitan centres” (fig.8). In other words, spatial interconnections among the distributed urban functions play a key role in the “città diffusa”, because they allow an extensive use of the territory as if it was a “wide mesh” city. In this sense Indovina (1990)

introduces the use of the term “città-territorio” (city-territory) while describing the functioning of the central Veneto polycentrism.

1.5 A WEAK URBANIZATION: THE INSPIRING MODEL OF ANDREA BRANZI FOR THE THIRD INDUSTRIAL REVOLUTION

Between provocation and utopia, since the mid-90s Branzi (2006) prefigures to seek for an ideal urbanization model which loses its tight bond with the historical debate about the correspondence between urban form and function, but which instead lies on the evolving relational flows among society, economy and land uses. Branzi builds its personal “weak urbanization” model around the concept of “uncertainty” which characterizes contemporary dynamics, and substitutes the “rigid certainties” on which classic modernity rooted its philosophical thinking and can be easily exemplified by the dichotomies between city and countryside, industry and nature. According to Branzi (2006) “we have gone from the age of functionalism to the age of functionoids, instruments that do not possess a single function, but as many functions as the operator’s needs”. In this sense, architecture has to lose the figurative code of its “cathedrals of the modernity”, and acts more like a “personal computer”, being adaptive to evolving societal needs, and like “agriculture”, integrating time as a design element. A weak urbanization model should even include agricultural and energetic production as necessary design challenges. It is interesting to notice that if Branzi takes as reference the resilient “favelas” model as an adaptive aggregative process to respond to contemporary liquid society’s needs, some decades before him even Yona Friedman (1978) speculated on the survival architecture of “bidonvillages” as a possible response to industrialization simulacra, focusing on their self-sufficient and synergic organisational model to provide water, food and weather protection to their inhabitants.

In this sense, the non-figurative architecture of a diffuse energy production model should blur the rigid limits between industry and nature. Those “energetic territories” which could produce renewable energies valorising the hidden energetic potential coming from the metropolisation of territories’ process will power the boundless and adaptive “weak urbanization”.

The physical interrelationship of “fossil fuels meshes” becomes a suitable territorial feature to propose their conversion as “energy backbones” for a diffuse energetic production.

The original interdependence of fossil fuels infrastructures turns out to be the main criterion to define the boundaries of our 150x150 km territorial case study in the North-Eastern Po Valley that we are going to analyse in the second part of the paper.

2 THE SCENARIO BUILDING OF THE “ENERGETIC TERRITORIES” OF THE NORTH-EASTERN PO VALLEY

The case study of the North-eastern Po valley is one of the richest in terms of presence of fossil fuels infrastructures in the whole Italian territory. Indeed, the three processing sectors of the fossil fuels industry are present at the same time on the territory, that is to say upstream (extraction), midstream (transport) and downstream (processing) activities. Some of the fossil fuels infrastructures are also interrelated by underground oil pipelines: storage oil tanks in Ravenna industrial harbour fed the power plant in Polesine Camerini (70 km) and the refinery in Porto Marghera is connected via underground pipelines with the one in Mantua (120 km). In addition, some underground gas pipelines connect some depleted gas fields in Emilia-Romagna to the national gas grid.

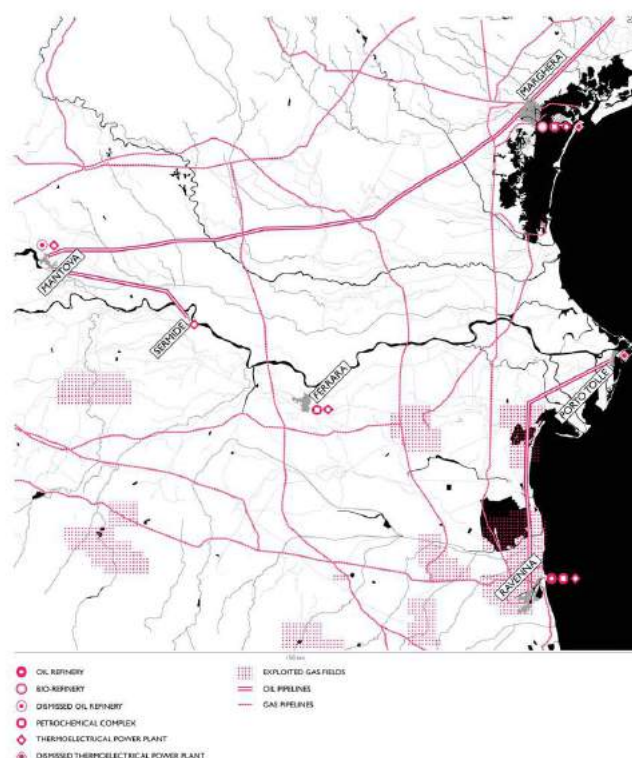

Figure 9 – The fossil fuels mesh of the North-Eastern Po valley (elaborated by the author)

The potential of fossil fuels meshes for a territorial restructuring of the Third Industrial Revolution resides in their physical and functional connections, which run through far and different territories. In this sense they could be imagined to be converted into “green energy backbones” for CO₂ recovery and H₂ storage, to which other diffuse energy production networks could hook up. In particular, CO₂ recovery network could use the existing oil infrastructures, while the intermittent electric energy storage under the form of hydrogen could principally function around the existing gas infrastructures.

The recovery of CO₂ needs to be boosted by activities that produce a huge amount of CO₂ emissions, as refineries, petrochemical sites and heavy industries are. Considering our territorial case study, the state of use of downstream sites is very diversified and this condition suggests a further step in the construction of our scenario: the still functioning refineries and petrochemical sites could temporarily keep the role of “CO₂ feeders”, while the dismissed oil infrastructures could be reconverted in “CO₂ eaters”. As even mentioned by landscape architect Dirk Sijmons in his interesting research about the dimensional relation between landscape and energy (2014), the necessary technological improvement consists of the application of the “Carbon Capture and Storage” (CCS) technology so as to intercept CO₂ from exhausted fumes. Carbon dioxide will be stabilized in a liquid state and then conveyed through the former oil pipelines. In this way, it will be necessary to set up an activity capable to absorb and digest huge quantities of CO₂ on the receiving site. Plants are the best devourers of carbon dioxide through the chlorophylline photosynthesis process, and in particular are algae.

Hydrogen economy is considered a necessary step to implement a massive renewable energetic transition (Rifkin, 2011). In fact, one of the critical problems concerning renewable energies is that electricity is produced intermittently and it is difficult to stock peaks of production. Hydrogen technology could solve the electric energy storage problem because, through hydrolysis process, electricity can be transformed in oxygen and hydrogen. Nevertheless, hydrogen is unstable and explosive and has to be stored in safe places. Some EU funded researches deepened these matters and one in particular, NaturalHY project (European Union, 2009), focused on the feasibility to transfer hydrogen through the existing gas pipelines network, mixing a hydrogen quota with the natural gas. The separation of hydrogen from natural gas will be made in apposite processing units, which will convey hydrogen to the storage place. Other researches were conducted to demonstrate that depleted gas fields are suitable storage sites for hydrogen (Mignard et al., 2016 and Basniev et al., 2010). Thus, the depleted natural gas reservoirs in Emilia-Romagna could

fade, so as those between “oil” and “landscape”, allowing to experience OILANDSCAPES as supportive backbones for a multi-scalar energetic and socio-ecological territorial restructuring.

T06 | TERRITORIAL COHESION: A MULTISCALE APPROACH

CO-CHAIRS: STEFANIE DÜHR; GIANCARLO COTELLA; EDUARDA MARQUES DA COSTA

The objective of territorial cohesion has since the adoption of the EU's Lisbon Treaty set the agenda for policies and activities concerned with 'spatial coordination'. Territorial cohesion has effectively replaced the terminology of 'spatial planning' and 'spatial development' in the EU's discourse. However, at the core of territorial cohesion and European spatial planning lie the same concerns, namely in relation to achieving spatial balance, sustainable development, and socio-economic wellbeing. A better coordination of activities across spatially-relevant policy sectors, across different levels of governance, and across administrative, institutional and cultural boundaries is considered important for territorial cohesion, with spatial planning offering a useful approach to pursue such objectives.

Yet, and in spite of much debate about possible interpretations and applications, the objective of territorial cohesion remains somewhat elusive. Many questions remain over how spatial coordination might best be achieved in different contexts and through which instruments. While attempts have been made to give 'territorial cohesion' a more central role in the EU Cohesion Policy 2014-2020, next to the longstanding objectives of economic and social cohesion, the policy is arguably not yet an integrated 'territorial cohesion policy' but maintains a largely thematic focus in pursuit of the EU's competitiveness and employment agenda. Territorial cohesion is, however, being pursued through experimental initiatives to promote multilevel and multisector governance solutions in transnational spaces (e.g. macro-regional strategies) as well as in regional and urban contexts (e.g. ITI's).

While the focus on this track is on territorial cohesion, papers are also invited that discuss questions of interest to the AESOP Thematic Group on 'Transboundary spaces, policy diffusion and planning cultures' more generally. Topics that could be addressed in this track, among others, are: how the objective of territorial cohesion is being defined and pursued in different contexts, through different policies and across different spaces; the effects of economic or political crises on territorial cohesion; how territorial cooperation initiatives seek to achieve territorial cohesion across collaborative spaces and which (spatial) outcomes are envisaged or have already been achieved; and how territorial cohesion is being pursued through EU Cohesion Policy (or other EU sectoral policies) in different spaces and places and which lessons can be learned from this for the future orientation of EU policies.

ID 1398 | SPATIAL PLANNING ACROSS EUROPEAN PLANNING SYSTEMS AND SOCIAL MODELS: A LOOK THROUGH THE LENS OF PLANNING CULTURES OF SWITZERLAND, GREECE AND SERBIA

Ana Peric¹, Charles Hoch²

1 INTRODUCTION

Europe today faces many challenges to the principle of integration. Migration crises fuel support for withdrawal from the European Union (EU), which motto 'united in diversity' has proven more deeply contested among a large portion of citizens across the member states. Yet the regional systems that each state relies upon require purposeful coordination and planning. However, these efforts portrayed comically as bureaucratic control build upon established networks that demonstrate how cohesion works to turn spatial interdependence into useful practical collaboration serving places. Further, these collaborations prove invisible because they result from complex spatial interactions that do not fit conventional territorial and jurisdictional sectors. Nevertheless, the multitude of agents making plans has never been greater. These networks focus on shared spatial projects and local purposes that search for deliberate practical compromises resolving differences that in principle remain unresolved. Identifying and fostering these networks for spatial planning may offer pathways to regional cohesion currently overlooked (Zielonka in Faludi, 2016: 76).

Collaborative spatial planning in Europe did not follow the European Spatial Development Perspective (CEC, 1999) or the principles laid out in the Territorial Agendas (EU, 2007, 2011). The Europeanization of planning (Dühr et al., 2007, 2016; Faludi, 2014, 2016) embraced a variety of approaches each linked to distinct combinations of political, social, administrative and legal systems (Newman and Thornley, 1996; CEC, 1997; Farinós Dasi, 2006; Reimer et al., 2014). We believe that what binds these approaches together is not a singular authority or purpose, but an evolving culture for spatial planning (Knieling and Othengrafen, 2009; During and van Dam, 2007; COMMUN, 2009). Planning practice is 'strongly rooted in and restricted to the specific cultural context of a society' (Othengrafen, 2010: 83). Understanding the how people use institutions to plan for places provides hopeful insight about system interactions that might govern uncertainty with shared rather than singular responsibility (Reimer, 2013).

Studying specific planning approaches within the context of time and place (Healey, 2011) focusing on 'how things are done' (Faludi, 2005) is crucial. We believe that examples of successful spatial planning will exhibit qualities of democratic involvement necessary for taking practical collaborative actions able to grasp spatial complexity, even as plenty or perhaps even most forms of spatial planning pay little head to the efficacy of such collaboration. The literature on planning culture tends to conflate many post plan making activities as 'planning' included as elements of a 'process'. The range and complexity of the relationships becomes too vast to comprehend. Analysts create imaginative scaffoldings to encompass and classify these relations, but in so doing become social scientists seeking out patterns of order for a place that lose touch with the contributions a plan may have offered the actors involved. In this paper, a functional pragmatist conception of planning is adopted, focusing on the human cognitive capacity for imagining and assessing the effects of future actions before taking one (Hoch, 2011, 2012, 2016). How do we identify and analyse instances of systemic spatial planning? What should we look for as we investigate functional plan making undertaken within a specific cultural context? The advantage of our constrained approach is that we focus attention on how differences in culture shape spatial plan making. Following this argument, the paper tries to elucidate: 1) a methodological tool for the analysis and comparison of planning practices, and 2) the ways on how culture influences planning practice in various contexts (observed through three case examples).

The paper is structured as follows. After a succinct overview, three planning models across Europe are illustrated: the comprehensive integrated approach of Central/Northern European nations, the urbanism of Southern Europe and a hybrid style among Eastern European countries. Nevertheless, as the planning context assumes not only the planning system, but also the planning culture, a methodological tool

(comprising the parameters of social setting, planning process, and planning environment) is briefly described in a second step. Then, we focus on elucidating the planning culture in Switzerland, Greece, and Serbia, through illustrating the planning practice in Solothurn, Patras, and Belgrade, respectively. Such an analysis clearly shows the 'cultural embeddedness' of planning and development. The paper concludes with the identification of similarities and differences in the planning approaches from different settings.

2 PLANNING TRADITIONS IN EUROPE

Before we proceed to elucidate the notion of planning culture and its manifestations in different case examples (as the central part of the paper), it is important to have a brief overview of the main comparative studies of planning systems and processes. One reason for doing so is to show the current collections of planning characteristics of European states as the background information which will make the central analysis more profound and local planning procedures more understandable, as well. On the other hand, it is important to actually highlight major drawbacks of the comparative studies, thus, making room for introducing the concept of planning culture.

The comparative study of spatial planning in Europe (Newman and Thornley, 1996) presented the comparison of sectoral state characteristics (political and administrative structure) emphasizing distinct national planning systems. The approach focuses on differences in formal legal authorization and administrative segmentation of that authority between central and local government. Spatial planning was sorted into five types: British, Napoleonic, Germanic, Scandinavian and Eastern European. Later analysis sponsored by the European Commission (CEC, 1997) added more dimensions, but exhibited a similar dualistic approach (public vs. private, central vs. local, goal vs. implementation). The typology in this case exhibited a functional organisation: land use management, regional economic planning, comprehensive integrated approach, and urbanism tradition. Since the analysis encompassed only 15 EU member states at that time, there has been a need for an update of this typology, provided by Knieling and Othengrafen (2009: 46) who introduced the Eastern European transformation processes as the fifth group of planning styles in Europe. National spatial planning system is usually a combination of several models, however this overview successfully serves for a better understanding on comparative issues among various planning traditions.

Although the studies provided useful comparisons of planning systems, their main drawback refers to their emphasis placed only on formal structures of planning. More precisely, by highlighting the legal and administrative features, it was practically impossible to take into account 'the role of cultural traditions, values, habits, and semantics' (Othengrafen, 2010: 88) and therefore try to explain various spatial developments in Europe. Nevertheless, it is important to gain an overview of the main planning typologies in regard with the case studies analysed in the third section. A brief review of the comprehensive integrated approach, urbanism tradition, and the hybrid planning style of Eastern European countries is provided in the following lines.

2.1 COMPREHENSIVE INTEGRATED APPROACH

Comprehensive integrated planning approach is experienced in the Scandinavian countries and Belgium, as well as in the most of Central Europe: Germany, Switzerland, and Austria. According to this planning style, spatial planning is conducted through a very systematic and formal hierarchy of plans, be these on the national, regional or local level. In most of the states belonging to this planning model, the regional level of planning authorities plays a key role in directing the spatial development. It actually represents a strong link between the local initiatives, on the one hand, and the national guidelines on the other. Therefore, spatial planning is understood as spatial coordination, i.e. systemic preparation and coordination of spatial policies of relevant bodies and authorities at various levels, rather than a tool for balanced economic development, i.e. spatial equity, as highlighted in other planning models. In terms of the planning scope, it is very wide, providing horizontal, vertical and geographical integration of spatial policies. The role of government is decisive in most of the spatial development issues. In other words, planning is mainly understood as the public sector activity, with major investment in planning stemming from various governmental structures, depending on the scope and complexity of the planning task. The planning system itself is considered mature – planning institutions are responsive, planning mechanisms

are developed and transparent, there is political commitment to the planning activities, and, finally, public trust in planning is a norm (CEC, 1997: 36-37).

2.2 URBANISM TRADITION

Southern European countries of Spain, Italy and Greece belong to the states with dominant urbanism tradition. This planning model is centred on structural planning and urban design through rigid building regulations, zoning and codes. Such a focus on building control and townscape shows a clear affiliation to the domain of architecture, i.e. planning as an independent discipline is still not properly established. Briefly put, it is mainly about design and creation of places, without taking into account the strategic dimension of planning. Therefore, it is logical that the spatial level mainly responsible for the planning issue is the local one, whereas the main instrument is building regulations. Despite the fact that within the mentioned states there is a plenty of planning laws and regulations, they are not well coordinated and therefore they miss a clear strategic vision for further development. As a result, the mentioned states usually suffer from an uncontrolled development and ad-hoc planning solutions. Additionally, planning activity is not recognised as a political priority, nor it has general public support. Finally, there are only limited mechanisms for citizens' involvement in the plan-making procedure. Therefore, it is very difficult to manage the ever-growing conflicts among different sectors, usually at the expense of the public interest. Nevertheless, there is on-going intention to improve building control, on the one hand, and to broaden the spectre of spatial planning and its influence on the other (CEC, 1997: 37).

2.3 HYBRID PLANNING STYLE

Transformative planning is today experienced within a great area of the post-socialist states in Europe. In the past, these countries were faced with the centralised hierarchical social model, while nowadays they are muddling through the transition period in order to achieve stable future based on completely different social norms than those previously implemented. Due to such a tremendous change in political and social context, the planning is also still considered to be in the process of transition from the top-down state planning towards the market-driven development, posed by neoliberal paradigm premises, introduced overnight. In terms of its spatial focus (national planning vs. local regulations) and the competences of government, in the past this planning style could be compared with the comprehensive integrated model – a strong role of the public sector, however with the advantage of the national government contrary to the decentralised planning system. In terms of planning laws and spatial division of the state, the cases of ex-Czechoslovakia and ex-Yugoslavia could be easily compared to Austria (Newman and Thornley, 1996). However, the fall of the Berlin Wall designated great changes in the broader social and thus in the planning context, too. The scope of the planning became narrowed and limited only to the activities related to the economic sector, while the main investments came from the private sector – in the beginning, from domestic investors, and recently, more foreign. Planning institutions are clearly immature, with planning experts still seeking to find their position in between strong governmental demands and the private sector initiatives. Therefore, spatial decisions are made without previous prioritisation and taking into account the citizens' voices, thus leaving no room for public trust in planning (Tsenkova and Nedovic-Budic, 2006). Due to the various pace that different post-socialist countries followed in recent three decades, there can be certain variations in the extent of the planning transformation. However, one is true: the post-socialist nation states still strongly attempt to catch up with European standards – the spatial planning field cannot be neglected in such a transition.

3 PLANNING CULTURE: A METHODOLOGICAL TOOL

To better understand specific spatial development across Europe, it is not enough to consider only the planning system characteristics – institutional, legal and regulative framework of planning policies. On the contrary, 'everyday planning practice', deeply rooted in the values, norms, belief systems, visions and behaviour of the actors involved in the planning process – planning culture – must be taken into account (Fürst, 2009; Getimis, 2012). Moreover, different socio-economic patterns as well as various perceptions of planning tasks and responsibilities strongly influence spatial planning (Sanyal, 2005). Furthermore, Friedmann (2005) places an emphasis on both the formal and informal ways of understanding, formalizing

and implementing the spatial planning tasks. Finally, Faludi (2005: 285-6) stresses the roles and attitudes of planners regarding the appropriate role of the state, market forces, and civil society in influencing social outcome. Therefore, we agree that the planning culture concept is a complex one, comprising several 'culture segments' or 'culture layers'. Two dimensions of planning culture are certain: 1) horizontal (e.g. planning process, decision-making arrangements), which is directly 'perceivable', but still fuzzy, easily affected and in a constant change, and 2) vertical (e.g. social structures/governance model, planning system), which is underlying and difficult to perceive, but pretty stable and deep-rooted (Gullestrup in Dühr et al., 2010).

Although the notion of planning culture entered both the planning theory and research field ambitiously trying to go beyond the classical 'planning system' concept, many of these studies are still at the level of general statements on institutional structures and far from an operational framework for analysis of the concrete planning cultures in different localities (Fürst, 2009). However, some research findings try to complement it with a certain 'planning culture' approach (Knieling and Othengrafen, 2009; Getimis, 2012). In fact, they provide an idea how to understand the notion of culture and its effect on spatial planning. More precisely, Knieling and Othengrafen (2009) provide the 'culturised planning model', while Getimis (2012) points out the aspects of the 'planning culture framework'. The main characteristics of both models are briefly described in Table 1.

Source	Aspects		
Culturised planning model (Knieling and Othengrafen, 2009)	Societal environment Underlying and unconscious; taken-for-granted beliefs; thoughts and feelings which are affecting planning	Planning artefacts Visible planning products; structures and processes	Planning environment Shared assumptions; values and cognitive frames that are taken for granted by members of the planning profession
Planning culture framework (Getimis, 2012)	Policy styles Values, perceptions and mentalities of the representatives of collective actions	Actor constellation and power Agenda setting; the problems/challenges to be addressed; the scale of planning practices that are initiated to resolve the problems	Knowledge forms Scientific (planning expertise); institutional (logic of institutions, managerial capacities); everyday (individual act in common-sense situations)
PLANNING CULTURE: A PRAGMATIST APPROACH	SOCIAL SETTING System conditions; institutional and organisational action; agents' beliefs; social learning	PLANNING PROCESS Deliberative plan making	PLANNING ENVIRONMENT Cultural awareness of planners

Table 1 – Interrelated aspects of the planning culture approach

In Europe, the reality of the many successful spatial planning efforts coping with different problems testifies to the usefulness of plan making. Therefore, we consider how certain spatial problems flow from the interactions of purposeful systems whose agents are unable to anticipate and comprehend how their own efforts contribute to the spatial problem at hand. The institutional context varies along with the vocabularies of complaint; but the familiar elements of spatial interaction and competing belief offer an opportunity for deliberate plan making efforts among the relevant parties. People responsible for the collective welfare or public good of each place face a problem generated by unexpected changes in economic and political relationships that extend beyond the local place. Following a pragmatist approach, we ask three questions: What conditions and beliefs shaped the problem situation generating plan making? How did the relevant actors or agents (people) make spatial plans for the place? How well did the plans inform the intentions of the actors whose choices and actions could influence future outcomes? More specifically, our approach includes the parameters of social setting, planning process and planning environment, which are at the core of the methodological tool for empirical analysis.

Social setting depends on the systemic factors, whereas these differ from the political forces to the economic incentives, both affecting the planning practice in a particular spatial context. The systemic interdependence of the varieties of interacting systems cannot be comprehended by any one person, but

requires forms of social learning across diverse webs of institutional and organisational action. Therefore, it is not only the expertise, but also 'experiential' knowledge and skills what counts. Involving people in making plans for places while introducing relevant impacts informed by scientific and moral assessment requires deliberation. The varieties of such deliberate learning provide examples of innovative planning practice that contribute to the judgments people take making and altering the places they inhabit and use. Finally, the profession of spatial planning for places proves culturally useful by helping those who make plans for a place better anticipate and prepare for current and plausible problems. Cultural awareness makes the planners: acquainted with the context where they operate, capable of constant capacity-building, able of conducting socially justified activities and, thus, producing sustainable spatial solutions.

Briefly put, the 'cultural embeddedness' (Alexander in Reimer and Blotevogel, 2012) or as Healey (2006) puts it 'spatial consciousness' – the extent to which concepts of place, spatial organisation and territorial identity are built in policy cultures, deeply affects the spatial development patterns within certain territories. Do these cultural differences in the plan making craft fail to address the basic functional questions? We study the plan making in Solothurn (Switzerland), Patras (Greece), and Belgrade (Serbia) to find out how the projects responded to system demands, changes to planning approach and the planning professionals' expectations.

3.1 PLANNING CULTURE IN SOLOTHURN, SWITZERLAND

The Borregaard AG (Norwegian lumber company) shut down a 107 ha wood industry plant in 2008 located in Solothurn. The site went from a revenue producing employer to an environmental brownfield posing a risk to public health. The canton elected officials did not ignore the problem, blame it on industry or turn for assistance to the national government. They coordinated purchase of the site together with three private employers. This extraordinary act reflected recognition of the scarcity of flat land in Switzerland and the promise of continued economic prosperity. The structural plan for the canton had anticipated this departure as early as 2005 setting in motion the idea that this site deserved attention as a resource for future redevelopment (Scholl et al., 2013). The plan was created as part of an already well established tradition of plan making that the people involved all understood and accepted.

3.1.1 SOCIAL SETTING

Switzerland is famous for its decentralized way of decision-making and informal planning procedures when tackling complex spatial problems. The concept of pluralism is anchored in the Swiss conception of the political state, with its direct-democratic institutions, while citizen participation is natural planning practice (Keller et al., 1996). Thus, the main goal of Swiss comprehensive spatial planning is to achieve consensus among the interests of spatially relevant stakeholders. Moreover, public voting on planning issues is deeply rooted in Switzerland due to its territorial limitation of available land reserves (Swiss Federal Council, 2012). Collaboration between various institutional levels during the policy-making process (in a 'bottom-up' manner), as well as the cooperation between different sectors (public, private and civil) is the major feature of Swiss spatial planning culture. Collaborative planning procedure in the brownfield redevelopment process in Solothurn caused the changes in the cantonal structural plan (as the official spatial development instrument), proving that cooperation finds a fertile ground within a consensus-based direct democracy (Staub, 2011).

Moreover, stable economic situation of the cantonal government makes the planning procedures easier. Since in case of Solothurn there was no interest from private sector to invest in land development, the cantonal representatives, having in mind that the site is of great cantonal importance, bought the land and thus saved it from further degradation (Staub, 2011). Such an action clearly demonstrates the power relations among various sectors in Switzerland, with a central role of cantons – both in terms of economic independence, and hence no need to sacrifice the land reserves through the compromising planning solutions, as well as in institutional capacity to coordinate the future actions horizontally (various sectors of cantonal representatives participated in creating new spatial solution), and vertically, with continuous interaction with both the municipalities and federal spatial planning office. Clearly, democratic cooperative 'steering style' – the power decentralization combined with the network-building among the participants with different roles – makes an optimal setting for collaborative planning procedures (Scholl et al., 2013).

3.1.2 PLANNING PROCESS

Swiss planning practice is not grounded on standardized procedures; the focus is on the 'tailor-made' solutions, pragmatism and action-orientation (Keller et al., 1996; Scholl et al., 2013). In case of Solothurn, the stakeholders' participation was organised in a transparent manner with considering different interests of various parties – citizens, private companies, authorities at various levels, and independent experts. Although differing in power, there was no restriction to the needs and demands of the less powerful stakeholders. Imposing the decision by the canton was not chosen as a proper solution. More precisely, cantonal representatives influenced the planning procedure in two ways: indirectly – by defining the guidelines in the structural cantonal plan, and directly – through initiation of and participation in the planning process and the selection of expert committee members (a body responsible for structuring the action plan, i.e. major milestones and deliverables throughout entire planning process). The possible misuse of such a superior position was prevented by a highly transparent planning process management, containing the following parameters: 1) role differentiation, 2) several consultation meetings, 3) at least three competing project teams, and, 4) joint development of the final strategy (based on the combination of different proposals, i.e. there are no winners). Those rules are part of 'test-planning' – informal planning procedure not regulated by the law, but surely contributing to an efficient and meaningful planning process (Scholl et al., 2013). The described procedure provides the opportunity for the stakeholders to "be smarter when working together" (Staub, 2011). Also, only "jointly recognized problems are the motives for cooperation" (Grams, 2011). Planner, as an expert, does not insist on his own opinion. On the contrary, the consensus building is the main prerequisite for the success of the 'test-planning' procedure.

3.1.3 PLANNING ENVIRONMENT

With a combination of direct democracy and the need for sustainable spatial development, Swiss planners have a high level of autonomy – they are pursued to create original planning concepts and individual approaches (Scholl, 2008). Finding a creative solution for the brownfield site in Solothurn was made possible due to involvement of specific expert group and a specific organisation of the planning process. Namely, in addition to the main sectors involved (cantonal officials, private investors, local community), the particular significance was assigned to the independent experts, i.e. the experts outside the cantonal office. Also, despite a large number of stakeholders, the whole process ran smoothly due to its efficient organisational structure divided into two levels – strategic and operational. At the strategic level, the main role of decision-making was assigned to the executive board (consisted of cantonal representatives). At the operational level, the most important body was the expert committee (composed of both cantonal and external representatives), whose role was: 1) the definition of goals, vision and strategy, and, 2) the evaluation of the proposals made by different project teams (based on previously defined criteria) (Scholl et al., 2013). The key negotiator in the entire process was the expert committee – a multidisciplinary team of experts with both technical knowledge and mediation and facilitation skills, with two main tasks: advising the executive committee and selecting the best planning solutions (Grams, 2011; Staub, 2011). Such a position of planning expertise that goes beyond its expected performance was the core of the successful planning approach.

3.2 PLANNING CULTURE IN PATRAS, GREECE

A reliable and direct railway connection between Athens and Patras, the largest city in Peloponnese, is a strategic project of high priority aimed at bridging the East-West division of high-performance transport infrastructure that exists in Greece for a long time. However, in recent two decades, an endless discussion and unsustainable studies about the integration of the rail tracks into the urban pattern have been developed without concrete results. This stems mainly from an administrative fragmentation of the waterfront areas along the existing railway line leading to inconsistent decision-making, which makes the local government, the OSE (Hellenic Railways Organisation) and the ERGOSE (the OSE subsidiary company in charge of real estate) reluctant to collaborate (Papamichail and Peric, 2017).

3.2.1 SOCIAL SETTING

Greek administrative planning framework was modelled after the Napoleonic structure, characterized by the 'fused system' – a system with a dominant national planning level, while there also laws for municipal plans (Newman and Thornley, 1996). Due to the institutional transformation during the 1990s, the decentralization of the planning responsibilities toward the regional administrations and local authorities was enforced. However, nowadays all the planning decisions still have to be in line with the national spatial planning guidelines. More precisely, national ministry has formal competences and responsibility for preparation of urban (municipal) plans, while cities mainly decide on building permits, in line with the planning tradition of urbanism. Briefly put, planning is translated into the design and creation of places and is mainly carried out at the local level, while there is evident lack of a strategic approach of the national government (Papaioannou and Nikolakopoulou, 2016). Together, this makes the spatial planning in Greece highly ineffective.

Moreover, due the current economic crisis, the financial framework is unstable and limited, which unconditionally leads to the fragmented decision-making processes taking place between different planning levels and actors, and thus ad-hoc developments (Pappas et al., 2013). Firstly, spatial planning lacks a vision because of the recent privatization of planning powers and services, outsourcing, and the pro-growth planning (Reimer et al., 2014). The HRADF (Hellenic Republic Asset Development Fund) illustrates the privatization phenomenon that transfers the responsibility of many services and public agencies into private entities. This affects directly the development and planning in Greece with the constant legalization of illegal constructions and/or stretching the scope of territories covered by the city master plans. Secondly, there is no a cooperation model among state, different administrative bodies and public organisations towards a common strategic spatial planning, thus causing the conflicts and delays for the vital strategic projects (Papamichail, 2015). Such an example is the attempt of introducing the railway line into the central city core of Patras.

3.2.2 PLANNING PROCESS

As assumed from above, the final decisions and approval of various plans and programmes are based on a top-down approach, thus creating a non-flexible environment for participation and collaboration. Although since the 1990s, there has been an effort for the new mechanisms of actor involvement toward the Europeanization of the Greek planning (Giannakourou, 2011), the development of planning policies and instruments has been proved as non-intersectoral and non-interdisciplinary, while overlapping responsibilities and interests at all administrative levels prevent any collaborative approach. The limited mechanisms for citizens' involvement as well as poor managing the conflict among different planning levels and actors are also the norm in the Greek spatial planning (Knieling and Othengrafen, 2016).

In the case of Patras, the prolonged conflicts are persistent mainly due to the administrative fragmentation of the waterfront area and consequently due to a lack of cooperation between the responsible authorities (Papamichail and Peric, 2017). Moreover, the local level does not have any competence in making plans on future railway development. Namely, the Greek Ministry of Transportation started a discussion about three scenarios of railway development in Patras, in an effort to meet the political interests of the municipality. The proposal included the by-pass, the underground and the ground-level solution. The discussion about the best scenario has recently continued with the presence of different actors, including the port authorities, ecologists, other political parties, the University of Patras and local organisations of neighbourhoods excluding the OSE, the ERGOSE, and planning experts, as well. Hence, the debate turned out to be pure political verbalism that insisted on the pharaonic plans, e.g. the by-pass solution, an unsustainable project of € 700 million with no proposals for the integrated model of city development. Once again, the fragmented decision-making and a top-down approach were implemented, excluding any collaborative attitude. Therefore, spatial planning is generally understood to be product-oriented, e.g. it is concentrated on the production of individual plans rather than on pursuing a continuous planning process, with a lack of coordination among the actors about institutional boundaries and a lack of effective monitoring mechanisms (Pappas et al., 2013).

3.2.3 PLANNING ENVIRONMENT

In Patras, planning experts were not involved in the discussion about the railway solution that greatly affect future urban development (Papamichail and Peric, 2017). This is a clear sign of an underestimated professional planning position. There are two main reasons behind such a situation. Firstly, local spatial planners are not formally competent to provide proposals that include even a pinpoint of strategic vision, i.e. strategic reasoning is reserved for the national planning offices within the relevant ministry, although it is highly ineffective. Local planners are in charge of providing building permits, thus supporting various decision-makers, mainly national government or private sector representatives (Othengrafen, 2010). Moreover, since each urban plan has to be in line with the national guidelines (and practically the plan is prepared by ministry), there is no room for local planners to show their possibly innovative approaches and a certain degree of independence. Briefly put, it is very hard to find a way for introducing integrated spatial and transport models (as truly strategic approach) within the highly centralised structure (Papamichail, 2015).

Another reason for a weak position of spatial planners lies in the specificity of their education. Only in the last 15 years, it has been possible for students to attend specific degrees in spatial planning (Othengrafen, 2010). Majority of spatial planning tasks today are undertaken by architects, whose focus is a bit different than this of strategic planning and creation of spatial visions for future. On the contrary, they deal mainly with urban design aspect of the built environment, without an idea on comprehensive planning approach. Finally, the skills immanent to planners in the Western world (negotiation, mediation, facilitation) are not experienced in the Greek context (Papaioannou and Nikolakopoulou, 2016). On the one hand, citizens' voices are not heard, except in case of threat to the self-interest, while, on the other, planners are mostly excluded from debate where other, powerful actors, have the leading role.

3.3 PLANNING CULTURE IN BELGRADE, SERBIA

Three years after initiating the idea on the Belgrade Waterfront project (during the political campaign of then-largest opposition party), the cornerstone for a 90 ha land on the river bank was set in October 2015, thus marking the beginning of the 30-year long development period. Moreover, due to its position (close to the confluence of two rivers and the historical city core), this brownfield site redevelopment is not only of city, but also of regional and even national importance, thus attracting mainly foreign investors (Maruna, 2015). The current construction work is financed by the investor from the United Arab Emirates (UAE).

3.3.1 SOCIAL SETTING

As other post-socialist countries, Serbia is faced with the decentralisation of power, reflected also in the decentralisation of responsibilities in the spatial planning domain, on one hand, and the adaptation to the neo-liberal paradigm on the other (Vujosevic, 2010; Vujosevic et al., 2012). However, the Belgrade Waterfront project clearly shows that spatial planning power decentralisation in Serbia is not real: although the city authorities should have the major role in defining the priorities for further development of the riverfront area, their role is marginalised; in fact, when it comes to the mega-projects, the tight cooperation between the city and national governance – in the way that all decisions made at the national level are simply imposed on the local/city level – appears as a necessary condition for any further spatially relevant action; finally, the illusion that the city mayor's voice is heard when debating about the future project lies in the fact that both the city mayor and the prime minister belong to the same political party (Maruna, 2015).

Although the success of the economic system's transition within the ex-central economy-driven post-communist states can be debated (Vujosevic et al., 2012), the Belgrade Waterfront is an example of a strong glorification of the neo-liberal principles without taking into account the public interest demand. More precisely, all negotiations during the preparation of the agreement with the foreign investor were subordinate to the developer's requests, while the national interests were masked under the veil of new workplaces and the assignment of the construction work to Serbian subcontractors. Concretely, according to the agreement between Eagle Hills, a company from the UAE, and the national government of Serbia, the state is obliged to remove the old railway tracks (currently at the site since this is the broader area of railway station still in use), invest in constructing the new railway station, provide all the infrastructural equipment to and on the site and even lease the land to the UAE investor for 99 years. Unfortunately, this

is a paradigm of the current spatial planning approach in Serbia: ad hoc solutions are today the only way of attracting investments for large redevelopment projects (Zekovic et al., 2015).

3.3.2 PLANNING PROCESS

In contrast to the former Yugoslav planning professionals who were acting in concert with the authorities, highly appreciating multidisciplinary in the planning process and being recognised as the bearers of public interest, Serbian planners are today completely side-lined for public interest lost its privileged position as the 'higher' reason that cannot be brought into the question (Vujosevic and Nedovic-Budic, 2006). Planners cannot cope effectively with the private interest requests expressed in the Belgrade Waterfront project for their expertise did not evolve through time: they do not know how to swim in the whirlpool of multiple interests, i.e. they did not adapt to the pluralistic society and still try to keep their exclusive position.

The global shift of the planning paradigm addressed the raising awareness of the stakeholders' collaboration in creating the spatial development policies (Vujosevic et al., 2012). Nevertheless, in the case of the Belgrade Waterfront project, strategic decisions were made at the political level (with the key role of prime minister!), hence, avoiding any kind of a public debate with a range of interested parties. The professional planners' society was completely ignored by the political power structures: on the one hand, they were the advocates of public interest, but what is worse, they never showed any understanding of a contemporary society's demands and the need of adjusting their own profile to it. Persistent adherence to the outdated position made them players without power in a stakeholder arena, thus easily disregarded by the powerful political structures. The civil sector, i.e. several non-governmental organisations, also raised its voice pointing to the irregularity of the legal basis of the Belgrade Waterfront project, thus trying to address the broader public audience. They were underlining the importance of safeguarding public interest and compliance with planning and construction legislation (Maruna, 2015). However, the exclusion of both the planning profession and the public in such an important project is a clear sign of an elementary ignorance of democratic decision-making.

3.3.3 PLANNING ENVIRONMENT

The previous paragraphs tackled the issues of planners' relationship to other stakeholders. However, here we want to draw attention to the professional expertise – their skills and knowledge needed when dealing with complex spatial problems. Briefly put, Serbian planning professionals place their expertise only on their technical knowledge (of producing the plans), without taking into account 1) the planning process itself (and hence the need to use the skills of facilitation, mediation, and negotiation while communicating with other interested parties), on the one hand, and 2) a broader social context in which the stakeholders' collaboration should take place on the other (Vujosevic et al., 2012). The clear example of the Serbian expertise position was the complaint of the National Association of Architects (NAA) to the spatial concept proposed by foreign architects and designers. To avoid possible confusion, most of the urban planning professionals come from the Faculty of Architecture, University of Belgrade or similar technical faculties of the other Serbian universities. The NAA president stressed the unfair domestic exclusion of experts in the project: the comment was mainly on the quality and design of the project, and not on the strategic decision-making procedure that caused such a design. In this way, the experts confirmed that they only reckon on their own technical experience with no understanding that a strategic decision-making process in spatial planning should include knowledge and skills from other disciplines, as well (Maruna, 2015).

4 CONCLUSIONS

As the empirical analysis shows, diversity in planning is constant in Europe and this can be hardly changed. The quality of the planning approach and further success in its implementation strongly depends on broader social context; the setting which do not pay enough attention on the planning as a powerful tool for directing future spatial development seems to be confused in providing proper answers to the challenging situations.

Looking through the lens of the social environment, Switzerland, famous for its decentralized way of decision-making, is also a clear example of reflecting its collaborative approach during the policy-making process (experienced at federal level) into the deliberative plan making. Moreover, within the Swiss Spatial Planning Law (revised in 2013), there is a clear demand for informal planning procedures when tackling complex spatial problems. On the contrary, Greece is highly influenced by a fragmented decision-making and a clientelism approach, thus remaining attached to rules and adopting a politics of resentment. Under the umbrella of the market-oriented pluralist society, the Serbian national governance is highly confused in a controversial attempt to re-decentralize the state administrative structure, and thus make some other levels more powerful in the spatial planning decision-making process, on the one hand, and to strive to achieve as tight as possible feedback with foreign private investors on the other.

Deliberative planning through the democratic actor constellations is a norm in the Swiss plan making. Mutual trust, joint actions and transparent decision-making procedures among the representatives of public, private and civil sector makes the culture of Swiss plan making highly collaborative. In Greece, plans cannot work because the problem is not recognized as a kind of uncertainty susceptible to resolution, but a conflict of injustice or identity. This hence results in unconventional and ad-hoc developments. In Serbia, there is a high disproportion in power between the national government, thus reaching a dominant position in negotiation with private sector about future spatial development, and other parties, be these the authorities at lower levels, citizens or experts, which are totally marginalised.

Swiss planners, as public administration representatives, have a high level of autonomy, which offers them an opportunity for creating the original planning concepts and individual approaches. In Greece, planning/planners are considered a 'supportive actor' (Othengrafen, 2010), sometimes only providing technical instrument for the decision-making to be done by politicians or private investors. Similarly to this, professional expertise in Serbia is highly behind the contemporary demands of the planning vocation; planning is deeply subject to politics.

To conclude, the illustrated differences flow from the variations shaping the cultural conceptions of the problems and the relevance of spatial plan making as a source of practical judgment for meaningful joint action. The Swiss plan offers such a good example of effective collaborative planning not because the plan making was significantly better than the plan making for the transport corridor in Greece or the brownfield in Serbia; but because the attachment to institutional patronage in Greece and political favouritism in Serbia undermined the relevance for spatial planning. However, analysts go astray as they imagine planners or plans responsible for relations of social mistrust and cynical detachment. The plans can provide important testimony to the kind of purposeful deliberation that may anticipate and avoid the social and economic damage of urban developments that wilfully ignore future consequences for others. Nevertheless, bureaucratic indifference and patronage along with political favouritism and corruption cannot be remedied by planning. Changing these conditions requires a host of social, political and economic changes that extend well beyond what plans can do.

1 INTRODUCTION

Significant attention has recently been paid to the new forms of territorial governance emerging at the scale of urban regions in Western Europe (Allmendinger et al., 2015; Janssen-Jansen and Hutton, 2011). In the planning literature, these new spaces of governance have been conceptualised as 'soft spaces' with 'fuzzy boundaries', as they are often located in between formal levels of governance, and are not necessarily univocally bounded (Haughton et al., 2010). It is claimed, that the new spaces of territorial governance do not as much replace formal levels of governance, as they seek to supplement existing

governance structures in strategic ways, e.g. around specific policy agendas, thus adding extra layers to an increasingly complex and fragmented governance landscape (Allmendinger and Haughton, 2009a).

As in many other European countries, Denmark has experienced an explosion in the number of informal governance networks working across formal boundaries in recent years. As part of this general trend, a number of city region networks have emerged around the biggest Danish cities. Drawing on experiences mainly from other Nordic countries, several of the networks identify themselves as 'business regions', and have formulated goals and visions revolving primarily around attracting businesses and a highly educated workforce to the region. In the Danish debate the concepts of 'business regions' and 'city regions' are often used interchangeably, as the networks, regardless of the self-proclaimed label, seek to address similar challenges. For convenience, we adopt the terminology of 'business regions' in this paper to describe the new governance networks at the scale of city regions.

In this paper, we explore the rationalities behind the emergence of business regions in and around the four biggest cities in Denmark. In order to get a sense of the nature of the strategic spatial planning that is practised in such spaces, we examine the spatial strategy-making initiatives that takes place in the auspices of those regions. We built our analysis on document analysis of strategies, visions, policy documents, official webpages etc., together with semi-structured interviews carried out with the key actors involved in the business regions.

2 SOFT SPACES AND A NEW PLANNING CULTURE

In this section, we discuss the driving forces behind the proliferation of new soft spaces in Western Europe, and elaborate our understanding of soft spaces as spaces of neoliberal experimentation promoting a new planning culture rooted in neoliberal ideology.

2.1 THE DRIVING FORCES BEHIND SOFT SPACES

The driving forces behind experimentation with soft spaces of territorial governance are many (Allmendinger et al., 2015). We can understand soft spaces as i) new state spaces emerging from continuous processes of state restructuring in the face of economic globalisation (Brenner, 2004a, 2004b); ii) spaces for experimentation with new approaches to strategic spatial planning in the context of urban entrepreneurialism (Olesen, 2012); iii) functional planning spaces reflecting a need to move beyond an absolute understanding of space inspired by relational geography (Davoudi and Strange, 2009; Haughton et al., 2010); and iv) networked forms of governance seeking to work outside the rigidities of statutory planning as a response to neoliberal policy agendas of policy delivery and effectiveness (Haughton et al., 2010).

According to state theorists, the production of new spaces of governance can be understood as the result of nation states searching for new 'scalar fixes' (Brenner, 2004a) or 'spatiotemporal fixes' (Jessop, 2000) in the face of economic globalisation. Since the 1960s, Western European nation states have experienced multiple rounds of spatial restructuring (Brenner, 2004a). Each round is characterised by reterritorialisations and rescalings of statehood, in which new scales and spaces are targeted for concentration of economic activity and experimentation with new forms of urban governance (Brenner, 1999, 2004b). In the most recent rounds of spatial restructuring, what Brenner (2004b) identifies as the rounds of glocalisation strategies, the experimentations with new forms of urban governance are customised to a few privileged 'new state spaces'. These spaces are argued to constitute the new key scales on which nation states compete.

As part of these processes of state restructuring, the form of urban governance changed from urban managerialism rooted in Spatial Keynesianism to urban entrepreneurialism rooted in a neoliberal ideology (Brenner, 2004a, 2004b; Harvey, 1989). Major European cities and urban regions regained the interest in strategic spatial planning and prepared spatial strategies, positioning cities and regions strategically within the global and European circuits of capital (Albrechts et al., 2003; Brenner, 2004a). Many of these (glocalisation) strategies were also concerned with developing new spatial imaginaries and identities for the new state spaces emerging in Western Europe at the time, such as the Flemish Diamond (Albrechts, 1998; Olesen and Albrechts, 2017) and the Øresund Region (Olesen and Metzger, 2017). We can thus

also understand soft spaces as “exercises 2 of re-branding, of shifting perceptions of a struggling economy for instance with a new, more positive imaginary” (Allmendinger et al., 2015: 219). The turn towards urban entrepreneurialism can in this context be understood as having paved the way for experimentations with strategic spatial planning in new soft planning spaces (Olesen, 2012, 2014).

The proliferation of experiments with soft spaces should also be understood as a result of an increasing concern with mismatches between administrative boundaries and the ‘realities’ of functional urban regions (Davoudi and Strange, 2009; Haughton et al., 2010). In many cases these mismatches have been deepened as a consequence of planning reforms driven by policy agendas of devolution and decentralisation, leaving behind gaps to be filled in by informal forms of governance (Haughton et al., 2010; Olesen, 2012). Soft spaces have also been conceptualised as more pragmatic approaches to spatial planning, focusing on ‘what works’ in terms of implementation and policy delivery (Allmendinger, 2011; Allmendinger and Haughton, 2009b). Here, soft spaces constitute deliberate neoliberal strategies to short-circuit formal planning requirements and move beyond the rigidities of statutory planning, in order to facilitate development and create a competitive advantage (Haughton et al., 2010). It has been noted that soft spaces are often constructed around highly selective policy agendas (Allmendinger et al., 2015), and that strategy-making in soft spaces tends to prioritise policy agendas of promoting economic development, whilst sidestepping formal planning responsibilities related to social justice and environmental sustainability (Haughton et al., 2010; Olesen, 2012). Furthermore, Olesen (2012) has suggested that soft spaces add to the increasing pressure on statutory spatial planning, and can act as vehicles for a neoliberal transformation of spatial planning.

2.2 THE POLITICS OF SOFT SPACES

As indicated above, soft spaces should not only be understood as functional planning spaces, but also as expressions of politics in the context of neoliberalisation and postpolitics (Allmendinger and Haughton, 2012; Haughton et al., 2013). We argue that soft spaces should not only be understood as products of the continuous neoliberalisation of spatial planning, but also as key spaces for “destabilising existing governance practices and planning cultures” (Olesen, 2012: 911).

Recent theorisations on neoliberalism suggest that processes of neoliberalisation have moved beyond the phase of ‘roll-out neoliberalisation’, in which the state supports market logics and competition through strategic investments in urban development and infrastructure projects (Peck and Tickell, 2002). According to Keil (2009), we have now entered the phase of ‘roll-with-it neoliberalisation’, characterised by an increasing normalisation of neoliberal practices and concepts. Several authors have suggested that contemporary strategic spatial planning experiments are struggling to live up to progressive planning aims in the face of roll-with-it neoliberalisation (Cerreta et al., 2010; Haughton et al., 2010; Olesen, 2014). Olesen (2012) has illustrated how soft spaces in Denmark were turned into spaces for promotion of economic growth and transport infrastructure lobbying, whilst discrediting traditional regulatory planning approaches. This suggests that soft spaces have become important political spaces for promoting neoliberal agendas of stimulating competitiveness, generating economic growth and attracting investments in transport infrastructures.

In fact, soft spaces seem to constitute important strategic spaces for promoting particular neoliberal versions of strategic spatial planning (Olesen, 2012), rooted in what Peck and Tickell (2002) have labelled ‘the growth-first-principle’. Olesen (2014: 296) highlights how strategic spatial planning processes rarely allow for “a critique of economic growth and competitiveness as the prime virtues of strategic spatial planning”. Along the same lines, Haughton et al. (2013: 22) have noted how soft spaces only seem to allow for demands to be voiced, which “do not question and disrupt the overarching framework of marketled development”. Spatial planning in soft spaces become depoliticised strategy-making processes, in which conflicting or political sensitive issues are removed or superficially glanced over in the name of promoting economic development (Allmendinger and Haughton, 2012). In this way, soft spaces are governed by a strong neoliberal governmentality of what is considered ‘relevant’ and ‘possible’ policy agendas. This post-political planning condition is nicely captured by Haughton et al. (2013: 232) stressing that “this new form of neoliberal governmentality has reworked the nature of planning itself”. Allmendinger and Haughton (2009a) argue that soft spaces have contributed to an opening up of the professional boundaries of spatial planning, which in term have become more fuzzy. Spatial planning has developed into a discipline of (much) more than merely land use regulation and managerial approaches. However, at

the same time the policy repertoire of spatial planning has become more narrow, focused primarily on promoting economic growth.

Contemporary reworkings of the planning cultures in Western Europe seem to be characterised by two dialectic processes of opening up and blurring the professional boundaries of spatial planning, whilst spatial planning at the same time is subjected to neoliberal governmentalities promoting a narrow set of policy agendas. It is these dialectic processes, we explore in the case of the Danish business regions, in order to develop an understanding of how these spaces contribute to transforming the Danish planning culture.

3 THE EMERGENCE OF SOFT SPACES AND A NEW PLANNING CULTURE IN DENMARK

In this section, we outline the context within which the emergence of business regions in Denmark must be understood. Adopting the terminology from Brenner (2004a, 2004b), we argue that Denmark has experienced three rounds of spatial restructuring in the last three decades, and that the emergence of business regions can be understood as a result of the most recent process of spatial restructuring, in which third generation glocalisation strategies have been prepared at the scale of city regions.

The emergence of urban entrepreneurialism in Danish spatial planning is often associated with the implementation of the Danish Planning Act in 1992, in which the aim of spatial planning was changed from promoting equal development to 'appropriate' development. In Harvey's (1989) terms, the 1992 Planning Act marked a shift from urban managerialism to urban entrepreneurialism. As part of the shift, the national government began to promote the capital city of Copenhagen and the Øresund Region as the new privileged spaces for urban development, investments in infrastructures, and concentration of economic activities. This reterritorialisation became the government's answer to the economic challenges that Copenhagen (and south Sweden) was facing at the time (Olesen and Metzger, 2017). We interpret the Øresund Region as a product of what Brenner (2004a) identifies as glocalisation strategies round I, and the first soft space in Denmark rooted in policies of promoting economic development and competitiveness.

The second round of spatial restructuring in Denmark rooted in glocalisation strategies, we associate with the implementation of the Governance Reform in 2007, and the wide range of spatial strategies that emerged as a consequence of the reform. The reform was implemented to introduce a more efficient governance structure, in particular within the public healthcare sector. However, the reform also led to significant reterritorialisations in terms of spatial planning, as the middle-tier of the planning system was abandoned and regional statutory land use planning decentralised to the municipalities (Galland, 2012; Hansen, 2009, forthcoming). In order to support regional development, various governance networks (public and private) were established at the regional scale, including regional growth forums and cross-municipal platforms for representation of municipal interests (Hansen, forthcoming). The explosion in the number of networks and platforms for representation of regional interests has in a Danish context been interpreted as a turn towards a pluricentric governance model (Pedersen et al., 2011; Sørensen, 2014). Many of the new networks were constructed with a point of departure in the formal regional administrative boundaries established in 2007. They were therefore not always considered appropriate platforms for strategic spatial planning. This led to a national interest, already from the initial phases of the implementation of the 2007 reform, in promoting functional urban regions for strategic spatial planning, in an attempt to 'fill-in' gaps in the Danish governance landscape (Olesen, 2011, 2012). The Danish government was in particular keen to promote Eastern Jutland as Denmark's second metropolitan area. This was partly a response to the rather one-sided focus of promoting growth in Copenhagen for more than a decade, and partly as a result of the realisation that the newly formed regional boundaries did not correspond well to the 'functional urban region' in this part of Denmark. As regional planning was under strong attack at the time, the process of preparing a spatial strategy for the Eastern Jutland urban region developed into a contested affair, played out between conflicting planning rationalities rooted in regulation and growth promotion, respectively *Introducing Business Regions in Denmark: Towards a new Planning Culture?* 5 (Olesen and Richardson, 2011, 2012). At the time, it was already evident that strategic planning in the soft space of Eastern Jutland was driven by a strong neoliberal agenda, actively seeking to redefine what it meant to prepare spatial strategies at the regional scale (Olesen, 2011, 2012).

We argue that Danish spatial planning has recently entered a third round of glocalisation strategies, which include city regions around second-tier Danish cities. This round of spatial restructuring is not the result of reterritorialisations promoted through planning reforms or in other ways inspired by the national level. We interpret the current round of reterritorialisation as the manifestation of a wider growth-oriented planning culture, which has been underway since the early 1990s. Danish spatial planning has now entered the phase of roll-with-it neoliberalisation (Keil, 2009), in which the promotion of growth, competitiveness and economic development have developed into taken-for-granted (if in practice not the only) goals of regional planning in Denmark. As a result, the second, third and fourth biggest cities in Denmark have upscaled their strategies to the city region scale, and created ‘business regions’ in collaboration with surrounding municipalities. Copenhagen has followed suit and rebranded the Øresund Region as Greater Copenhagen. On the contrary to earlier rounds of spatial restructuring, the promotion of business regions is primarily a municipal project, with limited national and regional interference, although the regional level has been accepted as a member of the business region in several cases. Table 1 summarises the three rounds of spatial restructurings rooted in glocalisation strategies in Danish spatial planning.

	Time	Soft space	Rationality
Glocalisation strategies round I	Early 1990s	The Øresund Region	Promoting the competitiveness of Copenhagen and the Øresund Region in the context of increasing European competition
Glocalisation strategies round II	Mid-2000s	Eastern Jutland	Promoting a second growth area in Denmark and functional urban region for strategic spatial planning.
Glocalisation strategies round III	Mid-2010s	Aarhus Business Region, Business Region North Denmark, City Region Funen, Greater Copenhagen	Promoting competitiveness and economic growth in and around the four biggest Danish cities.

Table 1: Spatial restructurings in Denmark from 1990-2016

4 THE EMERGENCE OF BUSINESS REGIONS IN DENMARK

In the third round of glocalisation strategies, a number of cross-municipal networks have emerged at the scale of city regions in Denmark. These networks identify themselves as ‘business regions’ or ‘city regions’, inspired by similar regional networks in the other European cities. The label of ‘business regions’ (in English) has specifically been adopted with inspiration from city-regional governance networks in other Nordic countries. In the general, the processes of constructing the Danish business regions seem to have been driven by an outward looking perspective, where inspiration has been taken from a range of city regions, including Amsterdam, Gothenburg, Hamburg, Manchester, Stavanger, Stockholm and Tampara. In this section, we examine the driving forces behind the construction of business regions around the four biggest cities in Denmark, as well as the nature of the strategy-making that take place in the auspices of these regions.

4.1 BUSINESS REGION AARHUS

Cross-municipal collaboration in the Aarhus city region has a longer genealogy. Since 1994, several municipalities, with the second largest Danish city Aarhus at the centre, have formally cooperated on business development activities. In 2010 Business Region Aarhus was formed, as it was recognised that there was limited local political support for the national government’s initiative to facilitate cross-municipal cooperation at the scale of the larger urban region of Eastern Jutland (Olesen, 2011, Olesen and Richardson, 2011, 2012). Hence, the creation of Business Region Aarhus marked a significant shift in Danish spatial politics, in the sense that the new region was constructed from below with a point of departure in local political agendas (rather than national spatial strategies). Since, the business region has expanded significantly. Today, it is made up of 12 municipalities, amounting to a population of around 960,000 inhabitants (Business Region Aarhus, 2016b).

Business Region Aarhus defines itself as “a political community of interests” (Business Region Aarhus, 2016a: 3), and is perhaps best understood as a cross-municipal network organisation working for

promoting growth and economic development in the Aarhus city region. More specific the aim of the organisation is to improve the conditions for business development in the region, and increase the region's competitiveness and visibility in a national and international context. This is also the focal point in the region's most recent strategy from 2016, entitled 'Eastern Jutland is working for Denmark' (Business Region Aarhus, 2016a). In the strategy, the business region outlines a number of goals that it seeks to realise towards 2018. First and foremost, the region wants to strengthen its position as the main growth area in Denmark outside Greater Copenhagen. One of the key issues addressed in the strategy is the need to expand the region's existing motorway corridor from four to six lanes. The business region has in recent years acted as the main lobby platform for attracting national investments in transport infrastructure to the city region.

Furthermore, a substantial part of the strategy is dedicated to marketing and branding efforts in order to attract businesses, residents and tourists to the region. In addition, an English webpage (www.businessregionaarhus.com) has been set up, targeting international businesses, expats and a highly educated workforce seeking to relocate to the region.

4.2 BUSINESS REGION NORTH DENMARK

Business Region North Denmark was formally launched in 2015 and is made up of 11 municipalities and the North Denmark Region. The region has a total population of around 600,000 inhabitants and is based around the city of Aalborg, the fourth largest city in Denmark. A key motivation for establishing the business region was an analysis in 2014, by all municipalities in the region, showing that municipal expenses would increase significantly until 2020. This led the mayors and heads of municipal administrations, as well as the North Denmark Region, to agree that joint action had to be taken to increase the income of municipalities, primarily through attention to business life, attracting investments and talents, and job creation.

The main goal for Business Region North Denmark is to stimulate economic growth and attract jobs to the region. The region has identified five focus areas: tourism, infrastructure, international collaboration, business development and job creation, and qualified workforce. In comparison to the other business regions, greater emphasis is put on the tourism industry, as the region is more rural and its economy more dependent on tourism than the other business regions. Strategy-making in Business Region North Denmark has materialised in the document 'Strategy – and action plan 2015-2016' (Business Region North Denmark, 2015). The strategy sets out the main goals for the business region within the five focus areas outlined above. In addition, the document highlights the importance of promoting synergies between the municipalities' independent growth strategies and Region North Denmark's Growth and Development Strategy (the RGDS). The business region considers it to be of significant importance to function as a shared political platform for the public authorities in North Denmark, the municipalities and the region, and to attempt to lobby and influence national level policy-making with a unified voice, in particular concerning transport and IT infrastructures.

An important aspect related directly to spatial planning is the up-front attention to coordination between the business region, the region and its RGDS activity, and municipal spatial strategies. This was initiated in 2014, even before the official opening of the business region, and has already resulted in a first effort to produce a shared chapter on development in North Denmark, in both the first RGDS proposal and in all municipal spatial strategies (Hansen, forthcoming).

4.3 CITY REGION FUNEN

City Region Funen has a population of around 450,000 inhabitants and was established in 2013. It consists of 9 municipalities, including Odense, the third largest city in Denmark. Geographically, the region consists of the island of Funen, except the municipality of Middelfart, which for 8 historical reasons have been part of the cross-municipal organisation the Triangle Area for many years. City Region Funen was established on the background of Project Funen (2011-12) with the ambition to strengthen the position of the region in national spatial planning. Funen, and especially the city of Odense, claimed that it was largely ignored in national spatial policies, in particular in the 2006 and 2010 national planning reports. The aim of creating City Region Funen was to articulate Funen as a functional city region and to articulate Funen's

strategic position on Denmark's 'growthmap'. City Region Funen has therefore not adopted the business region label.

In City Region Funen's 'Strategy Funen 2014-2017', the overall focus is to create and strengthen the spatial frameworks necessary for growth (City Region Funen, 2014). Furthermore, the strategy explicitly mentions an ambition to create a coherent urban region, which has to be developed as an active part of the Greater Copenhagen region as well as becoming more tightly connected with West Denmark. More specifically, the region focusses on transport and digital infrastructures and on becoming a test laboratory for new green technologies and solutions for future global challenges (City Region Funen, 2014).

As was partly the case in North Denmark and Aarhus, City Region Funen has the objective to produce a shared plan strategy. However, the region is more ambitious and intends to let this strategy function above the municipal strategies. This special attention to spatial strategies is also made clear through the intention to focus on "principles for interaction and development between cities. Including development of a common strategy for a coherent development of the cities" (City Region Funen, 2014: 3). This is remarkable in a Danish context of business and city regions, as it seems to reinvoke, into regional policy, some of the planning mechanisms that were removed from the formal regions in 2007.

4.4 GREATER COPENHAGEN

'Greater Copenhagen' is perhaps best understood as the new marketing brand for the Øresund Region. Greater Copenhagen was launched in 2014 as a marketing platform for municipalities and regions on the Danish side of the Øresund Strait, who increasingly had become disappointed with the stagnating development of the Øresund Region. The brand of the Øresund Region was no longer perceived as adequate for promoting the region internationally (Olesen and Metzger, 2017). The Swedish partners were included in January 2016 and the organisation was formally renamed as 'the Greater Copenhagen and Skåne Committee' - in everyday speech 'Greater Copenhagen'.

In many ways, Greater Copenhagen has adopted the Øresund Region's vision of creating a friction-less cross-border region, in particular in terms of overcoming institutional and national borders. In comparison to the Øresund Region, less emphasis is put on region building and cultural integration. Instead, Greater Copenhagen has developed a more narrow policy agenda, focusing on generation of economic growth and attracting international businesses and talents to the region. In the first years of its existence, a particular effort has been dedicated to building up the brand of 9 'Greater Copenhagen'. The marketing efforts have been highly professional and streamlined both internally and externally. The Greater Copenhagen's webpage features for example a 'tool box' (in Danish only), where municipalities can download the logo, a design manual, photos and templates for marketing purposes. In terms of strategy-making, Greater Copenhagen is still in an early phase. Its vision towards 2020 'We are Greater Copenhagen' is a two-page flyer setting out the region's overall goal of being "an international node for investments and knowledge on the level as the most successful metropolises in Europe" in 2020 (Greater Copenhagen, 2016a: 1). Furthermore, the vision identifies internationalisation, attracting international businesses, investments, tourists and highly educated workforce as its main goals, alongside creating a coherent labour market and an attractive business climate. As part of its aspiration of becoming an international node, Greater Copenhagen has also prepared a transport charter, a policy document advocating for the need for substantial investments in transport infrastructure in the region, including the ongoing expansion of Copenhagen International Airport, high speed train connections via the future Fehmarn Belt link, and additional links across the Øresund Strait (Greater Copenhagen, 2016b). Table 2 summarises the main characteristics of the four business and city regions.

	Business Region Aarhus	Business Region North Denmark	City Region Funen	Greater Copenhagen
Established	2010	2015	2013	2014
Number of municipalities	12	11 + Region North Jutland	9	46 (DK) and 33 (SE) + the Capital Region, Region Zealand and Region Skåne
Population	960,000	600,000	450,000	3,900,000
Key priorities/ goals	- Main growth area outside Greater Copenhagen - Attracting businesses and residents in knowledge based industries - Investments in transport infrastructure - Tourism	- Tourism - Infrastructure - International collaboration - Business development and job creation - Qualified workforce	- Economic development and growth creation - Attracting residents - Transport infrastructure - Digital infrastructure - Green technologies and energy planning	- Marketing and branding - International node for investments and knowledge - Attracting investors, tourists, businesses and talents - Integrated labour market - Creating an attractive business environment
Strategic documents	Strategy 2016-2018	Strategy and action plan 2015-2016	Strategy Funen 2014-2017	'We are Greater Copenhagen' (vision 2020)

Table 2: The main characteristics of the four business and city regions

5 CONCLUSIONS

We interpret the emergence of business regions and city regions as the result of recent spatial restructurings and reterritorialisations associated with the institutionalisation of roll-with-it neoliberalisation in Danish spatial planning. The business regions can be understood as third generation glocalisation strategies involving rescalings of local-regional growth ambitions. The business regions are perhaps best understood as hybrids or assemblages, fusing municipal practices of business development and job creation, branding and marketing, transport infrastructure lobbying, and spatial development, and upscaling these practices to new regional soft spaces, with the aim of adding more political weight to local-regional growth agendas.

At the same time, we interpret the new business regions as important political spaces for representation of municipal interests in the continuous scalar struggle with the state and the formal regions about who has the power (and authority) to dictate regional development agendas. In this sense, the business regions represent municipal glocalisation strategies aiming at filling-in gaps at the regional scale, resulting from the Governance Reform in 2007. The business regions' cry for recognition in national spatial policy-making represent in this context an important symbolic milestone for the municipalities in the process of region building.

Following Allmendinger and Haughton (2009a), we interpret the business regions as important spaces for reworking the nature of Danish spatial planning. We understand these reworkings as being shaped by two dialectic processes of opening up and blurring the professional boundaries of planning, whilst at the same time narrowing the scope of planning to a few policy agendas centred around the creation of economic growth. The business regions constitute in many ways the institutionalisation of growth-oriented regional spatial planning, which has been in the making since the 2007 Governance Reform. In this sense, the business regions are symptomatic of a new Danish planning culture at the regional scale, centred around policy agendas of economic growth, job creation and business development (Hansen, forthcoming).

However, at the same time, the business regions also constitute important political spaces for transforming the Danish planning culture more widely, as spatial policy-making at the auspices of the business regions is intended to influence and structure spatial strategy-making at both national and local scales. In this sense, we can understand the business regions as vehicles for a neoliberalisation of strategic spatial planning across scales of governance (Olesen, 2012).

The struggles between contested planning rationalities reported from previous strategymaking experiments in soft spaces in Denmark (Olesen and Richardson, 2012) have been superseded by a new market based logic installing business development and job creation as 'sensible' and the 'necessary'

policy agendas (Haughton et al., 2013). We interpret this 'businessification' of spatial planning in Denmark as part of a wider development trend in society, in which spatial planning increasingly is being streamlined in the context of neoliberalisation and post-politics (Allmendinger and Haughton, 2012; Haughton et al., 2013).

ID 1478 | THE ECONOMIC CRISIS MODELLING THE TERRITORIAL COHESION. THE FRENCH CASE

Cristina García-Nicolás¹

¹University of Castilla-La Mancha.

cristina.garcia@uclm.es

1 INTRODUCTION

The economic and financial crisis since 2007 was a brake on economic growth, accompanied by a reduction in public and private investment. In addition, the European Union lost weight in a globalized economy. The development and application of the principle of competitiveness seeks to counteract the negative effects of the crisis. To this end, it moves not only to the economic and business sphere, but also to the territorial context. Competitive and synergistic territories are now the focus of numerous development and investment policies. However, other territories with characteristics that do not favour investment run the risk of falling behind in a process marked, above all, by innovation.

The Eighth Progress Report on economic, social, and territorial cohesion. The regional and urban dimension of the crisis was published in 2013, although it offers information only up to 2011. Its analysis covers aspects such as poverty, social exclusion, the labour market, migration, and regional convergence. From the main conclusions drawn from the study, we will highlight the following. First, the increase in regional divergence after a long period of convergence. They re-emphasize the central pentagon in front of the peripheries, and the urban versus the rural areas. Secondly, the cities present heterogeneous situations, better resisting the large capital cities, even though poverty and social exclusion rates increase within them. About EU Member States, between 2007 and 2011 the countries most affected by the crisis in terms of GDP and the labour market were Latvia, Greece, Ireland, Lithuania, Estonia, and Spain. Portugal, Denmark, Bulgaria, Hungary, Italy, and Slovenia also suffered a high impact of the crisis.

The crisis exacerbated some existing problems such as aging, unemployment or obsolete economies. The result has been the appearance of territories with little chance of being competitive. Nor should we forget

that the economic crisis is a brake on the cohesion process. Not only do differences between Member States increase, but there are strong divergences within Member States.

One possible solution is the real development of territorial cohesion, linking it to the creation of functional territories. This, according to Walsh (2016), should respond to the following objectives: 1. Favour And d) large metropolitan areas (1.5 million inhabitants and more). OECD (2013): Definition of functional urban areas (FUA) for the OECD metropolitan database. On this issue can also be seen Dijkstra L., Poelman H (2014). A harmonised definition of cities and rural areas: the new degree of urbanisation. Working papers, 01/2014, European Commission, economic development by strengthening vertical and horizontal (economic) relations; 2. Achieve efficiency in the provision of public services. Territorial planning would contribute to this by favouring the necessary synergies; 3. Reduce environmental impact; 4. Improve understanding of functional relationships, i.e., develop multilevel governance. In this case, a certain degree of economic autonomy would also be needed in the distribution of aid, and policy in decision-making. In all this, decentralization will play a fundamental role. In addition to management and decision-making capacity, sub-central levels of government, especially regions, will have to observe the principle of responsibility for designing the regional development of their territories.

This paper is structured as follows after this introduction: Section 2 reviews the principles governing the concept of territorial cohesion, not to mention the context of the current programming period (2014-2020) and the Europe 2020 strategy; Section 3 analyses the territorial distribution of competitiveness based on the Regional Competitiveness Index in its latest version of 2016; Section 4 includes the study of the French case and the third stage of the decentralization process, analysing the positive and negative aspects of it. The final section provides briefs conclusions, in addition to bibliographical references.

2 TERRITORIAL COHESION AND THE EUROPE 2020 STRATEGY

When we talk about territorial cohesion, it is necessary to consider a series of concepts that overlap and interrelate: polycentrism, territorial cooperation, multilevel governance, and an integrated approach to territorial fact. Territorial cohesion could be understood as the balanced distribution of human activities in the territory. It entails the transfer in terms of territory of the aim of sustainable and balanced development, assigned to the Union in Article 3 of the Lisbon Treaty:

The Union shall establish an internal market. It shall work for the sustainable development of Europe based on balanced economic growth and price stability, a highly competitive social market economy, aiming at full employment and social progress, and a high level of protection and improvement of the quality of the environment. It shall promote scientific and technological advance.

Included after the reform promoted for the 2007-2013 programming period, the territorial dimension had been gradually gaining institutional recognition since the first mention in the Second Cohesion Report (2001). The amendment of the Treaty at the Lisbon Summit of 2007 - signed on 13 December - retains the previous references to territorial cohesion and incorporates new ones in Title XVII which becomes "Economic, social and territorial cohesion", as well as to include in Article , and within the objectives of the European Union, the promotion of social, economic, and territorial cohesion and solidarity between Member States. The territorial dimension is fundamental if cohesion is really to be achieved, and more in the context of an increasingly wide and diverse geographical area, as indicated by the Council in 2006: "it will help to develop sustainable communities and to prevent uneven regional development from reducing overall growth potential".

This incorporation of the territory into regional development strategies has had two main pillars: spatial development, which involves planning, cooperation and combating regional divergences through the Structural Funds; and a specific attention to cities on Urban (both the pilot project and the later Community Initiative). The incorporation of the territorial dimension into the cohesion process marked the start of the 2007-2013 programming period, reinforced by two key texts: The Territorial Agenda and the Leipzig Charter on Sustainable European Cities.

Territorial cohesion involves equal access for citizens and economic agents to services of general economic interest (SGEI), irrespective of the territory to which they belong (Article 16 of the Treaty).

However, the realization of territorial cohesion needs a new concept of governance that simplifies "the processes of regulation and intervention of the public powers and facilitates the decision-making of the other social agents, especially the economic ones" (eg Farinós, 2008: 12). The main objective will be, then, the effectiveness and efficiency of the public policies on the territory and its development. We are, therefore, also referring to the concept of planning (economic) or land-use planning. It has different characteristics both at Member State and Community level. In the French case, 'Aménagement du Territoire' would imply a social and fundamentally economic construction on the territory, linked to the idea of nation, while the concept at the community level would be more linked to cooperation of different actors - public and private - in all sectors, which would imply a decentralized and multilevel understanding (eg Faludi, 2005).

Apart from the differences mentioned, territorial planning has two good points of support: the principle of subsidiarity - that is, ensuring that a decision is taken at the closest level to the citizen - and political-economic decentralization, because it is imperative that subnational or sub-central governments, whether regional or local, have a certain normative and decision-making capacity.

About the current programming period, the territorial dimension of the Structural and Investment Funds is much more pronounced than in the previous period. The Common Strategic Framework (CSF) includes a section dealing with the main territorial problems. States are required to carry out an analysis of the potential and development capacity of the Territories. Likewise, it is expected that States will ensure the complementarity of European territorial cooperation programs with country-specific programs within the investment objective for growth and employment.

The latter relates to the Territorial Agency of the European Union 2020 which, in turn, takes into account both the V Report on economic, social and territorial cohesion and the Europe 2020 Strategy (E2020S). The achievement of the E2020S is linked to the "policy-making in the territories" (§1). Eurostat's report on socio-economic indicators³ shows that some of the objectives related to competitiveness factors are far from being achieved. Employment, expenditure on R&D, greenhouse gas emissions, early leavers from education

3 THE TERRITORIAL DISTRIBUTION OF COMPETITIVENESS

The concept of competitiveness is, basically, linked to urban areas. However, the economic and financial crisis of 2008 has shown that it is not the urban areas that have best behaved during and after the crisis. Dijkstra et al. (2015) have divided into four types of regions: rural, urban, intermediate, and rural urban near cities. It is these last two that have shown a better performance in the rate of economic growth and employment. Depending on their geographical location, the behaviour of these territories has also been different (see Table 1). In EU-15 economic growth followed the urban hierarchy during the first period of the crisis. Nonetheless, capital cities and non-metropolitan regions were the hardest hit. By contrast, in the EU-13 the medium and small metropolitan areas were the best performers, maintaining the growth rate and curbing the loss of jobs (Dijkstra et al., 2015).

Average annual real change in %	2000-2008			2008-2011		
	GDP per head growth =	Productivity growth +	Employment per head growth	GDP per head growth =	Productivity growth +	Employment per head growth
EU-15						
Capital metro	1.44	0.88	0.56	-0.79	0.34	-1.13
Second-tier metro	1.29	0.70	0.59	-0.76	0.15	-0.91
Smaller metro	1.20	0.67	0.53	-0.59	0.24	-0.83
Non-metro	1.15	0.75	0.40	-0.77	0.20	-0.98
Total	1.27	0.76	0.51	-0.70	0.24	-0.94
EU-13						
Capital metro	5.49	3.64	1.85	-0.26	1.04	-1.30
Second-tier metro	4.85	4.08	0.78	1.43	1.30	0.14
Smaller metro	3.66	3.56	0.09	1.38	1.17	0.21
Non-metro	4.47	4.45	0.02	0.57	1.70	-1.13
Total	4.88	4.31	0.56	0.66	1.44	-0.78

Table 1. GDP per head growth in EU metro regions 2000-2008 and 2008-2011
Source: Dijkstra *et al.* (2015: 946).

Figure 1 summarizes all the constituent elements of regional competitiveness in a pyramid scheme that is based on eight fundamental elements (environment, decision centres, social structure, regional culture, economic structure, innovative activity, regional accessibility, and skills of workforce). On this basis are the five axes that will show the competitiveness of a territory: research and technological development, SME development, FDI activity, infrastructure and human capital, and institutions and social capital. The goal, at the top of the pyramid, is to maintain standards of quality of life, namely the welfare state.

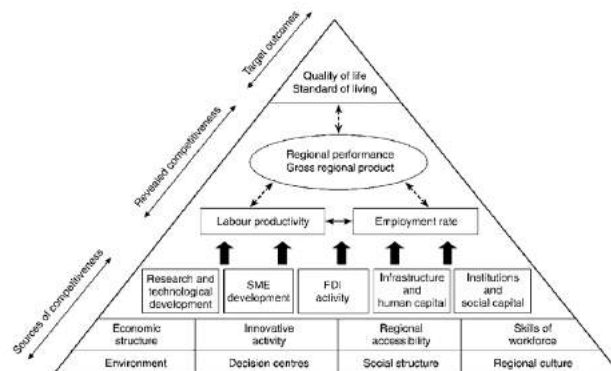

Figure 1. Pyramid model of regional competitiveness
Source: Gardiner *et al.* (2004: 1048).

This section is based on the regional competitiveness indices carried out in 2010, 2013 and above all in the last edition of 2016, which include 262 regions. As we have already mentioned, competitiveness has become a fundamental objective of cohesion policy. It is also part of the Europe 2020 Strategy. The underlying idea behind the competitiveness value is that this factor can reduce interterritorial differences. Thus, after the existence of the "blue banana" in the 90's of the last century, the RCI seem to confirm the configuration of networks of cities that contribute to organize the territory around them. We would be facing competitive territories that distribute population and resources to those who are not. However, on the Map 3 showing the evolution of the index over the three reports made, the existence of centres and peripheries is clear.

The development of the Regional Competitiveness Index (RCI) raises two important questions about the territory: one is the unit on which to work, being the most practical option to resort to NUTS (Nomenclature of Statistical Territorial Units); And the other is the choice of regions, since in several notable cases such as Greater London, administrative regions – linked to statistical units and sub-central levels – are intertwined with functional regions, more linked to the very concept of competitiveness. Another aspect to consider is territorial diversity in urban and rural areas, as well as intermediate areas, in the sense that creativity linked to innovation and therefore to competitiveness seems to be related to urban areas, be they cities or the so-called region-cities. The following figure (Figure 2) shows the key elements of territorial development, showing how the economic development policy – supported by a strong emergence of the city-region – is one of the cornerstones of the triangle that revolves around the territory and is completed by economic competitiveness and creativity, all elements interrelated.

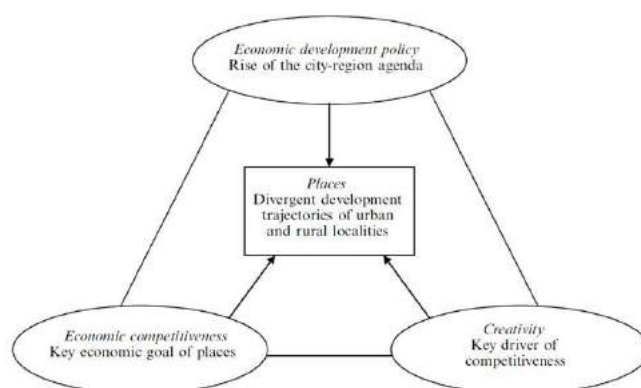

Figure 2. Conceptual framework for territorial development
Source: Huggins and Clifton (2011: 1343).

If we review the pillars of each of the factors at the regional level in the case of France, we will obtain an image of the development of each of them in the configuration of competitiveness. Thus, with regard to institutions, while France is in 11th place, when descending to the regional scope Brittany is the best situated territory followed by Aquitaine. In the case of macroeconomic stability, only the state level is possible, with France occupying the 16th position. Infrastructure Île de France ranks first, followed by Nord-Pas-de-Calais and Alsace. At the other end are Corse, Limousin and Brittany. In the pillar of health, Île de France returns to occupy the first place, followed at distance by Rhône-Alpes. Finally, basic education is analysed only at the state level and France ranks 16th.

Region	Institutions	Infrastructures	Health
Île de France	120	14	29
Champagne-Ardenne	143	71	187
Picardie	121	35	196
Haute-Normandie	155	81	182
Centre	118	83	172
Basse-Normandie	129	148	180
Bourgogne	132	93	183
Nord-Pas-de-Calais	131	23	197
Lorraine	145	88	167
Alsace	133	46	121
Franche-Comté	128	98	173
Pays de la Loire	139	116	162
Bretagne	48	175	193
Poitou-Charentes	91	150	164
Aquitaine	75	158	155
Midi-Pyrénées	136	155	36
Limousin	117	203	179
Rhône-Alpes	89	86	81
Auvergne	125	172	170
Languedoc-Roussillon	134	142	184
Provence-Alpes-Côte d'Azur	149	106	140
Corse	164	240	166

Table 1. Basic dimension. Regional ranking, 2013

With regard to efficient factors, higher education and lifelong learning have a better situation in Île de France and Alsace, while Corse and Bourgogne occupy the last positions of metropolitan France. Île de France, Limousin and Aquitaine are at the top of the ranking in terms of labour market efficiency, while Languedoc-Roussillon, Picardie and Provence-Alpes-Côte d'Azur are last. In the case of market size, the best situated region is Île de France, followed at considerable distance by Picardie and Alsace.

Region	Higher education and lifelong learning	Labour market efficiency	Market size
Île de France	49	66	2
Champagne-Ardenne	162	141	135
Picardie	146	153	58
Haute-Normandie	151	143	82
Centre	188	109	107
Basse-Normandie	199	107	144
Bourgogne	217	132	136
Nord-Pas-de-Calais	123	187	81
Lorraine	137	144	112
Alsace	82	111	69
Franche-Comté	155	119	129
Pays de la Loire	141	118	127
Bretagne	117	62	142
Poitou-Charantes	206	100	147
Aquitaine	184	98	139
Midi-Pyrénées	145	110	148
Limousin	181	76	163
Rhône-Alpes	144	117	95
Auvergne	200	126	145
Languedoc-Roussillon	167	174	149
Provence-Alpes-Côte d'Azur	153	149	116
Corse	247	133	215

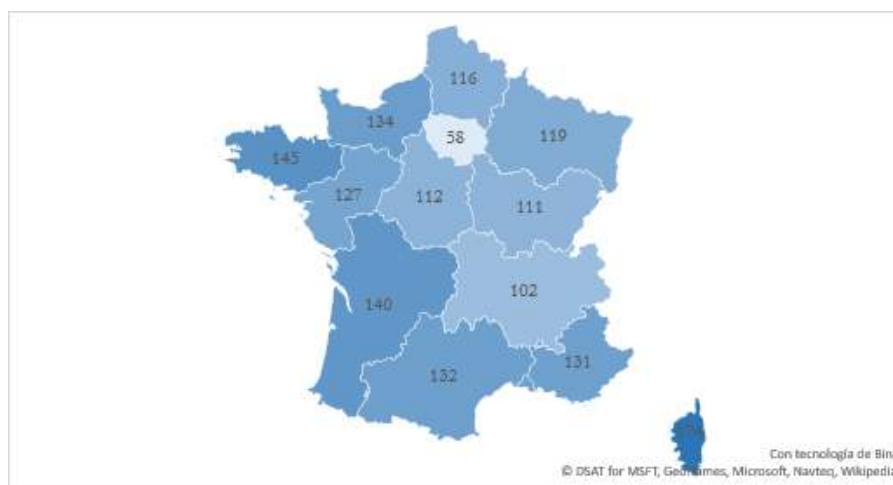

Table 2. Efficiency dimension. Regional ranking, 2013

In the last group of factors, technological readiness has two sub-pillars corresponding to the national and regional levels. The first one covers the business environment, while the second deals with variables related to personal use (individuals and households) of new technologies. While at the national level France is at an intermediate level, at regional level the differences between Île de France - followed in this case by Aquitaine, Midi-Pyrenees and Limousin - and the rest of the regions, with Nord-Pas-de-Calais in the worst place. The pillar of business sophistication highlights the situation of Île de France, Rhône-Alpes and Provence-Alpes-Côte d'Azur are the best located, while Picardie, Basse-Normandie and Auvergne occupy the last positions. Finally, the pillar of innovation has three key centres: Île de France, Midi-Pyrénées and Rhône-Alpes. In this case at the other end is Corse, Poitou-Charantes and Bourgogne.

Region	Technological readiness	Business sophistication	Innovation
Île de France	103	3	13
Champagne-Ardenne	127	164	201
Picardie	127	132	158
Haute-Normandie	127	101	100
Centre	127	75	121
Basse-Normandie	127	126	146
Bourgogne	127	140	173
Nord-Pas-de-Calais	142	63	154
Lorraine	123	115	149
Alsace	123	87	70
Franche-Comté	123	136	116
Pays de la Loire	133	67	131
Bretagne	133	90	80
Poitou-Charantes	133	95	174
Aquitaine	109	70	92
Midi-Pyrénées	109	55	16
Limousin	109	138	162
Rhône-Alpes	137	40	41
Auvergne	137	125	127
Languedoc-Roussillon	118	69	124
Provence-Alpes-Côte d'Azur	118	44	51
Corse	118	180	227

Table 3. Innovation dimension. Regional ranking, 2013

The following map shows the 2016 competitiveness index applied to the new regions. The data of Île-de-France make a marked difference with respect to the averages of the metropolitan territory. The indicated indices respond to the average of the metropolitan territory. The indicated indices respond to the average of the old regions .

Map 1. Distribution of the Regional Competitiveness Index. France, 2016
 Source: Annoni, *et al.* (2017). Annexes.
http://ec.europa.eu/regional_policy/en/information/maps/regional_competitiveness

The diverse levels of development that the factors analysed show us their relationship with the French decentralization process. Territorial disparities respond to several factors, including population, employment, 'metropolization' policy, and innovation and competitiveness clusters, among others.

4 FRANCE AND THE DECENTRALIZATION PROCESS

In a broad legislative framework, Law No. 2015-991 of August 7, 2015 on a new territorial organization of the Republic (NOTRe) has consolidated the region as a territorial collectivity (Constitutional reform 2003) with broad powers: to promote economic, social, sanitary, cultural and scientific development of the region, support access to housing and improve housing conditions, support municipal policy and urban renewal, and promote education and management policies and equality of their territories, as well as ensure the preservation of their identity and the promotion of regional languages while respecting the integrity, autonomy and powers of departments and municipalities.

In addition, a process of fusion of municipalities, started in the 90's of last century, has accelerated, which has changed the map of the country at the local level. At present, the following groups are distinguished: a) 196 agglomeration communities including 4,610 municipalities and accommodating 21,813,717 inhabitants. b) 11 urban communities that group to 359 municipalities, and total 2,534,713 inhabitants. c) 13 metropoli that include 676 municipalities and a population that ascends to 15,275,673 inhabitants.

The reduction of 22 to 13 regions in metropolitan France is a consequence of the entry into force - in January 2016 following the election of the regional councils - of the Law of 16 January 2015. The modification of the regional map has resulted in the apparent reduction of interregional differences in both demographic and economic terms from the statistical point of view. However, GDP data (Graph 1) show the regional differences as well as the territories with the highest economic growth. Île-de-France, not included in the graph, is a third of the national total.

Graph 1. Gross domestic product at current market prices by region, 2006-2015
 Source: Eurostat

Brière and Koumarians (2015) argue that the new regions are more homogeneous in demographic terms, since they combine territories aged with others that maintain their dynamic of natural growth or by migratory flows. However, there is also an unequal distribution of this population (Graph 2) favoured both by a process of 'metropolization' - which implies the increase of the weight of large cities by increasing population, the density of communications networks and the concentration of organisms of all kinds - as well as by the attraction of employment poles that include agglomerations and urban areas.

Graph 2. Population at regional level, 2016
 Fuente: Insee.

We have already mentioned that one of the main elements of territorial inequality is the unemployment rate. The latest data published by Eurostat in April 2017 indicate a national total of 10.1% for 2016 (Graph 3). Above this average are the following regions: Champagne-Ardenne, Picardie, Haute-Normandie, Nord-Pas de Calais, Lorraine, Alsace, Languedoc-Roussillon, and Provence-Alpes-Côte d'Azur. The causes include obsolete economic sectors, the absence of skilled labour or the lack of innovative sectors that create jobs.

Graph 3. Regional Unemployment Rate, 2016
 Source: Eurostat.

The analysis of the factors that have been considered for the elaboration of the competitiveness index shows a great divergence between the old French regions, being above the average Parisian region in most of the factors. However, it is a good guide to design regional policies that respond to the needs of each territory. These policies based on horizontal transfers or fiscal measures should ensure redistribution. We are talking about ensuring a fairer distribution of economic, social, and territorial character. The main problem in the French case is that, so far, has not been able to speak of effective fiscal decentralization, since reliance on state transfers is very high.

As Faludi (2013: 1304) states, "Territorial cohesion is thus said to promote a better balance between competitiveness and equity by 'spatialising' the European model of society." This may well be the aim of the newly established (May 2017) 'Ministère de la cohésion des territoires', whose subjects of work include the city and territorial planning.

ID 1544 | PLANNING FOR A SUSTAINABLE SHORELINE DEVELOPMENT

PERSPECTIVES ON NORWEGIAN COASTAL PLANNING

Kjell Harvold¹; Arne Tesli²

¹Norwegian Institute for Urban and Regional Research (NIBR);

²Oslo and Akershus University College of Applied Sciences; NORWAY

kjell.harvold@nibr.hioa.no ; arne.tesli@nibr.hioa.no

1 INTRODUCTION

Norway has a long coastline, around 103.000 kilometers. With a population of 5,2 millions, this leaves every Norwegian – young and old – with an average of 20 meter coastline. Still, the competition over space along the shoreline is becoming more severe every day (see for instance Hersoug 2013:159). In Norway, the coastal shoreline constitutes – as in most other countries – a very valuable and important, but at the same time a vulnerable area, and a large number of stakeholder groups and actors live, work and interact in the coastal shoreline areas.

Over the past decades, significant changes have emerged in terms of development opportunities and perspectives and regarding the management of the coastal area. While shoreline planning traditionally had a focus on preservation and adjustment to traditional economic activities, mainly fishing, the situation has changed drastically. Today, the shoreline planning also has to incorporate and integrate a number of new opportunities and challenges, such as aquaculture, the tourist industry, the construction of new recreational houses, etc. However, a considerable part of the developmental changes along the coast are not only a result of presented or approved plans, but are to a large extent a result of incremental local changes and adjustments. In a large number of municipalities, developmental changes in accordance with approved plans appear to be overruled by approval by exemption clauses (or dispensations – in Norwegian: dispensasjoner). In a sense, one may talk about this as an exemption based development of the coastal shoreline, and not as a plan-oriented development approach.

Even in the face of rapid changing demographic, social, environmental and economic realities, where the need for (long-term, medium-term and short-term) planning becomes more urgent and important, the planning focus appears to continue this practice, where exemptions (dispensations) often tend to overrule existing plans.

The municipality is the principal planning authority in Norway. However, the local level has to accommodate to national signals and guidelines. Regional and state authorities can also interfere or object to elements in the local plan if they feel that it violates national regulations or intentions. In section 2, we make a brief presentation of the Norwegian planning system.

Our study draws upon case studies from municipalities at the west coast of Norway, in the county of Hordaland (presented in section 3 in this paper).

The national legislation and the planning system is in many ways challenged by local actors, who often want to have more room and opportunities for development initiatives, and thus want a more flexible system based on local preferences and decisions. In section 4, we discuss the different approaches from a discourse analytical perspective. In section 5, we present local attitudes and viewpoints within the discourse perspective.

At the end of the paper (section 6), we argue that, in order to improve the Norwegian coastal shoreline planning, there is a need for a stronger coupling of, or interconnection between, the nationally stated objectives and goals, on the one hand, and the local level perceptions and practices, on the other.

2 THE NORWEGIAN PLANNING SYSTEM AND MANAGEMENT OF THE COASTAL ZONE

The building and planning regulations for the coastal zone of Norway date back to the 1950s. In 1954, a temporary act was passed in Parliament, and here building development in certain coastal areas were prohibited. About a decade later, in 1965, a new act introduced the principle of banning of building along the coastal shoreline for the whole country. A new significant change came in 1986, when the regulations for the coastal zone were integrated in the Planning and Building Act (PBA), and this came into force nationwide.

Finally, the PBA was further modernized in the first decade of the 21 century, and a new PBA came into force in 2009. The first paragraph (1-1) in the new PBA states that the act shall promote sustainable development for the benefit of all individuals, for the society and for future generations. Somewhat later in the same paragraph (1-8) the significance of the coastal zone is emphasized. According to paragraph 1-8, development in the coastal zone – defined as the area within the first 100 meters from the shoreline – is prohibited. In this zone, closest to the sea, special concern shall be given to nature, culture and outdoor activities, as well as to other public interests.

The 2009-Act in many ways marks a milestone in the management of the coastal zone: In opposition to the “old” act, from 1986, the coastal zone regulations are now presented already in the opening paragraph. Furthermore, the regulations are stricter than in the previous acts: Possibilities for exemptions (or dispensations) are, for instance, reduced (Harvold et al 2015:15).

At the same time, however, the authorities have opened up for some differentiation regarding the planning regulations and development along the coast. A specific National Policy Guideline (NPG) came into force in 2011. The NPG “for a differentiated management for the shoreline along the sea” divides the Norwegian shoreline into three management zones. Zone 1, around the Oslo fjord (with the highest population density in Norway and the strongest development pressure), allows for very limited development. In Zone 2, primarily along the southern tip of Norway (Sørlandet) as well as around some of the larger urban areas in other parts of the country, there are some options for some activity. Whereas in Zone 3, the rest of the country, there are some openings for a somewhat more liberal practice.

Still, however, the principle of a building ban along the coastal shoreline, linked to § 1-8 in the Planning and Building Act, applies for the whole country. However, the message of the National Policy Guidelines appears to be that exemptions (dispensations) from the law regulations may to a certain extent be more acceptable in zone 2 and 3, compared to within zone 1. Moreover, some kind of economic activities (tourism, fishery etc.) might face less obstacles in establishing and developing in zone 2, and not least in zone 3.

3 METHOD AND CASE STUDIES

This paper is based on a four-year (2016-19) research project funded by the Norwegian Research Council. A key element in the project is to study the development in the coastal zone in two different parts (counties) of Norway; Vestfold in the Oslofjord region (in the south-eastern part of Norway) and Hordaland on the western coast of the country. In this paper, we focus on the development in the coastal zone of Hordaland.

Our study is based on analyzes of official documents, like plans, papers to local and county councils and not least interviews with public officers at the local and regional level. At the regional level, we have interviewed representatives of the County Council and the County Governor's office. The County Council represents the municipalities at the county level and is a political body. The County Council Office provides guidance to the municipalities, i.a. on planning issues. The County Council is also responsible for preparing the regional plan. Of particular interest in this context is a draft of a regional coastal plan made for parts of Hordaland county, prepared by the County Council (“Regional kystsoneplan for Sunnhordaland og Ytre Hardanger”). The County Governor is the state representative at regional level, and it is the duty of this office to ensure implementation of national policy objectives.

The municipality is the formal planning authority for the entire territory, including the coastline and out to one nautical mile from the shoreline. All local councils are responsible for preparing a municipal plan, and it is compulsory that they include a spatial part. These plans have to be revised every four years. Furthermore, the local councils are responsible for preparing legally binding regulatory plans. One of the four municipalities in our study is located on the mainland, but with a considerable coastline. The three other municipalities are island communities. All four municipalities consider the management of the coastal zone area, as a very important local issue. In terms of population, the municipalities are small or medium in size. They have a mixture of primary, secondary and tertiary industry, but are more reliant on the fishing (and related) industry than the average Norwegian community.

Hordaland is in many respects an interesting county when it comes to the management of the coastal zone. According to the National Policy Guideline described in section 2 in this paper, The municipalities in Hordaland have partly been defined as belonging to zone 2 (marked with orange colour in the map) and partly in zone 3 (yellow in the map)

Figure 1: Map of Western (and Southern) Norway, with zones for shoreline management indicated.

The map (Figure 1), illustrates the situation. Hordaland is situated in the northern part of the map, covering the coastline from the municipality of Sveio (south in Hordaland) to the municipality of Austrheim (to the north of Hordaland). Our interviews include conversations with planners both in zone 2 and 3 municipalities in Hordaland.

As depicted in the map, the southern tip of Norway (Sørlandet) belongs to zone 2 of the NPG system. We can also see part of eastern Norway, where the coastal communities are marked red (zone 1, with the strictest practice). White coloured municipalities are communities without coastline towards the sea.

4 DISCOURSE ANALYSIS AND COASTAL PLANNING

4.1 DISCOURSE ANALYSIS

Knowledge can be generated and expressed in different verbal discourses and ways: Verbal discourses – what people talk about and how they are talking about it – are culturally and socially constructed. At the same time, it can be argued that the discourse practice refers to something outside itself, to some kind of objects (see for instance Gotaas 1999:9). A much-referred Foucault quotation summarizes this position. Discourse practices may be defined as:

“...practices that systematically form the objects of which they speak” (Foucault 1972:49, quoted from Gotaas ibid).

This approach has been used to analyze different understandings of a problem or an interaction. Basically, one may find different discourses in all kind of discussions or debates. The perspective on environmental problems or challenges may differ from country to country (Kaarhus 1999), just as approaches for, for example traffic and communication, can differ from city to city (Koglin 2015).

In planning processes, there is a strong discourse pluralism, and in these processes there is often very much at stake for the participants. In a Norwegian study, Stokke and Skogheim (2007) found that different discourses were clearly apparent in the coastal zone. When local communities took a strong standing on either development or protection of the coastline, Stokke and Skogheim found a high degree of “discourse pluralism” (ibid:34).

In the Norwegian coastal planning, we observe at least two “dominant” and different discourses. One can be said to be the one inspired by the ideology and the intention of the Planning and Building Act. The way national authorities present the message of this approaches in planning is in many ways “top-down”. We describe the ideas of the national Planning and Building Act in the next paragraph (4.2). But there is also, at least, one other way to look at the planning system, namely a “bottom up” approach. In section 5, we will present how local actors in Hordaland look upon the coastal management and development.

4.2 MANAGEMENT OF THE COASTAL ZONE, ACCORDING TO THE PLANNING AND BUILDING ACT

The planning in the coastal zone has to operate within the framework provided by the Planning and Building Act (PBA), depicted in section 2 of this paper. As mentioned, paragraph 1-8 in the act, states that the area within the 100-meter belt from the shoreline is not to be touched: It is a clear prohibition of development that in principle applies for the whole 100-meter area:

“Within the 100 meter belt along the shoreline special considerations shall be given to nature and culture environment, outdoor activities landscape and other public interests” (as the first part of paragraph 1-8 in PBA states).

However, there are some exemptions: for example for the development of transport needs; boathouses; communication lines along the coast, etc. Still, in general, there is a ban when it comes to development of built environment in the 100-meter coastline belt. In a planning perspective, the coastline is not to be touched: Primarily it is an area for recreation and outdoor activities, as well as for the traditional fishing industry.

The coastal shoreline should thus be planned and regulated through the Planning and Building Act. Plans should be made at the local level. If there is a need for exemptions (or dispensations), this ought to be regulated through a hierarchical system of dispensations. The main philosophy is to preserve the coastline as it is. The key elements in the management of the coastal zone embedded in the Planning and Building Act is summarized in Table 1 below.

Key elements	Management approach
General view of coastal zone	Area left for recreation and/or activities clearly defined to the coastline according to tradition (such as fishing, etc.)
Means of control	National legislation and law for planning: Applications for exemptions (or dispensations) will have to be considered and handled within a hierarchical system
Goals	Preserve the coastline as it is. When exemptions (dispensations) is considered, certain criteria and standards should be applied and given priority (impacts or consequences for the public, accessibility to the shoreline, etc.).

Table 1: Management of the coastal zone, according to the Planning and building act

In the next paragraph, we present local perceptions and perspectives on the management and the development of the coastal zone.

5 LOCAL PERSPECTIVE ON COASTAL MANAGEMENT

5.1 GENERAL VIEW ON COASTAL ZONE

In daily life we see that actors at the local level often have a perspective that challenges the views described in the national formed planning and building act. Many politicians and private developers and business enterprises located at – or close to – the coastal zone want to explore and utilize the possibilities and opportunities that can be found in this area. This relates to a number of sectors and industries. It can be traditional industries as well as new types of business enterprises: housing; cabins; tourism; transport; agriculture; fishing; aquaculture; a series of other types of industries; etc.

One actor from a relatively small island municipality in Hordaland pointed out:

“In general I would say that the state, both nationally and regionally, are too concerned about protection. Here, in our municipality, we have strong private enterprises who want to develop the local community. For them it appears as if the state primarily want to make plans for protection – and not plans for development.”

A public officer in another municipality was somewhat more positive to the role of the regional state:

“The regional level follow our local planning, fairly “tight”. Still, we have a good dialogue. Regional state often have very specific points of view, regarding where development may – or may not – take place. Therefore, the reactions from the County Governor’s office seldom come as a surprise, even though they do not concur with our views.”

The last quotation indicates that the dialogue between the state representatives and the municipality can function fairly well. At the same time, both quotations indicate that the state authorities have a somewhat different perspective on what the focus should be, when it comes to coastal management. Whereas state authorities appear to embrace a protection perspective, the local interest groups and stakeholders talk about natural resources and values in terms of how these resources can be utilized for employment, income and further development of the local community. In this perspective, the relevant local actors predominantly look for possibilities. The coastal zone is an arena for new activities, both in terms of tourism and new forms of industry that takes advantage of the possibilities along the coastline.

5.2 WHO SHALL DECIDE?

In principle, the municipality is the key formal actor in local planning in Norway. At the same time, the state authorities can interfere or object to a plan, and thus stop the local process. Our interviews with local actors, indicate that there is a strong local interest and awareness related to the coastal zone. One informant stated that:

“Our culture is based on life in the coastal zone. Even farmers, who primarily is concerned with agriculture, has a boathouse and a boat. This is what we have grown up with in generations – back to the Viking age. In this tradition, it is self-evident that everyone should have access to the sea.”

Several of our informants emphasized that local knowledge should be very important in the management of the coastal zone. At the same time, one planner pointed out that things were about to change:

“We have to realize that the coastal zone is a limited resource. If everybody shall have access to the sea, then a new planning approach is necessary, especially in the urban areas. In urban areas it is necessary to accommodate for public access to the sea.”

Even though many of our informants observed a society under considerable stress and change, the main message appears to be that the local actors have the best understanding of the local challenges, and that they therefore are best qualified to assess what should be done along the local coastline. There also seemed to be differences between different communities. Municipalities with a small population and little pressure for new building activities, had other perspectives than larger communities with significant developments. In a large municipality with considerable growth, the interviewed planner stated that:

“In our municipality we have quite a different perspective on new developments compared with smaller communities: We focus much more on high density developments than smaller municipalities. Therefore, the development of apartment complexes is here considered as an alternative to detached houses.”

In other words, there are differences between the local communities. At the same time there appears to be a consensus among our local informants that there should be a stronger emphasis on local autonomy when it comes to the management of the coastal shoreline. As one of our informants pointed out:

“Local developers sometimes react very strongly to state authorities decisions. In the developer’s eye, state authorities only focus on protection, not on local development.”

5.3 WHAT SHOULD BE THE MAIN GOAL WITH COASTAL MANAGEMENT?

The main goal for a local coastal management is hard to summarize based upon the interviews we have performed. Still, a main argument appears to be that local actors are better judges of what should be a “good” local development, than central authorities.

Certainly, the problem appears not to be a lack of plans, as seen in the local perspective. As one planner pointed out:

“In our region we both have a regional plan and an inter-municipal plan, that both have been sent on hearing. I very much doubt that the plans ever will be adopted. Especially, I see problems with the inter-municipal plan. Still, some ideas from the plans may be useful, like some basic data and information presented in the plans and some of the thoughts about common guidelines for management of the coastal zone, suggested in the plans.”

A common denominator between the local actors appears to be that local analysis should be given more weight. This analysis is not always easy to put into a conventional plan. Still, local focus is both on development and protection. But, as one of our informants pointed out:

“Protection and development must be seen in a local context.”

The main philosophy behind this approach seems to be to encourage new activities and new employment and development in rural areas along the coastline, by giving more emphasis and focus to the needs at the local level. Therefore, local development, initiated locally, should be given predominance over formal rules and regulations initiated at the national level.

5.4 A LETTER TO THE MINISTER

The whole idea behind shoreline development in a multifunctional local context, is well summarized in a letter written by nine mayors in southern Hordaland (Sunnhordaland) to the Minister of internal affairs in 2014. The nine mayors see problems with the present management of the coastal shoreline in their municipalities. They point out that national statistics are inadequate for southern Hordaland: part of their coastline is available for the public, despite of what the national statistics indicate. They also point out that the national prohibition on building in the first hundred meter from the shoreline (based on § 1-8 in the planning and building act, see also section 2 in this paper) is not suited for the situation in their local communities. They therefore asked the minister to repeal the building prohibition for their region. As they point out in the letter:

“If one really would like to do a groundbreaking work, when it comes to development of democracy – and create motivation for local electorates – an approach should be to let the local coastal zone be management by local democracy.”

In the letter, the majors ask the minister to develop a local pilot project where the region – with all nine municipalities – should be given right to manage the coastal zone independent from national control. However, in a letter from the minister, the suggestion was turned down. Still, the letter from the mayors illustrate the difference between local and national perspective on coastal zone management.

5.5 A MULTIFUNCTIONAL LOCAL COASTAL MANAGEMENT

The key elements in this local perspective is a multifunctional approach embedded in the management of the coastal zone area is summarized in Table 2, below.

Key elements	Management approach
General view of the coastal zone	Area available for new activities: New forms for recreation, new housing (both recreational and residential) activities and new types of enterprises
Means of control	Decisions should be taken at the LOCAL level. The local level is most important, and the coastal zone should be regarded as a local resource
Goals	Encourage new activities and new development and employment in rural areas, by focusing on the needs at the local level. Local development is more important than formal and hierarchical rules initiated at national level

Table 2: Management of the coastal zone, according to multipurpose politics

As Table 2 indicates, the coastal zone should – in a local perspective – not only be a multipurpose area. Some of it can be protected and used for recreational purposes only. However, at the same time there are a lot of other purposes that may be relevant, like the establishment of areas for new residential homes, and areas for development of new types of enterprises, that are relevant along the coastline. A key element is that decisions regarding the shoreline should be taken at the local level. If local actors think that one should encourage new activities along the shoreline, no central regulations should hinder such developments.

6 CONCLUSION

We see two quite distinct discourses in Norwegian shoreline management, one inspired by the Planning and building act, and one inspired by a more local multipurpose perspective (see also Table 3).

Key elements	"Central": Planning and building act	"Local": Multipurpose approach
General view of coastal zone	Area left for recreation and/or activities clearly defined to the coastline according to tradition (fishing etc.)	Area available for new activities: New forms for recreation, new housing (both recreational and residential) activities and new types of enterprises
Means of control	The law-system and planning: A system of hierarchy will have to consider applications for dispensations	Decision should be taken locally, and the coastal zone should be regarded as a local resource
Goals	Preserve the coastline as it is. When dispensations is under considerations, certain standards should be given priority (like consequences for the public, accessibility for the public etc.).	Encourage to new activities and new employment in rural areas, by focusing on the needs at the local level. Local development is more important than formal and hierarchical rules set up on the national level

Table 3: Management of the coastal zone, two approaches

The actual adjustments in the coastal zone management today are inspired by both perspectives: on the one hand, there is an acceptance of the significance of protections of – at least – some parts of the coastal shoreline. On the other hand, there is a perception and understanding of the necessity of local co-determination and involvement in the land use planning. As others have pointed out, there is thus a flowing transition between politics and law (Schultz and Myklebust 2014). In the coastal zone planning and management in Hordaland, we see that different interests are played out in local discussions and decision-making. The results in each case are not always given beforehand.

ID 1553 | SPATIAL PLANNING POLICIES AND THE INTEGRATION MODELS AS A MEAN FOR A BETTER DELIVERY OF SERVICES OF GENERAL INTEREST

Špela Kolarič¹, Naja Marot¹, Barbara Černič Mali¹

¹ University of Ljubljana, Department of Landscape Architecture

spela.kolaric@bf.uni-lj.si ; naja.marot@bf.uni-lj.si ; barbara.cernic-mali@uirs.si

ABSTRACT: The provision of services of general interest (SGI) is a competence of authorities at different governance levels. Until now, public administrations and the service providers, tend to have a strictly sectorial approach to the SGI delivery, leading to incomprehensive, isolated solutions. This causes a mismatch between the people's needs and the services provision. Furthermore, it contradicts the EU efforts for a territorial and social cohesion. Additionally, in the times of austerity, the public funds limitation especially affects the remote mountain territories and border areas. Harsh (local) economic conditions (fewer jobs), population ageing, dispersed settlement, and the geomorphology hinder the provision and supply of the SGI in these territories. To overcome this deficiency, new approaches of the SGI provision should be sought and identified. Therefore, hereby spatial planning and sectorial policies and the related models of integration (sectors, actors, funds, services, policies etc.) are investigated. The paper builds on the research done in the transnational project INTESI (Integrated Territorial Strategies for Services of General Interest). The analysis of the coverage of SGI in the spatial planning, and other (space related) sectorial policies documents (regulations, strategies, plans, guidelines, etc.) was done in five Alpine countries (Italy, Switzerland, Austria, France, and Slovenia). The aim was to find out if the integration of the policies (or measures) for the SGI provision is already present in these documents, to what extent, and what the problems that need to be addressed are. In addition to the seven sectors (regional development, transport, telecommunication, basic goods, health care, social care, and education), relevant "umbrella" regulations (e.g. the constitutions, state laws on delivery of SGI, etc.) have been inspected for each

country. The integration models and their elements have been investigated considering the authorities, administrative levels, actors, funds, etc. Altogether, 257 documents have been reviewed. The analysis revealed the level of integration in the Alpine Space is moderate. The integrated solutions mostly occur between the following sectors: health and telecommunication, health and social care, and basic goods and telecommunication (e.g. post offices in grocery shops). The analysis also showed that to some extent countries secure the SGI by the same means, according to the EU common market regulations. However, looking into more details, there are differences among them. For example, in comparison to the other Alpine countries, the SGI provision in Switzerland is, in terms of the time and distance accessibility, very strictly and in detail regulated. In relation to the identified gaps, the study reveals these could be solved by adapting the existing spatial (national, regional) strategies and plans, as some of the examined documents (e.g. transport and telecommunication policies) do not even address the SGI provision as a topic of spatial planning. To enable a better SGI supply and delivery, the implementation of the integration models should urgently be considered to link the following sectors and services: (public) transport with all the other inspected sectors, and the telecommunication with the health/social care, basic goods and education.

1 INTRODUCTION

Lately, several reports are showing that member states (shorter MS) will struggle to implement the European Union's (EU) policy ambitions (e.g. Territorial Agenda of the European Union 2020 and Commission White Paper on SGI) to provide quality SGI everywhere within the union (ESPON, 2013a). According to the ESPON (2013a) report, the provision of SGI is mainly a domain of member states at national, regional and local level, since aspects such as a minimum level of availability, accessibility, affordability, quality and variety of a specific SGI are mainly not determined by the EU legislation. Therefore, the impact of EU's policies on the implementation and delivery of SGI is fairly weak. The management and the administration of services is an issue to be dealt with foremost by providers of SGI, and new concepts like integration have been sought for. The integrated approach to the SGI provision is important for the Alpine areas due to their characteristics, such as dispersed settlements, dynamic and steep terrain, decreasing and ageing population, and a challenging infrastructure construction (e.g. transport, telecommunication), which make the supply difficult and often economically unviable. The analysis of the INTESI regional reports shows that there is a need for the integration of policies and services in all participating countries. Foremost, the transport sector should be better linked to all the other inspected sectors (telecommunication, education, health, social care and basic goods). Furthermore, the services within the sector itself need to be connected (e.g. coherent timetables of different modes of transport- train, bus, metro, etc.). In the times of the "digital society", the integration of the telecommunication services with other sectors (health, social care, education, transport, and basic goods) is also recognized as important. It is considered that the information communication technology (ICT) represents an opportunity for the (economic, social, etc.) development of Alpine areas, as it could bridge the challenges related to "physical" remoteness and the hindered accessibility, by enabling the SGI services on-line. The integration of social and healthcare policies and services is also in demand.

The terms "services of general interest (SGI)", "integration", and the "models of integration" are within the context of the INTESI analysis understood as follows. The SGI definition is adopted by Gløersen et al. (2016), who divided SGI into services of general economic interest (SGEI), non-economic services (NSGI), and social services of general interest (SSGI), according to the nature of their provision. This is determined by who is the provider of the service (public/private/NGOs & social enterprises) and how is the service delivered to the users (are the prices market or state regulated, is the service free or subsidised, etc.).

The understanding of the integration was based on the interpretations by Healy (2006), and Lloyd & Peel (2005). Healy (2006) explains it as a concept of four overlapping dimensions: (1) the (co)aligning of strategies and policy, (2) policy (re)framing, (3) connection between policy and action (policy and implementation), and (4) co-operation among actors. Lloyd & Peel (2005) provide a more detailed explanation and connect integration with different governance elements such as linking actors, sharing knowledge etc.:

"Integration can imply co-ordinating strategy-making to avoid conflicting policies and to generate win-win situations. It might also imply broadening a policy frame to encompass a new issue. It can also suggest closing implementation deficits that can arise between policy and action. Finally, it implies linking actors together, sharing and developing

knowledge for mutual benefit, often to overcome a fragmentation of institutional environments or a need to enter partnerships to achieve common goals. It is recognized that in pursuing integration, the ways in which it works in practice will be determined by local cultural practices and path-dependent factors (Lloyd & Peel, 2005)."

Based on these interpretations, the INTESI project group formed a definition of the integrated territorial strategy, which is: "a strategy for the SGI provision based on the 4 main principles: quality, availability, affordability, and accessibility, which takes into account peoples' actual and future needs in a given territory, territorial dimension, and the benefits of the synergies between the different SGI sectors (Report on Transnational Workshop, 2016, p. 21.)."

The literature review shows there is no commonly accepted definition of the integration models. Different studies, mostly performed in the frame of ESPON (2013a, 2013b) have formulated individual definitions. Gløersen et al. (2016) describe the two single-element models (a- horizontal integration of actors during policy and programme preparation, and b- the integration of the financial instruments), and one combined model (c-integrating finance and policies) of integration, which lately occur in relation to the SGI provision. The INTESI study understands the integration models as the integration of (1) actors, (2) policies, (3) administrative levels, (4) financial sources, and (5) other integration (e.g. of services, measures, sectors, etc.). Within the context of this study, the integration model can include only one of these five integration models (a singular model), or it combines at least two (a combined model).

2 METHODOLOGY

The information included in this paper results from the INTESI analysis, comparing 5 participating countries and their regions (Austrian Tyrol and Carinthia, Italian Lombardy and South Tyrol, French Auvergne Rhône-Alpes, Slovenia, and Swiss Canton du Jura), and the 8 examined sectors (general, regional development, transport, telecommunication, basic goods, health, social care, and education). The data for the comparison analysis was retrieved from: (a) the Database of the Existing Strategies, (b) 7 Regional Reports: Tyrol (AT), Carinthia (AT), Lombardy (IT), South Tyrol (IT), Auvergne Rhône-Alpes (FRA), Slovenia, and Canton du Jura (CH), and (c) the Transnational Workshop, which were all prepared or conducted within the INTESI project.

Problems related to the SGI delivery, were identified mainly through the information gathered through the interviews of the relevant stakeholders, which were conducted by PPs and summarised in the regional reports. To study the integration models in the inspected documents mainly the database was used to perform the numerical analysis (presence of the integration models in numbers by countries and sectors, number of combinations, the most common models and their complexity). The identification of the integration models used in practise was done comparing the regional reports.

A) DATABASE OF THE EXISTING STRATEGIES

The database includes 257 documents altogether, from which Austria participated 36 documents, France 59, Italy 59, Slovenia 45, and Switzerland 58. The documents are described with 18 basic categories (e.g. name of the country, sector, name of the document (original), name of the document (English), administrative level, type, year of adoption, duration, major objectives). The profiles of some documents additionally include information on governance models, measures, type/source of finance, stakeholders and their comments. When making the selection, the countries aimed for a balanced representation of the documents at all the administrative levels (national, regional, local), and in all the sectors. Although, the overview of the submitted documents (Figure 1) shows a rather equal division of around 30 per sector (12-15%), the regional development is with 49 (19%) better represented, opposite to the less represented basic goods sector with only 9 documents (3%) (Regional Collection of the Strategies, 2016). The reason for that is, the countries either have a small number of regulations targeting the basic goods supply (Slovenia, Austria, and Italy), or do not even have any (Switzerland and France).

Figure 1: Overall number and share of the documents by sectors

As shown in Figure 2, legislations prevail as a document type (127%), followed by strategies (25%), guidelines (6%), programmes (5%) and plans (5%). A more detailed division of the collected documents by regions is presented in Figures 4 and 5.

Figure 2: Overall number and share of the documents by type

The information from the database was mainly used to conduct the numerical analysis (Excel), e.g. to find out the number of the documents including the integration (overall, by sectors), the occurrence of the integration models (actors, administrative levels, finances, policies, and other) in the documents (by sectors, by countries), and the occurrence of the sources and types of finances in the documents (by sectors, by countries).

Figure 3: Number of the documents submitted in the database per region by sectors

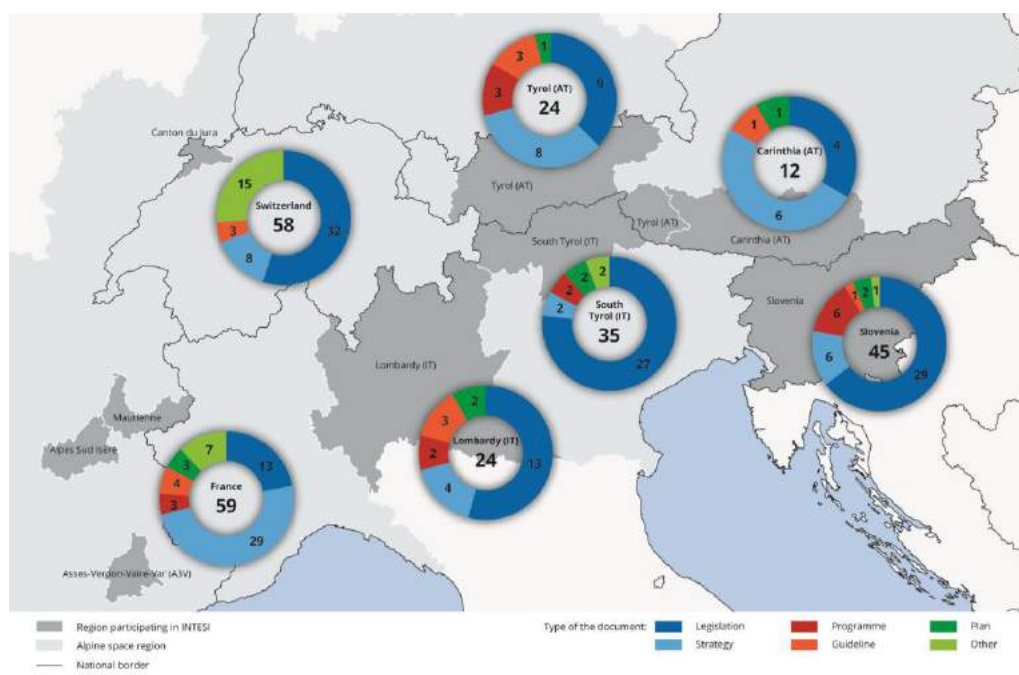

Figure 4: Types of the documents submitted in the database in numbers by regions

B) REGIONAL REPORTS

The analysis is based on 7 regional reports for Tyrol (AT), Carinthia (AT), Lombardy (IT), South Tyrol (IT), Auvergne Rhône-Alpes (FRA), Slovenia, and Canton du Jura (CH). To collect the information on the selected strategies for the SGI provision (e.g. their implementation process, measures, efficiency, the ways of financing, the related governance models, and responsible stakeholders), in addition to a detailed review of the documents, the PPs also conducted interviews. UL had prepared the questionnaire for the interviews with 12 questions which the PPs then translated into their national languages. The PPs also had the liberty to add/remove some of the questions depending on what information they needed from a particular interviewee. Altogether, 70 interviews were conducted in all the participating regions: 8 interviewees in Tyrol (AT), 12 in Carinthia (AT), 13 in Lombardy (IT), 8 in South Tyrol (IT), 9 in Auvergne Rhône-Alpes (FRA), 10 in Slovenia, and 10 in Canton du Jura (CH). The interviewees were the stakeholders (e.g. mayors, public officials, services providers) from various governance levels (state, regional, provincial, local), who the PPs have identified as important for the SGI provision and the making of the related policies in their TAs or broadly. The information gathered was later summarised in the regional reports.

C) TRANSNATIONAL WORKSHOP

The Transnational Workshop was conducted on 29th June 2016, and included 19 participants who were divided according to the countries into five groups: Austria - 5 people, France – 4, Italy – 4, Slovenia - 5 and Switzerland – 1. The aim of the workshop was to provide an input for the comparison among the countries. A special focus of the workshop was on the understanding of the SGI definition, the integration concept, and (the presence of) the integrated strategies in the participating countries. Additionally, the existing governance models were identified that support the SGI delivery in the integrated aspect.

3 RESULTS

3.1 PROBLEMS OF THE SGI DELIVERY

The study shows, general problems such as a dynamic and steep terrain, dispersed settlements, scares, decreasing and ageing population, are common to all (7) of the analysed regions. The only region not

tackling the difficulties of the over ageing and furthermore, reporting a population increase is Swiss canton du Jura (Regional Report Canton du Jura- Switzerland, 2016). Reviewing the regional reports, 14 problems were identified altogether in relation to the SGI delivery in the remote alpine regions. If the PPs did not specify in their reports to which specific sector the problem that they have identified and listed refers to, it was considered that the issue is present in all the inspected sectors. When selecting the ones present in at least 3 of the analysed regions, 5 problems stand out (Table 1): (1) Accessibility of SGIs in mountainous regions highly depends on the spatial location and the quality of public transport, (2) Underdevelopment of the infrastructure and services in terms of poor quality and/or supply, (3) Costs (expensive delivery, austerity, no allocated funds, no investments, etc.) of the services in Alpine areas, (4) Unresponsiveness of the governance system to the actual (changing) needs of the local communities, (5) The strategies are too broad and often lack the specification of measures (how to do something), responsibilities (who should do it), and monitoring mechanisms. The challenges related to the accessibility, clearly demand the integration of individual services with the transportation. In relation to the high cost (problem 3), the integration of services would enable a more efficient use of financial sources. The last problem is of governance nature. The lacking specification of measures, responsibilities, and monitoring mechanisms could be addressed by a better integration of actors, administrative levels and policies.

PROBLEMS	SECTORS REGIONAL DEVELOPMENT	TRANSPORT	TELECOMMUNICATION	BASIC GOODS	HEALTH	SOCIAL CARE	EDUCATION
1. Poor accessibility of services							
2. Underdevelopment of the infrastructure							
3. Costs of services in the Alpine areas							
4. Unresponsiveness of the governance system							
5. Too broad and general strategies							

Table 1: Problems of the SGI delivery in the Alpine regions

3.2 THE PRESENCE OF INTEGRATION

Using the information in the database, the analysis of all the 257 documents shows, more than a half (64%) include the integration as a concept. However, looking at the number and percentage of the analysed documents that include the integration by countries shows, there are differences among them (Figure 5). Italy and France evaluate, 90% of their documents include the integration, whereas, in Swiss documents the integration is not present at all. The Austrian documents comprise the integration in 78%, and the Slovenian in 67%, which is the lowest among all the participating countries, except for Switzerland.

Figure 5: The numbers and percentage of the analysed documents including the integration by counties

Figure 6: The number and percentage of the analysed documents including the integration by sectors, in relation to the total number of the documents per sector

As shown in Figure 6, the analysis reveals the highest percentage of the documents that comprise the integration belongs to the regional development sector (76%), closely followed by the documents referred as “general”. The basic goods, transport, telecommunication, and education sectors all include the integration in roughly 60%, whereas the health care documents include it in 47%. The integration as a concept is at least present in the social care sector (32%). However, these results should be considered in relation to the total number of documents per specific sector as shown in the figure. Concerning the distribution of the integration in the sectoral documents, the results of the INTESI transnational workshop (Report on Transnational Workshop, 2016) show a very similar picture. According to the participants, integration is mostly present in the strategic regional development documents, followed by the telecommunication, transport, general sector and health sector. Similarly, to the database analysis, the results of the workshop indicate a lack of integration in the social care sector. The workshop’s participants also stated the integration is missing in the sector of basic goods, whereas the database analysis shows the concept is present in 64% (7 out of 11 documents). However, in all the countries together, only 11 documents have been selected for this sector, which implies that the provision of basic goods is not managed by the strategic SGI policies, but is mainly a subject to the market conditions.

3.3 EXISTING INTEGRATION MODELS

Looking at the models of integration (actors, policies, administrative levels, financial sources, and others) a more detailed analysis of the documents, which include the integration shows, the cooperation among various actors (e.g. national authorities, regions, municipalities, interested public, service providers, etc.) is prevailing in all sectors (Figure 7).

Figure 7: The number of the occurrences of the integration models in the documents by sectors

The integration among the administrative levels (e.g. national, regional, municipal, local, etc.), best represented in the general, transport, and health related documents, is also one of the more often occurring models. The integration of financial sources is more common in the health, social care, education, and regional development sectors. However, as further confirmed by the interviewees, in most cases the “declared” integration of actors, administrative levels, or finances, presented in the documents, does not indicate an integrative and “intersectoral” approach to the SGI delivery in practice. That is also supported by the fact that the policy and other (e.g. services or sectors) integration models are the least common in all the sectors (Figure 7). Therefore, the results the “declared” rather than the actual “implemented” integration.

As one document can predict two or more integration models (e.g. actors, finances, and policies), a more detailed analysis looked at the combinations of the recognised integration models in the analysed documents. Altogether, 162 combinations of the 5 integration models or elements (actors, policies, administrative levels, financial sources, and other) were identified. The analysis revealed, the documents comprise 117 different “combined” (when at least two integration models are predicted- e.g. actors and finances) models, which largely prevail over the 45 “singular” (when only one integration model is predicted- e.g. integration of actors) models of integration. However, looking at the various combinations, Figure 8 shows the singular models (comprising 1 element) are next to the models combining two elements (45), the most common, followed by the once combining three (41).

Figure 8: The combinations of the integration models identified in the documents in numbers

The combination of all the five models (5E models) was noted twice, once in the transportation and once in education sector. In the models with four elements (4E models), the combination of actors, policies, administrative levels and finances is the most common (altogether 24 examples present in all the sectors except of general and basic goods). In the models comprising three elements (3E models), two combinations stand out. One combines actors, administrative levels, and finance (17 cases in all sectors, apart from the general and basic goods), and the other actors, policies, and administrative levels (16 examples, all sectors, apart from education). In the two-element (2E) models, the two obvious combinations are of the actors and administrative levels, and the administrative levels and finances. The most common among the singular models is the one integrating actors (20 examples, most in the social care sector), followed by the integration of the administrative levels (13 examples, mostly in the general and regional development sector).

Figure 9 illustrates that the most complex models of integration are present in the general and regional development sectors. These two sectors are overarching, guiding and connecting different policies, actors etc. More simple integration solutions are present in the sectors of social care, health, basic goods and telecommunication, in which actors and administrative levels, or administrative levels and finances are joined. In the education, the 3E-model connecting actors, administrative levels and finance stands out. In the social care sector, the integration of actors is predominant.

Elements key: A - actors, Adm - administration level, P - policies, F - financial sources, O - others
 Models key: e. g. 5E-model - 5 (number of elements) E (abbreviation for element)

Figure 9: Division of the combined and singular models of integration by sectors

3.4 EXAMPLES OF THE INTEGRATION MODELS IN PRACTICE

The descriptions below are summarised from the regional reports in which the authors sometimes referred to the "integration models" and sometimes to the "cases" or "examples of integration". As shown in Table 2, most of the existing integration models linking the governance elements (actors and administrative levels) do not mention the sector integration. An exception to that is the Tyrolian exploitation of synergies among the ongoing civil engineering projects, when expanding broadband. The governance elements the model applies to are in Table 2 marked with X.

Examples	Type of the integration model		
	Actors	Administrative levels	Policies
STRALE!K (Carinthia, AT): is a strategic rural development programme. It addresses all topics of the SGI, and defines individual solution approaches for their maintenance. It provides: of guidelines and objectives of the SGI delivery. It is a base for various department strategies. There is a special governmental office dedicated to the implementation of this programme			X
Establishment of regional management (Tyrol, AT): established for the implementation of regional strategies/concept/programmes. Members are the municipalities, tourism associations, district chambers and interested companies from the region. The aim is to pursue a target-oriented cooperation of the regions with the provincial government, federal government, and the EU, and promote the strategic regional development	X	X	
Synergies among civil engineering projects (Tyrol, AT) Broadband infrastructure expansion is conducted at the local level by exploiting synergies in the course of civil engineering projects conducted by public or public-owned carriers (gas network, district heating network, sanitary engineering, road construction, etc.)	X		
Social entrepreneurship (Slovenia) a promising future model for integration and provision of mostly social services (child care, elderly care, social inclusion, etc.), funds and stakeholders.	X		X
Service plans (Auvergne Rhône-Alpes, FRA) is an integrated territorial approach model to SGI delivery. By law French departments (administrative level similar to municipalities) must have their Departmental Plan of Improved Accessibility to Services of General Interest (SDAASP), which calls for shared services governance, and to coordination and innovation in the provision of services, taking into account the specificities of each territory

● Carinthia (AT) ● Tyrol (AT) ● Auvergne Rhone - Alpes (FRA)
● South Tyrol (IT) ● Lombardy (IT) ● Slovenia

Table 3: Existing examples of services integration in the participating regions

The services integrating 3 sectors are: the Transport services for the out of school activities by students and youth (South Tyrol-IT), the Mobile health and social services for elderly (both present in South Tyrol-IT; RR South Tyrol- Italy, 2016), and a Postbus (it. Auto-postale), integrating transport of people, medicines and goods, which is in place in Lombardy. A Digital ecosystem E015 is a service also introduced by Lombardy, which allows for the communication among the IT services of public and private actors operating in multiple sectors: transport, hospitality, tourism, culture, etc. (Regional Report Lombardy- Italy, 2016). There are other integration models such as a Mountain Virtual Hospital (MVH), an experimental model of mountain hospital (introduced by the region of Lombardy within Valchiavenna Area Strategy), which uses innovative services and new technologies, such as tele-medicine, home-based tele-radiology, points of care, de-localised diagnostic treatment-rooms (Regional Report Lombardy- Italy, 2016)

4 CONCLUSION

The analysis of the 257 sectoral (regional development, transport, telecommunication, basic goods, health care, social care, and education) and “umbrella” (e.g. constitutions, national regulations) policy documents concerning the SGI provision in the Alpine regions revealed several problems of the services delivery (e.g. services accessibility, high supply costs, failure to meet the actual needs for services, poor specification of the responsibilities and measures in the strategies), which could be addressed with the implementation of the integration of services, actors, administrative levels, finances, policies etc. The study shows, the integration concept is present in more than a half of the inspected documents, majority of which are sectoral laws and regulations. However, there are significant differences among the participating countries. Whilst the Swizz documents do not address the integration all, the concept is introduced by 90% of the documents in Italy and France, 78% in Austria, and 67 % Slovenia. Looking at the sectors, most (roughly 70%) of the regional development (laws, strategies, plans, or programmes) and umbrella regulations include it, whereas it is only present in 32% of the social care documents, which is the least among all.

The analysis of the integration models (in this study understood as the integration among actors, policies, administrative levels, financial sources, and others) reveals, the cooperation among actors is prevailing in all sectors. The integration among the administrative levels (e.g. national, regional, municipal, local, etc.), best represented in the general, transport, and health related documents, is also one of the more often occurring models. The integration of financial sources is more common in the health, social care, education, and regional development sectors. The combinations of the integration models occurring in the individual documents were also studied. Altogether, 162 combinations of the 5 integration models or elements (actors, policies, administrative levels, financial sources, and other) were identified. The analysis revealed, the documents comprise 117 different “combined” (when at least two integration models are predicted- e.g. actors and finances) models, which largely prevail over the 45 “singular” (when only one integration model is predicted- e.g. integration of actors) models of integration. Next to the singular, models combining two elements (45), followed by the once combining three are most common. The most complex (combining more elements) models of integration are present in the general and regional development documents, as these sectors are overarching, guiding and connecting different policies, actors, sectors etc. More simple integration solutions are present in the sectors of social care, health, basic goods and telecommunication. Furthermore, various existing examples of the governance (e.g. STARLEIK in Carinthia, regional management in Tyrol, social entrepreneurship in Slovenia, etc.) and sectoral integrations (e.g. Regional card for services in Lombardy, provision of meals for elderly in cooperation with local producers in Italian South Tyrol, mobile services like groceries, pharmacies, etc.) in the SGI provision have been identified in all the participating countries.

Although, the study shows the integration models are present in all the inspected sectors, and all the countries except Switzerland, the interviewees explain the “declared” integration of actors, administrative levels, or finances, recognised in the documents, is not transferred into an integrative approach to the SGI delivery in practice. That is further confirmed by the analysis showing, the integration of policies and other elements (e.g. sectors, services, measures) is seldom. Thus, to improve the accessibility and supply of SGI in the Alpine regions, above all transportation and telecommunication services need to be linked with other sectors. Therefore, the policy makers should ensure, the new spatial planning policies will offer comprehensive solutions and reflect these needs by encouraging and enabling the integration models. However, their success largely depends on the far-reaching power of the planning policies in the inspected regions. As shown, the general and regional policies already present a good base for the integration, which they at the moment fail to deliver. An interesting observation of the analysis is also that the stakeholders fear to use new ways and models of the SGI delivery (e.g. the available digital tools), which might also explain the difference between the declared and actual integration to some extent.

ID 1560 | RETHINKING PLANNING CULTURES: FROM EVIDENCE-BASED RESEARCH TO CONCEPTUAL IMPLICATIONS

Karina Pallagst¹

¹ University of Kaiserslautern

karina.pallagst@ru.uni-kl.de

1 INTRODUCTION

Planning cultures was for a long period of time perceived as merely an academic concept. However, in recent years, scholars have turned to evidence based research to provide a more profound understanding of the notion of planning cultures (Othengrafen et al, 2015). Notwithstanding, planning offers a plethora of topics potentially serving as windows of investigation for planning cultures. The aim of this paper is to synthesize insight from two different angles of investigating planning cultures: shrinking cities and border regions. Starting out with own research on shrinking cities and planning cultures (Pallagst et al 2013; 2016), and border regions and planning cultures (Pallagst, forthcoming), this paper introduces results and methodological frames from both realms. In particular, the author's previous research on shrinking cities made clear that planning cultures can be investigated by evidence based research utilizing the shrinking cities phenomenon. In the second part of the paper the author will make an attempt to derive preconditions from this evidence based research for a critical reflection of planning cultures, which might necessitate a rethinking of the notion of planning cultures.

With the active embrace of urban shrinkage in the German planning discussion, one might speculate whether growth has come to an end as a dominant paradigm in planning – at least in this country. This aspect is striking when considering changing planning cultures; for international comparative research it is important whether this change will be a general trend, or, an aspect that is driven by local or national specifics. In the US, for instance, there is speculation that the political consensus for urban growth is diminishing (Purcell, 2000) and the author has called for a shift in paradigm when it comes to US planning for shrinking cities (Pallagst, 2007). The shrinking cities phenomenon thus offers an opportunity to investigate the principles upon which spatial planning has traditionally been based and, by this means, it may help shed light on changing planning cultures.

2.3 EVIDENCE BASED RESEARCH ON PLANNING CULTURES AND SHRINKING CITIES

In current planning debates the term ‘shrinking city’ usually describes a densely populated urban area that has on the one hand faced a considerable population loss, and is, on the other hand, currently undergoing a profound economic transformation, with some symptoms of a structural crisis (Pallagst, 2008). According to Oswalt (2006) more than a quarter of the world’s metropolises shrank in the 1990s and, notwithstanding ongoing urbanisation processes, this number will continue to increase. With growing interconnectedness both on a European and on a global scale, a significant emerging task for planning researchers is to facilitate a wide-ranging exchange on economic, social, and environmental developments. Hypothesis of the research was that the dynamics of urban shrinkage most likely trigger changes in planning paradigms, planning systems, planning strategies and planning cultures in the respective countries.

Pallagst et al investigated shrinking cities as a window for possible changes in planning cultures in the frame of the EU project PlanShrinking (2010-2015).

In order to derive a typology of planning cultures applicable for the context of shrinking cities, the authors modified Othengrafen’s culturized planning model (Othengrafen 2010) describing the general context of planning cultures towards shrinkage (see figure 1). Figure 1 demonstrates general criteria of planning culture, supported by a specific criterion for shrinking cities: shrinkage context. ‘Societal context’ displays the ‘backbone’ of a planning culture with a range of more general understandings, ‘planning context’ describes the beliefs of the planning profession, and ‘planning toolset’ refers to the methods at hand. The category, ‘shrinking context’, comprises those aspects which might trigger change in planning cultures due to shrinkage and its implications on urban development and planning reactions.

Figure 1: Facets and layers of planning culture with reference to shrinking cities
Source: Pallagst et al 2013.

In addition, the PlanShrinking research traced several preconditions for the joint research of planning cultures and shrinking cities:

1. Both topics -- planning cultures and shrinking cities -- can be labelled emerging topics in spatial planning. Just like planning cultures, shrinking cities has been widely underrepresented in international comparative urban and regional research.
2. The shrinking city phenomenon is a multi-dimensional process, comprising cities, parts of cities or metropolitan areas that have experienced dramatic decline in their economic and social bases. Urban decline and the loss of employment opportunities are closely linked in a downwards spiral, leading to an out-migration of population (Pallagst, 2008). However, despite the fact that globalisation is a trigger for urban shrinkage, economic transformations do not affect all cities in the same way; on the contrary, shrinkage can show very different characteristics depending on national, regional and local contexts (Cunningham-Sabot and Fol, 2007). Research on planning cultures is usually attributed to a national context of a planning system – however, this also involved different levels of planning (from national to local).
3. Planning cultures serves as an academic concept which is lacking an evidence base, whereas shrinking cities is a planning challenge vividly engaging practitioners and academics likewise in search of urban or regional solutions.

When for example examining the US and the German planning realms, it becomes apparent that they offer very specific yet different planning cultural settings (most different systems). While the US planning culture has been labelled 'market oriented' (Pallagst, 2007), the German one offers a more elaborate multi-level planning system, often criticised as being inflexible (Heemeyer, 2006). In an earlier publication on planning in the US, the author argued that a paradigm shift is taking place in planning from 'growth-centred planning' to 'shrinking smart' (Pallagst, 2009).

Case-study analyses carried out by the author and her team focused on exploring documentation, archival records, and planning documents regarding planning and rebuilding activities in selected case study cities. A stakeholder-based analysis (by means of 6 qualitative interviews in each city with e.g. city government staff, land bank staff, housing companies, and NGOs, on site investigations, and a workshop with select interviewees in the year 2012) aimed at gathering in-depth knowledge about experiences with applying strategies to steer the development of shrinking cities. These investigations were looking into the process of shrinkage, and possible changes in planning strategies and thus planning cultures. In addition, the authors further investigated the case of Flint in the year 2014 with specific focus on aspects of the new master plan of the city. The reason for the choice of Flint was – among other aspects – the new place type category 'green innovation area' introduced in the master plan. This investigation was facilitated by an on-site visit and qualitative interviews with 8 stakeholders (land bank staff, city government staff from various departments, the Charles Stewart Mott Foundation, NGOs).

The following research questions were investigated:

- Which are the trajectories of shrinkage in the case study cities?
- Which actions were taken in terms of planning for decline?
- How is the implementation of these measures taking place?

2.4 LESSONS LEARNED FOR PLANNING CULTURES FROM INVESTIGATING SHRINKING CITIES

It turns out that shrinkage is indeed challenging existing planning cultures in a way that planning paradigms are shifting from growth centered planning towards more realistic and sustainable development paths.

The cases investigated demonstrate that industrial transformation affects manufacturing towns to a large extent, inducing unemployment, housing vacancies, and population losses – the usual downward spiral. What is striking is that the attitude towards shrinkage seems to change: when looked at the types of strategies to cope with shrinkage, most cities found their way past the phase of ignoring shrinkage and are in an intermediate state of maintaining the urban fabric and actively planning for a smaller and more sustainable type of urban development, where greening and right-sizing play a role. The downward spiral

could potentially be turned into new perspectives for the cities. Among these are new visions and possibly also employment perspectives, mostly in the frame of right-sizing, greening, or leveraging substitute industries.

For many shrinking cities it is a fact that planning has changed to a dramatic extent from growth as the main focus to reusing abandoned land and managing vacancies. Redeveloping vacant land is probably the main opportunity for shrinking cities to adapt to past and future challenges. This might be facilitated by right-sizing, strengthening the urban core, green infrastructure, and substitute industries.

All in all, the PlanShrinking research suggests that due to the large amount of economic, social and urban fabric related problems, shrinking cities seem like the new labs for experimenting with planning under crises and changing conditions.

3 INVESTIGATING PLANNING CULTURES AND BORDER REGIONS – A FIRST ATTEMPT

3.1 SHIFTING THE EVIDENCE BASE: WHY INVESTIGATE BORDER REGIONS IN TERMS OF PLANNING CULTURES?

The author's previous research on shrinking cities made clear that planning cultures can be investigated by evidence based research utilizing the shrinking cities phenomenon. Nonetheless, planning offers a plethora of topics potentially serving as windows of investigation for planning cultures – one of them being border regions. Research by Sorensen (2015) further underpins this argumentation: He suggests that planning cultures might change when faced with as he calls it “critical junctures of institutional change and innovation in planning systems” (Sorensen, 2015: 33). One of these critical junctures might be the context of border regions.

Tus the aim of the following part is to shift the window of investigating planning cultures from the evidence base of shrinking cities towards the realm of border regions. The following paragraphs will make a first attempt in order to derive preconditions from shrinking cities research for the field of border regions.

3.2 SOME THOUGHTS ON THE CHARACTERISTICS OF PLANNING FOR BORDER REGIONS

Border regions are areas of high spatial relevance for many European countries like e.g. Germany with borders facing nine neighboring countries. In general, planning conditions and planning requirements are in flux due to new spatial challenges like demographic change, migration flows, and EU requirements in line with territorial cohesion. The situation is growing in complexity in a cross border setting as different planning systems and different planning styles come together in border regions.

Planning as a discipline has been shaped – among others - by the Association of European Schools of Planning (AESOP) representing topical discourses among planning scholars throughout Europe. On its website, AESOP declares:

‘To us planning is a tool to promote and manage change with a spatial approach. It is also a tool for the preservation of the environment and our cultural heritage. The core of this task is to conduct planning activities in such a way that society benefits and that economic, environmental, social and other goals are met’ (Association of European Schools of Planning, 2014).

This definition shows that planning today is deeply embedded in society and culture. When looking at the specific realm of border regions, planning in this particular setting is facing additional challenges arising from the cross-border situation, which are:

1. Different planning traditions and planning cultures: planning cultures are assumed to be congruent with nation states, but even within nations there might be various planning

cultures. In turn, border regions are accommodating multiple planning cultures which have brought about different planning styles and different planning tools.

2. A lack of cross-border knowledge on planning processes and planning tools: planning practitioners are operating in their specific administrative setting, be it a local entity (planning office of a community or district,) or a regional body. As planning across the border is operating under different conditions and is bringing about new legal or operational changes on an infrequent basis, keeping up with the evolvement of planning is a challenge in itself, and this is often not at the heart of the planners' day-to-day work.
3. Different governance styles: Operating and implementing planning is in line with national governance styles, and usually on a formal basis planning is intertwined with existing legal frameworks entrusting planning competencies to governmental bodies. This means that for some planning tasks there is no matching counterpart on the other side of the border.

But even when there are wide-ranging challenges, usually at the same account opportunities come up. For the specific situation of planning for border regions these are:

- In terms of the fact that planning has the potential to adapt: The opportunity of bridging cultural gaps by reaching out across planning cultural boundaries.
- In terms of conceptualizing planning: The chance of creating (although not always implementing) joint territorial visions for parts of or the entire border region.
- In terms of governance: The possibility of building strong partnerships and networks which in turn help to enhance the flow of knowledge between cross-border planning realms.
- In terms of planning's implementation: The ability to create, explore and apply new tools specifically tailored to the situation of border regions.
- In terms of the supranational (EU) level: The prospect of becoming testing labs for the grand European scheme of territorial cohesion

The ability and the willingness to collaborate across borders can be seen as a specific European learning process (Platzer, 1993). Growing economic interdependencies trigger the creation of new inter- and supranational levels of cooperation. In line with the proclaimed Europe of the regions, which has been a European paradigm since the 1990s (Irmen, 1992), the role of the nation state might become less relevant in border areas, however, the border region as a territorial entity becomes a prominent feature of territorial development.

Nevertheless, in terms of their spatiality, border areas are not necessarily realms of homogeneous conditions, but they might display spatial bottlenecks and challenges such as: polarized economic, social and demographic development, gaps in traffic and transportation (in particular transit), social requirements and infrastructure needs in terms of education and health care.

These challenges might be severe, putting the quality of life in border regions to a test, which might in turn lower the regions' attractiveness in economic, social and environmental terms. This is where planning comes into play as a discipline with the potential to steer, guide, and collaborate in terms of and actors in terms more livable development paths.

However, based on their distinctive planning traditions, countries involved in cross border planning have their very own planning systems. These usually operate on different administrative levels, and specific actors operating on these levels have the competency to fulfil planning tasks and deliver planning artefacts, be it actual plans, zoning codes, strategic documents, or visions (Pallagst, forthcoming).

Planning operates in quite different administrative systems, with a mismatch in institutions and formal planning documents. Based on planning cultural characteristics we encounter the following:

- Different local and societal conditions.
- Different legal framework.
- Different planning and administrative levels.
- Different graphics.
- Different scope.
- Different actors.

- Different plan content.

Some of these differences in planning tools will be demonstrated in this thematic issue by the article for the greater region by Bechtold et al, showcasing relevant topical examples of planning documents of the Greater Region.

Yet, all over Europe the complexity of planning for border regions is aggravated by planning tools which are supplied in a cross border mode, such as project funding tools (e.g. INTERREG), governance tools (e.g. EGTCs), monitoring tools (e.g. GIS in border regions), policy tools (e.g. ESPON), and visioning and development tools (e.g. regional development concepts). This compilation shows that in border regions, several planning tools exist, covering a wide range of planning activities. At this respect the question might come up, if border regions display a planning system, maybe even a planning culture of their own? But, as long as there is no formal competency for planning which reaches out across existing national borders, all planning activities remain in the sphere of informality.

An in-depth comparative analysis of planning tools cannot be delivered at this point, as this paper's purpose is addressing research requirements rather than investigating cross-border planning styles. In this respect, a research frame will be suggested in the following part.

3.3 PRECONDITIONS FOR A RESEARCH FRAME FOR PLANNING CULTURES IN A CROSS-BORDER CONTEXT

In a first attempt to conceptualize planning cultures and border regions, the author suggests a research frame (see figure 2) derived from the facets and layers of planning culture in terms of shrinking cities (see figure 1). This research frame (figure 2) adds the border context as a new component to the planning cultural context.

Aspects to be considered within the border context touch base on three levels related to time, offering potential for further research are the following

1. Historical traces:

How do path dependencies manifest themselves in planning in a border context, in particular in terms of the question in how far planning in border regions has already adapted. This ties in with Sorensen's (2015) plea for historical institutionalist analyses of comparative planning contexts.

2. Status quo:

Which challenges in terms of space and governance do border regions have to face in their respective setting? Which planning instruments/tools/strategies are applied and implemented, and what is their spatial impact?

3. Future development:

In how far is the border context contributing to a knowledge transfer or exchange among planning professionals in the border context? How can we effectively leverage potentials of policy diffusion?

4 CONCLUSIONS

What can we learn for planning cultures in the context of border regions? Compared to the shrinking cities research, which usually draws on comparative approaches between cities not necessarily in close proximity to each other, the border context is different. Here, areas from at least two countries form a regional setting, which enhances complexities for the realm of planning cultures to a wide extent. Moreover, not only different planning cultures, but also different planning systems, and a multitude of different planning tools and different stakeholders collide.

This has most likely implications for existing planning tools, but additional challenges arise from the fact that in the particular realm of border regions, new cross border planning tools are cropping up, almost shaping a planning system of their own. In this particular context, the question arises, what the status of these tools will be, and what kind of interdependencies arise between them and the set of national planning tools. And, more pronouncedly, if there is potential to shape a border regional planning culture of its own. With many border regions existing along Europe's regions, the evidence base is there, now research on planning cultures needs to follow.

ABSTRACT : Seeking to contribute to a more nuanced understanding of the processes of rescaling in European macro-regional strategies, this paper aims to develop and test a conceptual framework to explain the underlying processes of rescaling. In an attempt to draw on the conceptual gateways in the main debates of scale and rescaling, we observe a mismatch with empirical observations on how stakeholders construct scale. As a result of a structured literature review, and based on empirical observations in the Danube region, we suggest that the key to understanding rescaling processes is the conceptualization of scale as a construct, constantly contested through multiple dimensions. Drawing upon recent developments within planning literature arguing for a co-existence between relational and territorial spaces and our empirical information, the paper suggests a multidimensional conceptualization of scale of four dimensions: (i) regulatory/jurisdictional; (ii) funding/resources; (iii) knowledge/values and (iv) network. We argue that scales consist of four co-existing dimensions which have impacts on social and economic relations as well as policy-making. Through the analysis of the Danube Region example the paper concludes that processes of rescaling often occur indirectly. We observe that case stakeholders make use of networks and knowledge at the macro-regional level in order to influence decisions in the funding and regulatory dimensions of the national and EU level.

KEYWORDS: scale, territoriality, rescaling, EU macro-regions, Danube Region, transport, navigation

1 INTRODUCTION

European macro-regional strategies aim to address common “functional challenges” and coordinate policy responses across multiple countries (EC 2013). Starting with the development of macro-regional strategies for the Baltic Sea (2009) and the Danube Region (2011), they have subsequently evolved to form a key aspect of European cooperation. Situated between the EU and the nation states, writings from several scholars in human geography, planning and political studies have started to discuss the rescaling of spatial policies in the wake of ongoing European integration (FALUDI 2010, STEAD 2011). Macro-regions have not generally extended political decision-making competences, despite their influence and role in recent policy-making. As macro-regional activities affect existing governance arrangements in more complex ways than representing a new political scale, the paper examines which processes of rescaling in EU policy making can be identified in the case of European macro-regions. Second, the paper questions how scalar constructions influenced by macro-regional activities can be explained. In analysing the various processes of rescaling and the ways stakeholders shape scalar structuration, we faced the challenge to

explain our empirical observations based on the existing theorization of scale. Hence, we third consider what we can learn for the theorization of 'scale' from these findings.

Starting in the 1980s, academic literature witnessed a considerable growth in debate around conceptualizations of 'scale' and processes of 'rescaling'. We summarize these academic debates in four phases. In the first phase social theorists and human geographers such as TAYLOR (1981, 1987) and SMITH (1981, 1984, 1990) engaged in theorization of scale and scalar organization of society. In the second phase in the 1990s and the early 2000s, contributions disputed the changing role of nation states in the context of globalization and European Integration. In seeking to overcome the notion of scale as 'taken-for-granted' most contributions were affiliated with forms of neo-Marxist (e.g. SMITH 1995; BRENNER 1999 A/B) or regulation theory (e.g. SWYNGEDOUW 1997A/B, JESSOP 1997, COLLINGE 1999,). The third phase was marked by poststructuralist writing challenging these political-economic approaches by disputing the use of the concept of scale as such (MARSTON 2001, MARSTON ET AL. 2005). More recently, scalar literature has turned to highlighting the overlaps of both strands in following a constructivist perspective, albeit their opposing philosophical roots (MacKinnon 2012).

These debates have helped to understand the nature of 'scale' and develop different perceptions. Nevertheless, the translations of these conceptualizations for analysis remains complex and challenging. More concretely, we argue that this theorization elucidates a processual understanding of scale but does not offer gateways to explain how scale is contested in a structured way. Seeking to contribute to a more nuanced understanding of the processes of rescaling, we argue that scalar theorization now needs to go a step further and explain how scale is constructed.

Most studies of rescaling either focus on the reasons and major developments triggering rescaling (e.g. globalisation), the different objects of rescaling processes, and/or the direction of processes of rescaling and the involvement of different groups of stakeholders. Many definitions of rescaling exist. Some follow a narrow understanding of the reallocation of state power. Others encompass modes of governance, policy relationships, agendas, networks or ideas (GUALINI 2006, STEAD ET AL. 2015). Interestingly however, many recent empirical studies of spatial rescaling in environmental and planning studies often consider 'scale' from the perspective of changes to jurisdictional arrangements and competence-shifts (KERN & LÖFFELSEND 2004, MC CARTHY & COHEN 2015; see also contributions in EPS Special Issue 2006 14:7).

As a result of empirical observations in the Danube region, we suggest that the key to understanding rescaling processes is an alternative conceptualization of scale as a construct, constantly contested through multiple dimensions alongside different fluidities. Hence, the paper aims to develop and test an alternative conceptual framework that reflects on the rationales of scalar activities in policymaking. This then enables us to explain the reasons and processes behind rescaling and the implications for scalar structuration. We approach the development of a framework by means of a structured literature review of existing conceptualizations of scale and rescaling and by drawing on our empirical observations research. The paper aims to contribute to the broader debate of 'scale' conceptualisations in support of theorizing and empirically analyzing rescaling.

The paper presents a multidimensional conceptualization of scale and suggests four dimensions: (i) regulatory/jurisdictional; (ii) funding/resources; (iii) knowledge/values; and (iv) network. These dimensions are explicitly and implicitly recognized in literature, most prominently the administrative and network spaces and scales. One point of departure on the theorization of 'scale' is a paper by MACKINNON from 2012 who presents the conceptual overlaps between political-economic approaches and post-structural writing. A second starting point are current developments around the co-existence of relational and administrative spaces within the territoriality debate. We explicitly take up the dimensions of access to funding and resources, existing values and knowledge basis, as well functional spaces, which are acknowledged in scale literature as rationales or parameters for stakeholder's activities. Based on our empirical evidence in the Danube region in the specific policy issue of navigation, we suggest that looking at these explicitly as own dimensions offers explanatory force as to how scalar construction come into being. Examining the recent activities in the thematic cooperation of developing the Danube Waterway under the EU macro-regional strategy for the Danube Region, we illustrate that all of these dimensions are essential within processes of scalar restructuring.

The paper is divided into four main parts. We begin by revisiting conceptualisations of scale in order to identify, understand, explain and interpret processes of rescaling in their complexity in EU policymaking based on a structured literature review. Second, we present an analytical framework, which we then test in the third part of the paper examining the case of the European macro-regional strategy for the Danube Region (EUSDR). Fourth, we discuss the implications for the further theorization of scale.

2 DEBATES ON SCALE AND RESCALING – A REVIEW

2.1 CONCEPTUALISATION OF SCALE

The concept of scale has been subject to a very rich academic debate within human geography and, more broadly, social theory. We distinguish between four main phases. The start of the debate around scale is associated with the seminal writings of TAYLOR (1981, 1987) and SMITH (1981, 1984, 1990). In this first phase scholars focused on the theorization of scale as a concept based on different philosophical traditions. In contrast to the materialist views on scale proposed by Taylor and Smith, Hart (1982) drew on the Kantist philosophical tradition and argues that scales are fictive (see Herod (2011) for further exploration).

In the second phase of the debate, mainly in the late 1990s and early 2000s, an important narrative was the changing role of the nation state in times of globalization and European integration alongside debates on new regionalism (KEATING 1997). In general, literature theorizing the ‘politics of scale’ (NEUMANN 2009, cf SMITH, 1992; COX, 1998; SWYNGEDOUW, 1997a/b; 2004; MARSTON, 2000; SHEPPARD/MACMASTER 2004) questioned scalar configuration and processes of scaling, rescaling and descaling. The state of the art around 2000 is summarized by a quote from BRENNER (2001, 592):

“[M]any geographers have elaborated processual notions of scale in their efforts to understand the ways in which entrenched scalar configurations are being reorganized [...]. Rather than viewing scale as a self-evident or pregiven platform for geographical processes, these scholars have introduced more dynamic conceptualizations in order to investigate the contested, and continually evolving, role of scale as a container, arena, scaffolding and hierarchy of sociospatial practices within contemporary capitalism.”

It is in this context that relational thinking became influential in theorizing scale, significantly drawing upon Lefebvrian ideas that territorial organization, social relations and institutional arrangements occur upon different levels, and that hence a spatial fix necessarily involves a scalar fix (1991). Key scholars shaping this discursive shift from more static to dynamic conceptualisations include BRENNER (2001, 2004), SWYNGEDOUW (1992, 1997a/b, 2004), AMIN (2002) and MASSEY (1999, 2005). Both MASSEY and AMIN have been instrumental in perceptions of new power geometries as a result of globalization. They have advocated the importance of networks, and argued for shifts away from the nation state as the primary domain of organization of world economy, maybe towards “spaces of flows” (CASTELLS 2000). SWYNGEDOUW for example conceives “scalar configurations as the outcome of socio-spatial processes that regulate and organize social power relations, such as the contested making and remaking of the European Union or the process of state devolution or decentralization” (2004, p. 26). This may include the “emergence of new territorial scales of governance and the redefinition of existing scales” and hence may result in changing regulations or social, political and economic organization of the Nation State (SWYNGEDOUW 2004, p. 26).

In the first two phases, most authors in the literature were in some way affiliated with certain brands of neo-Marxist theory (e.g. SMITH 1995; BRENNER 1998, 1999 a/b) or regulation theory (SWYNGEDOUW 1997a/b, JESSOP 1997, COLLINGE 1999, UITERMARK 2002). The main arguments brought forward are the social constructiveness or production of scale through various social actors and the historical contingent process of political contestation (DELANEY and LEITNER, 1997). This constructivist perspectives, according to LEITNER, “involves conflict-laden power struggles” of “individuals, groups and institutions” independent whether played out through material or rhetorical practices (2004, p. 238).

In the third phase, post-structuralist writing challenged the political-economic approaches (MARSTON 2000, MARSTON ET AL. 2005, JONES 1998, MOORE 2008, COLLINGE 2005). These researchers argued that the materialist nature of political-economic approaches grants ontological meaning to scale. In contrast, MARSTON ET AL. (2005) suggest “a flat ontology”, arguing to abandon the notion of scale. In

highlighting, the epistemological meaning of scale MOORE (2008) agrees with MARSTON ET AL. denial of an ontological reality of scale, suggesting that “it is not necessary to retain a commitment to the existence of scales in order to analyse the politics of scale” (2008, p. 213, italics in original). This approach was not uncontroversial (LEITNER/MILLER 2007, COLLINGE 2006).

In the last decade, scalar literature has turned to identifying overlaps between these two major strands, and has offered some interdisciplinary perspectives to scale. The common concern of both POLITICAL ECONOMIC AND POST-STRUCTURALIST WRITING was to overcome the notion of scale as pre-given following the “traditional Euclidian, Cartesian and Westphalian notions” (BRENNER 2001, 592) highlighting the evolutionary components of sociopolitical contestation. MACKINNON emphasised that there is A “shared concern with the construction of scale and how this is shaped by wider social relations and networks providing basis for theoretical providing a basis for theoretical rapprochement and synthesis.” (2011, p. 22). Herod (2011) summarizes the academic debate around scale as presenting opposing views of the nature of scale as static versus evolutionary, epistemological versus ontological, Marxist materialism versus Kantist idealism and the move from topographical to topological conceptions of space and scale.

Most recently, the interdisciplinary perspective has been strengthened by MC COHEN & CARTHY (2015). In the environmental studies there is also a strand of theory-building on the environmental or natural dimensions of scalar configurations (NEUMANN, 2009, MC COHEN & CARTHY 2015, SWYNGEDOUW 2004, 2007, CASH ET AL. 2006). Environmental studies refer to the perimeters of natural resources as scale (e.g. water catchment areas, animal migration corridors) (CASH ET AL. 2006). Serving as a bridging figure between environmental studies and social sciences (SWYNGEDOUW, 2004) notes that “scalar configurations, whether ecological or in terms of regulatory order(s), as well as their discursive and theoretical representation, are [...] an outcome of the perpetual movement of the flux of sociospatial and environmental dynamics”. (2004, 132). Meanwhile, COHEN & MC CARTHY (2015) differentiate between a rescaling to jurisdictional or natural space and make a case that the environmental dimension and ecosystem spaces deserves “to be drawn out more explicit in scalar scholarship” (2015, 3).

Based on the review, we perceive a lacuna in scale literature to move beyond questioning the use of the concept itself towards a deeper understanding as to how scales are contested. Poststructural literature has claimed to expurgate the existence of scales. We however retain the notion of scale for two reasons. First, based on our empirical observation it is a concept that underpins general views of the world and subsequently produces some kind of ‘scalar fixed’ rationales. Secondly, adopting the evolutionary and processual understanding of scale, we perceive scale as a dynamic construct constituted of different horizontal dimensions alongside which stakeholders action radiuses are detectable. This is influenced by recent developments in planning literature.

2.2 LEARNING FROM THE TERRITORIALITY DEBATE

Theorisation of scale coincided with close engagement with social theories within human geography, which lead to “a re-thinking of many of the core concepts of the discipline, including space, place, landscape, region and scale” (PAINTER, 2010, p. 1091) under the rise of relational thinking. The vast amount of literature approached scale “in similar fashion to the region” (MACKINNON, 2012) and approaches to ‘territory and territoriality’. Both concepts have undergone substantial transformation through the movement away from the perception of fixed entities according towards a constructivist view.

In the last decade in the human geographic literature, and more explicitly in planning literature, various academics have sought to overcome the dialectic between relational and territorial approaches towards territoriality (HAUGHTON ET AL. 2010, PAINTER 2010, AGNEW 2015, PAASI 2004). For example, PAASI AND ZIMMERBAUER (2015, 2) highlight that “[e]specially researchers studying the links between regional and urban planning, governance and policymaking have stressed the need to balance the relational and territorial views.” Processes of planning often remain situated in their jurisdictional boundaries and competence fields in need of coping with these overlapping developments, networks and so on (COCHRANE and WARD 2012). With regard to spatial configurations, the introduction of the concept of “soft spaces” by ALLMENDINGER ET AL. (2009) was perceived as a cornerstone. The concept reflects the mutually constitutive ‘hard’ and ‘soft’ spaces of governance. It is not surprising, that planning scholars welcomed this framework to think with, and it rapidly found basis for explaining many regional configurations in Europe and worldwide (e.g. FALUDI 2011, PETTERSON/FRISK 2016, SIELKER 2016).

The concepts of scale and territoriality are closely intertwined with a scale describing its relation to other spaces. The overlapping notion of different types of spaces is closely connected to somehow scaled networks and frameworks that are increasingly porous and malleable. Recently JESSOP (2016) presented a modified territory, scale, place and network (TSPN) scheme to explain the relations between these core concepts. Here he conceives the notion of 'soft spaces' as "networks of differently scaled places" (p. 24). The seemingly insurmountable opposing understanding of constructivist views as opposed to the Westphalian notion of scale is increasingly dismissed. The persistence of state structures and some elements of territoriality for state structuration have lately been perceived as contingent, but subject to change as well. Hence, some constructivist thinking, and even poststructuralist thinking, has made its peace with the idea that territorial spaces are as well never fixed, though they are more resistant to change (HEROD, 2011).

In line with these arguments, we perceive both the existence of networks as well as administrative or state spaces as elements of scalar structuration. Before embarking on the presentation of our multidimensional framework, we now turn to the literature focusing on the processes of rescaling.

2.3 CONCEPTUALISATION OF RESCALING

Following McCann rescaling can refer to "the process in which policies and politics that formerly took place at one scale are shifted to others in ways that reshape the practices themselves, redefine the scales to and from which they are shifted, and reorganize interactions between scales" (2003, p. 162). Narrow and broader definitions of rescaling can be found (GUALINI 2006). A narrow understanding of rescaling describes the reallocation of power and competences, particularly over resources and regulations (FÜRST 2006). A broader understanding of rescaling encompasses the restructuring of all kinds of governance, cooperation and social power relations. Most academic writing with a conceptual interest in rescaling is to be found in critical geographic literature thereby disapproving perceptions, which are conceived to have an underlying rationale of a purely state-centring rescaling of power (Brenner, 1999). The introduction of relational thinking and the post-structuralist argumentation were important contributors to a broader notion of rescaling, in which the social construction of all forms of interaction served as an explanatory background. In the context of European integration KEATING (2013), writing on the issue of new regionalism, captures rescaling as "the process by which systems of social regulative, collective action, representation and legitimation are migrating to new territorial levels" KEATING 2013, ix).

The various understandings of the processes of rescaling reflect a divide between relational and some kind of 'territorial' thinking. UITERMARK (2002, p. 748) notes that "usually, the re-scaling literature leaves the 'softer' issues aside and focusses on the 'hard' issue of power". His view is that "both of these issues are equally important with regard to regulation". However, there is often a gap between empirical studies and these theoretical debates. The theoretical debate has advanced and begun to acknowledge the importance of these 'soft' issues. Somewhat detached from the conceptualisations in most empirical studies particularly within environmental or planning studies the question of re-scaling remains largely associated with questions of changes in authority, power, legitimacy or more broadly speaking increasing influence in processes, on decision-making (KERN & LÖFFELSEND 2008, see as well EPS Special Issue 2006 14:7).

The rescaling literature has generally focused on one or more of the four realms (or questions): (i) the directions of scaling processes (from where to where?); (ii) the reasons for changes and contestations leading to 'scalar jumping' (why?); (iii) the objects of rescaling (what?); and (iv) the involvement of different interest groups, agents, networks or actors involved and the implications for governance and influences of different groups (who?).

Much of the scaling literature in empirical studies focus on the first realm, although not always explicitly. The question of directions of rescaling is part of the discussion on hierarchically nested scales. An important element of scale theorization was to show the entangledness of the different scales, most importantly the relation between the local and the global scale (SMITH 1993, BRENNER 1999, COX 1998b, SWYNGEDOUW 1997). In times of globalization, the 'hollowing out' of the nation state was an important narrative, giving more importance to regionalism and global cooperation (BRENNER 1999). In an empirical case study in the context of transnational cooperation for sustainable development in the Baltic Sea region KERN & LÖFFELSEND (2004) describe the outcome of new governance arrangements

as a transfer of national authority in three directions: (i) upwards to the level of international and supranational institutions; (ii) sideways to civil society actors; and (iii) downwards to subnational actors. This distinction is helpful in explaining the directions of rescaling for example in the context of environmental governance (STEAD, 2014).

The reasons for rescaling are sometimes presented in relation to large societal phenomena and economic forces such as capitalist influences on economic systems and structures (e.g. COX, 2013, BRENNER 2004) or the agendas of particularly influential stakeholders (e.g. SMITH A. 2013, Special Issue in Political Geography 17 (1) 1998, MARSTON 2000).

In accordance with the narrow definition of rescaling, the issues of authority, power or legitimacy can be affected. For example, FÜRST (2006, p.9) argues that “a shift in political agendas, problem-solving and policy-legitimization” can be seen as rescaling. Meanwhile, in the context of European cooperation STEAD ET AL. (2015) argue that rescaling can include “policy making agendas, processes, networks or power, or alternatively [...] ideas, argumentation or identities related to policy” (p. 105-106).

Another realm identified in rescaling literature concerns the question ‘who’ is involved in scale making. For example, MEADOWCROFT (2002) links scalar construction to the involvement of different interest groups, arguing that rescaling leads to broader and more inclusive processes, but at the same time contributes to more fragmented and differentiated approaches as different groups participate in different contexts, according to their interests (MEADOWCROFT, 2002). In his early writings, Neil Smith develops the idea of ‘scale jumping’, describing the “ability of certain social groups and organizations to move to higher levels of activity” (MACKINNON, 2011). The notion of ‘scale bending’ (SMITH 2004) describes that ties between certain scales can be undermined by social groups and individuals mostly in the context of “fragmentation of pre-existing scales” (SMITH 2004, 2005).

Many empirical studies adopt rather narrow definitions of rescaling (see above). Given the rich debate on scale and scalar configurations, it is surprising how little empirical work has been presented from these perspectives.

3 TOWARDS A NEW FRAMEWORK FOR ANALYZING RESCALING PROCESSES

3.1 BRINGING THE SCALE AND RESCALING DEBATES AND EMPIRICAL OBSERVATIONS TO THE DEVELOPMENT OF AN ANALYTICAL FRAMEWORK

The conceptual framework set out below has been developed with the aim of explaining processes of rescaling in policy-making processes in EU macro-regions, which contain large networks involving a great variety of actors. The framework specifically addresses how processes, ideas and competences move across different scales and are transferred between them, and by whom. The case of the macro-regional strategies serves to highlight rescaling in the context of a multiplicity of ‘layers’ of policy and scales.

The initial development of macro-regions questioned the development of a new scale of policy intervention (Stead 2011). Applying PERKMAN’S (2007) framework for the construction of new scales in three steps (political mobilization, governance building, strategic unification), macro-regions can be considered as a new scale. However, we do not limit ourselves to describing institutionalization processes, we also identify the interlinkages and the entangledness with other scales. In line with McCann’s observations on the “reorganization of interactions between scales” (2003), we suggest that new forms of cooperation lead to changes at other scales.

We identify a variety of processes of rescaling, the objects of which are not a priori known. While the results of the various attempts for scalar reorganization can be clearly identified, the underlying processes remain largely ‘behind the scenes’. Explaining the processes of rescaling is complex but the rescaling literature has a tendency for the oversimplification of analytical schemes for the analysis of competence shifts (e.g. sideways, upwards or downwards).

Our framework is influenced by arguments around contested rather than static theorization of scale. The two most helpful starting points for the framework are related to the construction of scale and the co-existence of networks and statehood scaling in scalar configurations. We agree with the concern of

political-economic and poststructuralist scholars on a social and political constructivist view towards scalar configuration. In line with the above, we perceive scale as constantly contested arenas and networks, which are not an a priori given. Generally, our framework connects with ideas from HEROD (2011, xvi) who argues that “there is always a tension between tendencies towards stabilization and those towards destabilization, even if at any one moment one of these appears to have won out”.

Much of the scale literature focusses on the question whether scale is perceived as ontologically or epistemological. In our attempt to analyse the ongoing processes it is secondary to us whether to characterize scale as ontological or epistemological, but we are convinced that the effects of ‘scalar politics’ (MACKINNON, 2011) have material effects. However, we follow the post-structuralist claim that it is not ‘scale per se’ as a conceptual given leading to its imposition on aspects of social and political practices. Hence, the conceptual framework focusses on ‘scalar’ practices as a way of identifying processes of stabilization or destabilization of scales, or ‘in-between spaces’ given the non-fixity.

We are influenced by recent developments in planning literature with its concept of soft spaces and fuzzy boundaries and the idea to overcome the simplistic dichotomy between scale as purely hierarchical elements of statehood levels and the idea of overlapping arenas. We believe that scalar configurations, be it in the frame of statehood scales or network scales, are always contested. More specifically, we perceive the construction of scale as mutually constitutive of the ‘hard’ as well as the ‘soft’ elements overlapping networks with state actors as one important impulse. In order to understand scalar structuration and the underlying social relations we see both the ‘softer’ and the ‘harder’ issues of rescaling as those which manifest the contestation processes. Furthermore, we argue that there are multiple dimensions of scale (or arenas) in which policy-making is taking place. This leads to a position, where apart from the jurisdictionally scales, commonly organized in the layers global, European, national, regional and local, numerous ‘in-between-spaces’ (PAINTER 2010) develop that come to form their own scales, often transgressing these layers.

As a result, and based on empirical observations in practice, we suggest that the key to understanding rescaling processes is an alternative conceptualization of scale as a construct, constantly contested through multiple dimensions alongside different fluidities. Hence, we theorise scale in differentiating how and through which means and elements, or as we call it dimensions, scalar production comes into effect.

3.2 THE NATURE OF THE ANALYTICAL FRAMEWORK

We suggest that scale can be conceptualized through four dimensions with different fluidities: (i) regulatory/jurisdictional; (ii) funding/resources; (iii) knowledge/value; and (iv) network. These dimensions are derived from explicit and implicit recognition in literature, as well as from our experiences in practice. Most obvious from the literature are the dimensions concerning regulatory/jurisdictional and network. We concur with COX’S approach (1998 a/b) that scales reflect the overlapping nature of different dimensions of scalar configurations, including legitimacy questions and network elements. This academic debates mirrors our experiences in the EU macro-regions. Stakeholders are well aware of their networks as well as the administrative spaces that serve as a parameter to their activities. Stakeholders recognize both relational and administrative spaces, and both influence their scalar activities. In addition, arguments around knowledge and values as well as resources and access to funding provide explanatory factors when looking at how and why stakeholders influence scalar politics. These two elements have implicitly been regarded both in post-structural and political economic literature as regards to stakeholders motivations and reasons for scalar politics (see for example MARSTON 2000 on the resources of middle class women or SMITH 2004 on scale bending). In our approach, we attribute these elements a more explicit role. Before applying the framework, we first offer a brief characterization of each dimension.

The first dimension refers to the regulatory or jurisdictional dimension of scalar construction. In policy-making processes, as in the case we will illustrate later, the jurisdictional and legitimate dimension remains an important notion of political action. All types of regulatory frameworks ranging from jurisdictional or legislative frameworks to all kinds of regulations, provisions or formalized procedures are one part of scalar construction. Depending on the phenomena analyzed, this can on the one hand involve regulations in form of jurisdictional means as for example represented by the state scales. On the other hand, this dimension describes as well different types regulatory framework at all scales (such as agreed rules on the household level).

The second dimension ascribes funding and resources as one element to scale construction. The examples we choose to illustrate our approach towards scalar construction and phenomena are from policy related processes rather than social phenomena. However, we see resources such as human resources, and financial means as one element allowing, restricting or facilitating all kind of activities. As regards to the question of what is either rescaled or influenced by developments at other scales, many scholars are concerned with changes in budgets or the (re)allocation of (human) resources from one scale to another (e.g. PERKMANN 2007, MARSTON 2000).

The third dimension we term as 'knowledge/value dimension'. With this dimension, we draw attention to the somewhat intangible parts of scalar construction reflected in 'common knowledge' and even more widely shared or sometimes contradicting societal values. All human activities are influenced by underlying values and knowledge. Coinciding with the definitions presented above, the narrow definition reflects on processes that come into effect through the jurisdictional and the resource dimension (e.g. budgets or human resources). The broader definition as well includes processes that come into effect through the knowledge and the network dimension (e.g. policy agendas or ideas). This dimension hence allows to reflect on who has what knowledge and what is discussed at what level, as well as on the values and identities involved. In the diversity of scalar related phenomena transfer of knowledge to different levels or the changing nature of discourses and hegemonic relations is important. Whereas some phenomena relate to knowledge in terms of information (such as problems of implementation in transport project) others relate to values and knowledge which are also moving across scales. Some scholars build their arguments explicitly or implicitly on examples where knowledge, values or identities persists (see for example MOORE (2008) on the Bosnian-Serbian identity and overlaps with traditional state boundaries). Knowledge and values can spread and transgress scales through public interactions and sometimes enter into the narrative of 'common sense' or the predominant 'canon of values'. The resulting scales here are to be considered as more fluid and porous and not necessarily geographically locatable.

Fourth, we see the network dimension as an important, fluid part of scalar construction. This dimension closely reflects relational and post-structural thinking as it refers to all kinds of networks, formally or informally construed. Networks transgress around different dimensions and layers at the same time.

Networks reflect the notion of 'spaces of flows' (CASTELLS, 2000) and the increasing role of informal, formal, temporary and institutionalised networks through which scales are built.

We reason that this multidimensional approach to scale offers a way to understand how scales are contested, formed or reoriented. Through these four dimensions scalar configurations come into effect. At the same time actors and stakeholders construct scale moving alongside these dimensions. Because of these interactions the different dimensions are constantly contested, triggered by social, economic and political changes. However, these dimensions differ in their fluidities to change, with jurisdictional levels to be on a general level rather resistant compared to networks that might be loosely organized (see Fig. 1).

Below, we apply this framework to analyse the case study of EU Strategy for the Danube Region strategy (EUSDR) and examine the extent to which this framework can provide useful starting points to conceptualize scale as a combination of co-existing arenas of these four dimensions.

4 TESTING THE ANALYTICAL FRAMEWORK WITH AN EU MACRO-REGIONAL STRATEGY

The first European macro-regional strategy was launched in 2009 for the Baltic Sea Region. This was soon followed by the development of the Danube Region Strategy (2011), and later the Adriatic-Ionian Strategy (2014) and the Alpine Region (2015). One key idea of macro-regional cooperation is to tackle common challenges through the development of a joint strategy by countries in the same geographic area. The geophysical characteristics are the building blocks for various areas of cooperation (e.g. navigation or environment). The EUSDR is organized in priority areas, representing the thematic foci for cooperation. The EUSDR addresses a total of eleven policy fields ranging from transport, environment towards education or security matters. Starting from this general prioritization in support of joint activities, the EUSDR sets the goal to make the Danube a better navigable river (EC 2011). For each priority area a governance structure is defined in order to coordinate implementation activities.

In this section, we seek to illustrate the dynamics of rescaling in the case of transport policies contained in the EUSDR. This issue has been chosen for two reasons. First, the use of the Danube river as an important transport corridor has been impetus for Danube cooperation. Second, this policy theme has received relatively high-level political attention and has become one of the most active fields of cooperation.

Methodologically, the case study is based on a textual analysis of meeting minutes, progress reports of the navigation/waterway priority area and official EUSDR documents. In addition, it is based on interviews with representatives from the Steering Committees, the European Commission as well as from the Shipping Associations in the Danube Region.

4.1 SETTING THE SCENE – TRANSPORT POLICIES AND PROJECTS IN THE DANUBE MACRO-REGION

The EUSDR involves the cooperation of 14 Danubian countries on the issue of transport along the Danube River corridor. The issue of navigation was very central to the development of a macro-regional strategy, not least since Commissioner Hahn called on national transport ministers to increase transport volumes on the Danube River by 20% between 2011 and 2020. The development of joint projects to achieve this goal is summarized below.

Soon after adoption of the macro-regional strategy, work began on implementing Priority Area 1a (“Mobility – Inland Waterways”) under the lead of Austrian and Romanian Coordinators with support of the Technical Secretariat at the ViaDonau GmbH, the Austrian waterway operator. A governance structure was set up for the implementation of the Priority Areas with a Steering Group as the central governance element. The group was formed of representatives from the 14 countries including representatives from public authorities, such as Ministries or Waterways and Shipping Offices. Several governmental and non-governmental organisation such as the Danube Commission, the International Commission for the Protection of the Danube River organisations or ProDanube International are observers to this committee. The committee is responsible for decision-making on joint goals and strategies. The decisions have, however, neither a formal character nor do they represent binding agreements.

In a second step, this Steering Group prepared the “Luxemburg Declaration” (Danube Ministers, 2012), signed by most of the Danube Transport Ministers, which provides political commitment to the development of a more effective waterway. In a third step, the Steering Group developed the “Fairway Rehabilitation and Maintenance Master Plan” based on a NEWADA project (FRMMP, 2014). This project included waterway companies. It covers the navigable tributaries in each country and the critical sectors. In addition, public authorities defined so-called common minimum Levels of Service as goals as well as different waterway maintenance activities. In a fourth step, the Master Plan was presented to the Danube Ministers, who subsequently gave it their endorsement (DANUBE MINISTERS 2014). Fifth, the Master Plan built the basis for National Roadmaps (2015) and the development of specific implementation activities. One example is the FAIRway Project whose scope is to procure the necessary equipment to carry out pilot activities for hydrological serves and to allow the identification of innovative approaches for fairway rehabilitation and upgrade. The eight beneficiaries from six countries (Austria, Bulgaria, Croatia, Czech Republic, Romania and Slovakia) obtained funding through the Connecting Europe Facilities. In February 2016 the FAIRway Project was launched with a total budget of ca. €22 million with ca. €19 million from EU contributions.

The development of joint waterway development policies for the Danube from 2011 to 2016 was triggered by discussions in the new macro-regional committees, which in return sought the necessary political support. The primary stakeholder triangle in its development are public authorities and observers in the steering group, transport ministers and waterway companies. The European Commission served an advisory role in the Steering committee meetings where the Master Plan development and the Project development were high on the agenda.

In sum, the macro-regional level represents a new cooperation arena, which over the last 5 years has led to project development and funding allocations at different levels. Below, we seek to illustrate how the ESUDR influenced scalar politics, and to what extent these developments represent processes of rescaling.

4.2 APPLYING THE MULTIDIMENSIONAL FRAMEWORK

Drawing on the four dimensions presented above, we elaborate on the ways in which the primary stakeholder groups explored and influenced these dimensions in the EUSDR generally as well as the FAIRway Project more specifically.

NETWORK DIMENSION

The interest to initiate and join new networks across the Danube countries was high during the early phases of developing the EUSDR (Blanked Name 2012, Blanked Name 2016). The Danube Cooperation is largely led by existing networks with different degrees of institutionalization. The networks created by this cooperation are manifold and reflect the overlapping hard and new soft spaces (Blanked Name 2014). These occur through the new informal, consultative governance structure of the EUSDR itself as well as in projects and wide range of activities and new institutionalized networks (such as the Danube-INCOnet, see website danube-region.eu). The networks cover different territories and show different constructions as regards to those four dimensions. Some build on informal arrangements, whereas others have been created in response to changes in the funding or legislative dimensions of scale.

The example of the FAIRway project illustrates how the new networks are closely shaped by the Priority Areas set out in the EUSDR. The implementation of activities in view of navigation improvements are supported and induced by the steering group, a new network itself. This committee offered the opportunity for the representatives of the public authorities to provide guidelines for joint activities through the decision on joint goals. The different interest groups and observers were able to raise concerns and bring needs to the attention of representatives. The Priority Area Coordinators based in Austria and Romania involved a technical secretariat with the viaDonau GmbH, a company founded to tackle difficulties of Danube shipping. The official framing of an EU strategy helped this network to make its voice heard at the group of the Transport Ministers. Through this 'upscaled' network of interest groups and public authorities in cooperation with the waterway associations and shipping companies, stakeholders were able to seek political support of the national transport ministers as a first step. This high-level political support then serves as basis to argue for changes in the legal and the funding framing. For the stakeholders involved and this new network the next step was to create an elementary and coherent knowledge.

KNOWLEDGE/VALUE DIMENSION

In the primary stages of macro-regional cooperation, the Priority Area Coordinators provided an overview of existing activities. The naming of the cooperation after the Danube river initiated broader debates as to whether there is a Danube identity. According to statements by different interviewees, cooperation and coordination between the different ministries and associations on the issue of navigability led to a revived feeling of being focused towards a common goal.

ViaDonau initiated and coordinated the development of the Fairway Rehabilitation and Maintenance Master Plan following the Newada and Newada DUO project. The goal was to identify in more detail joint activities around quantitative data. The Masterplan named the challenges of the navigable tributaries and summarized data from the 11 riparian states. This includes country reports laying out how many days in a year the Danube was navigable (e.g. the daily draught or dredging activities). Based on this, the Steering Group identified the sections in which the joint goals of 2.5 m of draught and 5.25 m minimum height under bridges 365 days per year are not fulfilled. These discussions subsequently shaped the discourse along the upper and lower Danube. Through the EUSDR process, information was made accessible to all stakeholders in the region. On the one hand, the knowledge itself was enhanced, then 'upscaled' and finally, led to new 'knowledge arenas'. On the other hand, these developments and the coordinated project was used to inform policy-makers and impact funding decisions on other levels, namely national and EU-wide funding.

RESOURCES/CAPACITIES DIMENSION

The dimensions of resources and capacities is a crucial dimension in scalar politics, often being the object of activities. In the Danube Region, the immense numbers of stakeholders involved (e.g. more than a 1000 participants at the Annual Forum in Ulm in 2015) reflects the allocation of human resources to activities related to the relatively new cooperation. However, one of the main important rationales of macro-regional cooperation are the three NO's: no new legislation, no new institutions and no new budgets. At first instance, macro-regional cooperation seems not to imply rescaling of allocation of funds.

The FAIRway project, however, reveals that stakeholders used the knowledge and network dimension of scale to influence funding decisions in the Connecting Europe Facility. Based on discussions in the Steering Group, the FAIRway project was developed in close cooperation by the Steering Group members with consultation for example from representatives of the European Commission (DG-Move). In addition, the results of the process were regularly directed towards political stakeholders by the Steering Committee members. An example of this is the political leverage triggered by the Transport Ministers endorsement of the FRMMP. As the EU funds aim to implement MRS, the respective funding decision by the CEF is directly linked to the EUDRS. Though not implying new funds the EUSDR has had an impact on the allocation of existing funds at the EU level. At the same time, the perimeter of the different projects is connected to the territorial coverage of the Danube Region. Therefore, this level has gained importance in terms of the use of resources and capacities, which in return necessarily implies changes at other scales.

REGULATORY/JURISDICTIONAL DIMENSION

The macro-regional cooperation builds on informal documents which are not binding (e.g. the Strategy Document and the Action Plan). Whilst the MRS in itself does not imply new legislation, it does offer a new framework which changes regulatory arrangements at other levels. One consequence is that the modus operandi for the development of projects has changed and the decision on funding is coupled to the support of the macro-regional Steering Groups.

The case presented here provides an example on how the macro-regional discourse shapes the political framing. The Transport Ministers did not provide new legislation with the Luxemburg Declaration. Nevertheless, this document has shaped ensuing decisions in the national and EU-wide context. National ministries are now more likely to take action that coincides with the priorities contained in the macro-regional strategy. In addition, the development of the FRMMP has provided a basis for joint goals, which are being introduced into national discussions and regulatory frameworks. These frameworks provide the building blocks for national funding decisions.

5 SUMMARY AND DISCUSSION

One of the goals of the paper was to analyse processes of rescaling in EU policy making in the example of macro-regional strategies. Based on a structured literature review around scale and rescaling as well as the empirical insights from the case study we developed a framework for analysis. In this paper, we argue for a multidimensional understanding of scale, where scalar (re)structuration can be explained through stakeholders interactions alongside four dimensions: regulatory/jurisdictional, funding/resources, knowledge/values, and network. This four-dimensional framework was tested in the Danube macro-region and the FAIRway project. We contend that processes of both stabilization and destabilization can be observed in rescaling processes.

5.1 DISCUSSION: HOW DO PROCESSES OF RESCALING OCCURE IN THE EUSDR?

The example of the EU Danube Region reveals the complexity of scalar structuration, configuration and production. The example shows how the macro-region and its strategy are composed and constructed by different overlapping 'in between scales'. The macro-regional developments indirectly influence those at other scales. These depend on the topics addressed, as in the case of navigation.

The example presented in this paper shows how stakeholders crossed over different scales and made use of the different dimensions of scale as a way to influence political priorities and decision-making at the EU and national level. The Steering Group is a new network through which public authorities can enhance their position in respect to the national context. In the case presented above, the knowledge and the network dimension were essential for stakeholders to gain political support. This, in turn, led to allocations of resources. Just looking at the example of the Steering Group, essentially driven by some active public authorities and the Technical Secretariat of the Via Donau GmbH, shows how this new network influenced the political decision-making and funding at the national and EU level. In order to achieve this goal they used the knowledge dimension in providing a new information base and directed this development towards the network dimension at the macro-regional level. The transport ministers draw on the regulatory framework, whereas the shipping companies draw on the network and knowledge dimension to influence the other dimensions. Clearly, different stakeholders use different dimensions to influence developments and change political priorities.

The multidimensional framework appears to be a useful tool to detect how scalar restructuration occurs. One example presented here was the development of the FAIRway project, which is a direct result of the macro-region and the politicization of Danube River related activities. The example illustrates that all processes and their outcomes are connected by the developments within the four dimensions, and that all of these dimensions are essential within processes of restructuration, albeit depending on the phenomena and actors involved with diverging weight. For example, the use of the knowledge dimension on the macro-regional level influences the funding dimension on the EU level.

5.2 DISCUSSION: IMPETUS FOR FURTHER THEORIZING OF SCALE?

We argue that following the developments of scale literature over the last few decades, theory now needs to enter into a new phase focusing on how scale is contested and the process behind rescaling. This next step can help to overcome the mismatch between theory and empirical complexity. In providing a conceptual framework, we aim to offer one approach as to how scalar construction can be theorized.

In our framework development we were guided by the idea to overcome the dialectic of scale as a purely hierarchical element of statehood levels and the idea of overlapping network-arenas. Inspired by the recent developments in the planning literature, arguing for a co-existence of relational and territorial approaches to space, we assume the co-existence of more resistant dimensions of scale as well as more fluid dimensions of scale. When analyzing territorial policies, such as transport, we are hesitant to expurgate the role of the statehood levels too fast and reduce it to a purely network notion. On the contrary, we argue that scales consist of four co-existing dimensions through which scales become apparent and through which effect is taken on the social relations and policy-making. Agents make use of these different dimensions according to their means, and hence construct "scale".. At the same time, stakeholders move across different dimensions and different levels, where scale may be somewhat difficult to detect.

6 CONCLUSIONS AND FURTHER RESEARCH

The paper started from the claim that, despite the richness of literature in theorizing scale, many conceptualisations of scale and rescaling do not offer very adequate gateways to explain the multiplicity of 'layers' of policy and scales that we observed empirically. Based on a structured literature review and the empirical evidence we have developed an analytical framework to scrutinize processes of rescaling in the Danube region, focusing on the specific policy issue of transport and navigation. We have then tested this multidimensional framework.

We conclude that the framework offers a helpful starting point to better illustrate how macro-regional cooperation can both destabilize and restabilize existing scalar structuration and leads to the construction of new 'scales'. Further, we conclude that looking at scalar politics explicitly through these dimensions offers explanatory force as to how scalar construction come into being.

More generally, the framework provides a more nuanced way of illustrating which agents and actors are operating within what type of scales and, through which means they become active in influencing

gorri.anisa@yahoo.com ; eledfagu@hotmail.com

ABSTRACT: In late 2013 the National Territorial Planning Agency (NTPA) in collaboration with the Ministry of Urban Development (MUD) of Albania took the initiative of drafting the First National Spatial Plan for Albania 2030(NSPA). The strong need of the country to jump to a new way of sustainable development was backed up by the political will and a new legal planning reform, paving the ground for new integrated planning instruments. Although this is not the first time plans are drafted in Albania this is the first national spatial plan for the country. The methodology for drafting the NSPA was based on three complementary steps: At first the metabolic analysis of the territory was performed for five main systems of the territory: water, food, infrastructure, urban and natural system. Secondly, the Declaration of Vision was drafted through a wide participatory process from different stakeholder form the government administration but also independent experts and academia. Third, the strategic proposals through flexible tools that allow for further exploration for best collaboration between national developing sectors and local governance. The plan followed an open and democratic approach reflected not only in the participatory drafting process but also on the strategic proposals that were offered. It was not the aim of the working group to have a restrictive plan with rigid land use maps but to provide a tool for the national and local administration and also private sector that would guide and advise on the best possible uses of the territory. The plan gives alternatives and describes possibilities for best cross-sector and inter-regional cooperation and proposes strategic projects of national importance for the sustainable development of the territory in the next 15 years. Major public hearing were held across the country, so people could have the chance to express ideas, to be informed but above all to be part of a national plan that would guide the territorial development for the next 15 years. The participation process resulted to a new increased level of awareness of the importance of territorial planning as a cohesive process to different governance sector of the administration. Strengthen institutional capacity for cross-cutting issues of territorial planning resulted essential to achieve a plan that aimed spatial balance, sustainable development, and socio-economic

wellbeing. Even though the NSPA is approved at the highest instances foreseen by the law, for the actual administration it is an ongoing process and its success depends on a large scale on continuous research of contextual planning issues and for every stage of its implementation or upgrade to assure an open transparent inclusive process with democratic participation.

KEYWORDS: National Spatial plan, territorial cohesion, participatory planning, governance policy

1 INTRODUCTION

Even though Territorial Cohesion concept is not new as such (Faludi 2006) first mentioned more than two decades ago in the Treaty of Amsterdam 1994 (Faludi 2004 citing Husson 1999, Husson 2002) (Vogelij 2010) than introduced in the European Spatial Development Perspective (ESDP – EC, 1999) as a decisive milestone presenting the ‘territory’ as a ‘new dimension of the European Policy’, while it only gain the attention for elaboration into an applicable concept in 2004 in the Rotterdam Acquis. It was then launched as one of the three main pillars of the EU (European Union) Cohesion Policy with the Green Paper on Territorial Cohesion (EC, 2008), and it was included in the Lisbon Treaty, in 2009, (Medeiros, 2016) (Vogelij 2010)

Also, the debate in recent years has shown that a strict definition of territorial cohesion is impossible. (Böhme and Gløersen, 2011). Although “Territorial cohesion is merely said to augment existing policies with a greater focus on development opportunities, to encourage co-operation and net- working, to pay greater attention to strengths of areas and by a better targeting of policy instruments” Rather than giving a definition, the message seems to be that nothing radically new is being proposed... (Faludi 2004) As main stakeholders emphasize different dimensions of the territorial cohesion idea, and because the concept has to be fluid enough to accommodate temporal change, any attempt to define it precisely will unavoidably result in excluding certain senses or aspects and thus lead to a poorer result. (Böhme and Gløersen, 2011)

When it comes to Albania we can say with conviction that it is about a totally novel concept and uncharted field.

While it is not the aim of this paper to explore the origin, meaning and importance of territorial cohesion as these are largely argued and previously explored. It is in the focus of this paper It is important to explore how this concept, fundamentally created as an instrument for territorial management in the member states, still further to formalize the role of the European Union in the competence of planning, guides and is absorbed in the highest levels of policy documents even for the states outside The Union such as Albania.

The paper presents an analysis of the National Territorial Plan of Albania 2030 with main reference on the Territorial Cohesion main characteristics. The focus is placed on planning practice, by analysing the case of the National Territorial Plan. The analysis is based on a literature review of the terminology and features of Territorial Cohesion and on participatory observations as the author has been involved in the process of drafting the National Territorial Plan of Albania 2030 as the team leader.

In the end, the importance of the test case stands in showing how European-level territorial cohesion policies can be adopted and downscaled on a national level of a country. And above all, when talking about territorial cohesion in Europe, "integration is a state of mind". Spreading knowledge and advancing with new concepts within the common interest of sustainable development overcomes borders.

2 THE CONTEXT OF DRAFTING A NATIONAL TERRITORIAL PLAN AND THE RELATION TO TERRITORIAL COHESION

It is understandable that Albania's long-term aspiration to join the EU since long has adopted a large number of European legal directives, but while the ESDP and Territorial Cohesion Policy are not even a requirement for European member countries, in Albania it has found a broad implementation that starts from the reformed legal planning framework, to the planning documents.

Of course, there are a lot of challenges in Albania when looked from the perspective of catching up with the rest of Europe. On the other hand, it is good to consider that many European countries and more are facing the same challenges as Albania in terms of overcoming spatial disparities, securing sustainable development and conservation of environmental sensitive areas, as well as fair access to services, and achieving territorial resilience, at a national level also at the European level.

As territorial cohesion is about place based policy making, paying particular attention to local development conditions, going below the regional level. (Böhme, and Gløersen, 2011), the policies of member states on territorial cohesion that address the spatial disparities issues are useful and make sense when applying their actions and measures even at a level state. If the country is a member of the EU or not, it is not a limitation to their implementation, because when it comes to environment issues, climate change effects but also on an everyday growing virtual market economy, have no physical boundaries.

In this background it is important to deepen the research on clearly identify those territorial cohesion policies that when downscaled at a state level planning documents can contribute to the main goals of territorial cohesion. Furthermore, as a policy that is nonbinding on EU member states, how it still can influence and be adopted to the main planning documents of non-member countries. In the text a subtle feature comes out that accompanies or in some cases even conditioned the implementation of cohesive territorial policies: it is the Political support. Then, this raises the question: How can a non-member country strengthen the role of planning institutions and authorities so that principles of territorial cohesion lead the policy making and be more resilient to it? Or how do the documents based on territorial cohesion affect the strengthening of this feature? Could the acquisition of the Cohesion Policy incentivise stronger, competent and conscientious institutions that formulate and guide political decisions? The above questions are seen in the case of drafting and empowerment of the National Plan for Albania 2030, as the highest planning instrument in the country.

Below are described, the three main contextual elements that have enabled this approach in the NSP of Albania 2030 (NTPA 2016): the legal framework of the territorial planning reform, accountable and responsible planning authorities and the administrative reform, developed at a same time frame 2013-2016.

Legal context: Although the evolution of the planning system in Albania from urbanism to territorial planning has been analysed before (MUD, 2014), it should be noted that by 2013 the planning reform process initiated from 2006 was not yet completed. Although in force, the innovative law that introduced and paved the way for the application of new territorial planning instruments, it could not be fully implemented in the absence of detailed regulations and planning documents. In this way, at the end of 2013, initiated as a top down incentive of the political force at that moment, a comprehensive realization of the legal reform in the area of territorial planning. This meant not only completing the law with by laws but also delivering manuals for better implementation and understanding the new planning concepts, for experts and local administration. Within the same years several initiatives were taken regarding the completion of planning documents as the NSP 2030, Integrated Coastal Plan for Albania, and Integrated Cross Sectorial Plan for the area of Tirana - Durrës. This was a very decisive moment since the design of the NSP was directly linked to the law enforcement.

Administrative reform: The drafting of the NSP came at a decisive moment of when Two other key reforms on territorial development were launched : the Administrative Territorial Reform, that reorganized the territorial administration at the local level from 365 municipalities and communes to 61 municipalities and the Territorial Regionalization Reform, which defined the middle level of territorial organization for cohesive development into four main regions.

The NSP is of primary importance to the success of these reforms, because its approval ensures a coherent planning from the national level to the regional and local level. However, analysis of the way these processes were accomplished are not subject to this paper. Here is stressed the importance and the relation of this favourable legal and political context for the drafting of a national spatial plan, where the demand for a unified vision of national sectoral policies was imminent. It should be noted that the process of drafting and co-ordination of the NSP by involving all the actors on all levels of administration and academia, also the public participation on public hearings in thirteen main cities of the country, was by no means a simple and unobtrusive process. The new context described above and the well-prepared working team positively influenced for its realization.

Institutional reform. In 2013 a new Ministry dedicated exclusively to territorial management (while formerly the territory was an issue under public work ministry) was established Ministry of Urban Development (MUD), dedicating its work on the main problems that impact the national territory facing: informal settlements, social housing and of course territorial planning. Also the role of National Territorial Planning Agency (NTPA) was enforced as the main institution that would assure the horizontal and vertical coordination of national and local authorities that had a say on territory planning and development (ministries, national agencies and municipalities). Having a holistic approach on territorial management of the territory from the main perspectives legal, territory administration and governmental authorities goes in line with the main territorial cohesion policies aims and objectives.

The approximation of Albanian NSP with the territorial cohesion objectives can be further identified when compared to actions promoted under the heading "territorial cohesion":

1.	Actions promoted under the heading "territorial cohesion"	NSP actions and Territorial Cohesion relation
	Smart growth in a competitive and polycentric Europe	To reach the level of polycentrism at the national level is proposed the hierarchization of urban centres and the identification of regional development poles. For purposes of this plan, urban centres and their hierarchies is based on central place theory, but is enriched with reflections that derive from
		additional dynamic functions such are related with: - Existing and proposed national infrastructure; - Concentration and the characteristic of deployment in relation to natural resources; - Balancing pressures and demands for urban development mainly in the western part; - Mitigating the tendencies of depopulation and poverty mainly in the peripheral eastern regions, orienting the spatial dimension of economic development policies on economies of agglomeration evolving from central places to regional development poles.
2.	Inclusive, balanced development and fair access to services	NSP is about balanced development, focusing on providing inclusive growth, fair access to infrastructure services and the reduction of spatial disparities. This dimension of NSP is embodied in the entire document but it appears more clearly when presenting projects that promote growth and access on underdeveloped areas (North, north-east and south east), with the east corridor and transversal corridors that assures accessibility and permeability to the territory and the urban settlements. Add public services on balanced distributed primary urban centres, and draws attention on providing appropriate connections of these centres with the areas and urban settlements around them.

3.	Territorial diversity and the importance of local development conditions	Territorial cohesion is about place-based policy making, paying particular attention to local Development conditions ()Particular attention in the NSP is given to the specificities of places and their comparative advantages in chapter 4 when exploring potentials and proposing for developing Regional Growth Poles and the specialised ones, according to territorial specifics.
4.	Geographical specificities	The NSP organizes the territory based on five territorial systems: urban, natural, agricultural, water and infrastructural. Approaching in base of territorial systems implies the recognition and organization of the territory through networks, corridors, spaces and nodes, interdependently linked by flows. These systems are organized in relationships between centres, corridors and areas on the basis of which the planning documents of the lower hierarchies will be detailed. They do not define the territory in rigid land use proposals, but describe and present different ways and possibilities of developing economic activities that go in line with the primary characteristics of the territories and by mutual way of cooperation.
5.	Environmental dimension and sustainable development	Environment and nature, because of their largely interaction character, consist in a network that do not belong exclusively to one territory or a group of population, they are part of a wider system. The concept of using resources that we do not own, but share it in time and space is essential in territorial development policies. The most typical example of this interaction is the impact on climate change experienced by different countries and peoples due to the inadequate exploitation of non-renewable resources and environmental pollution. The NSP is associated with the drafting of Environmental Impact Assessment that addresses measures and actions that define the way of NSPs policies implementation to assure environmental protection.
6.	Governance, coordination of policies and territorial impacts	Territorial cohesion is about the need to maintain dialogue with other sectors to strengthen the territorial dimension in various policy fields. This coordination is ensured not only during the process of drafting the plan through public consultations and institutional coordination but also through the functions of a central government institution such as the NTPA, whose primary legal task is to ensure a coordinated process vertically and horizontally, transparently and in compliance with the applicable legal framework (Article 4 Law 107/2014)Broadly speaking, the topic focus on governance and cooperation processes – as a key aspect of territorial cohesion – rather than actual territorial development features.

Table 1 NSP Albania 2030 actions and Territorial Cohesion relation

NSP can relate more to territorial cohesion. Firstly, it established an inter-institutional communication network and linked experts and technicians of public administration in a dialogue and collaboration beyond formal communication. It established the territorial planning issues in a real and objective relationship with the environmental, economic and social issues affecting long-term development. It brought all of the

sectorial policies under one single framework and designed a model for sustainable spatial development for the next 15 years for the country to follow. It served as a school for capacity building and increased knowledge related to territory management issues for many ministries and government agencies that until then were operating under single isolated sector issues, ignoring the bigger picture that spatial planning can provide. Thus NSP the Albania 2030 conveys a vision of the future territory of Albania following the principles of Territorial Cohesion. In its aims and guidelines it provides a general source of reference for actions with a spatial impact, taken by public and private decision-makers so that policy interventions can be better targeted and thus they can support more effectively the development the country and the use of its so far unrecognized or underexploited territorial potentials.

4 PLANNING AS ON GOING CHALLENGE. NEXT STEPS FOR IMPLEMENTING ALBANIAN NSP 2030

The challenge lays on how the NSP can be implemented and better adopt when the concepts where it is based are flexible and fluid? How can principles and policies coordinated with developed concepts of European countries, go down to actions and concrete measures for implementation? For this, the steps being pursued in the implementation of the NSP and the realization of its objectives are:

- Drafting the monitoring platform for the implementation of the NSP. The staff is working by consulting the appropriate indicators used for this purpose at European level (KITSCAP). Also, co-operation with domestic institutions of statistics such as INSTAT and monitoring agencies is the foundation of this venture.
- Meetings with the academy and universities to further explore new and more efficient ways to improve the ongoing territorial management process, but at the same time make territorial cohesion issues part of the local universities research programs related. This not only to address the coherent challenges of spatial development but also to build models of best cases and the forecast the future role of Albania relating territorial cohesion when in EU.
- Meetings with local government focusing on the most disadvantaged municipalities in development, to explore more ways to implement NSP and benefit from the national policies that the document provides for them.
- Meet with all the municipal technical staff for the establishment of a municipal data system that will help to measure the realization of NSP objectives in terms of polycentrism, access to services, economic growth, environmental protection, innovation address spatial disparities and more.
- Continuous communication with ministries for the implementation of national strategic projects that integrate the country's economy with the region.
- As well as communication and cooperation with Regional Agencies to promote balanced regional development.

5 CONCLUSIONS

The NSP Albania 2030 is a fine example showing that territorial cohesion policies and actions can be adopted and implemented with success even when down scaled at national levels.

Interinstitutional collaboration and public communications are the best direct methods to achieve awareness on territorial planning and on sustainable development issues.

The succeed of flexible planning instruments and the application of open methods of communication depends on the consolidation of institutions in charge of planning coordination. In relation to this, NSP remains still a document that seeks to be fully perceived in the heart of its objectives by the policy makers and the government entities that deal with territorial management and development. The enforcement of NTPA role, as governmental institution to achieve the above mentioned objectives is indispensable for Albania, not only for national territorial cohesion achievement but for strengthening the position of the country in the region and implementing a long lasting vision for sustainable spatial development . Last but not least, it was shown that while talking about territory cohesion, "time" which lays between countries and EU integration, is also in planning, relative and a variable that can be stretched and pressed depending on

the results and actions that are taken under the sustainable spatial development process. Therefore, in European studies and platforms related to developing and implementing territorial cohesion and sustainable spatial planning, countries like Albania outside the Union, and even more the Balkans, should not be excluded, on the contrary involved, as the benefits of cohesion overcome formal boundaries.

ID 1611 | METROPOLITAN GOVERNANCE APPROACHES IN DEVELOPING SUSTAINABLE EUROPEAN CITIES

Natalia Pertiwi Ginting¹

¹Institute for Housing and Urban Development Studies (IHS), Erasmus University Rotterdam.

pertiwinatalia@gmail.com

1 INTRODUCTION

Metropolitan areas involve several jurisdictions at different levels of authority and different interests. National policies in political and economy systems might influence the distribution of power and resources among territorial authorities in steering the metropolitan area development (Nicholls, 2005; Boudreau et al, 2006). Furthermore, other actors besides the government typically have conflicting interests among them. Consequently, some policies are formulated and implemented without coordination among related actors and without sufficient consideration on sustainability (Nicholls, 2005; Boudreau et al, 2006; Firman, 2008; Islam, 2014).

In dealing with complexity of metropolitan area characteristics, individual actors within metropolitan areas obviously cannot work independently. Coordination among them is required, especially in addressing negative impacts of economic and social activities on environment and the provision of public goods and

services. Institutional improvement of metropolitan areas through examining governance models is inexorable (Firman, 2008). Institutional changes are needed to make urban governance more effective in achieving sustainable city (United Nations Human Settlements Programme, 2009). In addition, transformation through social and political action is required in managing city to be sustainable (Hopwood, et.al, 2005).

Many studies claim that governance has important role in implementing sustainable development in metropolitan area (Davidson, 1996; Haughton, 1997; Firman, 2008; Gleeson and Spiller, 2012). In the metropolitan context, governance is understood as relations between private, civil society, and public sector that require collective action to achieve common goals (Boudreau et al, 2006; Hudalah et al, 2014). As metropolitan development has become global concern, many studies have been conducted to introduce some models of metropolitan governance required to cope with the urgency of sustainable development.

Metropolitan governance issue has often been discussed in planning for sustainable cities in European countries (e.g Bulkeley and Betsill, 2005; Stigt et al, 2016).

Since different actors in metropolitan area have different kinds of interest and degrees of power, sustainability as a development goal is difficult to implement (Nicholls, 2005; Firman, 2008; Hudalah et al, 2014). Accordingly, it is necessary to understand how metropolitan governance would work to promote the sustainable cities within the metropolitan area. Nevertheless, the framework of metropolitan governance for sustainable city development is rarely discussed in urban studies. Hence, this study will offer that framework to analyze which aspects of metropolitan governance largely affect the implementation of sustainable cities.

This article will first address the challenges of metropolitan area development and the application of metropolitan governance approaches. Subsequently, the concept of sustainable cities will be explained. Lastly, metropolitan governance framework for sustainable development will be discussed.

2 METROPOLITAN DEVELOPMENT AND GLOBALIZATION

Urbanization that occurs almost in every part of the world brings positive and negative consequences either on social or physical aspects. It is irrefutable that urbanization promotes the economies of scale, creativity, innovation, and increasing productivity (Dente, 1990; Ambruosi et al, 2010; Gleeson and Spiller, 2012). Nevertheless, uncontrolled urbanization has caused many environmental problems, such as air pollution, the loss of biodiversity, flood risk, drinking water scarcity (Kenworthy, 2006; Ambruosi et al, 2010).

The rapid population growth in the cities has brought pressure in the urbanization processs generating the emergence of metropolitan areas. The core city of metropolitan interacted with its neighboring cities, created linkages with them, and shared the burden of public service provision (Newton, 2012). With regards to the expensive land and deteriorating environmental quality in the main city, sub urban areas has become the options for the new residential development (Sellers and Hoffman-Martinot, 2008; Newton, 2012). The agricultural land in the periphery continues to decrease as the result of escalating demand for affordable housing. Gradually, sub urban areas have been developed as cities that also bolster the function of the main city within metropolitan area as the center of jobs and services (Dente, 1990). Externalities (such as pollution, waste) generated from activities in the core city that have impact on its surrounding cities within metropolitan area are inevitable. Moreover, the division of public good provision has become contentious among jurisdictions in the metropolitan area. For example, most cities are hesitant to provide landfill in their own jurisdictions.

Metropolitan region is characterized by socio-economic, environmental, and political administrative interdependences among local government jurisdictions in the region (Firman, 2008). The main city where business centers or multinational headquarters are mainly located usually provides more job opportunities, variety of amenities, and entertainment facilities compared to the surrounding cities (Newton, 2012). Hence, the main city remains attractive place for people to work or to operate business. Apparently, commuting or mobility from the periphery to the center has become part of metropolitan characteristics.

Globalization has also brought consequences on metropolitan area development regarding the transnational capital flows and public infrastructure provision that persuades competitiveness and imperil the environmental sustainability. As Kearns and Paddison (2000) pointed out, globalization may result in spatial disparity, social segregation, and the loss of power of urban governments to control globalized economic activities. They noted urban governance as political and administrative processes in utilizing resources to get things done. In addition, they argued that quality of urban governance which refers to the quality of public policy making and delivery of public goods and services (Stead, 2015) needs to be improved through the capacity building in dealing with urban complexity and rapidly changing circumstances related to globalization.

Understanding metropolitan characteristics and the problem of metropolitan is essential in achieving effective metropolitan governance which is indicated by development of trust among actors (institutional cohesion) and the achievement of sustainability goals. Dente (1990) argued that metropolitan problem needs to be defined properly in order to provide appropriate solution. He made differentiation about metropolitan types resulting in various definition of metropolitan problems which require synoptic and adaptive approaches to design metropolitan governance models. To determine the suitable institutional design for metropolitan governance is challenging, especially when it comes to accountability, coordination, integration, and sustainability.

3 METROPOLITAN GOVERNANCE APPROACHES

The rapid expansion of urban areas beyond established municipal boundaries and the rising complexity in managing externalities and public service provision has driven the growing concern for metropolitan governance requiring strategic vision, facilitative networks, local leadership, political and community support (Williams, 1999). Metropolitan governance can be defined as the pursuit of collective goals through inclusive and coordinated strategies and institutional arrangements at the metropolitan scale (Pierre, 2005; Hudalah et al, 2014). Gleeson and Spiller (2012) argued that effective metropolitan governance is crucial to human well-being, environmental sustainability, and economic growth. Effective metropolitan governance refers to effective administration and accountable politics in producing responsive decision making and strengthening local democracy (Kearns and Paddison, 2000; Stead, 2015).

Key institutional challenges in metropolitan governance involve the allocation and distribution of authority, capacity development, financial improvement, and social equity (Firman, 2008). Subsidiarity principles in resource and power or function allocation need to be applied in metropolitan governance (Ambruosi, et al, 2010; Gleeson and Spiller, 2012). Moreover, Firman (2008) argued that in managing metropolitan area, key factors that need to be considered are coordination mechanism to ensure the integration between planning and development as well as strong links to the national government system in order to obtain political support.

In Western Europe, the orientation of metropolitan reforms is to promote regional growth, integration, and competition for mobile capital investment in the context of globalization (Brenner, 2012). Considering the globalization of economy and competitiveness, metropolitan areas also need to sustain an attractive quality of life (Rondinelli, 2001). Furthermore, Kearns and Paddison (2000) argued that metropolitan governance needs to seek new ways to be creative, build strengths, and access and utilize resources in the face of growing social complexity and globalization. As stated by United Nations Human Settlement Programme (2009), planning for sustainable cities must be revisited by embracing geographical context and overcoming governance fragmentation.

Transformation in metropolitan governance can be analyzed through developing institutionalist framework and governance processes that require networks, stakeholder selection process, discourse, and practices as Coaffee and Healey suggested (2003). Rules and the roles of interactive processes should be also observed as the implications of dynamic governance (Edelenbos, 2005). In understanding how new institutional capacities get built, interaction between actors needs to be examined (Coaffee and Healey, 2003; Hudalah, 2014). Set of interactions appeared from the need to exchange resources to achieve the collective goals will define which actors are on the center of the network or at the periphery, and who will be excluded (Fawcett and Daugbjerg, 2012).

Uncertainties and complexity embedded in metropolitan area characteristic inherently can be analyzed by using network governance approach (Koppenjan and Klijn, 2004). Network governance is required in complex public decision making process ((Klijn (2005), Koppenjan (2007)). Klijn (2007) pointed out that decision making process from network perspective requires process management that involves content management, participation mobilization, and institutional design. In this perspective, the assessment of outcomes is not simply based on the realization of goals. Therefore, the outcome will be emphasized on the content, process, and institutional arrangement. According to Koppenjan and Klijn (2004), the content refers to the result of interactions of actors such as ex-post satisficing or win-win situations; the process might include the duration, stagnation, reliability, and innovation; lastly, the institutional arrangement is characterized by trust, quality of relations, and rules. In addition, problems are defined within multi-actor setting; thereby the problems are socially constructed based on perceived interests.

In applying network governance approach, several assumptions need to be considered as follows (Koppenjan and Klijn, 2004):

- Interdependencies between actors lead to more or less durable interaction patterns;
- Interaction patterns result in network characteristic, a shared language, shared rules, and mutual trust;
- Institutional factors constitute the behaviour of actors and influence cooperation in the network;
- Institutional characteristics result in a certain closedness of the network in relation to the outside world;
- When problems cut across networks, interaction and cooperation is restrained;
- Institutional factors are shaped, sustained, and adapted under the influence of interactions.

Concerning challenges of governing metropolitan areas, Sellers and Hoffman-Martino (2008) justified institutional alternatives for governance within metropolitan areas as below:

- Supra community reform

Fragmentation of municipalities limits their ability to deal with important issues that transcend their territories, e.g land use planning, the environment, public transportation, and economic development. Many local governments are perceived as inefficient and disconnected from the expectations of their citizens. Therefore, creating overarching metropolitan governments replacing a multitude of existing local authorities are in favor. However, many scholars argue that the optimum scale for public services are different from one service to another; hence it is difficult to estimate the right scale of metropolitan government (Newton, 2012).

- Territorial polycentrism

Metropolitan governments are criticized for their red tape, high operating costs, and remoteness from their citizens. It is more efficient and democratic for the localities within metropolitan area to compete among themselves for the production or sale of public services than to leave those services to one monolithic government entity to offer inhabitants wider choice of residential areas. Thus, small jurisdictions with multilevel governance are preferable. In this context, multilevel governance means inter-governmental relations between cities and their surrounding regions at different levels.

- The new regionalism

From new regionalism perspective, metropolitan governance should be understood as inter-municipal cooperation which is characterized by pragmatic responsiveness in execution; the adaptation of existing territorial units and governments above the municipal level to manage emerging challenges of metropolitan regions; strengthening democratic legitimacy; improving management in metropolitan area; and close association with private sector. In this perspective, coordination of strategies, interaction, and institutional support is essential. State governments are expected to focus on harmonizing interests from various stakeholders rather than to compel their own ideas.

Various models of metropolitan governance have been encountered as well. Those models are developed based on some criteria which are related to the key actors and goals. Hudalah et al (2014) distinguished the metropolitan governance models into three categories based on rational, historical, and sociological approach. As a result, metropolitan governance models can be recognized as three main forms including

voluntary cooperation, consolidation, and collaboration. Nevertheless, developing metropolitan governance models specific for sustainable cities by considering the aspects of governance process and institutional design still needs to discuss further.

Furthermore, Pierre (1999) described the models of governance through analyzing different sectors in urban politics and the degree of inclusion of organized interests in urban governance. Based on those analytical aspects, he differentiated urban governance into managerial (output performance oriented), corporatist (emphasis on the role of local government), pro growth (public private action oriented), and welfare (networks of government oriented) models. He also developed urban governance definition into three categories (Pierre 2015, p. 452-453):

“Governance as a theory offering analytical framework; governance as normative model showing model of public-private interaction and cooperation at the local level; and governance as an empirical object of study to investigate to what extent different social, political, and economic forces tend to produce different models of urban governance which require comparative approach”.

Feiock (2009) developed tools of regional governance using institutional collective action (ICA) approach. Based on ICA framework, metropolitan governance models can be distinguished into six main categories (Feiock 2009, p.361-374):

“Regional authorities offer the rescaling of geographic and functional jurisdiction. Managed or coordinated networks refer to the collaborative relations among local government actors, lead agencies/organizations, and network of private contracts. Regional organization is established based on federal/state laws, non profit organization, government agencies, regional councils, metropolitan planning organization, or regional partnerships. Contract networks link local government in legally binding agreement. Collaborative groups and councils involve informal associations, multilateral agreements and working group coordination. Policy networks refer to networks interaction, consensus, and flexibility in decision making”.

Digaetano and Strom (2003) constructed modes of governance into clientilistic, corporatist, managerial, pluralist, and populist based on governing relations, governing logics, key decision makers, and political objectives. Governing relations range from dominant client to inclusionary negotiation. Governing logics vary from reciprocity to mobilization of popular support. Key decision makers might involve politicians, clients, powerful civic leaders, civil servants, organized interests, and community movement leaders. Political objectives might be material, purposive, and symbolic.

In the case of Lisbon Metropolitan Area (LMA), the current governance system is based on two tiers of administration which mainly engage central government and local government although the coordination between the two is not intensive. Nevertheless, different institutional forms of cooperation have characterized its institutional arrangements. This situation has contributed to the perplexing administrative responsibilities and boundaries of service delivery in LMA. Silva and Syrett (2006) demonstrated that metropolitan governance in LMA has evolved historically and geographically through specific governance regimes and dynamic interaction of national state systems, local contexts, and broader global forces. Yet, they found out that institutional arrangements in LMA faced challenges in “leadership and strategic vision, coordination and integration of services, democratic legitimacy and accountability” (2006: 114). They also argued that central state apparently showed significant role in promoting structural governance change, primarily through decentralization process and interaction with EU.

Following the study of metropolitan institution in Swiss urban areas, Sager (2004) showed how different metropolitan institutional setting influence the quality of political negotiation process and the decision outputs. In his study, he categorized the coordination based on the policy implementation and formal and substantial rationality. Moreover, analytic dimensions of metropolitan government model have been operationalized according to the degree of centralization, consolidation, professionalization, and political economy. He discovered positive effect of fragmentation on the quality of deliberation since Swiss has applied very strong federalism principles. Furthermore, his findings revealed that “voluntary, positive, and policy driven coordination and substantially rational coordination decisions are found in centralized rather

than in decentralized institutional settings, in fragmented rather than in consolidated metropolitan areas, and in project structures with a strict separation of the political sphere of negotiation from the technical sphere rather than in negotiations without such clear distinction" (2004: 247).

Similar to the characteristics of metropolitan problems, spatial problems have also emerged in regional seas in the European Union (EU) since there is no single authority is responsible for the problems at the regional seas and there are various activities taking place in the marine space (Van Tatenhove, 2013). Consequently, joint actions through integrated marine governance arrangements are needed in dealing with environmental and spatial problems in the coastal areas in the EU. Van Tatenhove (2013: 300-301) mentioned that "the institutional setting of EU marine governance is shaped by different rules, arenas, practices, and locations that guide and shape the political and policy processes." He underlined that through understanding the nature of the swings of the governance pendulum (tension between fragmented arenas) and the institutional ambiguity (gap between institutional setting and specific jurisdiction), institutional capacity (ability to develop shared knowledge and mobilize resources) can be improved.

He further explained that the process of institutional change could be layering and conversion meaning adding new rules to the existing institutions and redirecting the existing arrangements. Finally, legitimacy is required to develop integrated governance arrangements. By legitimacy, Van Tatenhove (2013: 303) referred to "the acceptability of policy and decision making" that can be distinguished as "input legitimacy (representation), output legitimacy (problem solving), throughput legitimacy (the quality of policy making process), and feedback legitimacy (the outcome of the policy process and the quality of the feedback relations)."

4 THE CONCEPT OF SUSTAINABLE CITIES

The city can function as an engine of growth and offer opportunities for inhabitants to increase their well-being. A city is the place where resources and capital are concentrated, to be utilized or transferred. According to Van Pelt (1990), social welfare improvement in the long term, which is not impeded by the degradation of environmental amenities or productivity, can indicate the sustainability of city. However, a trade-off between social welfare and environmental quality typically exists. For example, to decrease poverty, developing countries mostly perform natural resource exploitation, which results in environmental quality degradation. Additionally, city sustainability can also be threatened by internal (e.g social behavior, government corruption) and external factors (e.g global climate change, wars).

For many decades, development approaches has largely accentuated economic growth as the main goal of development which eventually resulted in income inequality and environmental degradation. Gross National Product (GNP) has been widely used as the main indicator to measure the well-being and the progress

of development. However, as social and environmental issues are rising, policy makers need to consider other well-being indicators for the sustainability of human race, such as happiness (Hak et al, 2012).

Sustainable development was initiated to add new goals to the traditional approaches of development by showing concern on the shrinking capacities of ecosystems in the global context and the environmental impact of economic development. The notion of sustainability itself has been introduced since 1970s (Whitehead, 2003; Shaharir, 2012) and it became globally acknowledged after Bruntland Commission formulated the definition of sustainable development. The concept of sustainable development intrinsically put emphasis on how to control the development by recognizing that the environment has limited capacity to equally fulfill the needs of present and future generation.

The implementation of sustainability concept has different implications on different scales concerning that environmental risk has been transferred across space. Nevertheless, as the number of people living in the cities has been growing very rapidly, cities are considered to play a significant role in dealing with global environmental problems (Opp and Saunders, 2012; Nijkamp and Pepping, 1998). Cities have been suffered from environmental problems; however cities are also suspected as the major cause of the intensifying ecological problems. For example, lack of green open space and high level of carbondioxide emissions generated from automobile dependence in cities have created urban heat islands. Moreover, city expansion also leads to changes in biodiversity, soil, and natural landscape.

Numerous frameworks of sustainable cities have been developed. According to Davidson (1996), a sustainable city can be achieved by applying sustainable development principles within urban planning, which emphasises the importance of capacity building in planning processes. Moreover, an advanced understanding of social and technical changes needs to be embedded in urban planning practices, in order to overcome sustainable development challenges (Williams, 2010). Consequently, a transformation through social and political action is required, to achieve urban sustainability (Hopwood, et al, 2005).

Extensive definitions of sustainability have also generated various conceptualizations in the field of urban sustainability research. Chiesura (2004) stated that the quality of life has become the main variable in defining a sustainable city; e.g. urban parks which provide social services and hence promote urban sustainability. Kenworthy (2006) argued that urban form and transportation are essential elements in creating an eco-city. Meanwhile, Nijkamp and Pepping (1998) clarified that urban sustainability is largely affected by energy policies. Camagni (et al, 1998) revealed that a sustainable city can be created through the integration of socio-economic, environmental, and cultural developments, within interconnected spatial systems. Haughton (1997) developed models of sustainable urban development which adopts reforms in governance, markets, and regulatory aspects, in cities and their hinterlands. Whitehead (2003) viewed a sustainable city as an object of political contestation and socio-ecological regulation. Accordingly, sustainable cities are created through regulatory processes and political discourses, within specific geographical and historical context of urban spaces.

5 METROPOLITAN GOVERNANCE FRAMEWORK FOR SUSTAINABLE CITIES

Many debates over metropolitan governance only address the structure or the form of metropolitan governance whether it is derived from public choice or consolidation model (Visser, 2002). However, there is no clear evidence if certain model is more effective than the other model in dealing with transboundary issues in a metropolitan region. Furthermore, Visser (2002) emphasized that interlocal behavior of actors influenced by political and organizational culture dynamics should be taken into account to offer deeper understanding about what factors or motives that tend to trigger or hinder the interjurisdictional cooperation in solving metropolitan issues. Accordingly, it is important to understand the values and perceptions of the actors that drive their behavior in having interaction, framing the issues or formulating the policy options. By understanding this, more effective strategies on how to promote cooperation, reduce the conflict, and diminish the isolation can be offered.

Meanwhile, some scholars still argue that flexible structure, such as coordinating board or ad hoc metropolitan agency, can be an alternative to a rigid structure in facilitating the interaction between city managers or administrators and functional specialists (Leroux and Karr, 2007; Termeer et al, 2010). Affiliation structure or informal interaction through networks is assumed to have brokering capacity in enabling local governments to enter the collaboration, providing opportunities for more contact between actors, and increasing trust among actors. More attention needs to put on the network scale in improving metropolitan governance systems and sustainability policy arrangements (Termeer et al, 2010).

Concerning the complexity of governance and sustainability integrated approach should be applied in providing conceptual framework of metropolitan governance in developing sustainable cities. As it is understood that governance is a process instead of the means or ends, the process of governance itself should be clearly examined. Yet, many scholars only focus on offering alternatives of institutional arrangements from a single approach.

This study adopted the dimensions of governance process stated by Coaffee and Healey (2003) that entail networks and coalitions, stakeholder selection processes, discourses, and practices. Eventually, these dimensions of governance process affect the outcome of preferred institutional design or arrangements on one side. On the other side, institutional design which is envisaged through positions and rules also influence the process of governance in the metropolitan area. Integrated approach is applied in this study; thereby considering the social and economic relations in political processes, systems of cultural values, and the role of self-interest in collective action. Sustainability itself is a goals that requires common perceptions or shared languages from involved stakeholders. In this study, sustainable cities are conceptualized as the outcome of socio-ecological policies as previously expressed.

Nicholls (2005) argued that the mayor of central city recently does not have enough power to mobilize resources in implementing the policy agenda for the metropolitan area as the surrounding territorial actors are increasingly empowered. As a result, interdependency among actors promoting the emergence of network in dealing with metropolitan issues is inevitable. Furthermore, Nicholls (2005) justified the relation between hierarchy and interdependency which underlie the outcome of metropolitan governance ranging from highly integrated to highly fragmented.

Networks and coalitions refer to the process of network building and expansion as well as how the actors interact in formulating and implementing the sustainability plan. In analyzing networks, several key indicators need to be formulated; for example, the frequency of interaction, reciprocity in interaction, attributes of the nodes of interaction, and the structure of the nodes of interaction. Social network analysis method can be applied in revealing the patterns of relationships or interactions among actors.

Stakeholder selection processes include the informal and formal methods in determining which stakeholders will be involved in the policy making and coordination. In analyzing the process in stakeholder selection, how certain individuals or groups are included or excluded from the governance process needs to be identified. In addition, the type of influence that the selected stakeholders bring during the process is important to be examined.

Discourses refer to the process of framing issues, problems, solutions, and interests through the mobilization of public opinion or distributing knowledge. Since sustainability concept is still obscure to some actors, discourse about sustainable city is essential in order to achieve common language and effective strategies of sustainable development. Conflicting interests should be diminished through narratives or communication strategy and commitment of the actors in stressing the sustainability issues need to be strengthened.

Practices refer to recurring actions or customs which are mostly influenced by cultural aspect. Informal gathering could be another example of practices besides routine meetings. Through frequent informal gathering, actors can feel less tension and less self-centered (Hudalah et al, 2014). Cultural aspect, such as cooperative endeavour in the case of Indonesia metropolitian, could also strengthen the democratic decision making process.

Positions indicates the competence of actors and what actions that actors should take. In defining roles, responsibility of each individual actors should be clear. Besides, the capacity of actors in making decision regarding sustainability policies as well as mobilizing resources to implement the policies should be improved. Rules imply the procedures that have been produced at a certain time and applied for a certain period (Edelenbos, 2005). Important elements in procedures are transparency, accountability, and implementability.

Coordination, integration, and cooperation will be maintained by the network of actors if certain principles are fulfilled. Those principles are the need to cooperate to achieve the goal of individual actors, the benefits of cooperation outweigh the cost, and strong leadership in convincing individual actors to gain long-term benefit of cooperation and distributing material incentives to sustain the cooperation (Nicholls, 2005). Stakeholders from private sector and civil society need to be involved from the early stage of sustainability plan to promote interactive governance (Edelenbos, 2005).

6 CONCLUSION

Formulating and implementing policies in order to achieve sustainability are quite challenging in European cities, particularly at the bigger scale like metropolitan region. Policies formulated by each jurisdiction usually have impacts on other jurisdictions within the metropolitan area. It is undeniable that government from different level cannot work alone without involving the private sector and civil society in managing and distributing resources and space for the sustainability of the well-being of metropolitan residents. Therefore, the government together with other stakeholders needs to take collective actions and strategies to attain their common goals. This argument has become the fundamental concept of metropolitan governance. Nonetheless, numerous stakeholders from different jurisdictions have different interests and capacity resulting in dynamic interactions that could also lead to uncertainties or conflicts in the decision-making process. As a result, network approach is required to understand how the actors interact when

they involve in the metropolitan governance process. The process of interaction and decision making eventually will have implications on the institutional design of the metropolitan region.

Many models of metropolitan governance has been developed; nevertheless, none of them fits all. Each model brings different advantages and disadvantages in relation to endorse sustainable development of cities within the metropolitan area. Inter-local government cooperation should be pursued through network buildings. Nonetheless, conflict arises from unequal distribution of power regarding hierarchy in institutional arrangements needs to be managed through interactive mechanism of governance and strong leadership.

In determining which governance model fits the situation of the metropolitan, some principles need to be considered. The clarity of positions/roles and rules are required. Actors who hold important roles in mobilizing resources and networks need to be competent in formulating strategies of sustainable development. Moreover, the more transparent, communicative, and simple the procedures, the more likely sustainability to achieve because each individual actors can track the progress of sustainability, correct the misconduct, and evaluate the ineffective strategies more easily.

Apparently, the institutional design is not the only factor that affect the realization of sustainable development. Consequently, it should also be understood that governance process largely affect the implementation of sustainable cities. How often actors interact and how strong ties of relation have been built predominantly influence the quality of governance process in dealing with sustainability issues. Inclusive stakeholder selection process and intensive discourse on sustainable cities could be essential factors as well in promoting sustainable metropolitan development.

ID 1656 | BRAIN TRAIN OR BRAIN DRAIN? EFFECTS OF HIGH SPEED RAIL ON THE SPATIAL STRUCTURE IN THE AGE OF THE KNOWLEDGE ECONOMY

Fabian Wenner¹; Alain Thierstein¹

¹Technical University of Munich, Department of Architecture, Chair of Urban Development
f.wenner@tum.de

ABSTRACT: Transport infrastructures facilitate access to people, knowledge, and markets, thus increase the “potential of opportunities for interaction” (Van Geenhuizen et al., 2007: 7) of a place and stimulating economic activity, leading to urban development. Particularly in Europe, High Speed Rail (HSR) has been of growing importance in providing passenger mobility on medium distances. During the last three decades, HSR has connected more and more cores of metropolitan regions, airports, and sometimes also previously unserved peripheral places nationally and later internationally. Its spread occasionally also led to a reduction in rail accessibility when conventional rail services were subsequently reduced. At the same time, globalisation means that the ‘knowledge economy’ (KE) is becoming a key driver of development especially in highly developed countries. The performance of firms depends more and more on knowledge as production factor, and the input of highly skilled workers. Locational factors of knowledge-intensive firms differ from those of ‘conventional’ firms. They seek a combination of ‘global pipelines’ and ‘local buzz’ (Bathelt et al., 2004), i.e. global connectivity together with a stimulating local environment of face-to-face contacts. Under these conditions, HSR stations come into focus as potential new nodes for future economic development, since the immediate surroundings of HSR stations profit most from a gain in accessibility and provide ‘spaces for dialogue’, which are of particular relevance for KE firms. There have been several studies on the structural effects of HSR lines, especially in the cases of the French TGV and Spanish AVE networks. Despite the strong growth of ridership, hopes of a dispersion of economic development away from the metropolitan centres did not always materialise. Instead, some cases suggest that HSR access leads to ‘brain drain’ effects, upscaling on Mega-Regional levels, and residential ‘super-suburbanisation’ instead. Other studies argue that positive economic effects exist, but are merely of a redistributive nature. In each instance, the influencing factors augmenting economic development in the

individual case, such as integration with the conventional network, and local absorptive capacity, must be more thoroughly discerned in research on transport effects. In this study, we present the results of a gravitational accessibility analysis of the German rail network in 1990, before the opening of the first HSR line, and its comparison with the 2017 values to quantify gains and losses in accessibility generated by HSR. The German case differs somewhat from most other European cases due to its federal, more dispersed spatial structure and the lack of a clear dominant centre. Furthermore we project accessibility changes by two ongoing HSR projects such as the new Berlin-Munich mainline via Erfurt and Nuremberg. We find that, besides obviously boosting accessibility in previously poorly connected areas, even stations which lose access to the intercity train network profit from HSR through greater overall network effects. However, the upgrading of the conventional rail network in East Germany after 1990 improved accessibility levels more than HSR projects. The results of the accessibility analysis can then be used for a range of 'quasi-experiments' for difference-in-difference analyses (cf. Ahlfeldt and Feddersen, 2010) of firm locations, especially in situations of high accessibility differentials, e.g. 'external shock' conditions in peripheral areas. As an outlook, we propose such a methodology to test the effects of accessibility changes on the development of knowledge-intensive firms, both in the immediate surroundings of new or upgraded HSR stations, as well as their regions.

KEYWORDS: High Speed Rail, Knowledge Economy, Accessibility, Urban Economics, Transport Planning, Spatial Planning

1 OVERVIEW

The last decades have seen the rise of High-Speed Rail (HSR) as a new type of transport infrastructure. Within and between many developed countries, especially in Europe, HSR has seen strong growth and has reduced rail travel times between metropolitan core cities in some cases drastically, while new lines continue to be developed. It has also occasionally improved the connection of previously peripheral areas if these were not just crossed by new lines but also received a station, while on the other hand, some regions have lost their connection to the higher order train network when they were bypassed by new HSR lines. Altogether HSR has greatly influenced the 'accessibility landscape' in Europe.

Due to their function as multi-scalar gateways, HSR stations gathered the interest of urban economists, planners, and economic development professionals as potential locations for new poles of development. This particularly applies in the context of knowledge intensive firms, which are of growing relevance, and which particularly value accessibility (Thierstein et al., 2008), i.e. the possibility to reach a high number of other people and firms quickly. Also, rail based public transport is among the more sustainable transport modes with growing importance for future planning strategies (UN Habitat, 2009). In planning, this nexus is known as transit-oriented development (Bertolini, 1999).

In this paper, we want to briefly review the rationale behind the premise that HSR access leads to economic development through the resettling of knowledge intensive firms, before we present the methodology and empirical results of an accessibility analysis of the German HSR network between 1991, the year of the opening of the first HSR line in Germany, and 2017. We also project further accessibility changes induced by two currently planned HSR lines. Based on this, we propose a methodology to explore the effects that HSR access has on locational decisions of knowledge intensive firms.

1.1 THE ROLE OF ACCESSIBILITY FOR REGIONAL DEVELOPMENT

Cities can be conceived as systems emerging from individual decisions by firms and households regarding their business or residential location and their mode of travel, among others (Parr, 2015). These decisions are mutually interdependent, resulting in a complex 'landscape' of push and pull-factors, path dependencies, and interlockings, between demand and supply of locations, reflected by land markets (Alonso, 1964). Usually, such urban systems develop only gradually over time, depending for example on demographic or social changes, or altered preferences. Only few events are strong enough to induce an 'exogenous shock' to the system, potentially resulting in sudden and sometimes dramatic shifts of demand, value, and ultimately use of land. Large public infrastructure investments can represent such shocks, since the sudden compression of time and space based on distances in (Euclidian-geometric) space (Plassard 1990 in Garmendia et al., 2012) simplifies access to people, knowledge, and markets

(Tierney, 2012) and thus leads to the redistribution of accessibility, i.e. “the potential of opportunities for interaction” (Rietveld and Bruinsma, 1998). Accessibility improvements hence form a potential tool to foster urban and regional development, and better a knowledge base could help urban and regional planning professionals in assessing and harnessing the potentials of accessibility improvements for their constituencies. Even though it is recognised that accessibility plays a major role in shaping urban development, it is important to note here that it is of course not the only influencing factor. ‘Soft’ locational factors, such as the image of a city or its landscape and cultural amenities have been of growing importance as cities increasingly become ‘consumer cities’ (Glaeser et al., 2001).

Research has been inconclusive, however, whether improvements in accessibility can really benefit peripheral regions. Uncertainty persists on three questions. First, whether increased economic activities can be observed in general, or whether they are dependent on additional local, case-specific factors or thresholds, and if so, which (Feitelson and Rotem-Mindali, 2015: 297-298). Second, whether increased economic activities – should they exist – are generative, or only of a redistributive kind (Holvad and Leleur, 2015). And thirdly and most importantly, whether a redistribution of economic activity is directed away from the cores to the newly connected peripheral areas, representing a potential for regional and transport planning to induce local growth, or, fuelled by the transformation to the knowledge economy, to the opposite, i.e. a ‘brain drain’ effect and even stronger concentration in the cores (Vickerman, 1997). What is assumed here also depends on the theoretical framework used.

1.2 SPILLOVERS OR CONCENTRATION?

On the one hand, neoclassical economic theory assumes automatic convergence between regions. Inequalities regarding wages, rents, and interest rates are expected to dissolve as labour and capital is redistributed among the regions according to the greatest profit. Persistent inequalities are, in this view, the result of differences in productivity or barriers to the free movement of production factors (Barro and Sala-i-Martin, 1992; Solow, 1956). Location theory, which incorporates transport costs, also describes quasi-automatic sorting of activities in space under equilibrium conditions according to accessibility (Alonso, 1964). Different land user groups showed varying willingness to pay for proximity to economic centres, with commercial users bidding highest, followed by residential users, leading to a bid-rent gradient in a monocentric environment. Weber (1909) developed a locational theory for industrial firms, describing their locational choice based on minimal transport costs, which depend on distance and weight of the transported good.

Under the neoclassical framework, reductions of travel times must lead to increased economic activity through the exploitation of reduced (time) costs, increased economies of scale and competition.

On the other hand, since 1990, a body of theories under the label “new economic geography” (NEG) (Krugman, 1998) has emerged. NEG theories encompass path dependencies, transaction costs, and localised agglomeration economies, which can result in persistent regional differences and further agglomeration of firms and workers in successful regions.

Despite shortcomings (Storper, 2010), both approaches provide useful theoretical underpinnings for the analyses of accessibility change effects, since the predictions they allow are fundamentally different, requiring varying strategies for regional and transport planning. On the one hand, in neoclassical models, improvements in accessibility in a certain area will in turn lead to a re-sorting of land uses and a redistribution of optimal equilibrium locations, particularly when considering isolated but interlinked nodes like railway stations. In this case, areas close to stations can be better connected with each other than with their respective hinterland. The lower land prices in the newly connected areas, together with now sufficient proximity to other actors – mediated via transport links – , will lead some firms and individuals to relocate, especially start-ups in their initial phase when cost sensitivity is high. On the other hand, improved accessibility might destroy ‘niches’ of firms when barriers to stronger cores are removed under a self-reinforcing NEG framework.

1.3 THE KNOWLEDGE ECONOMY

Agglomeration economies become particularly important in light of the shift of European economies away from traditional industrial production towards 'knowledge economies' (OECD, 1996). Knowledge as a production factor is constantly becoming more important in developed economies, both as input and output in the production process (Kiese, 2013), and consequently attracting a focus of research (Lüthi et al., 2011). Industrial production is subject to technologisation, and demands a highly skilled labour force, or is shifted to locations with lower labour costs as part of a globalisation of value chains (Sassen, 1994). Under these conditions, cities and regions are successful when they manage not only to attract innovative, 'knowledge-intensive firms', but also highly skilled 'knowledge workers' as part of the 'creative class' (Florida, 2003).

Knowledge-intensive firms depend more than enterprises in other sectors on spatial proximity to customers, (potential) employees, and even competitors from the same field, since knowledge, especially symbolic and analytic knowledge, is often 'tacit', i.e. related to a certain local or personal context and cannot easily be codified or transferred across space (Asheim and Hansen, 2009). Since innovation is nonlinear and usually interpersonal, it makes frequent, even random, face-to-face contacts of actors necessary to create 'spillovers'. This gives rise to substantial agglomeration economies on behalf of the firms. But also employees tend to concentrate in cities with a high number of knowledge-intensive firms, since the larger labour market gives them a greater variety in employment opportunities. This particularly applies to cultural and creative industries, which are a partial subgroup of knowledge-intensive industries. They are assumed to have the highest propensity to settle in a diverse urban surrounding, profiting from 'urbanisation economies'.

However, literature on spatial aspects of innovation also points to the fact that in order to avoid a „lock-in“ of actors within their local knowledge context, interregional or even global contacts alongside the local milieu are indispensable (Bathelt et al., 2004). Despite the progress in IT and communications technology (Castells, 1996), at least temporal proximity of actors in this context is still necessary as well. Hence, network economies must complement agglomeration economies for knowledge intensive firms.

The knowledge economy is however relevant to this research for another reason. Knowledge workers usually have an above-average propensity to use public transport for medium and long distances as it allows using travel time for work, which becomes more important with increasing valuation of time.

1.4 THE DEVELOPMENT OF HIGH-SPEED RAIL

Besides airports and highway infrastructure, in recent years especially High-Speed Rail (HSR) construction has attracted the attention of planning researchers and economic geographers.

The European Union Directive 96/48 (European Council, 1996) defines in Art. 5 (3c) as HSR "specially built high-speed lines equipped for speeds generally equal to or greater than 250 km/h, specially upgraded high-speed lines equipped for speeds of the order of 200 km/h" and, in exceptional cases, upgraded lines with lower speeds in the case of "topographical, relief or town-planning constraints". For this paper, we focus on specially-built high speed lines only, since these create stronger disruptions to the economic framework and are thus better suited for significant pre-post comparisons.

HSR lines started to complement and replace 'conventional' rail starting in the 1960s with the Shinkansen in Japan (Tokyo-Osaka), and from the 1970s on in several European countries, such as Italy (1977, Rome-Ponticelli), France (1981, Lyon-Paris), Germany (1991, Hannover-Würzburg), and Spain (1992, Madrid-Seville). After decades of losing shares in the passenger market to individual motorised transport and airlines, HSR was seen by railway administrations as a chance to regain competitiveness on medium distances up to 800km. The number of HSR lines and stations as well as passenger figures in Europe have been growing constantly since (UIC, 2009), also as part of the Trans-European Networks (TEN) initiative of the European Union. HSR has taken foothold in other countries outside of Europe as well, while the relation to air transport has shifted from competition to a more mixed form that recognises the need for symbiosis for longer distances (Lijesen and Terpstra, 2011).

Figure 1: High Speed Rail in Europe. Source: own illustration using Eurostat, 2014; OpenStreetMap, 2016

Figure 1 shows that HSR strategies differ between countries: Networks in unitary countries and countries with a strong national capital city feature more direct links between the capital and secondary cities, while those of federal countries, often with a more balanced settlement structure, show more tangential links. While most networks were initially developed nationally, the European dimension of the network was strengthened during the last decade with the planning and opening of several international links such as the Paris-Brussels-Cologne/Amsterdam corridor. While network operators in Italy have almost completely refrained from constructing stations outside of larger cities, the Spanish network operator strongly invested in new stations on the countryside. Germany takes a middle position here, while France saw a strategy change from ‘gares de betteraves’ to more centrally located stations. Despite three decades of HSR research, the effects of these differences remain under-investigated in ex-post analyses (Preston, 2012). Regarding Germany there is no comprehensive review of scientific literature yet.

1.5 REGIONAL ECONOMIC EFFECTS OF HIGH SPEED RAIL

Three main approaches to specifying the regional economic effects of HSR are used in literature: Aggregate measures, e.g. the comparison of overall regional transport investment with unemployment measures or GDP growth (Aschauer, 1989), more detailed spatial computable general equilibrium (SCGE) models, and project-specific calculations such as CBA and hedonic price approaches (Iacono and Levinson, 2015: 244). While most of the approaches are suitable to arrive at approximate cost-benefit

ratios for planned HSR projects based on the utility for current users, they have difficulties in capturing catalytic effects and induced urban development, which is especially relevant to planners. We will concentrate on the latter for this paper, since we propose a methodology based on this method that potentially takes into account catalytic effects using firm location data.

Firstly, difference-in-differences analyses of pre- and post-intervention land values in both a treatment and control area have been used to estimate the economic benefit for a location that received an accessibility increase by disentangling the influencing factors (Ahlfeldt, 2011). The difference-in-differences analysis establishes a clear link between accessibility changes – positive and negative – and land prices. However, it is important to realise the limitations of this approach, based on the imperfections of land markets and value estimation methods. Studies using the difference-in-difference approach on house prices found only minor effects of HSR access so far, for example in the case of Taiwan (Andersson et al., 2010). Rather, several authors point to the fact that HSR stations also come with negative externalities that impact land values, such as noise and crime (Gargiulo and de Ciutiis, 2010; Armstrong and Rodriguez, 2006; Bowes and Ihlanfeldt, 2001), accidents and impacts on landscape appearance (Chang et al., 2014).

Using land values in a difference-in-differences approach also makes it possible to analyse the assumptions of market participants regarding future effects, since land values are determined by expected future earnings. However, they cannot inform us about the long-term, catalytic effects of improved accessibility, since an increase in land values is not automatically followed by urban development. Hence, a difference-in-differences approach using firm location data seems to be a promising method.

On the regional scale, the role of the size of newly connected municipalities on the actual effects of HSR is often highlighted (Ureña et al., 2009). If two cities or airports are connected by HSR, a number of studies found that the line will work in favour of the already stronger one of the two, and to the detriment of the weaker counterpart, as well as the countryside (Terpstra and Lijesen, 2015; Plassard, 1992 in Garmendia et al., 2012). Accordingly, HSR has been found to support upscaling on Mega-City level in Europe (Morris et al., 2003) and in the case of the Pearl River Delta area in China (Hou and Li, 2011). There is a danger of increased peripheralisation of unconnected smaller localities within the region and rising spatial imbalance (Monzón et al., 2013), which requires “careful planning and policy intervention to effect necessary ancillary investment” (Vickerman, 1997: 36). When following cohesion and regional development goals with mega transport infrastructures such as HSR, integration with conventional and regional rail is also important to maintain a polycentric structure (González-González and Nogués, 2016). Some authors doubt the usefulness of HSR for regional dispersion of economic activity altogether, as in the case of the Japanese Shinkansen network (Sasaki et al., 1997).

On the other hand, Mohino et al. (2014) find significant growth effects in Spain, depending on “the context, the physical, economic, and locational circumstances, and the HSR network/services characteristics” among them distance from other centres, land availability, intermodality, station location, plans, and other station assets. A polycentric and well-integrated Mega City Region, helped by HSR connections, is a strong catalyst for economic development in the age of the knowledge economy: “A flourishing knowledge economy hinges on more intense social interactions, which means a more intelligent allocation of resources across the landscape” (Tierney, 2012). However, in the case of rural stations close to strong metropolitan centres, HSR stations can contribute to unwanted suburbanisation (Demuth, 2004).

Finally, HSR research has also focussed on the stations themselves and their immediate surroundings: How can cities turn the accessibility gain into concrete advantages, manifest in urban design (Bertolini and Spit, 1998; Trip, 2008; Thierstein, 2014)? Researchers have studied the ‘Bilbao effect’ of star architecture on its surroundings creating spillover effects for the entire city (Alaily-Mattar et al., 2017, forthcoming) which is also employed for HSR station buildings, especially in Belgium and Italy. Even if the station itself is not redeveloped, an increase in accessibility can lead to an induced form of ‘gentrification’, when landowners are incentivised to refurbish or sell their real estate due to rising land values, sometimes not unintended. Municipal planning administrations often try to support such developments by financing the reconstruction of public spaces and disused rail land around the station. How this process occurs in practice needs contextual review in each single case.

To sum up, most studies indeed find evidence for increased economic activity around nodes of improved accessibility, but assess that it is redistributive in nature, and depending on further influencing factors (de

train connection in each 2-hour timespan over a period of eight consecutive hours on a working day. In case of differing travel times for these connections, the slowest available time was chosen. We selected 1991 as reference year since 1990/1991 was the last timetable year before the inauguration of the first HSR line, Hannover-Würzburg, and the first after reunification between West and East Germany.

To assign weights to the stations, we used the population of functional travel-to-work regions (“Stadt-Land-Regionen” developed by the BBSR (2014)). The 266 travel-to-work regions in Germany are comprehensive, non-overlapping and contingent spatial units based on commuter flows representing functional spatial relationships. The weighing factor of a station was defined as the population of the containing travel-to-work region in the applicable year, divided by the numbers of long-distance-train stations in that region, excluding airport stations.

Not all regions are served by regular long-distance trains. However, accessibility changes through HSR introduction may also affect these regions indirectly through regional train connections to the HSR nodes. Hence for all travel-to-work regions not served by long-distance rail (1991: 132; 2017: 154), a ‘central station’ was defined, based on its importance in the regional context. In most cases, this was the main station of the dominant municipality within the region. In case the chief city did not have any railway connection (1991: 9; 2017: 8), the most central station within the rail network in that region was chosen as ‘central station’ instead (e.g. Bad Bentheim instead of Nordhorn, Gerolstein instead of Daun). There was no travel-to-work region without railway access in either 1991 or 2017. The ‘central stations’ receive the full weighing factor of the containing region. This avoids a ‘disconnection bias’ (regions no longer served do not feature in the calculation anymore, hence overall accessibility might be increased even though less regions are connected).

Additionally, 64 interchange stations were considered that provide links between ‘central stations’, but are not in regional centres themselves. These stations receive no weighing factor. Subsequently all regular regional train connections between these regional centres, the interchange stations and those of the core network were added to the list of connections. In a few number of cases this meant that also connections with a lower frequency than 2-hourly had to be considered. These form the supplementary network.

A potential accessibility underestimation bias in gravitational analyses can arise in border areas, when metropolitan centres just across the border are not counted in. Hence we added a buffer around the country of 90 minutes rail travel time. As spatial base units in this zone we used 64 NUTS3 regions and their most important urban centres, which are spatially comparable to the functional travel-to-work regions used within Germany. All train connections to and within these regions were also added to the list.

This resulted in a list of 444 stations with 1300 connections in 1991 and 501 stations with 1353 connections in 2017, respectively.

Based on this connection dataset, we calculated gravitational accessibility measures for all included stations, using the formula in Figure 3. Each main station j was assigned a weighing factor W . The gravitational accessibility of a municipality i is then defined as the number of people that can be reached, applying a distance decay factor β on travel time. This way, nearby municipalities are weighted more than municipalities far away. We applied a decay factor of $\beta = 0.015$, which translates into a ‘half-life’ of approximately 45 minutes, meaning that a person in a municipality 45 minutes away is weighted half as much as a local inhabitant. This reflects the assumed strong agglomeration effects for knowledge-intensive firms, but also takes into account that we’re looking at day-long business trips and not commuting relations, for which a higher decay factor would be applicable.

$$Gravity[i]^r = \sum_{j \in G - \{i\}, d[i,j] \leq r} \frac{W[j]}{e^{\beta \cdot d[i,j]}}$$

Figure 3: Formula to calculate gravitational accessibility. Source: Sevtsuk and Mekonnen (2011)

For interchanges at stations, a changing time of two minutes was assumed. If the change was between travel modes (e.g. train and bus), the assumed changing time was 10 minutes. No hierarchy of train service levels was applied – for each station-pair connection, the fastest route was chosen. We used a

cutoff threshold at 270 minutes travel time, since we assumed passengers to prefer air transport for longer journeys, but distance decay for these travel times is already very high anyways.

To model the changes in accessibility induced by the two planned HSR lines between Nuremberg and Erfurt, which is due to open in late 2017, and Stuttgart to Ulm, which is planned to be completed in 2022, the analysis was repeated with a manually adapted timetable dataset with the expected future travel times.

Our chosen approach necessarily entails a number of shortcomings due to reasons of simplicity. Firstly, the dataset is timetable-based, i.e. does not take into account delays but assumes an ideal traffic situation. Secondly, we used the travel-to-work regions as spatial units for both 1991 and 2017 even though real functional spatial relations shortly after reunification differed significantly from the potential, especially in border areas. Thirdly, it was assumed that the entire population of the regions can reach the central stations with no further spatial drag, though this potentially introduces a slight bias in favour of larger metropolitan regions.

4 RESULTS

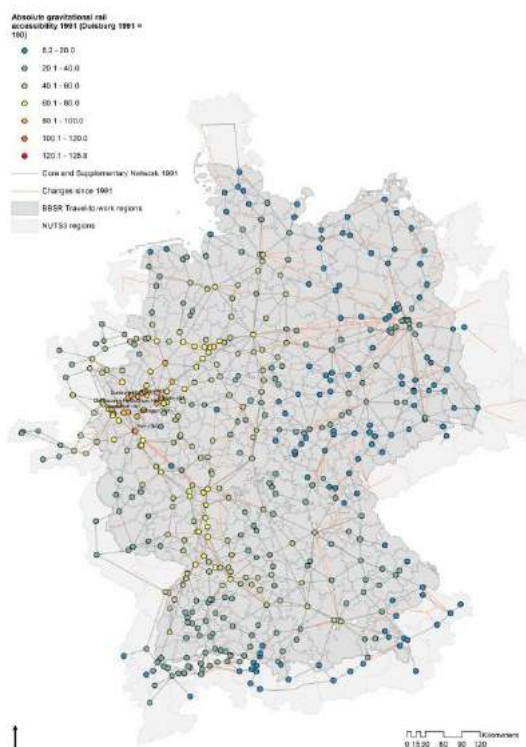

Figure 4: Absolute gravitational rail accessibility 1991 (Duisburg 1991 = 100).
Source: own illustration using BBSR (2014)

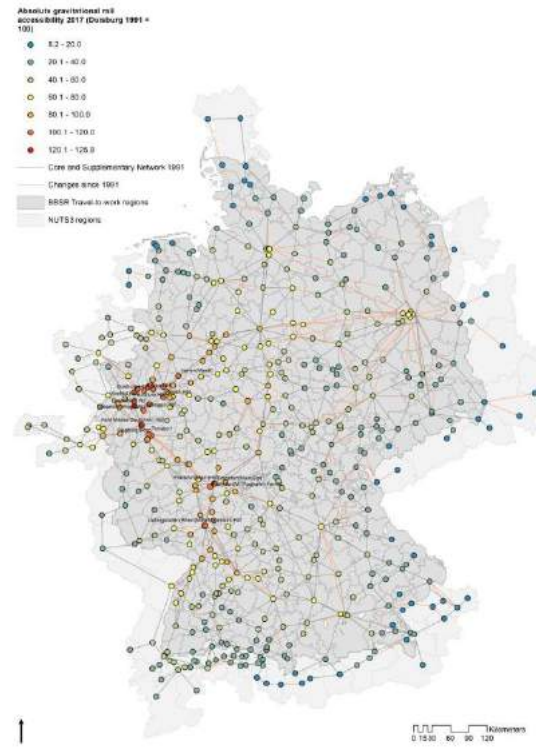

Figure 5: Absolute gravitational rail accessibility 2017 (Duisburg 1991 = 100).
Source: own illustration using BBSR (2014)

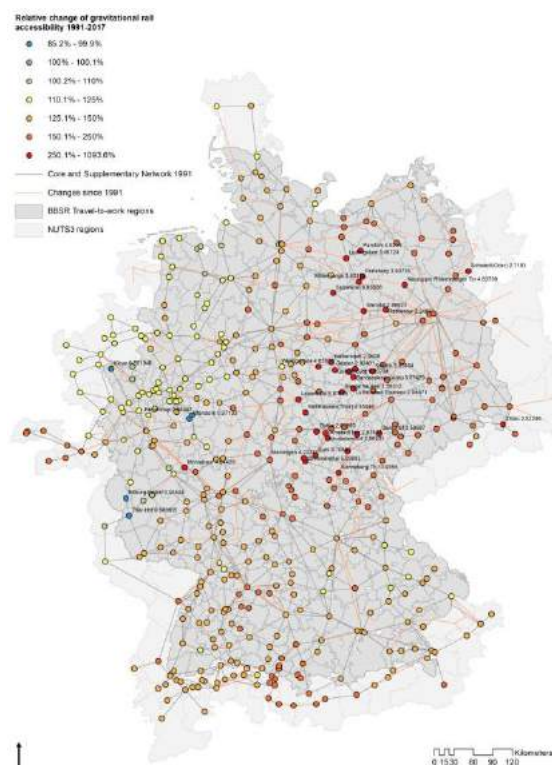

Figure 6: Relative change of gravitational accessibility 1991-2017 Source: own illustration using BBSR (2014)

Figure 4 shows the absolute accessibility of population by rail for 1991, using a 45 minutes half-life threshold. The values are normalised on the highest value, which is Duisburg Hbf (cf. Table 1). This result may be surprising given Duisburg's status today as a post-industrial city with below-average economic performance, compared to its neighbours in the south, but this has not always been the case, and can be explained by its central location in the largest urban agglomeration in Germany. The ten stations with the highest accessibility in 1991 are all located in the Rhine-Ruhr region.

	Station	Accessibility (Duisburg Hbf 1991 = 100)
1	Duisburg Hbf	100
2	Essen Hbf	98,71
3	Düsseldorf Hbf	98,34
4	Dortmund Hbf	96,73
5	Bochum Hbf	95,60
6	Köln Hbf	94,20
7	Wuppertal Hbf	92,66
8	Hagen Hbf	92,14
9	Oberhausen Hbf	90,57
10	Solingen Hbf	90,42

Table 1: The ten most accessible rail stations in Germany 1991

If we compare the absolute values with those of 2017 in Figure 5 and Table 2, we can see that the centre of gravity has somewhat shifted to the south. The most accessible station is now Cologne, and several stations from the Rhein-Main area, such as Frankfurt Main Station and Frankfurt Airport have made it to the list. With Mannheim a city even further south is on 7th position. Smaller towns of the Ruhr area do not feature anymore in the top 10, even though it must be noted that total accessibility improved for all stations in the area. This coincides with the economic stagnation the Ruhr has experienced in the analysed timeframe, compared to the economically more successful south.

This effect is clearly due to the opening of a new high speed rail link between Cologne and Frankfurt in 2002, which reduced the travel time between the two cities from 2.5 hours to one hour. The line has been

well used since and led to further economic integration of the two metropolitan regions (Ahlfeldt and Feddersen, 2010).

	Station	Accessibility (Duisburg Hbf 1991 = 100)
1	Köln Hbf	125,78
2	Köln Messe/Deutz	122,54
3	Düsseldorf Hbf	121,8
4	Frankfurt(M) Flughafen Fernbf	119,72
5	Duisburg Hbf	118,21
6	Frankfurt(Main)Hbf	113,78
7	Mannheim Hbf	113,09
8	Wuppertal Hbf	112,85
9	Düsseldorf Flughafen	112,75
10	Essen Hbf	112,67

Table 2: The ten most accessible rail stations in Germany 2017

A look at the relative gains and losses in accessibility between 1991 and 2017 in Figure 6 and Table 3 shows a completely different picture, however. It becomes clear that the strongest gains in relative terms did mainly not occur in regions with high speed rail investment, but in East Germany, which saw substantial and comprehensive improvement of its dilapidated rail infrastructure in the two decades after German reunification. An almost tenfold relative increase of accessibility was estimated for the small town of Sonneberg in Thuringia, which had a peripheral boundary location within the former GDR rail network, adding to the longer travel times. Only one station among the ten stations with the strongest positive relative changes is not located in East Germany: Montabaur, an intermediate stop on the Frankfurt-Cologne HSR line that was added due to regional political pressure. While this shows that HSR can induce substantial accessibility improvements, the upgrading of conventional rail in East Germany has proven to be more effective in rising accessibility levels, though from a low initial state.

The comparison of timetables for West Germany has revealed that on many conventional rail lines, travel times have not changed at all between 1991 and 2017, and in some cases even increased by a few minutes. While this may be due to increased margins to offset delays, some stations show a substantial relative reduction in accessibility, which is in some cases due to both a shrinking regional population as well as deteriorating supply of rail connections. This particularly affects the 'inner periphery' regions of Eifel and Sauerland. Kleve, with a reduction of 14.8% is a specific case since the former local transboundary railway connection to the Netherlands has been cut, despite EU initiatives to (re)connect transport infrastructures internationally.

	Station	Accessibility change
1	Sonneberg(Thür)	+993.6%
2	Salzwedel	+595.6%
3	Leinefelde	+487.7%
4	Grimmenthal	+410.0%
5	Montabaur	+384.4%
6	Neuruppin Rheinsberger Tor	+383.7%
7	Wernigerode	+383.6%
8	Mühlhausen(Thür)	+355.0%
9	Meiningen	+322.3%
10	Parchim	+302.1%
...		
440	Trier Hbf	-1.9%
441	Attendorn	-2.9%
442	Finnentrop	-5.7%
443	Bitburg-Erdorf	-6.5%
444	Kleve	-14.8%

Table 3: Strongest relative changes in gravitational accessibility

	Station	Accessibility change (Duisburg Hbf 1991 = 100)
1	Limburg Süd	+106,06
2	Vaihingen(Enz)	+82,63
3	Montabaur	+75,95
4	Frankfurt(M) Flughafen Fernbf	+53,44
5	Limburg(Lahn)	+45,12
6	Leinefelde	+44,46
7	Salzwedel	+41,57
8	Wolfsburg Hbf	+41,48
9	Siegburg/Bonn	+40,18
10	Hanau Hbf	+39,44

Table 4: Strongest absolute changes in gravitational accessibility

Table 4 shows absolute changes in accessibility between 1991 and 2017. It also contains the completely new stations Limburg Süd on the Cologne-Frankfurt HSR line and Vaihingen(Enz) on the Mannheim-Stuttgart HSR line, of which there are relatively few in Germany compared to other European countries. These achieved extremely high accessibility levels from the start and should offer highly attractive location conditions for knowledge-intensive firms. In terms of absolute gains, also other new HSR lines feature prominently, e.g. Wolfsburg Hbf on the Berlin-Hannover line. Interestingly, the first and longest new HSR link opened since 1991 between Hannover and Würzburg seems to have had less influence.

	Station	Accessibility change
1	Coburg	+66.02%
2	Sonneberg(Thür)	+59.12%
3	Bamberg	+20.23%
4	Lichtenfels	+20.05%
5	Erfurt Hbf	+19.03%
6	Kulmbach	+17.98%
7	Weimar	+15.98%
8	Neudietendorf	+15.03%
9	Kronach	+14.62%
10	Arnstadt Hbf	+12.01%
	...	
498	Mehltheuer	-0.05%
499	Plauen(Vogtl) ob Bf	-0.04%
500	Jena Paradies	-1.35%
501	Saalfeld(Saale)	-7.40%

Table 5: Strongest relative changes in gravitational accessibility after the opening of the Nuremberg-Erfurt HSR line in December 2017

With the available data we next modelled probable future changes in accessibility after the opening of two HSR lines currently under construction, the lines between Nuremberg and Erfurt, which will be opened in 2017 and is expected to reduce travel times between Berlin and Munich to about 4 hours, and the line between Stuttgart and Ulm, which is part of the Trans-European corridor from Paris to Bratislava. We show in this paper the expected accessibility changes resulting from the Nuremberg-Erfurt line in Figure 7 and Table 5.

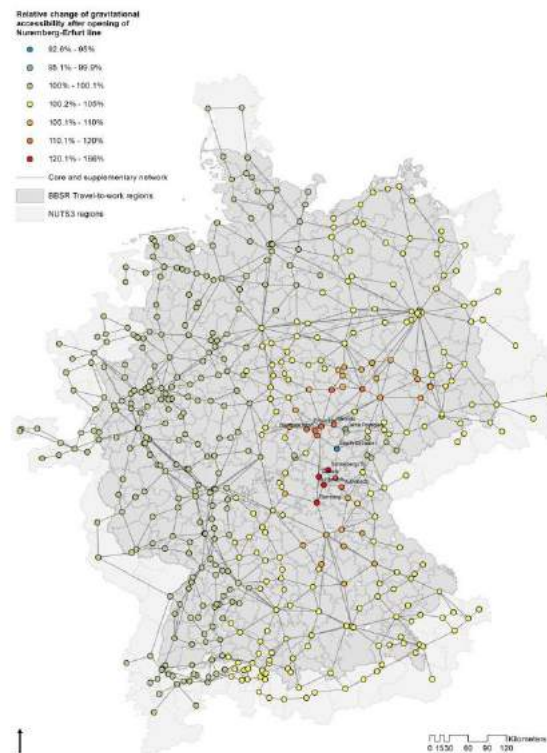

Figure 7: Relative change of gravitational accessibility after opening of Nuremberg-Erfurt line Source: own illustration using BBSR (2014)

The Nuremberg-Erfurt line will be the one of the first in the German context that leads to a substantial reduction of conventional long-distance rail on the existing main line between Nuremberg and Leipzig. Hence, the project creates winners and losers regarding accessibility. The towns of Jena, Saalfeld, and Lichtenfels, located on the existing line, will lose their frequent direct connections to Berlin and Munich, and will be relegated to regional trains to connect to the new HSR line in nearby Erfurt. However, the relative and absolute accessibility differences are small compared to the gains realised at other locations, among them once again the formerly peripheral Sonneberg and Coburg. In terms of rail accessibility, Sonneberg is clearly the region profiting most from German reunification. Lichtenfels even realises a relative gain, since the connection to the HSR with interchange in Coburg is still faster than the existing direct connections. However, the benefits for peripheral regions depend a lot on the stop frequency, which is still unclear in the case of Coburg but will likely be not more than a few stops a day.

To conclude, we can confirm our hypothesis that accessibility improvements of HSR stations have been significant, but with the major qualification that in relative terms, the upgrading of the East German rail network has had even stronger effects on gravitational accessibility. This is despite the replacement of long distance rail with regional trains in many parts of East Germany since 1991, which led to a reduction of the number of people living in travel-to-work regions directly served by long-distance rail (1991: 61.3 Mio.; 2017: 56.6 Mio.).

HSR effects in Germany have been more evenly spread, due to the more dispersed settlement structure and patchy implementation of HSR. This contrasts with the experiences of more spatially hierarchized countries like France and the UK, where effects are often directly dependent on realised travel time to the capital city (Chen and Hall, 2015).

5 INTERPRETATION AND OUTLOOK

What was treated as a premise for this paper we want to investigate in more depth in the future: The assumption that an induced change in public transport accessibility through High-Speed Rail can spread knowledge-intensive firms from metropolitan cores to smaller centres in the region and so help to promote regional economic development, and whether there are location-specific, temporal, or rail-service related

factors that can influence this effect, particularly the local centrality of the station and the interconnectedness with other modes of transport. The accessibility analysis has revealed that there are a number of stations that received significant positive shocks in terms connectivity, such as Limburg Süd and Montabaur on the Cologne-Frankfurt line, Vaihingen(Enz) on the Mannheim-Stuttgart line, and Bamberg and Coburg on the future Nuremberg-Erfurt line, which should allow KI firms to settle.

In order to do this we propose a difference-in-differences approach, comparing the number of firms in knowledge-intensive branches, the number of their employees, and their revenues immediately around 'treated' stations as well as their city-regions with those in comparable regions that have not received HSR investment. Such firms datasets are readily available and present a rarely used source for regional economic analyses so far.

ID 1675 | COORDINATION OF TERRITORIAL COHESION BY EUROPEAN TERRITORIAL COOPERATION AND TRANS-EUROPEAN TRANSPORT NETWORKS - THE CASE OF CROSS-BORDER TRANSPORT

Baete Caesar¹

¹University of Kaiserslautern

beate.caesar@ru.uni-kl.de

1 INTRODUCTION

Territorial cohesion aims at fostering a more balanced and harmonious development of the European regions, making use of individual regional strengths for an overall EU benefit and linking them effectively to ensure a higher territorial integration of the Member States among others. Furthermore, cooperation across administrative borders is to be promoted actively (Commission of the European Communities 2008).

The two policies European Territorial Cooperation (ETC) and Trans-European Transport Networks (TEN-T) are intended to contribute to several aspects of territorial cohesion: the ETC Policy focuses on the support of European border regions, contributing to a European integrated territorial development and promoting the exchange of experiences across borders (European Union 2006). Therewith, the effects of the administrative borders shall be minimized and territorial cohesion shall be increased (European Commission 2005). The TEN-T Policy shall efficiently link the national transport networks of the Member States and make them interoperable in order to contribute to a borderless European territory. Additionally, remote regions are to be integrated to the residual territory (European Union 2012), bottlenecks in the European transport system are to be removed and missing-links to be constructed (European Parliament

and Council of the European Union 2013d). Thus the two policies can be seen as promoters of territorial cohesion.

The aim of this paper is to analyse the contribution of the two above named policies to an important element of territorial cohesion: cross-border transport connections including infrastructures and services. The findings are based on field research in the cross-border region Greater Region Saar-Lor-Lux+.

After a description of the objectives of the TEN-T and ETC policies and their related funds in a first step, the influence of the policies is analysed. This is done by comparing the original EU objectives with the involved Member States' national transport policies, the regional and sub-regional policies and the cross-border policy documents. Additionally, the implementation of these objectives in the form of projects in the cross-border regional transport reality is evaluated. Finally the contribution of the two policies to territorial cohesion is evaluated.

2 EUROPEAN TERRITORIAL COOPERATION (ETC) AND TRANS-EUROPEAN TRANSPORT NETWORKS (TEN-T)

This chapter shortly presents the two policies European Territorial Cooperation (ETC) and Trans-European Transport Networks (TEN-T) including their objectives concerning cross-border transport and their implementation incentives.

2.1 OBJECTIVES

The TEN-T and the ETC policy both aim at supporting cross-border transport. Between 2007 and 2013 the ETC policy aimed at supporting cross-border TEN-T projects and the linkage of secondary networks to the TEN-T. Furthermore, the cross-border transport development across borders was to be coordinated. The European regions were to be connected better with each others (Council of the European Union 2006; European Parliament and Council of the European Union 2006). The TEN-T policy strongly promoted the removal of bottlenecks and the creation of missing links in cross-border sections because being of high European added value. Furthermore, it was aimed at improving the linkage to new Member States. The TEN-T priority projects were to focus the funds on border crossings (European Commission 2001; European Parliament and Council of the European Union 2004). Between 2014 and 2020 the ETC policy has aimed at removing bottlenecks in important cross-border transport infrastructures and at making transport mobility more sustainable. Secondary and tertiary networks are to be developed and linked to the TEN-T corridors in order to improve the access to the TEN-T. Additionally, transport planning across borders shall be facilitated (European Parliament and Council of the European Union 2013c, 2013a). Between 2014 and 2020 the TEN-T policy has aimed at supporting cross-border sections between the closest urban nodes including the reduction of CO₂ emissions. Again, bottlenecks are to be removed and missing-links are to be established (European Parliament and Council of the European Union 2013d, 2013e).

Besides that, the EU transport related policies defined general transport development objectives. 15 EU policy documents were analysed that had influenced the two funding periods (see figure 1). Objectives printed in bold font have been named by a high number of these policies. One of them is the improvement of cross-border infrastructures. This shows the high relevance of cross-border transport in the EU policies.

Aims	%	Aims	%
Transport Infrastructure network	93	Transport Services	87
Remove barriers, improving efficiency	100	(Urban) public and soft mobility	47
Linking TEN-T and secondary networks	40	Transport Safety	73
Relieve routes/ Fighting congestion	40	Cross-border services	47
Intermodality/ Interoperability	80	Environmental and sustainable issues	100
Intelligent transport systems	33	Alternative modes of transport	80
Freight corridors	27	Alternative fuels/ Climate Change	67
New technologies/innovations (research)	60	Minimizing environmental harm	93
Improving mobility of freight	60	Sustainable Transport	93
Improving the mobility of citizens	93	Exchange of practices/ better coordination	47
Accessibility of remote areas	100	n=15	
Connecting neighbouring/ new Member States	60		
Improving cross-border infrastructures	87		
Improving user-friendliness	33		

Figure 1 – Transport related objectives of the EU Transport and Cohesion Policies
Source: Own depiction, Kaiserslautern, 2017.

The implementation of these aims in the Member States and cross-border transport reality will be tested in the course of the paper.

2.2 IMPLEMENTATION AND INCENTIVES

The TEN-T and ETC policies are redistributive policies. They are not legally binding but their voluntary implementation shall be secured by financial incentives (so-called 'ideational transfer') (Stone 2004, 562f.).

Until 2013 the TEN-T Programme funded cross-border transport projects being part of the TEN-T network (European Parliament and Council of the European Union 2010). Economically lagging behind regions were additionally supported by the Cohesion Funds (Commission of the European Communities 2009). Since 2014 the TEN-T have been funded by the Connecting Europe Facility (CEF). It is additionally supported by the Cohesion Fund (European Parliament 2014; European Parliament and Council of the European Union 2013e). The funds are distributed in annual and multiannual work programmes (European Commission 2014). The ETC has been funded between 2007 and 2013 as well as between 2014 and 2020 by the European Regional Development Fund (ERDF) which was distributed in multi-annual programmes. Eligible cross-border (INTERREG A) and transnational cooperation spaces (INTERREG B) have been defined (European Parliament and Council of the European Union 2006, 2013b).

According to Knill (2006) and Smith (1973) the implementation of policies strongly depends on the political, administrative and cultural structures of the Member States which implement the policy. Different responsibilities and attitudes towards the aims of the policies are factors which can lead to varying policy outcomes in different Member States. The ETC itself is often described as a platform of exchange and learning for the implementation of sectoral EU policies (Timms 2011, 521).

The findings of a top-down outcome analysis which is based on a comparison of the two policies' aims with the cross-border transport reality will be presented in the following. Additionally, intermediate stages of the policy implementation process are analysed: in a case study the EU policy aims are compared with the domestic and cross-border transport related policy documents and the aims of conducted cross-border transport projects will be explored. This shall allow an evaluation of the TEN-T and ETC influence on cross-border transport.

3 INFLUENCE OF THE TEN-T AND ETC POLICY ON CROSS-BORDER TRANSPORT IN THE GREATER REGION SAAR-LOR-LUX+

This empirical section of the paper seeks to analyse the influence of the two EU policies on cross-border transport within a cross-border region: the Greater Region Saar-Lor-Lux+. The findings were drawn from a recently conducted case study research. The research is based on a policy document analysis whose results were complemented with findings of face-to-face or phone elite interviews conducted with stakeholders working in the different administrative levels of the Member States involved in the cross-border region as well as in cross-border cooperation bodies.

3.1 CROSS-BORDER TRANSPORT IN THE GREATER REGION SAAR-LOR-LUX+

The Greater Region Saar-Lor-Lux+ (in the following abbreviated as Greater Region) is a cross-border region in Western Europe comprising the regions Wallonia, Rhineland-Palatinate, Saarland, Lorraine and the country Luxembourg. Several cross-border bodies exist in the region as can be seen in figure 2.

Figure 2 – Location of the Greater Region Saar-Lor-Lux+, Source: Mission Opérationnelle Transfrontalière 2015

The Greater Region is characterized by strong cross-border commuter flows. Almost 213.000 commuters crossed the national borders within the Greater Region on a daily basis in 2015 with an upward trend (Interreg Großregion 2015).

How the cross-border transport topic is addressed in the domestic policies of the Member States and the cross-border policies of the Greater Region will be explored in the next section.

3.2 DOMESTIC AND CROSS-BORDER POLICY DOCUMENTS

The analysis of domestic and cross-border policy documents includes the 15 EU policies, mentioned above, 102 domestic transport policies from Belgium, France, Germany and Luxembourg and 24 cross-border policies which relate to transport.

The relation of the domestic and cross-border policies to cross-border transport is depicted in figure 3. It is differentiated in three objectives relevant for cross-border transport. Each bar shows the percentage of policies which mentioned the objectives in the different policy frames. The linkage of the TEN-T network to secondary networks is mentioned rarely, this objective is supported most by the German policies. More policies aim at improving cross-border infrastructures and services: The cross-border policies promote these two aims most, followed by the Luxemburgish policies. The German policies promote these aims

least. Cross-border services are not promoted that much in the EU policies. It appears to be rather an issue promoted on domestic and cross-border level.

Figure 3 – Contribution of the domestic and cross-border policies to cross-border transport, Source: Own depiction, Kaiserslautern, 2017.

In Germany, the improvement of cross-border transport infrastructures and services is promoted most frequently by the subregional planning policies. Also the French inter-municipal planning documents consider these objectives more important than the regional and national policy documents. In Belgium cross-border infrastructures and services are promoted most by the regional policies. With the exception of France, the regional levels of the residual countries consider these two objectives much more important than the national levels. With the exception of Germany the regional levels' policies consider the linkage of TEN-T and secondary networks most important. In Luxemburg only the national level develops transport related policies. Several domestic policy documents name prioritized cross-border projects. In Belgium the regional level policies do so most, whereas in Germany and France, most policies which define concrete cross-border projects are produced on subregional respectively inter-municipal level. The comparison of the countries shows that cross-border transport is preferably dealt with on different administrative levels which can hamper the coordination across borders.

When comparing the relevance of the residual EU transport objectives - depicted in figure 1 - in the EU, the domestic, and the cross-border policies, the national policies are most similar to the EU aims. This is not the case in Belgium. Here the regional policies of Wallonia are more similar to the objectives' relevance in the EU policies. The subregional levels show stronger deviations than the higher levels which speaks for a lower influence of the EU policies. According to interviewed stakeholders the subregional levels i.e. the Planungsregionen in Germany and the départements in France as well as the provinces in Belgium are influenced more by the domestic than the EU policies. The cross-border policies deviate most from the EU policies. They focus more on the individual needs of the cross-border region.

Several challenges have been named by the interviewed stakeholders which hamper the direct influence of the EU policies on the domestic policies. These are among others missing obligations from the EU policies, missing motivations of the Member States and missing financial means to fulfil the objectives. Furthermore, the different transport planning cultures and systems hamper a similar implementation of the EU aims. Also in the case of cross-border transport the motivations of the Member States and their administrative levels, expressed in the policy documents, differ.

This section presented a first attempt of tracing the EU policies' influence on the domestic and cross-border transport policy documents and illustrated first patterns. Still it needs to be taken into account that only the definition of objectives has been analysed which does not automatically ensure their implementation. Several interviewed stakeholders have criticized the low contribution of certain administrative levels to cross-border transport although their policy documents' aims promoted it. Thus there might be a mismatch between the promotion of aims and their final implementation.

3.3 CROSS-BORDER TRANSPORT PROJECTS

According to the interviewed stakeholders the cooperation in the cross-border transport development of the Greater Region is aggravated by several challenges such as missing financial means, technical barriers, a high variety of individual needs and objectives, different transport planning approaches and cultures, hampered communication because of different languages, missing political support and motivations as well as internal competitions which make it very time intensive.

This chapter presents some cooperation attempts in the Greater Region with concrete project outputs and evaluates the relevance of EU support in the cross-border transport reality.

3.3.1 EU SUPPORTED CROSS-BORDER TRANSPORT PROJECTS

Three types of EU supported cross-border transport projects were analysed in the last (2007-2013) and current (2014-2020) funding period: INTERREG A, INTERREG B and TEN-T projects.

Figure 4 – Contribution of the EU funded projects to the EU policy aims, Source: Own depiction, Kaiserslautern, 2017.

As can be seen in figure 4 the projects of the three different funding programmes focus on different aims. INTERREG B projects contribute most to the linkage of TEN-T and secondary networks, cross-border infrastructures and services are supported most by INTERREG A projects. From these three categories the TEN-T projects support cross-border services and infrastructures more than the linkage of TEN-T and secondary networks. As more TEN-T projects have been funded than INTERREG A projects, the contribution to cross-border transport was the highest of the funds of the TEN-T policy. The INTERREG A and B projects have also been influenced by the objectives of their Operational and Cooperation Programmes which were developed by the regional administrations involved in the Greater Region. All projects were not been entirely financed by the EU but were co-financed together with the Member States. The funding programmes INTERREG A and B cannot afford to support large infrastructure investments because of restricted funds. Still they complement investments here and there. The TEN-T projects mostly focus on the improvement of high speed and primary infrastructures, often relate to freight transport and the overall improvement of technical standards. INTERREG A projects mostly focus on smaller scale transport infrastructures and services. Only one project of the last funding period conducted a study on a part of a TEN-T corridor. INTERREG B projects contribute to both categories, but mostly focus on the smaller scale, even urban transport themes are supported.

When comparing the EU transport objectives' relevance in the EU policy documents and in the EU supported projects, the INTERREG B projects on average seem to be aligned most to the EU policies with a deviation of 25%. INTERREG A and TEN-T project deviate slightly more (32 and 34%). The highest mismatches exist in the promotion of the accessibility of remote areas, transport safety and sustainable transport. These objectives have not been mentioned often by the EU funded projects.

The aims of the INTERREG A projects do not cover all EU aims like the INTERREG B projects do, instead they are more focused on certain categories. Because of their thematic orientation, the TEN-T projects have not contributed to the objectives urban transport development and the accessibility of remote areas but besides that to most categories.

Overall the EU funded projects are considered to have motivated stakeholders from different countries to approach cross-border transport challenges because of the financial incentives. These allow further investments in times of empty coffers. Especially the INTERREG projects facilitate the exchange of local and regional stakeholders and are said to deepen contacts for future cooperations. Furthermore, because of the multiannual definition of objectives the EU policies can steer the focuses of projects. The TEN-T projects are approved on EU level. In the case of INTERREG projects the final decision about the project acceptance is decentralized to the regional levels of the involved Member States which might contribute to a higher consideration of the local transport needs in the decision-making.

3.3.2 NATIONALLY FUNDED CROSS-BORDER TRANSPORT PROJECTS

Besides the EU funded projects, there is a high number of initiatives and projects which have been implemented without EU incentives. Some of them were developed for the whole cross-border region. These, however, dealt with a better coordination of the transport development instead of cross-border infrastructures or services. Most projects have been developed bilaterally between neighbouring countries. In most projects Luxemburg was actively involved. Besides a high cooperation between Germany and France, only a low number of cooperation attempts have been created between Germany and Belgium as well as Belgium and France. Luxemburg itself developed own projects with relevance for cross-border commuters.

Most cross-border initiatives which were promoted without EU support focused on the provision of public transport services across borders. Several also promoted cross-border infrastructures including the construction of park and ride infrastructures, the expansion of rail tracks and motorways. The residual projects conducted studies or facilitated the coordination of the transport development across borders.

The projects show a high motivation of the Member States, respectively regions, – especially in those with strong commuter flows – to improve the current transport services and infrastructures. However, some projects were discontinued because of missing political support. Besides the Member States, cross-border bodies have coordinated several cross-border initiatives on lower cross-border scale. As one of the most frequently named challenges of these projects were the high investment costs, several of these running projects aimed at being supported or were supported with EU funds in the past.

The cross-border projects also refer to several EU policy objectives such as the promotion of alternative transport modes, the reduction of congestions, and an increased user-friendliness of public transport, but not all. These objectives have also been promoted by the domestic and cross-border policy documents. Therefore it is difficult to prove a direct EU policy influence. The individual objectives of the projects are considered to reflect the local needs in the cross-border transport system of the Greater Region and its binational cross-border relations.

3.4 EVALUATION OF THE INFLUENCE OF ETC AND TEN-T POLICY ON CROSS-BORDER TRANSPORT IN THE GREATER REGION SAAR-LOR-LUX +

According to the project and document analysis and the stakeholders interviewed certain trends can be perceived. Both policies aim at contributing to better cross-border transport and strongly lobby the relevance of this objective. Besides that they promote further transport related aims. The Member States have included several of the EU aims in their domestic policies especially the national levels strongly

promote these aims in most countries. The relation of the domestic policies on cross-border transport increases on the lower administrative levels. In France and Germany the subregional levels strongly promote cross-border transport, however, the direct influence of the EU policy objectives is reduced at the same time. This might indicate the disengagement of the promotion of cross-border transport by EU policies and the relevance on the domestic levels. Instead the concernment of the respective level seems to be more decisive. On the regional Belgian level, Wallonia, however, the policies are most similar to the EU objectives and cross-border transport is promoted most. However, stakeholders from the subregional level criticize the low engagement of Wallonia in the cross-border transport reality. Still, a certain influence of the EU transport related aims seems to exist in the policy documents.

All cross-border transport projects reflect several transport related aims and thus seem to be influenced by the EU policies at least to a certain extent. The contribution of the EU funded projects to the EU aims can be traced back easier as they have to relate to at least some EU aims in order to be approved. The different funding programmes show different focuses and thus can complement each other quite well. All of them offer an important financial support. In order to receive these funds, the EU funded projects need to achieve their defined objectives. Therewith the implementation might be ensured to a higher degree than in non-EU funded cooperations. In terms of the projects' quantity the TEN-T projects contribute most to cross-border transport. However, they focus mainly on the improvement of long-distance connections.

Still as long as they contain more than one stopping point in the Greater Region, this can be of added value for the internal accessibility, especially as the Greater Region covers a relatively large territory. INTERREG A and B projects focus less on large scale infrastructures; they however, strongly promote the mutual comprehension and bring stakeholders from the different countries together which might be of added value for future projects. The non-EU funded projects illustrate the high relevance of concernment, needs and pressure for the development and implementation of cross-border initiatives: Many projects have been developed around Luxemburg because of the high commuter flows. These factors strongly facilitate investments in cross-border transport and might be more decisive for the expansion than the EU policies.

4 CONCLUSION: CONTRIBUTION OF ETC AND TEN-T POLICY TO TERRITORIAL COHESION

The missing obligatory nature of the European transport policies which would be needed to effectively harmonize the transport standards of the Member States and minimize a decisive cross-border transport barrier was often criticized by the interviewed stakeholders. Additionally, the EU transport related policy aims are very broad and not targeted to the individual needs of cross-border regions as they shall be valid for the whole EU. Still the financial incentives which are aligned to the implementation of EU objectives are a high motivation and opportunity to implement cross-border projects and EU objectives.

In order to efficiently improve cross-border transport additional domestic investments are necessary as the EU funds are scarce and can only support a small number of projects. As the domestic policies show similarities to the EU transport objectives it is likely that also the non-EU funded cross-border transport projects will implement the EU policies' aims to some extent. However, the influence of these projects is less direct and cannot be easily traced back. Especially the non-EU funded projects are strongly shaped by the domestic political will and implemented due to urgent local needs.

Although not always a direct EU influence of the ETC and TEN-T policy could be determined in the transport policies and projects of the Greater Region some of the two policies' broad aims could be detected on all transport related levels which shows a certain level of harmonization. As the two policies are not obligatory the provision of funds is of high relevance for the implementation of their aims and a possibility to improve cross-border transport and contribute to territorial cohesion. However, compared to the perceived cross-border transport challenges the number of EU funded transport projects has been low and could improve the situation only to a small degree.

The findings of this paper are based on the analysis of the cross-border transport in one case study, the Greater Region Saar-Lor-Lux+. In order to find out if the perceived trends can be generalized for the whole

EU, a second case study will be conducted in the Polish-German border region Brandenburg-Lubuskie which has a different initial situation than the Greater Region.

1 INTRODUCTION – METHODOLOGY AND DEFINITIONS

Cities are changing day by day - they are in the constant circle of life - arising, decaying, reviving. However, their changes are mostly connected with its users - nowadays we can observe increasing participation of inhabitants, local activists and non-governmental organizations in the urban regeneration processes (Żylski, 2014). Authors present the impact of EU Cohesion Policy 2014-2020 on regeneration processes which are implemented in Polish towns, cities and metropolis when emphasizing general formal and legal framework including examination of the possible distribution of EU funds for regeneration projects within the regional operational programs. Authors focus on different approaches to the implementation of Cohesion Policy in Polish regions - and researched into Pomeranian province and Mazovian Voivodship as study cases.

First, there is a need to establish definition needed to the research. The definition of the regeneration process used in the research comes from the Polish legislation (Act on regeneration, 2015). The regeneration process is defined as 'a process of counteracting crisis situation in the degraded areas, lead in complex approach due to integrated actions in favor of local community, space and economy, concentrated territorial, conducted by regeneration stakeholders, basing on local regeneration program'. Moreover, it is important that the groups of stakeholders are also listed there. Among them, inhabitants of the area, owners, perpetual users, administrators, other inhabitants, local entrepreneurs, units of local government are mentioned. The importance of various stakeholders' participation is also mentioned in The Guidelines for regeneration actions in operational programs 2014-2020 prepared by Polish Ministry of Economic Development (2016). Participatory approach is important for the social dimension of the regeneration. Participation of the local communities and multiple stakeholders in reimagining and reinventing public spaces. Moreover, it strengthens the connection between the place and its users (Placemaking and the future of city – draft, 2012). The pioneer in the placemaking – community-based approach to the regeneration process - is U.S. nongovernmental organization Project for Public Spaces which has helped numerous communities in creatina public spaces together. Basing on the polish

legislation, the participatory approach consists of preparation, leading and evaluation the regeneration process ensuring the active participation of stakeholders during consultations and works of The Regeneration Committee (JL, 2015). In that part of the research, more important than the definition of participation method is the methodology of it. There is a growing need for authorities but especially for communities to understand that the consultation of the regeneration process is not the only activity for various actors to participate the whole process. Creighton James L. (2005) in his publication mentioned 4 steps of Continuum of participation: 1. Inform the public, 2. Listen to the public, 3. Engage in problem solving, 4. Develop agreements. However, the step: 'Engage in problem solving' is the most extensive in tools for co-operation between various actors. Moreover, Sherry Arnstein (1969) evolved eight-rung Ladder of Citizen where the highest rungs are 'Delegated Power' and 'Citizen control' what shows how much citizen are able to do. The rightness of choosing the participatory approach for the urban planning involves Jane Jacobs' philosophy - 'Cities have the capability of providing something for everybody, only because, and only when, they are created by everybody' (Jacobs, 2014).

2 REGENERATION PROCESSES IN THE CONTEXT OF EU COHESION POLICY

The fundamental, overarching document regulating regeneration processes in Poland is partnership agreement between the Poland and the European Union signed in May 2014 (Polish Ministry of Infrastructure and Development, Programming Financial Perspective 2014 -2020 - the Partnership Agreement). Both the Assumptions of the Partnership Agreement and the resulting draft of this document were prepared in cooperation with key stakeholders - ministries and regions. Into account have also been taken the opinions of the social and economic partners. Objectives of the Agreement are identical to the objectives of the Poland National Development Strategy 2020 while maintaining synergy with the Strategy Europa 2020, ie. increase competitiveness, social and territorial cohesion and improving the efficiency of the administration. The instruments for implementation of the Partnership Agreement are national operational programs, including the National Regeneration Plan, and in consequence also voivodship development strategies, regional strategic programs and regional operational programs decisive for the allocation of funds from the European Union. The intervention of regeneration processes within the Regional Operational Programs 2014-2020 is based on funding from the two European funds: the European Social Fund (axis 6 Education) and the European Regional Development Fund (axis 8 Conversion). Financial support for regeneration activities from EU Funds through ROP's (Regional Operation Programs) is possible only through an integrated regeneration project involving interventions both the social (Axis 6 ESF) and spatial (Axis 8 ERDF) aspect. The implementation of the two-fund project formula is a conclusion drawn from the 2007-13 mechanism in which various actors involved in degraded areas often failed to coordinate the work of the joint vision set out in the strategic document. More on the impact of ROP's in regeneration processes on the example of Pomeranian voivodship (below).

3 REGENERATION IN POLAND

Over the past quarter century, the socio-economic transformation in Poland, triggered primarily by the transformation of the political system and the challenges of pioneering free market economy, has revealed the progressive process of urban degradation. In recent years, unfavorable demographic and spatial processes have also contributed to this, among them: the depopulation and aging of the inhabitants of the centers, the uncontrolled dissipation of urban development and the dominance of individual motorized transport in urban areas. Based on the results of 2010 research, which identified in total at least 120,000 ha of areas that require regeneration in Poland – it's almost 22% of all urbanized land in Polish towns and cities, of which 11 percent are historical inner cities, 4,2% post-industrial lands, 2,6% large-panel building estates and 3.3% post military, post railway lands. About 2.2 million people lived in the city center's requiring regeneration (Ziobrowski and Jarczewski, 2010).

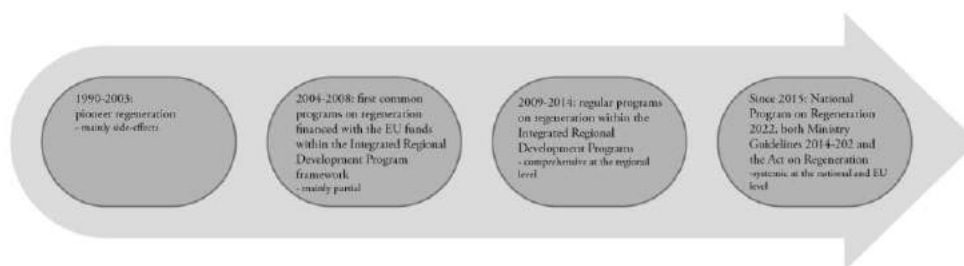

Figure 1 - Evolution of regeneration processes in Poland
Source: own study based on Musiał-Węclawowicz (2007).

Regeneration in Poland, over the last twenty years, is gaining in importance and intensification (figure 1). It is now regarded as a factor in the development and improvement of living conditions. It is also clearly highlighted in the government documents defining the country's development directions: National Strategy for Regional Development, National Spatial Development Concept 2030, National Development Strategy.

3.1 INSTITUTIONAL AND LEGAL FRAMEWORK OF REGENERATION IN POLAND

Regeneration requires as much holistic approach as possible. This means that many legal acts have to be respected when implementing regeneration projects. The process is a unique conglomeration of various activities, so each change in a statutory should facilitate the comprehensive measures, while no legislative change should not hinder and complicate them (PMID, 2014).

Since 2015 the regeneration processes in Poland are being conducted out within the legal framework set by the dedicated basic act of Polish law - Act on Regeneration (JL, 2015). For the first time Polish legal system, presents an issue of regeneration as a multilevel, complex approach within multi-unit co-operation. The act anchors the implementation of regeneration processes within the competence of Gminas (eng. basic land administrative units/municipal offices) by introducing a definition on regeneration and its stakeholders, adding regeneration processes to Gminas own tasks (by the amendment of the Act of 8 march 1990 on municipal self-government (JL, 2016) and public purpose within the meaning of the Act on real estate management (JL, 2016), enhance local participation, equip municipalities with dedicated planning tools - special zone of regeneration and local regeneration plan.

The enrollments of the Act on Regeneration obliges Gminas to prepare a complex Municipal Regeneration Program (pl. Gminny Program Rewitalizacji) fulfilling the guidelines set by the experts representing Marshals' Offices (polish provincial offices). It is a strategic document which includes diagnoses, plans and coordinates actions to achieve the expected changes after regeneration. It also coordinates the regeneration activities with a number of other municipal documents, resulting in extensive effects. Moreover, according to the provisions of the Act, the Regeneration Committee is set up for mediation and advisory purposes and to ensure the participation of all interested stakeholders. What is important, the act emphasizes the importance of participation of local inhabitants by introducing this concept regardless the notion of consultation existing in the earlier legal framework. Municipal regeneration program which is a resolution of the municipality council, does not constitute a local law - it is therefore not a source of common law provisions, it does not bind the addressees of legal norms. It is an internal document binding its principal leader (and the project promoter) - the mayor of the municipality. Even though ESF and ERDF support is dedicated to the areas where there is the worst socioeconomic situation, it is important to remember that the municipal regeneration program - similarly to any economic program - refers to the whole area of the town over a longer period of time. The mandatory components of the Program referred to in the Act are shown at figure 2.

Figure 2 - Mandatory components of Municipal Regeneration Program in accordance with the Act on regeneration (2015)
Source: Own study based on the Act of 9 October 2015 on regeneration (2016)

Even though the Act contains a number of general principles for conducting this process, such as a mandate for participation or a duty to rely on analysis, there are no rigid premises for the designation of regenerated areas and detailed rules for its conduct. This remains the competence of municipalities, which should shape this process adequately to their needs. Support is provided by the Marshal's Office as a leading institution of the ROP, and is based on the Ministry of Economic Development's guidelines (2016). The ministry guidelines are only a part of larger regeneration thematic module, led by the mentioned above National Regeneration Plan 2022 (2014). The Plan is an extended interpretation of the conduct of regeneration processes as a comprehensive and integrated action. It defines regeneration programs as the operational framework and coordinating platform for regeneration activities, formulating the principles for their creation and implementation.

3.2 REGENERATION AT THE REGIONAL LEVEL

The European Union has allocated to Poland 82.5 billion EUR over the 2014–2020 period, which makes Poland the largest beneficiary of Union assistance. The new EU Funds perspective, as well as new Polish law, have definitely changed the way of regeneration programs realization. Firstly, the delimitation of regeneration area is more restricted. This is the field of cooperation between Municipals' and Marshals' Offices. Compared to the previous billing period, the role of an adequate, in-depth diagnosis, based on multifaceted socio-economic analysis has increased. Nowadays it is necessary to fulfill the restrictions of regeneration areas delimitation worked out by Marshals office experts.

	Mazovian Voivodship	Pomeranian Voivodship
Organizer	Mazovian Unit of Implementation EU Programs	Voivodship Regeneration Work Group (representative of Marshall's Office)
Participants	Gminas of Mazovian Voivodship.	Two groups of participants: - 9 municipalities belonging to Metropolitan Area of TriCity negotiating within framework of metropolitan development strategy - 22 municipalities outside the metropolitan area competing in the competition for implementation of ROP integrated projects
Objective	Helping Gminas to initiate processes leading to the regeneration of degraded areas thanks to preparing programs of the regeneration processes.	Negotiate a best solution for sustainable development of the region with respecting local conditions and needs.
Funding	Contest for Gminas for co-financing the process of preparing or actualization of the programs on regeneration.	Funding for Municipality Regeneration Program comes from PO POWER; the integrated regeneration projects are funded by ROP's funds: part of it determined by ITI Strategy of Metropolitan Area of TriCity, rest have a contest for co-financing.

Table 1 - Comparing approaches in the Mazovian and Pomeranian Voivodship. Source: Own study.

4 MAZOVIAN VOIVODSHIP

Regional Operational Program for Mazovian Voivodship 2014-20 (ROP MV) is based on The Guidelines for The Regeneration Process in Operational Programs 2014-20 (Polish Ministry of Economic Development, 2016). ROP MV provides funds for complex regeneration process of crisis areas.

Funding is possible only if regeneration project of particular Gmina is listed in the List of Mazovian Voivodeship regeneration program, There are two ways to register the program on the list. One is to take part in Contest for Gminas for supporting the process of preparing the regeneration programs. The other is to take part in the recruitment. Gminas which apply to fund their projects have to fulfill such requirements as: following the rules from the Regeneration Program, being at the List of Marshall's Office mentioned before, meet basic criteria of particular elements and features (complexity, concentration, complementarity – of space and problems, procedures, finances etc.).

In the Instruction for preparing regeneration programs for ROP prepared by Mazovian Marshall's Office there is underline the importance of social participation and structural changes in crisis area in those programs. In the regeneration program there should be the description of participation of diverse groups of stakeholders in the way enabling to check the level of the participation. Moreover, the stakeholders' contribution is defined as the foundation of each part of the process. Despite the obligation of incorporation of various stakeholders, there are any imposed tools of participation, what gives Gminas opportunity to individual choice (Instruction..., 2016).

5 POMERANIAN VOIVODSHIP

In the Pomeranian Voivodship the regeneration is determined by the assumption of two strategic documents

- the POMERANIAN 2020 Strategy and the Regional Strategic Program ACTIVE POMERANIANS 2020, whose provisions are the main basis of the Pomeranian ROP for the years 2014-2020. ROP Pomeranian includes thematic objectives such as inclusion in the labor market (ESF funds), social services (European Social Funds), and support for physical, economic and social regeneration of the poor – comprehensive regenerative actions (European Regions Development Funds). Funding for the integrated regeneration projects is implemented in the Pomeranian Voivodship in two ways:

- the towns within the Metropolitan Area of the TriCity are supported by the mechanism of the Integrated Territorial Investments,
- the towns outside Metropolitan Area can be supported within competition. Different funding conditions results with different conditions for implementing the regeneration processes (figure 3).

Figure 3 - The differences in conducting revitalization processes in Pomeranian towns
Source: Own study based on Wiczerzak (2017).

Regeneration, which is based on the funds of the new financial perspective in the Pomeranian Voivodship, started with a series of trainings for urban self-governments. The result of the meetings was the declaration of accession signed by the local self-governments. Both the rules of who and how should be involved in the Regeneration Working Group were discussed during the meetings. The team assess the merits of the submitted applications by Gmina's, both in terms of giving feedback on the projects of regeneration programs as well as the delimitation of regeneration areas themselves. The working group consists of 12 people from different departments of the Marshal's Office of the Pomeranian Voivodship

(regional programs, regional and spatial development, European funds, education and sport, Pomeranian Office for Regional Planning and Regional Center for Social Policy). Such a group of experts guarantees comprehensive care of the process, with particular emphasis on competences in social services, socio-occupational activation, NGO specificity, spatial planning and community management.

In the meantime, the legal framework for regeneration processes has been changed (2015 – National Regeneration Plan, Act of Regeneration) as well as the ministry guidelines have been updated. Under which the Ministry of Development has shown willingness to co-organize the competition for the preparation of regeneration programs. The self-government of the Pomeranian Voivodship, in cooperation with the Ministry of Development, has used the support from the POWER program to equip local governments with funds and tools to develop their own principles for the implementation of comprehensive regeneration activities within the Municipal Regeneration Program.

After signing the agreement between the Ministry and the government of the Pomeranian voivodship, the task of formal and substantive evaluation of programs was officially entrusted to working team for the voivodship the Regeneration Working Group. It was the group that had consulted and approved the municipal regeneration programs of Pomeranian towns and cities. It also decides on the range of Integrated Regeneration Projects. This process follows the successful model of negotiation developed during the initiation of ITI and Integrated Territorial Agreements (ITA – ITI based model of negotiations between regional and local government. Described in details in 5.3.). At present (May, 2017) the competition for Integrated Regeneration Projects has started. 31 cities of the Pomeranian Voivodship joined the contest: 9 out of 13 cities metropolitan area and 22 out of 27 cities outside the metropolitan area. In this financial perspective, as in the financial perspective of ROP 2007-2013, the biggest beneficiary will be the capital of the Pomeranian Voivodship - Gdansk. In all of the Pomeranian Voivodship the total area designated for regeneration is 2,485 ha (0.1% of the total area of the voivodship). All in all, over 143,000 people live here (6% of the voivodship's population) (Marshal's Office of the Pomeranian Voivodship, 2016).

5.1 NEGOTIATIONS BETWEEN LOCAL AND REGIONAL GOVERNMENT

The process of negotiating both public and EU funds for regeneration processes is derived from the practices of ITI - refer to the Metropolitan Area of the TriCity, and ITA - for the remaining eight Functional Urban Areas. The negotiations within the framework of ITI and ITA was primarily to provide preferential access to EU funds under the ROP 2014-2020 for investments in favor of development of the region, at the same time corresponding with the local needs. In this way financing from the ROP is accomplished by prioritizing projects that are diagnosed within the framework of agreements of local government units affiliated by the ITI and the ITA, and then negotiated with the managing authority of ROP WP 2014-2020 (the Pomeranian Voivodship Board).

The first stage of cooperation with local governments was the consultation on the delimitation of regeneration areas aimed at identifying the part of the city which is in the relatively worst socio-economic situation. This is based on an analysis of the internal potential, depicting the differentiation and general condition of the city, in line with the Guidelines for the programming of regeneration projects under the ROP WP for 2014-2020. The methodology of in-depth socio-economic analysis indicated by the experts of the team assumes the use of various sources of spatial information as well as analyzes of the contents of literature and others. The indicators chosen for the analysis focused on two groups: the mandatory indicators, referred to the average values in the region and optional, referred to the average values in the analyzed town in the indicated subsystems, with the latter are chosen during the consultation. The reports resulting from the delimitation of regeneration areas were the starting point for further work on municipal regeneration programs and for reconciling the scope of the integrated regeneration project.

As a director of the Regional Program Department of the Marshal Office of the Pomeranian Voivodship, Jan Szymański, said "The admission of the formula for an integrated regeneration project within the framework of the Regional Operational Program for the Pomeranian Voivodship 2014-2020 aims to ensure the coherence, efficiency and sustainability of the regeneration programs for degraded areas" (Attractive cities for active residents. Preparation of regeneration programs for integrated operations in the Pomeranian Voivodship (2016) Gdansk: Marshal's Office of the Pomeranian Voivodship, 2016)

Figure 5 - An integrated project on regeneration within ROP WP 2014-2020

5.2 THE CASE STUDY OF THE CITY OF GDANSK

Gdansk is a city in the north of Poland, one of the main academic centers and the most important port city in Poland. It currently lives in about 430 thousand inhabitants. The city is particularly important for the identity of the Poles, due to the over-thousand-year tradition of the city -port, the Free City of Gdansk, and, above all, the birthplace of the Solidarity movement, which in the 1980s liberated Poles from Communism. Urban tissue, drastically destroyed after the Second World War and then hastily rebuilt and consolidated by modernist prefabricated blocks of flats, has suffered a severe degradation in the face of unfavorable social and economic trends. Degradation progresses both in terms of technical consumption and aging of functional infrastructure and residential development as well as erosion of social relations and the emergence of numerous economic problems. Regeneration in the full sense has been taken related to the Local Regeneration Program in the years 2009-2015.

5.2.1 LOCAL PROGRAM ON REGENERATION IN GDANSK (AN OLD APPROACH)

The municipality of Gdansk in the years 2009-2015 carried out 4 revitalization projects in the following districts: Dolne Miasto, Dolny Wrzeszcz, Nowy Port and Letnica. All projects were co-financed by the ERDF under the Pomeranian ROP 2007-2013 axis 3 Urban and metropolitan functions. City of Gdansk completed projects for approximately 104 million PLN (around 24 million EUR) with ERDF co-financing of 56% of the value of the projects.

5.2.2 MUNICIPAL REGENERATION PROGRAM OF GDAŃSK (A NEW APPROACH)

In the financial perspective for the years 2014-2020, the aim is to implement projects that will respond to the challenges of socio-economic activation of inhabitants of regeneration areas.

The area of regeneration	Approximate number of inhabitants of the area in 2016	Approximate area in hectares
Bishop Hill-Old Chelm	2 484	126
Down Town-Rampart Square	6 129	69
New Port-Letnica-Wisloujście Fortress	10 111	178
Orunia	6 933	102

Table 2 - Basic characteristic of the regeneration areas in Gdansk
Source: Own study based on: *Municipal Regeneration Program of Gdansk*

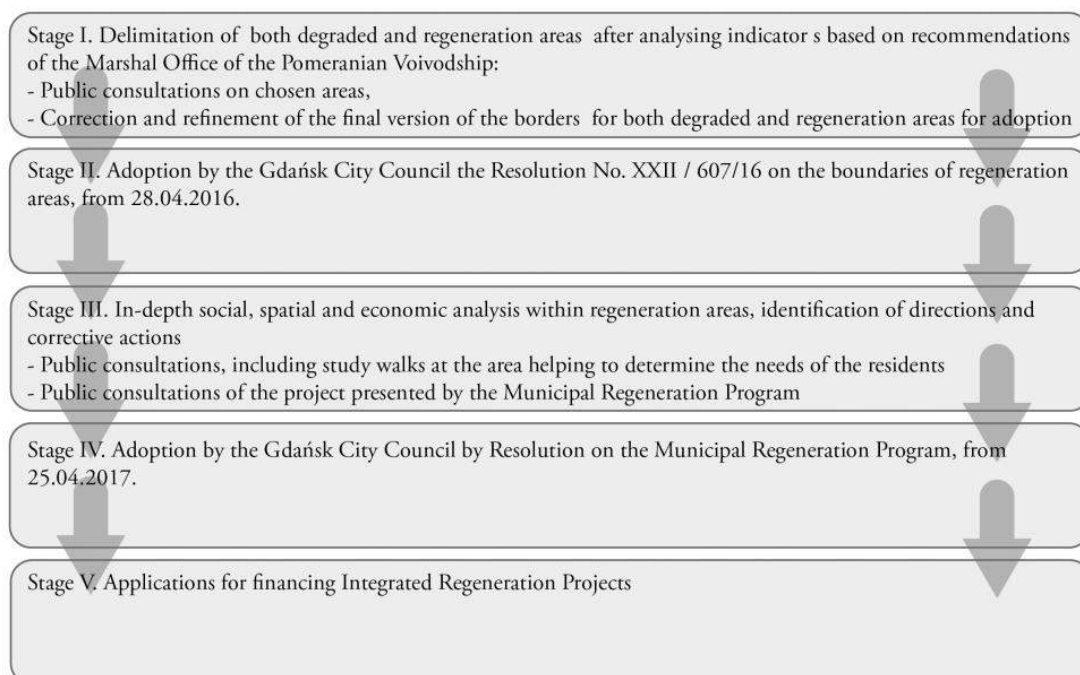

Figure 6 - The chronology of the process of regeneration of the new financial perspective in the city of Gdansk Source: Own study based on Municipal Regeneration Program of Gdansk.

Before joining the negotiations on Integrated Regeneration Projects, the municipality of Gdansk consulted with voivodeship regeneration working group about selecting and delimiting of the regeneration areas. Based on the indicators developed in the consultation, an in-depth socio-economic analysis of urban space was undertaken to identify 12 areas requiring intervention. As a result of further analysis, 4 regeneration areas were selected from the above: Biskupia Górka with Stary Chelm, Orunia, and once again as a continuation, Nowy Port with Wisloujście Fortress and Dolne Miasto with Wałowy Square. Selected areas represent a small percentage of both the area and the number of inhabitants of the city

(table 2). Every effort has been made to ensure that the revitalization program is integrated, multi-faceted, including a crisis area identified on the basis of the diagnosis.

5.3 LOCAL PROGRAM ON REGENERATION IN BYTOW (OUTSIDE THE METROPOLITAN AREA OF TRICITY AND THE ITI INSTRUMENT)

The authorities of the town of Bytów (located in the central part of the Pomeranian Voivodship) chose an „old approach” which was practiced before the act on regeneration has been adopted and is still accepted within Polish framework. The new Local Regeneration Program will be a required instrument for applying for funds within ROP 2014-2020. It is worth noting that the process of working on the document took place in parallel with negotiations between Pomeranian towns and the voivodship regeneration working group (explained above). This is an important element of integrating both regional and local policy concerning regeneration processes.

At the beginning of the work on the document mentioned above, there was a series of workshops and information meetings organized where, as a result, the delimitation of the degraded areas of the town of Bytów was established. This was a summary of the important first stage of the planning of regeneration process because shortly thereafter, the Management Board of the Pomeranian voivodship with the Resolution No. 1325/101/15 approved the list of recommended areas to support them with the integrated regeneration projects within ROP 2014-2020.

An important stage within the work on the Local Regeneration Program was a survey conducted among residents. The main aim of the study was to get acquainted with the opinion on the attractiveness of the area of "Miła Street" (delimited degraded area), the problems noticed there, its strengths and weaknesses, and possible directions of development. The survey form was available on the website of the town and in paper version available at the Municipal Office in Bytów. In addition, the questionnaires were distributed to students and teachers of local schools, housing managers, members of the consultative team, NGOs, entrepreneurs working in the delimited area, councilors, representatives of Bytów municipality councils and residents. As part of the questions, the respondents indicated the most attractive investments which should be implemented in the first place.

The detailed range of the regeneration process has been worked out within the meetings addressed to the group mentioned above and related with the area of "Miła" (ie. streets: Gdańska, Słoneczna, Miła, Działkowa, Pogodna, Wery, Sikorskiego, Górna, Pochyla, 1 Maja, Staszica, Mierosławskiego i Sychty) conducted by an external company.

Completion of the preparation of the document coincided with the Pomeranian Voivodship Board' Resolution No. 1374/201/16 reconciling the range of integrated regeneration projects that were negotiated by the Regeneration Team of the Marshal's Office of the Pomeranian Voivodship with the Towns entitled to support within ROP 2014 - 2020 located outside the Metropolitan Area of the Tri-City.

The document is finished and its partial financing was negotiated. Now it is the time to observe the process of implementation of agreed projects and applying for funds from other sources, which will enable to complete planned regeneration process.

6. LESSON LEARNT

The role of regeneration processes in the regional policy implemented in Poland after 2020 is bound to increase. At the same time, in a new financial perspective, one can expect a significant reduction in the scale of the EU intervention or at least a change of its structure, as different priorities and areas will be supported when the category of some Polish regions, probably including Pomerania, will change from Less-Developed to Transition regions. There is a need to create more independent systems of the EU funding schemes and could carry out the regeneration processes supported in institutional, organizational and financial manner. In order to achieve this goal, the greater involvement of national funding sources – managed by central, regional and local authorities, is required. There is also a need for a new type of development projects – multithreaded, based on partnership and creating a competitive advantage, which

also needs to be based on the improved thematic and spatial concentration of intervention. The 2014-2020 perspective shows new, better approach to the regeneration projects - not only the renovation of public space will be taken into consideration, but also activities increasing social development. Instructions and guidelines prepared by the government for Gminas encourage to incorporate various stakeholders into the regeneration process and do not show the preferable tools of participation what gives Gminas the opportunity for individual choice. A question may be asked: is the participatory approach useful in the improvement of inter-communal cooperation? They surely show an innovative approach to the bottom-up development programming at supra-local level. When the projects within regeneration programs are negotiated, the shape and range of various investments, crucial for the development of the territories in question, is decided. When all parties involved sit down together, they are able to reach a compromise allowing for the implementation of the most important projects for improving the life quality on polish cities and towns.

ABSTRACT: Starting from the 1990s, an increasing number of studies and reports focussed on the heterogeneous landscape for territorial governance and spatial planning in Europe. The geographical coverage of these comparative analyses broadened over time, paralleling the progression of the EU integration process. However, until now the Western Balkan countries have been ignored by the majority of the studies, mostly due to their fragmentation and geopolitical instability. As the pre-accession negotiation proceeds, such analytical gap should be overcome through the collection of evidence that may support the EU in developing a more sound and effective cohesion policy. This paper makes a first step in sketching out and comparing the evolution of the territorial governance and spatial planning in the Western Balkan Region since the late 1980s. More specifically, it first presents a general overview of the geographical and socio-economic situation, to then explore the evolution of the administrative and legal frameworks for spatial planning as well as of the tools that characterise each national context. Highlighting similarities and differences between the countries at stake, our work exposes the complexity of the subject and sets the stage for further research on the matter.

KEYWORDS: Spatial planning system, Territorial governance, Western Balkan Region, European integration, Transition.

1 INTRODUCTION

Modern spatial planning systems rose as a consequence of the Industrial Revolution, when increasing urbanisation rates, and the movement of population away from agriculture towards the industrial and services sectors created substantial development pressures across countries. In response, most government established procedures to channel these pressures and resolve conflicts between competing

land uses. Over time legislations was introduced in each country to establish the principle that public authorities are empowered to monitor and control territorial development and prepare plans, identifying what types of development would be permitted and where. In this light, territorial governance and spatial planning system may be defined as the system of institutions allowing and determining the spatial organization of social and economic life within a particular national context, through multiple processes of vertical (between policy levels) and horizontal (between policy sectors and between public and private subjects) coordination (Janin Rivolin, 2012).

The evolution and consolidation of territorial governance and spatial planning systems occurred at different times in different European countries from the late nineteenth century onwards, depending on political attitudes towards the acceptability of public powers over land regulation and development (which may be regarded as infringing on individual rights to exploit private property) and varying perceptions of the value of planning in different contexts. Hence, the specific histories and geographies of particular places, and the way these interlocked with national institutional structures, cultures and economic opportunities contributed to generate a highly heterogeneous set of territorial governance and spatial planning systems in Europe.

The fascination of taking an international view of planning lies exactly in the great diversity to be found within spatial planning systems and approaches that have evolved in the countries, as demonstrated by the proliferation of comparative research on territorial governance and spatial planning systems in the European Union (EU), since the late 1980s (Davies et al. 1989, Newman & Thornley, 1996; CEC, 1997; Nedović-Budić, 2001; ESPON, 2006; COMMIN, 2007; Reimer et al., 2014; ESPON & TU Delft, 2017). Over time, these analyses have broadened their geographic scope to include the new countries joining the enlarging EU (Table 1). However, despite their central geographical position and the advancement of pre-accession negotiations for most of them, the countries of the Western Balkan Region (WBR) have been left out from almost all comparative attempts, mostly due to their geopolitical instability as well as to the fragmentation that characterizes this area. With many of these countries soon to become full EU member states, their exclusion creates a gap in the empirical analysis and theoretical understanding of spatial planning in Europe. This gap must be overcome, if the EU aims to promote an economic, social and territorial cohesion policy to the benefit of all its citizens (ESPON, 2015).

This paper reflects on the evidence collected by the authors in more than a decade of comparative spatial planning research in Europe and, in particular, on the polymorphic territorial governance and spatial planning environment that characterizes the WBR (Figure 1). In doing so, it sketches out and compares the evolution of the territorial governance and spatial planning systems of six countries in WBR from the fall of the communist regimes until the present day. Such evolution is understood as a consequence of various driving forces: on the one hand, the transition of the countries under scrutiny from centrally planned to market oriented economic models and their progressive embedding within the broader globalization and EU integration processes (Cotella & Janin Rivolin, 2010, 2015; Stead & Cotella, 2011); on the other hand, the complex path-dependency deriving from the specific national historical, geographical and socio-economic contexts which determine the actual direction of transformation as a reaction to external and internal stimuli (one hand, the transition of the countries under scrutiny from centrally planned to market oriented economic models and their progressive embedding within the broader globalization and EU integration processes (Cotella & Janin Rivolin, 2010, 2015; Stead & Cotella, 2011); on the other hand, the complex path-dependency deriving from the specific national historical, geographical and socio-economic contexts which determine the actual direction of transformation as a reaction to external and internal stimuli (one hand, the transition of the countries under scrutiny from centrally planned to market oriented economic models and their progressive embedding within the broader globalization and EU integration processes (Cotella & Janin Rivolin, 2010, 2015; Stead & Cotella, 2011); on the other hand, the complex path-dependency deriving from the specific national historical, geographical and socio-economic contexts which determine the actual direction of transformation as a reaction to external and internal stimuli (Table 2; Figure 2,3).

Table 1 - The geographical coverage of comparative analyses of spatial planning systems in Europe.
Source: Authors' Elaboration

Figure 1 - Western Balkan Countries included in the analyses

After defining what the study considers as territorial governance and spatial planning systems, and deriving from the latter the main variables for the comparative analysis, the paper provides an overview of the development of spatial planning in the WBR during the socialist period and introduces the main drivers that have shaped the current development and consolidation of the territorial governance and spatial planning systems in the six countries under study. Section four constitutes the core of the work, and explores and compares the countries on several variables: (i) the administrative and legal framework for spatial planning; (ii) the main planning authorities involved; (iii) the spatial planning instruments produced at each territorial level; (iv) the main spatial planning issues and (v) the future challenges.

Overall, the paper produces an initial comparative overview of the territorial governance and spatial planning systems of the Western Balkan countries, that highlights the heterogeneity and the fluidity of this complex landscape. In so doing, it allows a formulation of a preliminary conclusions and considerations for further more extensive analysis.

2 SPATIAL PLANNING IN THE WESTERN BALKAN REGION: TRADITIONAL ARRANGEMENTS AND MAIN DRIVERS OF CHANGE

Spatial planning after WWII in the countries of WBR was often referred to as a subordinate to centralized economic planning, which represented a key function of a communist state. Albania was characterized by a strong top-down communist model with centrally-controlled spatial planning, where local urban authorities had responsibility for development coordination but lacked decision-making power. On the other hand, Yugoslavia detached itself from the Soviet centralised planning model during the 1950s and developed 'a participatory system of integral (i.e. comprehensive or integrated) planning' (Nedović-Budić et

al., 2011:430) that had a partially decentralized system within each of the individual republics (Hirt & Stanilov, 2009). The regime that operated in the former Yugoslavia was a form of 'market-socialism' operating through 'societal self-management' and decentralized decision-making processes, with the municipality being the basic local government unit holding considerable executive power (Nedović-Budić et al., 2011). Still, until the late 1960s, some of the main issues of planning practice in Yugoslavia were seen as bureaucracy, political complacency of planning organizations, technocracy of their employees and the lack of wide and transparent public participation (Petovar, 2012). Internally, the main driver of socialist development in this early post-WWII period, was described as the 'renewal strategy', with the mission to restore the function of the urban tissue destroyed in the war and to provide housing for new workers and their families who migrated from rural to urban areas under the state-sponsored industrialization.

The Albanian State continued to play a dominant role in planning and plan approval throughout the 1970s (Eskinasi, 1995), when the 1976 Constitution banned private property completely (including private plots in rural areas) and reduced public engagement to a symbolic role (Mele, 2011). By this time in former Yugoslavia urban land was in societal (public) ownership, while most of land in rural areas was privately owned. However, both Albania and former Yugoslavia witnessed processes of land nationalization under the communist government (Turnock, 1989). In both contexts, land ownership allowed the State to act as the main pillar of the urbanization process, 'central investor' and initiator of urban development (Petovar, 2012).

In post-WWII former Yugoslavia planning professionals were educated mainly in the field of engineering and architecture and operated in a technocratic mode that excluded any economic justification of planning proposals. Nevertheless, the profession evolved rapidly with the successful introduction of spatial planning degrees and an integrated approach to planning from late 1970s (Cavrić, 2002). This coincided with the establishment of planning as an interdisciplinary field on its own (i.e., separate from architecture, economics or engineering) in both the realms of education and practice. In parallel to the innovation in planning practice, the later era of the 1970s and 1980s saw the institutionalization of extensive public participation that became a legally mandated element of the planning process (Law on Planning and Construction, 1961; 1974). The decentralized system that promoted 'cross acceptance' in the decision-making process was practiced in Yugoslavia for more than a decade ahead of some of the traditional market-economy societies (Cullingworth, 1997), with most scholars referring to this period as a 'golden age' of planning and development (Vujošević & Petovar, 2006). Similar, although less radical transformations of the planning system were by mid 1980s evident in Albania as well (Nientied, 1998).

At the beginning of the 1990s, systematic regime changes, political pluralization and socio-economic reforms were initiated in the WBR, as a consequence of the collapse of the Soviet Union and the subsequent dismantling of communist institutions in all satellite countries (Mojović et al., 2009). Post-communist Europe saw a multi-dimensional process of transition to democracy, market and decentralized governance, as it became increasingly influenced by globalization and Europeanization processes (Tsenkova & Nedović-Budić, 2006; Faludi, 2014; Cotella & Berisha, 2016a, 2016b). The introduction of market economic principles occurred through a series of macroeconomic reforms that entailed rapid privatization and the almost complete withdrawal of State aid, in turn leading to the shutting down of numerous production plants, growing unemployment and increasing social costs (Brada, 1993). The already existing heterogeneity of WBR countries was reinforced by these processes and the new economic systems that worsened the situation of the weakest countries and widened the regional disparities. At the same time, the disintegration of former Yugoslavia during the 1990s and the Albanian civil war in 1997 (as a consequence of the financial crises, the so-called pyramid schemes) emerged as major destructive and disruptive forces with regard to the ongoing transition.

As it will be argued in the following section, the transformation of territorial governance and spatial planning in each context depended on the system's capability to follow and adapt to each of those transition processes. The influence of each countries' distinctive pre-socialist, socialist and post-socialist past affected its capability to transform through a concurrence of path-dependent logics that contributed to a variety of outcomes in terms of both territorial governance and spatial planning (Tosics, 2004; Tsenkova & Nedović-Budić, 2006; Cavrić & Nedović-Budić, 2007; Szelenyi, 1996; Enyedi, 1998; Petrović, 2005).

3 TERRITORIAL GOVERNANCE AND SPATIAL PLANNING AFTER 1989

The initial period of the post-socialist transition of 1990s in most countries of the WBR was characterized by a fluid, unregulated institutional framework. According to Hirt and Stanilov (2009), this 'institutional vacuum' was dominated by private economic interests close to the political establishment. Various authors claim that the transition was mostly characterized by extreme 'battles for capital' manifested in the form of accumulation and grab for resources and 'investors' urbanism', with urban land being a major target in this process (Vujošević, 2003). Within the complex framework of political and economic transition, the privatization of land and housing in Albania and almost all public housing stock in the former Yugoslavia took place (Hirt & Stanilov, 2009). At the same time, encroachment on public space and illegal construction rose to a major scale. In Yugoslavia this phenomenon worsened due the social consequences of the wars and in particular the increasing demand for housing by refugees and internally displaced persons (Žegarac, 1999), with spatial planning abandoning the mentioned 'golden age' and losing 'the ground beneath its feet' (Vujošević & Petovar 2006). At the same time, Albania remained stuck with socialist perplexed procedure of obtaining building permits and intensified rural-urban migration, that overwhelmed the capital city of Tirana with 25 per cent of informal housing developed during the 1990s (Deda & Tsenkova, 2006).

The turn of the millennium brought forward a renewed enthusiasm for the transition to democracy, economic liberalization, marketization and political decentralization, also as a consequence of the normalization of the geopolitical tensions that had characterised the previous decade. Most of the countries reformed and/or amended their legislative frameworks for spatial planning multiple times (Figure 4), as a consequence of growing influence of globalization and EU integration, and in the attempt to accelerate the procedures of obtaining construction permits, to adapt to the administrative and institutional re-organization, to legalize informal development, and to include public participation.

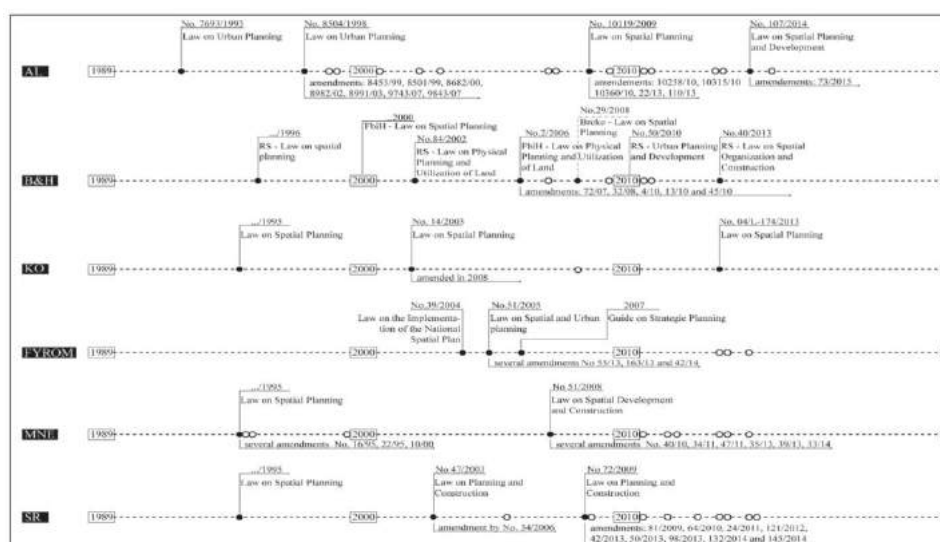

Figure 4 – The main Spatial Planning reforms since 1990 until 2016.

Within these evolving circumstances, planning professionals are required to possess new types of knowledge and skills with respect to market forces, while aiming to recognize and balance a variety of interests of new stakeholders within the decision-making process (Vujošević & Nedović-Budić, 2006). Post-socialist transformation of Western Balkan region countries also means that spatial planning practice should be able to recognize and meet the specific needs of the local context in which it is carried out. Thus, it should be able to confirm the prevailing political culture and adapt to the institutional framework, acknowledge the resources and constraints of local development, and, deal with the variety of interests, as well as traditions, at both national and local level (Friedmann, 2004). This means that the countries are to direct their spatial planning systems in line with a variety of internal and external factors. In order to understand current tendencies and possible future trends related to spatial planning, the following subsections presents and compares the key characteristics of current spatial planning systems in the countries under study.

3.1 ADMINISTRATIVE SUBDIVISION AND MAIN SPATIAL PLANNING AUTHORITIES AT EACH TERRITORIAL LEVEL

The current administrative organization of the countries included in this research is the result of a major process of restructuring that started in the early 1990s. The process of a post-socialist (de)centralization contributed to a different configurations of administrative hierarch in each country (Table 3). Indeed, in most of them, the administrative restructuring process was driven by new internal process (above all political, geographical, functional, economic and historical and contingent factors), with the exception of BiH and KO where a prominent role, in state restructuring, was played by the international community.

In this regard, the Albanian system represents an outcome of the recent administrative and territorial reform implemented from 2014 . The reform is based on the law which reduced the number of local administrative units from 373 to 61 with the aim to improve coordination at the local level and to reduce the existing territorial differences (primarily the economic and demographic regional disparities). In line with this perspective, the government is engaged on reforming the number and role of Qarku (districts), reducing the present 12 Qarku (districts) to only three or four administrative regions. In the case of BiH, the existing administrative subdivision is the result of the Dayton Peace Agreement signed in 1995. The agreement structured the BiH system in four levels: the central government, two independent Entities - the Federation of Bosnia and Herzegovina (FBiH) and Republic of Srpska (RS). While the Brčko District has been introduced few years later in 1999 , the cantonal level that further subdivide FBiH in cantons and the local level represented by the municipality and large cities such are Sarajevo and Banja Luka. The territorial administration system of KO includes only two levels of government, the national and the local, both instituted for the first time in the 2000 by the UNMIK mission and later ratified by the Republic's Parliament in 2008. This subdivision aimed at reducing the internal ethnic conflicts recognizing that 27 municipalities have Albanian majority, 10 Serb and 1 Turkish (Mamusha). Similarly, also the FYROM and MNE administrative systems are characterised by two levels: the central and the local. However, FYROM also introduced 8 statistical regions that include the all rural and urban municipalities, while the Special Law on the Territorial organization of MNE organized the territory in municipalities and the capital. Finally, the territory of SRB includes one autonomous province Vojvodina, cities, municipalities and the capital city of Belgrade as special territorial unit .

	AL	BIH	KO	FYROM	MNE	SRB
Central	Albanian Government	Government of Bosnia Herzegovina	Government of KO	Government of Macedonia	Government of MNE	Government of SRB
Meso Level 1	12 Qarku/District	Entities (FBiH and RS) District of Brčko	-	-	-	Autonomous Province Vojvodina + 3 other NUTS-2 regions
Meso Level 2	-	FBiH – 10 Cantons	-	-	-	-
Local	61 Municipalities including the city of Tirana	FBiH - 79 Municipalities, including the city of Sarajevo RS – 62 Municipalities including the city of Banja Luka	38 Municipalities including the city of Prishtina	80 Municipalities including the City of Skopje	21 Municipalities including the city of Podgorica	150 Municipalities, 23 cities and the city of Belgrade

Source: Authors' Elaboration

Table 3 - Administrative Subdivision of the countries of the Western Balkan Region.

As shown in the Table 3, the territorial administration system is different from one country to another. Adopting an historical perspective, the process of decentralization contributed at introducing new administrative levels, reorganizing the existing one or open up new statistic regions, while, simultaneously, at the local level has been reduced the number of local unites given more importance to the important cities as the capitals. It is interesting to note that in many cases the process of decentralization remains on

the paper while the central level has a considerable power. Differently from the other countries, in BiH the state level institutions remain fundamentally weak while the entities are largely autonomous.

The reasons behind these differences vary, ranging from the consequence of settlement of the war consequences in the case of BiH and KO to historical and geographical reasons. Be that as it may, the unique territorial subdivision of each country had important implications on the subsequent adjustments of the legislative frameworks for spatial planning and led to the introduction of a variable bodies responsible for spatial planning and territorial development, and to a differential distribution of spatial planning competences among administrative levels (Table 4).

	AL	BIH	KO	FYROM	MNE	SRB
Central	Council of Minister National	No Planning Authorities at the national level	Ministry of Environment and Spatial Planning	Ministry of Environment and Spatial Planning	Ministry of Sustainable Development and Tourism	Ministry of Construction, Traffic and Infrastructure

Table 4 - Main bodies responsible for spatial planning within each country

While in the majority of countries the national level authorities hold relevant responsibilities, in case of BiH they do not have any spatial planning competencies due to the specific political sub-division of the country. Additionally, in all countries except in BiH, the ministries are in charge of decision-making at national level in the field of urban development, environment and spatial planning. Some differences are present within MNE Ministry which focuses its responsibilities on sustainable development and tourism, and SRB Ministry which positions spatial planning under the field of construction, traffic and infrastructure. However, it

should be mentioned that the name of Serbian Ministry changed several times since 1989. Albanian spatial planning system also allows for specific competences in the hands of the Council of Minister and of the Territorial Council at national level. In addition, AL and FYROM have an Agency for Spatial Planning, While KO and MNE feature Institutes for Urban Planning which operate at the national level and is specifically responsible for the development of spatial planning tools. A similar agency existed in Serbia until it was revoked in 2014.

When it comes to the meso level, KO, FYROM and MNE have no spatial planning authorities. On the contrary, in AL the Qarku councils hold specific planning competences in relation to each district. Moreover, the case of SRB represents a particular case in relation to other countries of the WBR. Although the country has no official regional administrative subdivision except for the Autonomous Province of Vojvodina, it adopted a Nomenclature of Territorial Units for Statistics (NUTS) which are recognized as units of planning, but not as administrative units. National government and Ministry are responsible for adoption of Regional Spatial plans (based on NUTS division) and Spatial Plans of Special Purpose. Moreover, there is a Province Secretariat for Urbanism and Environmental Protection which is in charge of the territory of Autonomous Province Vojvodina.

Unlike other countries, BiH meso level represents the highest level of decision-making in the field of spatial planning. In Bosnia and Herzegovina both the FBiH and the RS features Ministries in charge of spatial planning. In particular, in the FBiH spatial planning lies within the competence of the Federal Ministry for Physical Planning, while in the RS are shared by the Government, the National Assembly and the Ministry for Spatial Planning, Civil Engineering and Ecology. In Brčko District, the main authority is the Department for Spatial Planning and Property Legal Affairs. In addition to this, each Canton of the FBiH (meso-level 2) features a Cantonal Ministry that share spatial planning responsibilities with municipal authorities and planning departments at the local level.

When it comes to the local level, local authorities are in charge of spatial planning in all countries, with SRB that further articulates different competences for municipalities and cities. In AL, KO and BIH competences are shared between the municipality council, the mayor and the department for urban/spatial planning. In FYROM, MNE and SRB, the municipal/city administration consists of local council, assembly, mayor, departments for urban planning and other public administration bodies that provide norms and standards for development. Additionally, these countries feature Local Planning Agencies and enterprises which can be public or private. What is important to notice is that in AL, KO and BIH spatial planning is under authority jurisdiction of local administration, while in FYROM, MNE and SRB besides administration there are also public and private enterprises in charge of spatial planning (mainly dealing with drafting of plans). Nevertheless, local public enterprises are not fully autonomous bodies - they closely cooperate with local administration and are often partly financed from the budget. However, the existence of these enterprises can still be observed as a sign of decentralization of planning activity, where most of the existing planning enterprises in ex-Yugoslav countries are established in 1960s.

3.2 SPATIAL PLANNING INSTRUMENTS AND ALLOCATION OF DEVELOPMENT RIGHTS

The administrative heterogeneity that characterises the WBR and the number of bodies responsible for spatial planning contribute the existence of number of instruments developed and implemented within each context, their character, and the coordination and integration within the various levels. Hence, this section will aim to present and explain the system of plans at national, regional and local level in the countries of the WBR. Moreover, it will aim to address the common trends as well as differences in the process of allocation of development rights, which is usually addressed as the main goal of each spatial planning system (Janin Rivolin, 2012).

Most of the countries included in this research (with the exception of BiH) assign spatial planning competences of the significance for the country development to the bodies at the national level, while the development of binding and more detailed spatial plans and instruments lies under the authority of the local government units, and local planning agencies in some cases. Although more strategic and less detailed in nature, spatial plans at national level in WBR are still considered as 'zoning' plans, if observed in relation to planning instruments in Western Europe which tend to move away from spatial and resort to strategic planning (Knapp et al, 2015). A common feature between all of the countries in this research is that they should follow a hierarchy of plans. This means that the local level plans should be in line with the

regional level plans, which should be in line with the national level plans (Table 5). Although the terminology of planning instruments varies between the countries, they show similarities when it comes to their scope and role, and it is possible to distinguish between three groups. First of all, there are national spatial plans that cover the entire territory of a country and are visionary, future-oriented and have 'strategic' elements. Their scope, content and coverage of these tools are wider than city-level urban plans, but less detailed. Second group features sectoral/spatial plans that usually focus on determined sectors/areas, for example, the National Sectoral Plans of AL. The third category includes those spatial plans which are adopted for particular projects of national and/or public interest. In AL these are called Detailed plans for areas of national importance, while in most other Western Balkan countries there exist plans of 'special purpose' (SRB, MNE) 'special zones' (KO) or 'special interest' (FYROM). Overall, it can be argued that in most of the WBR planning activity at national level aims at influencing the future strategic distribution of activities, environmental protection, planning and development of projects of national interest, indicating the regional and national priorities for economic and social development, amongst other things. National level plans are more strategic and less oriented towards defining norms and standards or land-use. Nevertheless, they still have a strong spatial and regulatory character (see for example the Zoning Map of KO introduced in 2013). Their main role is the coordination of local spatial plans, the organization of networks of settlements and infrastructures, and often also the horizontal and vertical coordination of decision-making.

	AL	BIH	KO	FYROM	MNE	SRB
National Level	General National Plan (GNP)	-	Spatial Plan of KO	Spatial Plan of the Republic of Macedonia	Spatial Plan of the Republic of MNE	Spatial Plan of the Republic of SRB

Table 5 - Planning Instruments for each Administrative Level
Source: Author's Elaboration

13 The law in power of the Federation foreseen two kind of Detailed Plans, the Regulation Plan and the Urban Planning Projects.

14 The law currently into force in Republika Srpska identified three kind of Detailed plans, the Regulatory Plan, Urban Planning Projects and Parcellation Plan.

15 The DIP - Detailed Implementation Plan is constituted by several planning tools at the local level such as: (i) the Zoning Plan, the Regulation Plan, the Urban Planning Projects and the Parcellation Plan.

Differently from the national level, not all of the countries of the WBR contain planning instruments at regional level (Table 5). In AL the only plans produced at the Qarku level is of sectoral nature, and aim at enhancing vertical coordination within the various sectors. On the other hand, SRB produces Regional Spatial Plans for the NUTS regions (explained in the section 4.1) at national level. These spatial plans still have more strategic and less regulatory character and serve for coordination of balanced territorial development, although SRB does not recognize regional administrative subdivision with the exception of the province of Vojvodina which has its own Spatial Plan for the Territory of the Province of Vojvodina.

The main exception to this trend is BiH, which features numerous planning documents at the meso level of the Entities FBiH and RS as well as of the FBiH cantons. Is interesting to note that in both Entities FBiH and RS, planning documents have similar characteristics; the spatial plan focuses on defining a shared long-term vision and strategy for the entire territory of respectively FBiH and RS, while the spatial plan of areas with special features/purpose establishes measures for planning implementation, hence, are considered more regulative and less strategic. On the other hand, the Brčko District produces a Spatial

Development Strategy that defines the long term goals of spatial planning (for 20 years), by establishing principles and goals of spatial planning area development, selecting priorities and instituting protection measures. When it comes to the FBiH Cantonal planning documents, these are of two kinds: the Spatial plans of Cantons of more strategic character, and the Cantonal Spatial Plans for areas with special features, that are of regulatory nature. Countries such as KO, FYROM and MNE do not have planning instruments at the meso level.

Finally, in order to direct spatial development, planning instruments at local level play a crucial role in balancing national and regional priorities, and local interests. In this regard, each country structured its planning system in line with its spatial, economic, social, political and environmental needs and perspectives. While national and meso level plans are usually described as spatial and more strategic in their nature, local plans in most WBR countries are characterized as urban/regulatory plans which provide substantive guidance, define norms and standards for spatial development.

Most of the countries of the Western Balkan Region included in this research vary in relation to terminology of local level plans, but also in their scope and possibilities to ensure development rights on the location. This section will aim to outline some general trends – similarities and differences between these spatial planning instruments within each country context.

Countries of the WBR usually recognize two types of planning instruments at the local level. These are legally defined as spatial (BiH, MNE and SRB) and general urban plans (all WBR countries) and are developed for cities and/or municipalities. As mentioned in the beginning of this section, local plans are to be aligned with the regional and national level plans. This kind of hierarchy of planning instruments is present at the local level as well, where detailed plans are to be in line with the general and spatial plans for cities/municipalities.

Spatial plans in BiH, MNE and SRB are developed for the purpose of defining main urban and rural land-use zones, natural areas under protection, infrastructural corridors, as well as other priorities of the local development. What is common for these plans is that they are adopted at the level of local municipality and contain rather strategic, but also to some extent regulative guidelines for future development. In BiH there are Municipal Spatial Plans which represent a strategic long-term plans with the main purpose is to harmonize the strategy of the Entities level (and Cantonal, in case of FBiH) to the local strategic priorities; In MNE there is a Spatial-Urban Development Plan which defines strategic objectives of spatial and urban development of the local government unit (municipality), in line with the planned economic, social, ecological and cultural-historical development.

Besides spatial plans in these three countries, all of the countries of the WBR have some form of general/regulatory urban plans at the local level. It can be argued that these local planning instruments have less strategic and more regulatory nature. Urban planning is considered to be the key instrument of land-use planning at local level. In international terms, it is often described as 'zoning'. General urban planning dates back to the socialist era. It has been under the authority of local communities for over 50 years, satisfying very important decentralization criterion within the sector of urban planning and construction.

These plans are usually separated in three groups based on their level of details. Firstly, there are general (AL, SRB, FYROM) or development plans (BiH, KO, MNE) which propose long-term strategic priorities of city/municipality development, land-use, intensity of development, borders of urban areas, and more. Secondly, there are city/municipality general and development plans which are more detailed than the first group. Although differently labeled (table 5), these plans are present in most of the WBR countries. In the Albanian case there are also Sectoral Local Plans which aim to enhance implementation of national and local sectoral strategies and programs. In KO, Municipal Zoning Map represents a regulatory document that determines the land-use and action measures for public and private investment for all the territory of the municipality. The lowest level of general planning instruments in WBR countries are so-called detailed plans. These plans define land-use and specific norms and standards for construction. In all of the mentioned countries these plans are obligatory for issuing of a construction permit, as further elaborated. Besides these, some planning systems include additional local planning instruments which work 'in concert' with the formal planning system and have similar, or even more detailed content than detailed plans. In the case of MNE these are Local Location Studies, in FYROM it is urban-technical documentation, while in SRB these are characterized as Urban Projects. These planning instruments can

serve for obtaining of the construction permit, and in some cases can even affect changes of the higher-level plan.

Allocation of the development rights, as well as the procedure for issuing building and construction permits represent some of the key points in relation to each planning system (Table 6). In all of the countries included in this research, the development rights are established by plans, both at the national and local level. In all of the countries of the Western Balkan Region, the process of allocation of development rights is operationalized in two main steps: (i) obtaining the urban/technical conditions which establish the land-use, norms and standards of development, and (ii) obtaining the construction permit, which allows for initiation of development process. Nevertheless, in order to complete the process of development and allow for its actual use, the developer needs to obtain an additional 'Use permit' in all of the countries mentioned in this research.

There is a general trend of accelerating the planning process in order to enhance issuance of development rights in WBR countries. For example, in SRB the construction permit can be obtained based on four different plans, while in most other countries based on three different plans (Table 6). Moreover, it should be mentioned that in all countries national-level plans can allow for issuance of development rights. For example, plans of special purpose (available in all WBR countries) can work as 'parallel' planning instruments that can allow for issuance of construction permit, besides the local level plan. In most WBR countries, these developments are proclaimed as 'in the public and national interest'. It is interesting to note that the legal framework of MNE recognizes this kind practice through Spatial Plan of Special Purpose where the 'national and public interest' is mostly concerned with the coastal/tourist development. Nevertheless, planning practice which enables national level documents to allow issuance of construction permits are not unusual when developing projects of national interest (for example infrastructural corridors) even in other Western European countries.

Besides the possibility to allocate development rights through national level planning instruments, in all of the WBR countries the detailed plans are the ones which provide sufficient guidance to allow issuance of construction permits. Nevertheless, additional planning documents which are not part of the formal system of plans can also enable issuance of construction permit in cases such are FYROM, SRB or MNE. For example, the planning system of FYROM recognizes this kind of practice through so-called urban-technical documentation where development rights are issued for the zones of 'the special interest'.

	Planning Instruments that may allocate development rights			Development rights Procedure (main steps)
	National	Meso	Local	
AL	Detailed plans for areas of national importance	-	General Local Plan and Detailed Local Plan	Development permit, construction permit and Use permit
BIH	-	FBiH - Spatial Plan of areas with special features RS - Spatial plan for an area with special purpose	FBiH - Detailed Spatial Plan RS - Zoning Plan and Detailed Plans BD - Detailed Implementation Documents	Development Permit, Construction Permit and Use permit
KO	Zoning Map of KO	-	Municipal Zoning Plan and Detailed Regulatory Plan	Terms of Construction and Construction Permit and Use permit
FYROM	-	-	Detailed Urban Plan (DUP), Urban Plan for Villages, Urban Plan Outside of Populated Spaces, Urban-Technical Documentation	Urban/technical conditions and Construction Permit and Use permit
MNE	Spatial Plan of Special Purpose (SPSP)	-	Detailed Urban Plan (DUP), Urban Development Project, Local Location Study	Urban/technical conditions and Construction Permit and Use permit
SRB	Spatial Plan of the area of Special Purpose (SPSP)	-	Spatial Plan of the Unit of Local Administration, General Regulation Plan (PGR) and	Urban/technical conditions and Construction Permit and Use permit

Table 6 - Planning instruments responsible of allocation development rights and procedures

4 MAIN FINDINGS

This section will aim to highlight some of the main findings which were derived from previous analysis on the characteristics of the administrative subdivision and spatial planning instruments in WBR countries. It can be argued that a particular nature of spatial planning systems in the WBR countries is reflected through a variety of administrative levels and bodies which hold responsibilities in relation to spatial planning practice, as well as a number of planning instruments for the implementation of development goals. Nevertheless, this particular nature of planning systems seems to be influenced by both path dependency as well as adjustment to market economy. These affect the specific pace of changes and challenges on the spatial planning agenda of WBR countries.

The territorial administration system is different from one country to another, where KO, FYROM and MNE have two levels of administration - the central (national) level, and the local level (municipalities and cities). On the other hand, countries such as AL, BiH and SRB have additional regional level of planning. This particular administrative subdivision of the WBR countries can be related to the path dependent nature of each system. On the other hand, if looking at the institutional setting in all of the WBR countries, it is important to note a tendency for (de)centralization of spatial planning by abolishing the role of public planning enterprises and assigning spatial planning activity solely under the jurisdiction of local administration. These public planning enterprises date since the socialist era and served to satisfy the criterion of decentralization of planning activity, where each municipality in Yugoslavia had its own institute (larger cities) or directorate (municipalities). Today AL, KO and BiH do not fully recognize such planning institutions, while in other countries of the WBR there is a strong tendency for their abolishment as well.

When it comes to the system of plans, WBR countries apply a variety of planning instruments at each level. It is common for all counties that they follow a hierarchy of plans, where national, regional and some local plans have a strategic rather than a strong regulatory dimension. Nevertheless, spatial planning in WBR countries is often characterized as 'zoning' within international terminology, and due to their spatial, besides strategic elements (maps). Hence, although national planning instruments do not have a strong regulatory nature, an exception from this practice are plans for the area of special purpose which are prepared for the areas of national interest of the country and contain land-use, norms and standards for development.

Differently from the national level, only AL, BiH and SRB contain planning instruments at regional level. These spatial plans still have more strategic and less regulatory character and serve for coordination of balanced territorial development. While regional spatial plans in AL aim at enhancing vertical coordination within the various sectors, SRB produces Regional Spatial Plans for the NUTS-2 regions (4.1) at national level, with the exception of the province of Vojvodina which has its own regional spatial plan. It should be highlighted that the highest level of planning in BiH is the meso level of the Entities FBiH and RS, as well as of the FBiH cantons, where plans for both Entities have similar characteristics.

While national and meso level plans are usually described as spatial and more strategic in their nature, local plans in most WBR countries are characterized as urban/regulatory plans which provide substantive guidance, define norms and standards for spatial development. These plans are legally defined as spatial (BiH, MNE and SRB) and general/detailed urban plans (all WBR countries) and are developed for cities and/or municipalities. Hence, urban planning is considered to be the key instrument of land-use planning at local level, and it serves to satisfy the decentralization criterion of urban planning practice which dates back to the socialist era.

Comparing each planning system in terms of allocation development rights, it is interesting to note that in each country the development rights are issued in coherence to plans provision both at the central (or entity level) and the local level. Here there are two observations to underline, the fact that all systems are

similarly framed in terms of allocation development rights, and, that not only local plans may allocate the right to develop. Across all cases, local urban plans are considered as the ones that provide sufficient data on the possibilities and constraints for development, and as such can allow for allocation of construction permits. Nevertheless, all of the countries in this research show that plans at the central and entities level are also able to allocate development rights within specific site and condition. Secondly, in some cases even planning documentation which is not part of the formal planning system can serve for allocation of construction permits.

This kind of practice points out at 'dual nature' of national level planning instruments which contain regulatory as well as strategic elements. Moreover, it points out at potential (re)centralization of planning systems, where national planning instruments can bypass the local, regulatory ones. On the other hand, the fact that at least three different planning documents in each WBR country can allocate development rights, point out at the tendency for acceleration of planning process in line with the requirements of market economy which may cause ambiguities in coherent implementation of plans.

5 CONCLUSION

Due to their complex past, fragmentation and geopolitical instability, the WBR countries have been excluded from the majority of studies on spatial planning and territorial governance. Hence, this paper represents a step towards overcoming such analytical gap, and through collection of evidence that may support the EU in developing a more sound and effective cohesion policy. The main aim of this paper is to sketch out and compare the evolution of territorial governance and spatial planning in the Western Balkan Region. More specifically, it analysed geographical and socio-economic tendencies, administrative and legal framework, as well as spatial planning instruments in the countries of the WBR.

Based on the evidence presented in this research, it can be argued that spatial planning systems of the WBR are complex systems with path dependent nature in relation to socialist/communist era and later transitional stages, but also face a variety of challenges in adjustment to the requirements of market economy and EU perspective. In that light, contribution of such comparative analysis is to highlight similarities and differences between the development processes of the WBR countries, explore their development path and hence provide basis tackling future challenges.

ID 1746 | SYDNEY IS NOT AUSTRALIA: WHAT CAN AUSTRALIAN TRANSPORTATION PLANNING POLICY MAKERS LEARN FROM THE EUROPEAN DIMENSION OF PLANNING?

Timothy Donnet¹; Tim Ryley²

¹ QUT Business School, Australia; ² Griffith University, Australia.

timothy.donnet@qut.edu.au ; t.ryley@griffith.edu.au

ABSTRACT: There is much that Australian policy-makers could (and should) learn from their European cousins. Vettoretto (2009) identifies “good governance” as one of the central strengths of Europe’s planning and policy-making practice, noting that policy-making should support, among other things, regulation through sense-making, strategic representation and advocacy. These tenets make the European approach to planning attractive to communities that feel isolated or left out of broader strategies for economic development that inform transportation planning. However, the transfer of European planning concepts to the Australian context, particularly for transportation, faces an uphill battle (as per Pojani & Stead, 2015). Australia’s major transportation planning agendas appear more interested on increasing mobility and urban densities in capital cities at the expense of improving regional community sustainability and connectivity. This has the effect of making busy transport systems busier, and promotes a classist system for promoting economic growth – not just between cities and regional areas, but between biggest city and next biggest cities, and so on. The density of international flights to Sydney and Melbourne make it commonplace, and often a pragmatic requirement, for residents who live anywhere other than the South East of the Australian continent to fly first to one of these two cities to access connecting international flights. This is the equivalent of having to fly from New York to Miami to fly to Lisbon, or from Lisbon to Istanbul to fly to South Africa. The inconvenience of having to fly South to fly North (intercontinentally) is only exacerbated for regional communities that first have to fly to a capital city, then on to Sydney or Melbourne, then on to their international destination. This makes international mobility the most inaccessible for the communities already provided with the least infrastructure, and struggling to maintain

sustainable communities due to the attraction of the populace away from regional agricultural communities and into the coastal cities. Furthermore, this inequity in accessibility works against the Australian Government's aspirations for promoting new (migrating) Australians to settle in regional areas. To provide strategic representation and advocacy for regional communities, Australia's transportation planning, and the planning and governance of its aviation network, can and should learn from a more balanced, more European dimension of planning. By reviewing the current state of the country's aviation network (airports, tourism assets, passenger routes, supporting infrastructure and supporting governance mechanisms), the authors have identified the policy-making opportunities for the Australian State of Queensland to learn from European planning approaches. By taking the European perspective of developing regulation through sense-making, this research identifies a range of aviation network design and regulation principles that promote the interests of regional mobility and inclusion, sustainable communities, and advocating equitable access to international transport and economic growth opportunities for the State of Queensland.

1 INTRODUCTION

It is a fascinating concept that for a country the size of Europe, flying from Australia's third largest city to the AESOP 2017 conference requires the presenting author to fly 733km south from Brisbane to the nation's busiest hub of Sydney, to then fly 18166km to the northeast to Lisbon (particularly when the route is 17930km if flown from Brisbane). Much of Australia's aviation growth has centered on Sydney, as both the country's primary financial hub and internationally marketed tourist destination. Sydney-centered aviation growth has been supported by Federal government initiatives to boost tourism to Australia, and a succession of Federal grants to boost the capacity of Sydney Airport via the development of the airport's third runway in the early 1990's. Much of Sydney Airport's airside expansion has taken place during a previous era of government, when major airports were still owned and operated by the Federal government, prior to the privatization of most of Australia's major airports in the late 1990's and early 2000's under the Airports Act 1996. The Federally funded infrastructure and international tourism initiatives has, in effect, created a self-fulfilling prophecy that favours international airline routes to Sydney over others. Other major airports around the country have successfully attracted and developed international routes over time, but the legacy of Sydney as the primary entry point for the country continues to act as a thorn in other states, particularly for regional and remote communities trying to access international air travel in an "as convenient as practical" way.

For those unfamiliar with the geography of Australia, Sydney sits at the southeast of the country in the state of New South Wales. While Sydney is the most well-known of Australia's cities, it is not the nation's capital (which is Canberra, 250km southwest of Sydney in the Australian Capital Territory). As an example of just how great an importance is placed on Sydney for representing other parts of Australia to an international audience, when the countdown to the 2018 Commonwealth Games was formally announced to the world stage by the event organisers, the announcement was made in Sydney, 680km south of the venue which is to be held at Queensland's Gold Coast. The Queensland state capital of Brisbane (>\$100 billion metropolitan economy, as per Clark, 2015), which is less than 70km from the Gold Coast, wasn't deemed a sufficient platform for announcing the news – it would appear that if news doesn't come from Sydney, it doesn't come from Australia.

This insight might seem overly harsh or too direct at first glance (and may indeed be a jaded view from a Queensland author), but it's important to note that the example above is an artefact of how Australian organisations see the branding of Australia as being firmly centred on the identity of Sydney. It is not too large a jump of imagination to expect that other nations around the world perceive Australia's identity as being that displayed by the Sydney image. Unsurprisingly, if passengers (and by extension, airlines) consider travelling to Australia, Sydney is the logical default port of entry. However, with aircraft movements capped for Sydney airport, and a strict curfew in place to limit the impact of aircraft noise on Sydney's residents, the ability of Sydney to serve as the central hub to Australia's domestic and international aviation network has an expiry date.

Melbourne, which sits at the south-east corner of Australia's mainland in the state of Victoria, 713km south of Sydney, hosts the country's second busiest international airport. The Victorian government has been developing an international and domestic branding strategy that aligns the promotion of the region's tourist attractions to Melbourne's primary port of entry – Tullamarine Airport – as a means of competing with Sydney's ability to attract and retain key international and intercontinental air routes. This strategy has had

its successes, with growth in international air movements outstripping Australia's other largest international airports, including Sydney. The outcomes of supernormal international air movement growth in Melbourne, coupled with the legacy of international air movements coupled to Sydney, has created a veritable gravitational pull of domestic travel to the south east of the country to access international, and especially intercontinental, air routes.

The development of a second airport for the Sydney area, Badgery's Creek Airport, has been announced but will likely take a decade to be built and become fully operational. This interim period, as Sydney Airport gets closer to its operational limits and before the new Badgery's Creek Airport comes online, presents an opportunity for rethinking the structural design of Australia's aviation network for connecting domestic and international routes to the country's population and tourist destinations. Reframed, there is an opportunity to leverage the impact of aviation network design to support a fundamental change in the ways in which the world perceives and accesses Australia, and shift the focus of Australia's international brand from the current Sydney-centric (and increasingly south east-centric) narrative to a richer picture of the country's culture and regional diversity. This paper critiques Australia's existing governance mechanisms for influencing aviation network design against some of the tenets of European approaches to planning. This allows the identification, exploration and advocating of some of the structural design features that would allow Australia's aviation network to support current Federal and State government agendas for regional mobility and inclusion, sustainable communities, and migrant employment, while also making a clear statement that Sydney is only a small part of a much bigger Australian tapestry, and so should be treated as such in policy interventions and national marketing agendas.

2 THE STRUCTURE OF AUSTRALIA'S AVIATION NETWORK

Europe is orders of magnitude greater in population size and density, when compared with Australia, and entertains an array of intercontinental connecting airports (Amsterdam, Paris, Frankfurt, Munich, Istanbul, Barcelona, Madrid, Rome, Zurich, Lisbon, etc.) to connect the diverse regions of Europe to the world. Domestic travel within Europe is supported by well-developed rail networks, and longer intra-European travel is made simple and cost effective by the abundance of major and regional airports serviced by a highly competitive market of airlines. This makes travel from one region within Europe to another relatively convenient and cost effective, and travel from one region within Europe to another continent quite direct.

In a similar way to Europe's diverse regionality and attractions, Australia hosts an enviable list of tourist destinations and regions that range from the urban shopping drawcard of Melbourne and the vineyards of the Barossa Valley in the south to the natural wonder of the Great Barrier Reef in the north, from the glistening shores of Surfers Paradise to the east to the more exclusive red dusty center of Uluru, and onwards to the horizontal waterfalls adjoining the Kimberley Ranges in the west. Australia has a diversity of destinations that attract international and domestic visitors en masse, yet as a country almost 4000km square, travel from one region to the next is almost exclusively by air – the difficulties in travelling between Australia's population centers is often referred to as the tyranny of distance (Dhakal, Mahmood, Wiewiora, Brown and Keast, 2015). Travelling from one region to the next, domestically, is therefore largely subject to the routes offered by airlines (of which there are few). The sparse population density of regional centers away from the coastline also means that the routes that do exist, often require government assistance to remain profitable enough for airlines to continue servicing them. Given the distances between population centers and the country's population density is not going to change any time soon, it would be logical to assume that a government agency considering the long-term economic and community development for the country would make attempts to improve the accessibility of regional and remote communities.

Australia has 138 airports (BITRE, 2009) that service the nation's capitals and regional centers, however there are far more small airports scattered throughout rural and remote areas that serve as important access points for mining operations and otherwise difficult to access communities. For example, there are 141 airports servicing remote and rural communities in the state of Queensland alone (compared to 40 airports servicing the state's capital and regional centers) yet these account, collectively, for less than 10.4% of the state's passenger volume (Donnet, Ryley, Lohmann & Spasojevic, 2017). Australia's domestic aviation network currently (as at March 2017) carries 59 million passengers per year with annual growth at 1.6% (BITRE, 2017a). This compares to the country's international connections at 37.94 million passengers with annual growth at 1.7% (BITRE, 2017b). While growth for the national's aviation network

appears, at face value, to be reasonable, the data tells a different story for Australia's rural and remote communities.

Donnet and Baker (2012) discussed the stress faced by rural and remote communities with respect to declining access to aviation services. Data for regional passenger and aircraft movements is currently only available for the period up to 2012 on the Australian Department of Infrastructure and Regional Development's publicly available database (BITRE, 2017c) as the government stopped tracking regional volumes compared to national totals, so remains a relevant point of reference for this discussion. Within the BITRE (2017c) data, it is apparent that while domestic airlines were able to increase movements to major airports by 59% from 2000 to 2012 (an increase of 293422 aircraft movements) and international aircraft movements increased by 49% (an increase of 55244 aircraft movements), regional airline movements decreased by 34% in the same period (a decrease of 242870 aircraft movements). This decline versus growth demonstrates there has been a considerable shift towards centralising aviation growth to Australia's capital cities. When comparing more recent international aircraft movements between the three busiest airports in the country (see Figure 1 below), it becomes apparent that Sydney's ability to continue attracting the lion's share of new routes has dissipated in recent years as it gets closer to its operational capacity, yet calls from government reviews state that "Sydney Airport will continue to be the most important airport for the Sydney region and for Australia, both for passengers and freight" (Mrdak, Haddad, Wielinga, Smith, Westacott, Mundy and Brown, 2012, p. 6). The recent announcement for approving Sydney's second major airport, Badgery's Creek, reaffirms the Sydney-centric approach to air transport in Australia, which appears at odds with Federal government initiatives calling for improved employment and economic growth in rural and regional areas of the country, which by definition, require improved access to air transport to make sustainable.

Figure 1 – Evidence of Sydney's decline in attracting new international routes.

Federal government regional economic growth initiatives are limited to a \$220 million Regional Jobs and Investment Package (RJIP) program, which provide support funding for businesses that adhere to assessment criteria, defined in a Local Investment Plan tailored to each individual region (business.gov.au, 2017). The approach taken by the government to stimulate regional growth appears an attempt to drive business creation and job demand in regional areas, in the hope that increased business attraction will lead to more diverse and sustainable revenue streams for regional communities. However, this approach places the cart before the horse; concessions supporting employment only attend to one aspect of business – availability of labor. Businesses require sufficient economic infrastructure (including accessibility) to develop a coherent and sustainable business strategy, and without access to adequate air transport, the available funding may only have a short-term impact on regional economies. That is, an integrated approach that places fundamental economic infrastructure development first, in regional Australia's case air-transport accessibility, is far more logical an approach for the long-term development and sustainability of regional economies and their communities. To do this, placing investment in a more distributed air transport network makes sense at a time that the country's incumbent international hub is reaching capacity.

2.1 QUEENSLAND: A MORE DISTRIBUTED AVIATION NETWORK

Looking within the Australian aviation network for a fractal that may provide learnings for a national approach to aviation network design, Queensland presents interesting network architecture. Queensland has two major population centers on its coastline, often referred to as South East Queensland, which includes the state's capital, Brisbane, and the beach tourist focused Gold Coast; and North Queensland, which includes the military and mining focused Townsville and the gateway to the Great Barrier Reef, Cairns. Each of the cities mentioned above have international airports, with the vast distances to travel from one end of the state to the other requiring two hubs (Brisbane in the south and Cairns in the north) within the state's domestic aviation network. For reference, the state of Queensland is seven times the size of Great Britain, so airline routes must span considerable distances between the state's population centers. The Queensland aviation network is illustrated in Figure 2, and demonstrates the practicalities of linking regional destinations (i.e. Weipa, Mount Isa, and Horn Island) to the north via Cairns and Townsville.

The practicalities of having a more local hub for North Queensland's regional communities makes sense, as it is inefficient to pour government funding into long concrete or bitumen runways for communities that could not sustain passenger volumes required for cost effective operation of aircraft capable of flying from Brisbane or even further interstate. Smaller communities with smaller runways create a physical hurdle for airline operations, where small aircraft can only travel shorter distances. While this appears common sense, the difficulty in expanding this network design and operating reality to the context of the Australian continent is for providing equitable access for regional communities to international transport. For example, in New South Wales, regional communities are often serviced by smaller aircraft operating on a "mail-run" route, which appears on a map as a single spoke extending from Sydney with multiple stops in regional areas before returning to Sydney. This creates a lengthy transit for passengers in the more remote areas of the state wishing to access international services from Sydney.

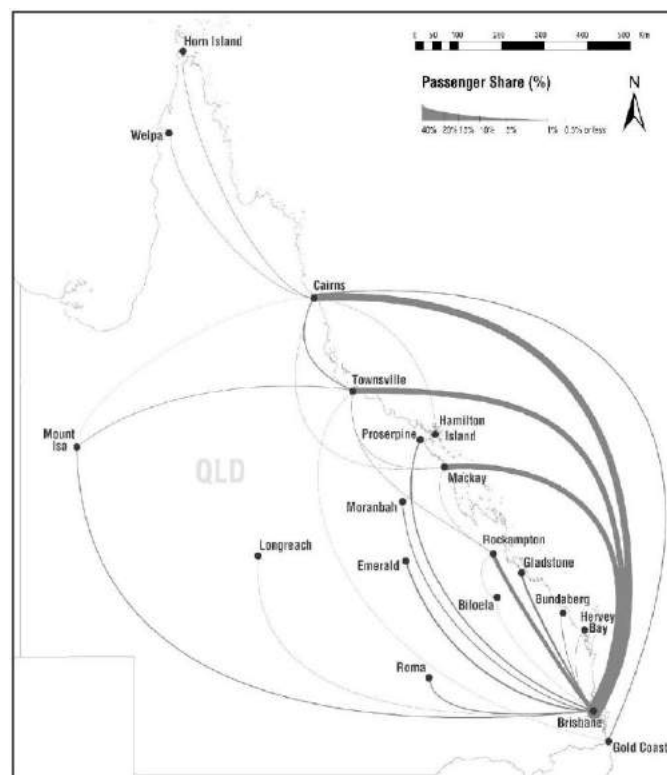

Figure 2 – Intrastate aviation routes for Queensland (from Donnet et al., 2017, p.6)

Figures 2 and 3 (sourced from Donnet et al., 2017, pp.8-9) provide insight to the nature of Queensland's aviation network connectivity to the rest of Australia, as well as to the world, respectively.

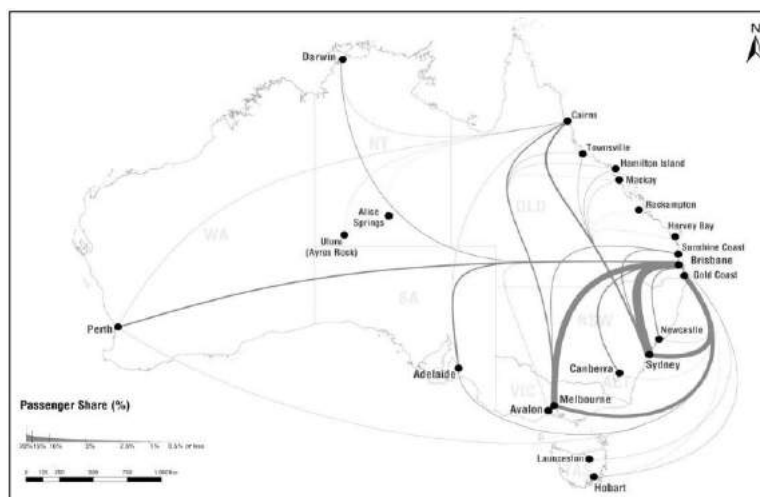

Figure 3 – Interstate routes between Queensland and other Australian states

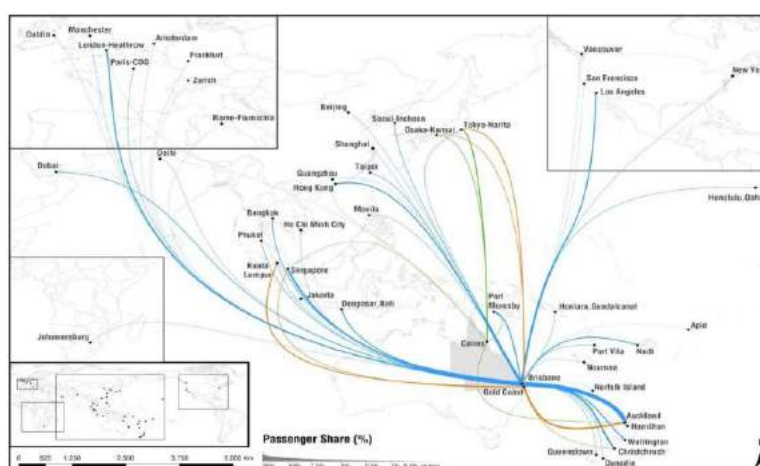

Figure 4 – International routes connecting Queensland to the world

The diseconomy of time and convenience is particularly relevant for regional communities that are often framed by lower socio-economic statistics and, with the support of current migration agendas supported by migrant peak bodies and the Federal government (see FECCA, 2015), become increasingly populated by residents with relatives overseas. Having a state or national aviation network that requires regional residents to commute hundreds, even thousands of kilometers south, only to hop on an international flight to the north, imposes additional costs and environmental burden to those already underprivileged by an imbalance in employment opportunities and economic infrastructure. In sum, there has to be a better way.

3 WHAT CAN AUSTRALIAN TRANSPORT POLICY MAKERS LEARN FROM EXAMPLES FROM EUROPE?

In comparison to Australia, Europe is advantaged by higher population densities and mature regional economies that deliver goods and services domestically and abroad, and destinations for international and intercontinental tourist travel. This has not been an accident, and is the product of each individual nation's long-term vision for meeting internal job and productivity demands as well as investing in fundamental infrastructures that support economic growth. As Vettoretto (2009) aptly states, good governance is a central strength to planning and policy-making practice in Europe, with a keen focus to robust decisions for investment and infrastructure development that are designed to work in the long-term against many variable scenarios. A technical report by Appold et al. (2008) identified an array of different governance structures used by jurisdictions around Europe (including Estonia, Spain, Germany, and Finland) that, at their core, demonstrate a robust focus towards progressing regional and national economic growth (i.e.

arbitration processes for airport development in Germany) while at the same time appreciating local contexts (i.e. tailoring airport expansion to protect local public values in Spain). Governance mechanisms that champion public engagement, be it by arbitration or by up-front negotiation, allow for greater buy-in by stakeholders but more importantly allow policy makers to critique the very nature of the vehicle of value creation (i.e. building a new airport) in the first place (as per Healey, et al., 2003).

In Australia, the more deliberative planning process is an element of policy-making that underdeveloped, and the political will to look towards the long term has been sorely missing in more recent times. Having had six different Prime Ministers since 2000, and what is essentially a two-party government system (by definition, Government and Opposition), policy making in Australia is often highly politicised, which means decisions for significant investment in regional infrastructure or changes to existing economic systems is typically met with fierce opposition in press and in Parliament (as discussed by Wegrich, Hammerschmid and Kostka, 2017). A decision to invest in one sector by the government of the time can easily be overturned or withdrawn in the following three-year term of government, which undermines the long-term vision and ongoing support required for nation building exercises – such as transitioning a transport network from one system of network structure to another. Creating an appetite for long-term agendas that are developed through a more deliberative consensus approach (i.e. similar to the slow but robust approach utilized in the Netherlands) presents an opportunity for critically rethinking some of the fundamental design principles that underpin the structure of Australia's current aviation network. For example, Australia's policies and initiatives place emphasis on market forces to meet demands as a means of ensuring efficient use of government funds. That is, the Australian government has shrunk its direct involvement in the provision of air transport to Australia through its privatisation of major airports and divestment from the national air carrier, Qantas. In doing so, the government attempts to steer businesses at arm's length through tax (dis)incentives and concessions for providing air services for regional communities, trusting that the market will provide services when revenue is available. However, as economically rational organisations, airlines provide lean services for regional communities, which does little for the attractiveness of regional communities to those outside of them.

Looking at past planning interventions in Europe for stimulating regional growth, fiscal strategies for decentralising economies have drawn criticisms for sub-national governments taxing businesses in ways that diminish their effectiveness in generating a positive economic impact (Thornton, 2007). However, Crescenzi and Rodriguez-Pose (2011) introduce the notion that successful regional growth is stimulated via innovation, rather than subsidising for increased density of existing industries, which requires investment in social infrastructures alongside economic infrastructure. This aligns with more seminal insights posed by Scott (1998) for flexible production systems in Western Europe that leveraged urban and rural assets and labor to improve value creation and stimulate regional development. From this European perspective, treating rural and regional areas as integrated parts of a broader value chain for the production of value traditionally nested in more metropolitan areas in presents an important opportunity for rethinking how the government approaches economic development initiatives for regional Australia.

Rather than aiming to improve economic development through financial support to businesses in a particular region, placing a focus on joining up businesses that are vertically linked within a supply chain (from city to rural/remote region) presents a far more attractive approach that explicitly places value in the role of regional Australia contributing to the broader economic performance of the country. That is, in advancing the major population centers the remainder of the country is not left behind in investment or in cultural spirit.

4 CONCLUSION

This paper set out to drive critical discussion for how to rethink Australia's aviation network structure to improve outcomes for regional and remote communities, and identify the inequities in current air transport routes connecting Australia's non-Sydney communities with the rest of the world. Current approaches by the Australian government that try to create self-sustaining regional communities may be enhanced by appreciating some of the more hands-on strategies that characterise trends of European spatial governance, and not leaving economic development to market forces alone. By shifting focus from self-sufficient (but still isolated) communities to more integrated, connected communities with direct economic ties to their value-chain-affiliated coastal economic centers, a more equitable platform for supporting and including regional Australia into economic and social growth can be founded. To do this, we propose that

rethinking, and more importantly championing (via policy as opposed to concessions), a formal network approach for Australia's domestic and international networks is required as a starting point for change. This is particularly relevant as the tyranny of distance remains a continual thorn in Australia's regional mobility, access to services, and business growth. This task is a formidable political minefield that could only eventuate from bipartisan support across all levels of government – the very European tenet of democracy via consensus is required for success. But at its core, the task is to answer a very straightforward question: How could Australia best organise its aviation network to deliver efficient, equitable air transport for its communities? The challenge has been set, and we look forward to hearing the debate that ensues from this beginning of a much larger discussion.

1 INTRODUCTION

In metropolitan regions, municipal borders and other administrative boundaries have long since been transcended by spatial patterns of interaction and land use. In the emergence of spatial patterns, multiple spatial scales intertwine – from the neighbourhood up to the functional region and beyond. Governments and their administrations often experience statutory limitations when trying to address these developments. Their territories are fragments of regions; they have difficulties detecting problems that are caused by factors outside of their spheres of influence and feel that addressing them is beyond their competence and political mandate. Planning instruments available to them, along with specific rules and regulations, are often too generic, rigid and defensive to address the specific development potentialities that are the product of intertwined issues and scales. Simultaneously, analytical information about regional spatial development is increasing, thanks to new technologies that can handle (big) data. More information and knowledge on what is going on beyond the horizon of a single city is not unproblematic, though. There is little experience about how to transform the insights and activities of single individuals and organizations into collective knowledge and action on a regional scale.

In response to these deficiencies of statutory planning, politicians, planning authorities and also civil and private organizations in numerous European regions are participating in informal, network typed governance arrangements, in order to coordinate sector issues and issues that play at different levels of scale (see for instance Allmendinger et alia, 2015). They seek, for instance, to integrate economic, transport and housing development, and water management stretching across multiple and multi scalar boundaries. Being voluntary associations with few formal planning instruments available to them, the resulting partnerships collaboratively engage in jointly creating inspiring and encouraging spatial agendas with the help of regional design.

Design is a creative practice, orientated towards finding solutions to problems in the built (and unbuilt) environment. It is a 'conversation with the situation' (Schön, 1983), driven by normative, desirable futures, and also by a wish to understand the 'holistic' wholes of a region and dependencies among its parts. The use of such creative and comprehensive design led approaches in planning often raises high expectations, usually associated with the intense use of spatial representation such as maps, models, and other geographic imagery (see for instance Thierstein & Förster, 2008). Such representations are expected to 'explain' the region: to increase understanding of interdependencies across scales and issues, and to focus attention on the places and locations that are affected. They are also expected to be persuasive as visualised 'storytelling about the future' (Throgmorton, 2003); they provoke thoughts and feelings, and therefore function as a kind of invitation to individuals and organizations to get involved in regional politics and planning. In the context of interactive design processes, visualizations and spatial representations are seen to be platforms or dialogues, malleable collections of spatial information that expose conflict, facilitate learning, and mediate in the context of complex governance settings. However, despite an increase of use

and high expectation, there is little understanding of how design performs in planning: what are the interrelations between design and planning in this relatively unexplored field?

This paper investigates aspects of design practice: the performances of regional design in collaborative planning decision making based on a comparative case study research. The 'evidence' comes from a joint conference of Munich University of Technology and Delft University of Technology¹. This was an occasion to compare regional design strategies that are used in different European regions, to discuss the different facets and dimensions of these practices and to assess their performance. On the occasion of this conference an analytical framework was developed to distinguish settings, practices and performances of design led approaches. The framework is applied to three case studies. The results in our view give insights into aspects of institutional settings and design strategies and processes that have influenced performances of design practice. A main aim of this paper is to present results from analysis. It identifies aspects of regional settings, performances, design strategies and processes that have influenced design led approaches in these areas decisively. This is about the identification of lessons on how design contributes to planning and governance capacity in a multiactor setting of regions which do not have a clear match with administrative boundaries. The second objective is methodological: how to analyse practice from a theory based methodology?

The paper is structured as follows. The next section introduces an analytical framework to identify interrelated aspects of design practice. The section thereafter briefly present the three regions on which we base our analysis. The next main section of the paper presents results from the actual analysis. The final concluding section reviews implications of the results for further research.

2 THEORETICAL FRAMEWORK

Few scholarly writings are dedicated to regional design and many of these build upon the seminal work of a small number of authors from the fields of architecture and urban design (Hillier & Leaman, 1974; Rittel 1987; Schön, 1983; Schön, 1988). These authors describe design as a reflective and argumentative practice, oriented towards the improvement of the built environment. Design has a holistic orientation also. It is an attempt at a comprehensive understanding of spatial development, a search for integral solutions that consider dependencies among parts. Since the built environment is a complex system, the act of designing is unlikely to evolve in a linear manner from problem definition to solution. It is more likely to be explorative, evolving during multiple synthesis evaluation iterations and steps in which problems and solutions are explicated, comprehended, reflected upon and adapted².

Writing on the use of design led approaches indicate that there are strong interrelations among planning decision making and design (Balz, forthcoming; Van Dijk, 2011; De Jonge, 2009; Balz & Zonneveld, 2015). A basic foundation of interrelations between design and planning is their common interest in plan-making, usually (not always) resulting in planning imagery. In the realm of design such imagery serves reflection and processes of abstraction as well as detailing. In the realm of planning: the use of imagery serves communicative ends and also has broader agency. In this realm imagery turns into spatial representation through which plan actors intentionally generating meaning by drawing on repertoires of existing symbols for the purpose of politics and planning³. Using notions from design theory (the iterative circles) and planning theory (planning cycles) a distinction can be made between (1) the setting as the specific planning context any design endeavour is embedded in, (2) the impact (performance) of design on decision making processes and (3) the characteristics of the design strategy and process. In this view: continuous rounds

The setting has been briefly touched upon in the introductory section: regional design takes place in a setting where a whole range of boundaries are becoming less distinct. 'Fuzziness' is probably an appropriate term here: It can be connected to spatial boundaries, but also boundaries between actors and

¹ This conference was entitled 'Shaping regional futures Mapping, designing, transforming!' and took place in October 2015. See: https://www.events.tum.de/frontend/index.php?folder_id=165. A follow-up conference took place in May 2017 at the University of Florence. See: http://www.dida.unifi.it/upload/sub/pdf/eventi/shaping-regional-futures/shaping-regional-futures_programme.pdf. Both links accessed June 2017.

² This section is based on: Balz (forthcoming).

³ A systemic view on these interrelations, has been developed by Schönwandt and Grunau, 2003.

different kinds of knowledge. Spatially, it is virtually impossible to demarcate 'the' region. Places have multiple characteristics and are connected in many different ways, leading to complex, multi scalar interrelations. Governance involves the continuous identification of planning problems and search for solutions, resulting in temporary and shifting relationships between public and private actors, political agendas, and territorial interests. What constitutes valid knowledge in such context is not self evident or even contested. Important questions are: do settings influence regional design? Can we identify aspects of regional design settings that are more decisive than others?

Performance in the context of this paper can be defined as the impact that design has on decision-making. If indeed regional design is about planning change and creating institutional capacity, what does this entail? Does it relate to a shared framing of territories; the formation of actor networks; the bringing together of different types of knowledge; the operationalization of planning in trajectories of concrete spatial transformation; or is it all of the above? Can we develop criteria to assess the transformative power of regional design? Where, why, and when does the impact of regional design depart from the impact of (formal) planning?

Also in relation to strategy and process the often highly complex spatial and institutional environment at regional level is of overriding importance as issues and actors are strongly interconnected. As a consequence, regional design evolves in a context of multiple and interrelated choices. It is about preparing and making such choices: During design processes, planning solutions emerge. But how to select relevant sub-spaces, activities, themes, and projects? Are there specific methods that are more apt than others? How to apply such methods in complex multi actor and multi scalar settings? How to bring the different language domains – verbal, visual, emotional – of regional design together?

3 THE THREE METROPOLITAN REGIONS

The above analytical framework and questions have been developed for the 2015 conference 'Shaping Regional Futures' in Munich (for more information see Förster et al., 2016). During the conference these were used for an analysis of regional design practices in three European regions. Representatives of three regions did receive the questions beforehand. In the next three paragraphs we give an impression of their responses.

For the Amsterdam Metropolitan Region (the Dutch acronym is MRA¹) the invited practitioners (one former senior planner from the Amsterdam municipality working for the MRA while the second one represented a major player in the region) reflected on how several regional design initiatives have influenced the formation of a vision of the so called Amsterdam Metropolitan Region. The city of Amsterdam with its 820,000 inhabitants (2015 figure) is surrounded by several small and medium sized cities and towns. Greater Amsterdam has 1.5 million inhabitants. The Amsterdam region is part of the Randstad Holland, the western and economically most vital part of the Netherlands. Spatial development of the Amsterdam region is the policy objective of several authorities and partnerships, each with its own vision of the future of the area, the MRA partnership among them. MRA is an informal co operation among 33 municipalities, two provinces, and one city region in the area. Its aim is to foster economic development and accessibility. It is rather common for sub national governments and coalitions among them to use regional design in the Netherlands. It is expected that design led approaches help to identify guiding principles for planning and also to clarify relations among governments.

The three representative from Zürich (two from administration and one from a consultancy) contemplated the making and use of the Metrobild Zürich². The Zürich Metropolitan Area is Switzerland's leading economic region with 2,3 million inhabitants and 500 municipalities in 8 cantons. The region boasts a high quality of life, significant spatial diversity in a relatively small area, and a strong position as an international economic hub. Major challenges are its dynamic growth, social disparity, strain on environment and resources, and cooperation and competition among municipalities and cantons. In 2010, the Zürich Metropolitan Area started the Metrobild process to visualise the area from the perspective of three different

2 See the (German language) website: <http://www.metropolitanraumzuerich.ch/themen/lebensraum/metrobild.html> (accessed June 2017).

design teams. The goal was to create a common understanding of the functionalities, qualities, and potentialities of the Zürich Metropolitan Area.

The Ruhr Region is a region with a long albeit complex history of cooperation. The present cooperation is known – in English – as Ruhr Regional Association¹. Two representatives – one from academia and one from the Association – reflected on the Ideenwettbewerb Zukunft Metropole Ruhr (an English proxy is Ideas Competition)². With 53 communities and 5.2 mio inhabitants in an area of 4,435 km², the Ruhr region is the 5th largest conurbation in Europe. The very polycentric region has been experiencing ongoing structural change since the 1960s, and managing decline and conversion will continue to form a major challenge in the coming decades. The Ruhr Regional Association is a municipally founded association, which has had its own legislative and regional planning powers since 2009. In order to create a statutory regional plan for the whole area, the association started a regional dialogue in 2011 – including an international (ideas) design competition which was seen as a new planning approach. Expectations were high: inspiring views from outside, outlines for new directions, enabling participation, creating transparency and openness, and initiate discussion and dialogue.

4 EMPIRICAL ANALYSIS

4.1 SETTING

The parallel workshops on the cases Amsterdam, the Ruhr, and Zürich raised a number of critical issues concerning the regional design setting. Probably the prime one can be phrased as: Fragmentation and fuzzy boundaries everywhere! The experts from all three case studies stressed the administrative fragmentation of their region, and the multiple overlapping sets of boundaries and 'regionalisations'. First seen as an anomaly and barrier, this condition turned out to be the 'normal' context within which regional design operates, i.e., a context of ambiguity. Institutional fragmentation and fuzzy spatial boundaries are a structural characteristic of the setting within which regional design evolves.

Cultures and traditions in cooperation and consensus finding matter a lot. Within a fragmented governance landscape, and against a background of multiple perceptions of what a region is and constitutes, regional actors and organisations nonetheless showed a capacity for joint discussion and consensus finding, albeit in various degrees. This capacity was associated with differing characteristics of the institutional context within which regional design initiatives evolve. The policy culture in the Zürich case is strongly influenced by the general, Swiss tradition of direct democracy and a culture of finding consensus and agreement, stretching out to intellectual discourse as well. In the Ruhr case, the 'Regionalverband Ruhr' is the umbrella organization of a spatially highly complex region. In spite of a long tradition of political struggles between individual cities, there is now a regional association – established in 2009 equipped with legislative and regional planning power – the result of structural change since the 1960s and continuing attempts to manage decline and conversions since then, for instance, through the International Exhibition (IBA: Internationale Bauausstellung) Emscher Park.

Compared with the Ruhr Area the Amsterdam Metropolitan Region is a relatively small region. With the informal co operation among 33 (number at the time of writing; 32 at the time of the conference) municipalities, two provinces, and one city region, over the course of ten to fifteen years it has become a rather intimate club – a dense social network of actors who are all familiar with each other. They started to gather to respond to what was felt as institutional fragmentation.

Looking at these three case studies, regional design takes different forms and organizational settings, and also effects and impacts vary greatly. Important incentives for regional design are making funds available for the design as such and the presences of mechanisms to connect and embedding in formal planning. Cultures and traditions in decision making matter for regional co operation but are not sufficient to stitch a region together. There is a need for additional incentives and benefits for regional cooperation and design, which together can be labelled as formal planning conditions. In the Amsterdam case, the prospect of external money from central government unified actors and has become a major incentive for regional

¹ See: <http://www.metropoleruhr.de/en/home/the-ruhr-regional-association.html> (accessed June 2017).

design initiatives exploring the future. The Dutch state maintains control over the largest part (over 95% of all taxes) of tax revenues. The planning system requires effective regional governance arrangements to claim financial support by means of argumentation. In the Ruhr region, the regional design competition 'Future of the Metropolis Ruhr' was the prelude to the revision of the formal regional plan. The ambitious regional design endeavour was also associated with the urgency of addressing economic structural change, and the need to take politically binding planning decisions which require sound argumentation.

In Switzerland, central government provides funding for its 'agglomeration programs', and the second tier level of the cantons has to provide matching funds. The Metrobild Zürich project was financed by the various cantons and municipalities which together form the 'Metropolitankonferenz Zürich' – the Zürich metropolitan association. The Metrobild initiative was meant to provide a common ground for developing a subsequent 'strategic spatial concept', which was eventually approved in November 2015.

In all cases, former experience with urban and regional design matters greatly. Such experience is an important resource for the regional design practices. The regional design endeavour in the Ruhr region built upon experiences in the 'IBA Emscher Park'. This was the first international building exhibition in Germany with a deliberate and distinct regional focus, which took place over an entire decade, from 1990 to 2000. The aim of this exhibition – mainly financed by North Rhine Westfalia – was to bundle public and private funding in strategic projects. This approach of steering structural economic and spatial change by means of small, locally motivated interventions came to be internationally known as 'perspective incrementalism' (see for instance: Lane 2000): a 'cloud' of local interventions held together by a perspective on the region's future. In 2010, another lighthouse project was started: 'RUHR.2010 – European Capital of Culture'. This mega event was expected to contribute to a stronger identity for the region, and to foster culture and creative industries as an economic base. Both events prepared the way for regional design reflecting on a common future for the region.

In the Zürich case, different regional design approaches from inside and outside public administration served as references: the 2005 'Urban Design Portrait' of Switzerland by ETH Zürich Studio Basel; the 2011 study 'Glattal – an Emerging City!' by the architects group 'Krokodil'; and the 2012 'Spatial Concept of Switzerland', meant as an informal planning and policy guideline at the federal level. These initiatives were not seen to have a direct influence on the 'Metrobild Zürich' process. It was, however, argued that images and narratives from these projects stayed in the minds of actors: they enhanced imagination, and also informed expectations concerning a new regional design initiative.

In the Netherlands design led approaches in planning are frequently used – a tradition that can be traced back to the emergence of urban planning at the turn of the 20th century. No one at the conference mentioned a link to specific design projects such as in the cases discussed above: It seems that it is quite natural to design for the purpose of planning.

There was agreement among experts that initiating a regional design endeavour within the fragmented landscape of governance – 'Setting the Stage' – is already an achievement in itself. Regional actors and institutions are generally quite hesitant to invest money and time in endeavours that have no predetermined result. For instance, in the Zürich case there was a remarkable consideration of the role that perceptions of regions play in setting up the stage for regional design. Here dominant perceptions and the focus on planning issues were identified from the outset and monitored via processes. Looking across the cases, there was agreement that regional design marks neither the beginning nor the end of a regional dialogue and cooperation process. Setting the stage for regional design seems to be half the battle in the sense of shaping mindsets about the present and future state of the region.

4.2 PERFORMANCE

When it comes to the performance issue, the regional design processes in Amsterdam, the Ruhr and Zürich could not be assessed on their long term impact yet as all discussed cases were relatively recent. However, the discussion allowed comparison of expectations on the performance of regional design. In all three case studies the experts stressed that regional design is a way to initiate and facilitate joint discussion and to provide a 'designerly' context for discussions and negotiations between administrations, societal actors, and civil society at large. They emphasized that regional design practices are not meant to define and identify a 'product': a concrete planning solution. This was summarized as 'Regional design as

a catalyst to qualify the region'. Design initiatives take place to improve deliberative processes. In fact, regional design proposals may disappear after having contributed to decision making. This does not mean that the actual content of regional design does not matter, on the contrary: insights into particular spatial environments, what constitutes these, how they develop, and how they might look in the future are crucial to initiate and steer discussion and dialogue. Insights into the qualities, strengths, and threats that spatial development holds and can hold in the future are a crucial factor in changing the minds of actors.

Experts in all cases agreed that regional design – the products as well as the processes – is highly instrumental in the identification of joint planning issues. Spatial representations and discussions about these focus attention, often on intricate 'soft' spatial qualities, strengths, and future potentials. The selection and detailing of these issues and bringing them to the attention of local and regional actors was regarded as a crucial design activity in all three case areas. The Zürich experts stressed the importance of design in 'framing', constructing a basic agreement on relevant planning issues in the region, agreement on outline challenges, problems and tasks that regional planning should deal with. One Zürich expert noted that the design process was shaped by a search for "public goods" in the Zürich Metropolitan Area: Once they were 'discovered', they continued to play an important role throughout the entire regional design process.

4.3 DESIGN STRATEGIES AND PROCESSES

The experts at the conference agreed that the performance of regional design can partially be attributed to the use of imagery: 'A picture is worth a thousand words'. Images allow for new readings and understanding of the region. Design imagery may be provocative but on the whole the performance of maps, models, and other spatial representations is not easy to predict. Is it possible nevertheless to 'plan' the impact and performance of imagery? Experts from the Zürich and Ruhr cases noted that competition settings foster the emergence of surprising and new imaginings and imageries. Some even favour a 'guerilla tactic' in the production and use of imagery. They argue that new and therefore influential representations always comes from outside public administration – from design initiatives at universities or in the context of private or civil initiatives, for instance.

A reoccurring issue in discussions on images is their narrative nature. The actual performance of imagery is closely connected with the storylines they imply. New reasoning in and through imagery broadens the horizon in discussions. In this respect, images of regional structures can have a unifying force. An example is the ring of 19th century fortifications at a distance of about 25 kilometers from Amsterdam, which is regarded as part of the identity of the Amsterdam Metropolitan Region and imaged on local maps of Amsterdam as well as regional imagery. As already explained above, the regional design practices in the three case regions are rather novel, making the impact rather difficult to detect.

In all cases, particularities of the region were an essential ingredient in design proposals. These particularities are often formed by numerous highly 'typical' smaller spatial entities within the region. They were regarded as building blocks. Identifying similarities across local, municipal levels turned out to be an important step in the representation of regions, but also in identifying 'fields of action'. In the regional design propositions for the Ruhr region, comparable neighbourhoods within municipalities became more important than administrative units themselves, for instance. A crucial design step in the Zürich case was the identification of differences among smaller entities or subregions as major constituent parts of regional diversity. Also in the Amsterdam case, the recognition that the region is highly diverse contributed strongly to a shared image of the region.

Mapping was an integral part of all three regional design cases. Mapping was seen as a process of joint fact finding, supporting a search for evidence of what connects the various parts of a region, and what constitutes interdependences between issues and places. Mapping was also regarded as an important tool in portraying possible and desirable futures. Several tools and instruments in mapping were discussed. Design experts in the Zürich case argued that Geographic Information Systems (GIS) turned out to be a powerful tool in both the analysis of regional data and the creation of imagery of regional futures. As noted above, the development of a common visual language was an explicit aim of regional design processes. Graphic designers who are skilled in moving between two and three dimensional images are particularly in demand on regional design teams.

As was noted above, regional design processes are processes of identifying planning issues and bringing these to the minds of actors. In this sense, they were engaged with the naming of issues and in this way creating a vocabulary for regional planning. That does not mean that the (new) vocabulary necessarily lead to a joint understanding of the region. Planning experts in the Zürich as well as the Ruhr case noted that the results of regional design competitions tend to be rather complex: designers often suggest multiple layers, issues, subregions, actors, and time horizons. This complexity in content, form and language may appeal to experienced urban and regional designers, architects, and academics, but threatens and repels politicians and planners that are responsible for letting these complicated constructs fall 'on the ground'. 'Make it simple' could be a strategy connect design to the realm of planning and politics. Design experts responded that simplicity can be extracted from complexity: an act of translation. In the Zürich case, a basic rulebook relying on a simple distinction between stable and dynamic spaces within the region was based on rather in depth analyses, for instance. Another comment on a design vocabulary concerned text and image: Crystal clear textual naming and labelling as well as mapping and drawing are equally important instruments in clarifying issues. Through this, regional design may help to establish narratives of the region, and these can become important drivers for regional discourse. It was argued that the multiplicity of notions in design proposals functioned as a fertile breeding ground for storytelling in the Zürich and the Ruhr cases. Designers proposed what was generally regarded as a full and rich image of the region, a repertoire of notions that inspired planners.

Discussions on design products and processes addressed the issue of how to connect design with planning processes. It was argued that from the outset designers should be sensitive towards the planning setting in which they work while at the same time claim a kind of free space in order to remain innovative. Potential commitment of local and regional actors should be carefully and continuously considered, specifically when regional design strategies aim at implementation. In the Amsterdam case, the importance of the embedding of design in formal planning was heavily emphasized. This means, for instance, that it is critical to take notice of existing plans. In general, designers should be skilled in working in an often contentious political context. They should also be aware of pragmatic or even opportunistic behavior that occurs in the context of complex social networks.

In all parallel workshops, it became evident that regional design is not a straightforward process, but often requires different steps and stages. In all cases, there was not one 'final' design product, but many in-between products that were presented, discussed, modified, and then presented again. Usually a broad range of different actors joined in, which turned regional design into a dialogue on planning. Such design processes resemble joint decision making processes. The difference is that the decisions are not about concrete projects or interventions but about understanding and the content of the design 'story'. To synthesize and link the diverse and often conflicting requirements and expectations of a broad range of different actors and institutions in one design process was seen to be a critical design activity. It is about informing others and being informed in a multi actor, collaborative setting.

Initiators, audiences and design commissions. Although in all three cases regional design evolved as a collaborative process, the concrete design practices differed in the organizations that initiated the design. Also, the design 'audiences' and the 'openness' of commissions differed to some degree. In the Ruhr and Zürich cases, designers had an open brief. Designers (and also the jury of the Zukunft Metropole Ruhr design entries) appreciated this freedom. The Metrobild Zürich process was carefully placed outside the daily routines of public administration. The temporary architects group 'Krokodil' designed a regional strategy without having an official mandate to do precisely this. They used the freedom given to turn towards a public audience and acquire public attention for their proposal, an effort that they called a 'guerrilla strategy'. In contrast, the Amsterdam case design processes had, through their thorough embedding in planning, a much more pragmatic orientation. They followed the negotiation patterns in the domain of planning and policy making. On an abstract level, one could say that all three design processes run parallel to political processes but that the connections are different, resulting in different degrees of freedom in relation to design content.

5 CONCLUDING REMARKS

In this paper we have set ourselves two objectives: 1) how to analyse regional design in planning context from a theory based methodology; 2) to identify lessons on how regional design contributes to planning

T07 | DIALOGUES IN DIVERSE, INCLUSIVE, AND MULTICULTURAL CITIES

CO-CHAIRS: WILLEM BUUNK; INÊS SANCHEZ DE MADARIAGA; ISABEL RAPOSO

The track welcomes papers that offer case studies, research methods and theoretical approaches that reflect, from a variety of perspectives, on dialogues in planning on inclusive and multicultural cities. European cities are shaped in era of rapid growth and urbanisation post WWII, now face vast challenges of major social, economic, political and migratory change.

Diversity within cities calls for cohesion, as promoted by the ECTP 'New Athens Charter' for inclusive and just cities, including gender dimensions. As there is great diversity between cities, there is diversity in approaches to deal with these complex challenges. Diversity in size, landscape, social structure, religion and wealth, and diversity in political culture, governance and adoption of technology produces a variety of strategies.

The track wishes to focus on the contribution of urban policies and planning on local and regional dialogue between stakeholders with different interests, different rationalities, different cultures (both traditional and alternative), and different moral points of view. The track also welcomes papers on the contribution of planning to national and transnational dialogues, as well as contribution to the discourse on values and ethics in planning and on justice.

ID 1309 | PLANNING FOR DIVERSITY AND SUSTAINABLE SPATIAL PLANNING RELIGION SPACE GENDER AND ETHNICITY

Clara Greed¹
¹UWE Bristol UK
claragreed@aol.com

ABSTRACT: Sustainability objectives are central to modern urban planning, shaping all aspects of. Originally, sustainability had three components, environmental sustainability, economic well-being and social equality: - Planet, Prosperity and People. But, the environmental aspects of sustainability have tended to predominate. This leaves little space for social issues, and aspatial (non-physical) factors such as belief and religion. It is argued, with reference to UK-related research, religion has major spatial planning implications for all aspects and levels of urban policy. Neglecting religion's existence results in an incomplete planning agenda which undermines equality, especially ethnicity-related policies. The implications of this gap are discussed with reference to the environmental, economic and social components of sustainability policy. There is little recognition of the contribution of religion to cities: rather a negative mentality predominates amongst planners. Ways of changing the planners' understanding, and mainstreaming religion into planning are discussed, drawing on methods used to integrate gender into planning.

1 INTRODUCTION

The urban planning policy agenda is strongly influenced by sustainability objectives with particular emphasis upon environmental issues. But, the original definition was much broader and included economic well-being and social equality as well as environmental balance. But it is environmental sustainability, as illustrated in this paper with reference to the UK, that has become the ersatz religion and zeitgeist of politicians, urban policy makers and academics (Boot, 2014: 186). However worthy and admirable it might sound to be concerned about 'saving the Planet', in reality this agenda provides little space for social policy (Dempsey et al, 2011), or for taking into account the wider value base of the policy makers, or the beliefs and religions of the planned. There is little consideration given to the ways in which particular sustainability policies might impact upon different groups of human beings in society, in terms of their class, gender, lifestyle and religion and so forth. Likewise there is little linkage between sustainability policy and social issues such as poverty, social exclusion, disability, unemployment, and homelessness. A strict application of sustainability policy, which puts environmental concerns above human considerations, may actually exacerbate the situation by creating a people-less approach to planning (Greed, 2011). In the UK, the 2010 Equality Act lists seven protected categories that should be taken into account in all aspects of government policy making, including (in theory at least) urban planning. These are Age; Disability; Gender Reassignment; Pregnancy and Maternity; Race; Sex (gender) and Sexual Orientation; and Religion and Belief. However, overall equality issues tend to be given low priority compared with environmental considerations (Greed, 2005; 2017). Religion is on the list but it does not follow that it will get as much attention as the other categories. Some issues are higher up the pecking order than others, and nowadays sexuality tends to be given primary attention as the factor defining a person's identity (Habermas and Ratzinger, 2007). Social class (which does not even appear on the list) used to be the primary social factor, arguably because planners could justify their unpopular policies by claiming they were planning for the working class and knew what was best for society. Religion, faith and belief, as will be explained, are very low on the pecking order.

But does it matter? Surely religion is only of interest to a few people in these secular times? For many years pundits have declared that we are now living in a secular society (Cox, 1965) and that the church is in decline. But there are still significant groups of people who need the time, respect, space, and building accommodation to exercise their faith. Firstly, there has been a major influx of immigrant groups and many give great importance to religion, as they come from countries which have never been secularised. Both Asian-origin Moslems and African Pentecostals have challenged the planning system in seeking planning permission for large buildings for worship and related community use. Demand has been generally been concentrated in ethnic minority areas particularly within the inner city. In many inner London boroughs over 60% of the population are now so-called 'ethnic minority' (in fact the majority) and they have set up scores

of small churches and meeting places (Onuoha and Greed, 2003). According to www.brierleyconsultancy.com, there are 500,00 Christians in black majority churches, and 1 million other Christians in Britain from Black, Asian and other minority groups, who are to be found in majority churches. Around 7,000 new churches have been started since 1980, and in the last ten years more new ones have started than old ones closed down.

Secondly contrary to the assumptions of Marx and other secularists (Tawney 1966; Cox, 1965), religion has not withered away but is also growing within the white indigenous population too in the suburbs especially in charismatic and evangelical congregations in both traditional and independent churches (Cox, 1995; Davie, 2015). Goodhew (2012) found that that adult membership of the Anglican churches in the diocese of London has increased 70% between 1990-2010, and much of this growth is due to immigration. Thirdly, demand for church expansion has also come from East European immigrants swelling UK Roman Catholic congregations. All these new groups do not want the sort of cold, cramped, inflexible accommodation offered by buildings vacated by traditional dying denominations, but are demanding the right to create their own worship spaces and related facilities. As will be explained all these religious changes do have a spatial impact which planners need to acknowledge.

2 CONTENTS

This paper seeks to explore and illustrate the relationship between spatial planning and religion. The implications of these requirements planning policy and regulation are discussed. Examples, throughout the paper, will be related to the UK situation but there are parallels with what is happening in other countries too. The methodological and conceptual approach will be summarised. The ways in which religion itself and faith groups are treated in the planning system at the local authority level will be discussed, not least how the pursuit of sustainability policy marginalises such 'social' policy areas. The paper will take into account the two main components of the UK planning system, namely the development plans prepared by each local planning authority which set out planning policy for the area in question, and secondly detailed development control and regulatory requirements, regarding applications for new development and changes to existing buildings. It is at this detailed level of interpretation and application of regulations that the faith groups have the most problems with the planning system, and where local planners have the most discretion as to how to apply planning regulations. Examples are drawn from the environmental, economic and social fields of planning policy and practice. In the final section I set out some recommendations on how to change the system, and will include a 'toolkit' on how to mainstream religion into planning.

3 METHODOLOGY AND CONCEPTUALISATION

Since material on 'religion' was often absent within planning policy and regulations, I adopted an approach similar to when I was researching 'women and planning' policies because in both cases I was looking for something that was often missing or invisible (Greed, 1994, 2005). When I had investigated the values, world view and characteristics of the planning subculture I found a male-dominated, secular, technically-minded profession (Greed, 2013). One can observe, what Doreen Massey identified as 'the reproduction of social relations over space' in this case the transmission of the planner's personal experiences and world view onto the built environment, through the vehicle of professional decision-making (Massey, 1984). In this process some policy areas are majored upon and others are marginalised, and religion, along with gender and ethnicity, is a major blind spot (Mc Clymont, 2015).

I sought information both on development plan policy and planning control regulations related to religion. I undertook a web search of all planning applications, appeals and case law that related to 'places of worship' including using key words such as church, gospel, mosque, faith, and the names of the various denominations. I used www.compasssearch.co.uk which, in association with the Royal Town Planning Institute, provides frequently updated reports on current cases and appeals. I also searched using DCS (Development Control Services Limited) which is a password-only professional planning law site. I looked for relevant articles in the planning press, such as in 'Planning' which can be accessed at www.planningresource.co.uk. Since many of the key cases are related to London, I also consulted the GLA (Greater London Authority) and Planning Aid for London (a voluntary advocacy group). I combined,

and triangulated this approach, with a more informal and anecdotal approach of simply talking to people from a range of churches and other faith groups on their experiences and views on the situation.

There are only a few other existing research studies, for example by CAG a planning consultancy which has undertaken four key studies on the attitudes and policies of planners towards the needs of faith groups (CAG, 2008 a and b, 2009, and 2013), related to the situation in London and in the Midlands, focusing on Pentecostal and Moslem faith groups respectively. Doing a web search for the words church, religion, belief, faith in development plans, I found, brought up the obligatory equalities statement mantra at the start of every policy document. But hardly any local planning authorities actually follow on by referring to these matters in their policy statements, and very few have a separate chapter or section just on religious land-use matters. But the word 'church' came up hundreds of times, but only because the documents are referring to geographical locations such as 'Church Street', and every town seems to have at least one, reflecting our more religious past when religion did shape city form and structure (Greed, 2017).

4 PLANNING POLICY

At an international level the sustainability agenda has dominated for many years. Environmentalism is a foundation of much government policy. However, the original definition of sustainability, as set out at the 1992 UN Rio Earth Summit by Mrs Gro Harlem Brundtland, (the first female Prime Minister of Norway) included (as stated) economic well-being and social equality as well as environmental sustainability. Through processes of subsidiarity, UN directive implementation, and the rolling out of the Agenda 21 programme, sustainability policy and regulations were transferred down to each nation state, in the UK's case through the intermediary of the European Union (EU) and into the UK, where the concept of sustainability had to be fitted into existing planning structures and cultures (Greed and Johnson, 2016: chapter 10). The planning profession appears more at ease with physical, land-use matters and has particular affection for issues that can be quantified and counted. Therefore planners were happy to undertake Environmental Impact Assessments which measured mathematically the environmental effects of development. But they shied away from the more qualitative and less controllable non-spatial aspects of sustainability. In particular, anything to do with gender and 'women and planning' has always been a challenge to the planning profession (Greed, 1994). In fact in the environmental movement women have often been seen as the cause of the problems for 'having too many children' so from the start it was not particularly friendly to women, and was rather judgemental towards ordinary people too (Greed, 2011).

In contrast to the emphasis upon environmental issues, there have been very few requirements to 'count' or assess the social and cultural impact of planning policy and development proposals, either within the sustainability context or in relation to the social aspects of planning. Indeed planners may imagine that the impact of so-called social types of development cannot be 'counted', be they childcare, worship, community development (Greed, 2005; 2016). But places of worship, such as churches and mosques, like factories, do have a tangible physical building and fixed location, and, as will be explained they do have an impact in a variety of ways upon the surrounding urban area, in terms of transport needs, community development and employment opportunities. Whilst the planning system surveys and keeps records of details of many different land-uses, including housing, industry, commerce, recreational land and so forth, religion remains 'beneath the planners' radar' (Mc Clymont, 2015). Since there is no survey of religious building requirements, it is very hard to say how much land is needed and whether there is an over or under-supply of building space that might be used for religious purposes, and how or whether the situation is affected by sustainability requirements. And there is no high-level policy guidance to judge planning applications by.

However, there have been attempts to introduce Equality Impact Assessment, to parallel Environmental Impact Assessment. The current system (Equality and Human Rights Commission, 2010) seeks to integrate equality assessment into all aspects of policy making for all government departments in all departments, including planning. This builds on previous individual requirements in respect of gender, disability and ethnicity inter alia, and a PSED Public Sector Equality Duty exists to ensure this happens. However, as we found when undertaking research on mainstreaming gender into planning policy and practice, take up has been very limited in planning departments and many planners do not seem to think it is anything to do with them, owing to the technical and environmental nature of their work. In contrast it was found such measures are more acceptable in more women-related departments such as social services, health, education and personnel departments. There was little concept that gender might have

implications for apparently people-less, or male-dominated policy areas such as sport, industry and transport planning: although all these do really have major gender implications. Likewise religion was not seen as an issue to consider within mainstream policy making and it seemed to be a minor matter that would only relate to specific church building applications.

Furthermore there are no detailed standards as to how much land or what size of buildings should be provided for particular religions, relative to numbers in the congregation or catchment area. But Mulkeen (2014) notes that in past there were some attempts to come up with some guidance especially when building the post war New Towns, when in more religious times it was considered essential that every neighbourhood unit should have space set aside for its own church. But as CAG (2009) notes nowadays there is no attempt to quantify the need for land for religious use, nor for local authorities to specify standards for levels of provision. If one compares the lack of reference to religion in development plan policy, with the situation regarding retail development one can see how discriminatory the situation has become. Entire chapters in development plans are devoted to establishing how many shops are needed, using sophisticated techniques, such as retail gravity models, to establish hierarchies of need and the extent of catchment area at national, urban, local and even international levels, ranging from the enormous pulling capacity of major, out of town, shopping malls, to the role of traditional city centres, and down to the provision of local corner shops. If the same principles were applied to places of worship, there would be surveys of the needs of the different religions and denominations, the extent of their respective catchment areas, the times of opening, and consideration of all the ancillary issues such as parking, public transport and community accessibility. For example, the new Pentecostal mega churches and large mosques attract national, if not international congregations, and are bigger than most traditional cathedrals, and may be compared to major sports arena and football grounds in terms of pulling power. But planning policy would also need to take into account the more local levels of provision, such as smaller scale city-centre churches, and small chapels and Gospel halls serving local neighbourhoods. So, many churches and other faith groups find there is no recognition of their needs in development plan policy and thus no guidance on where they should locate when they approach their local planning office for permission to develop.

5 CONTROL OF DEVELOPMENT

Planners tend to shunt religion 'down' , out of the strategic policy making level, and into the local level of building control, confusion and ignorance seems to reign at this level too. There are many examples of churches trying to obtain premises in inner city locations, near to where their congregation lives (which would reduce the carbon footprint in terms of travel and contribute to the social strength of the area) and being refused. In desperation churches have been pushed further and further out and end up applying to use vacant industrial units, where they are likely to fall foul of antiquated planning laws. The Use Classes Order (UCO) sets out a series of categories of land use, such as shops (class A1) and cafés (A3), businesses (B1) industry (B2) , dwelling houses (C3), and non-residential institutions (D1) and places of assembly and leisure (D2) (Greed and Johnson,2014: 49). Churches, mosques and other religious building come within D1 alongside community centres, museums, exhibition halls and so forth, whereas some ancillary religious uses would come under D2 which is concerned with public halls, cinemas, sports facilities etc. So there is no separate Use Class just for religious buildings and they have mixed up with all sorts of other social and community uses.

But, this was not always so. Andrea Mulkeen (2014, page 23) found that between 1948-1987 religious buildings were separated out into their own Use Class, under the post war planning legislation that was the basis of the modern planning system under the 1947 Town and Country Planning Act. But they were amalgamated with other uses following the 'streamlining' of the system in 1988. One of the biggest problems caused by religion not having its own proper use class and being put in with leisure and places of public assembly is that it is seen as an economically non-productive commodity which actually detracts from employment and urban regeneration. There are many examples of churches trying to obtain premises in inner city locations, near to where their congregation lives (which would reduce the carbon footprint in terms of travel and contribute to the social strength of the area) and being refused (Greed, 2016). Robert Wickham a planning consultant specialising in representing religious groups has produced statistics that show there is a greater level of refusal of planning applications from religious buildings (Wickham, 2014). The high level of refusals and other planning problems faith groups encounter when seeking planning

permission will now be illustrated with reference to examples related to the three component policy areas of environmental, economic and social sustainability.

6 REASONS FOR REFUSAL

In summary the reasons for refusal that seem to come up again and again are as follows:

1. Economic and employment factors: 'taking' buildings and land allocated for employment and urban regeneration (even when they are empty and churches generate employment opportunities) for 'non-productive' religious uses.
2. Urban conservation, design, and external appearance issues: concerns about the overall character of an area, Advertising and signage, impact of minarets and foreign architecture (even in predominantly Moslem or ethnic minority areas).
3. Social issues around social cohesion and destroying the character of the area, issues about 'outsiders' disrupting the community and upsetting diversity balance.
4. Transport and parking issues seem to be applied particularly harshly, even when people tend to walk to church, or use minibuses or public transport.
5. Technical issues around building control, public health regulations and noise, pollution and disturbance, amenity, which seem to be especially harshly applied.

In the next subsections the environmental, economic and social implications of these attitudes will be discussed with reference to planning policy and sustainability, using examples, particularly from the ongoing saga of The Kingsway International Christian Centre (KICC) which encapsulates so many of the issues. Transport and technical considerations will also come into the discussion.

6.1 ENVIRONMENTAL FACTORS

The highest priority is given to the environmental aspects of sustainability within the UK planning system, and this is manifested strongly in transport policy and control over the use of the private car to reduce people's carbon footprint, (regardless of whether any public transport exists outside of London). Because this branch of sustainability practice is linked to transport planning it has inherited all the quantitative, people-less characteristics of previous generations of transportation planners, a silo of planning which has never been famed for concern with human beings (Greed, 2012). For years all the necessary social journeys to service the family in terms of doctors, post offices, government departments, and childcare were seen as merely social leisure journeys (Greed, 2004). So there was no place in this arrangement for church journeys which were seen as individual mainly taking place on at the weekend and so were of little importance to transport planners mainly concerned with the journey to work. Many small churches have had problems with restrictive controls on car parking spaces, with little allowance for the fact that elderly and disabled people may need to travel by car and some people come from quite a distance with no Sunday bus service available. On the other hand some Jewish and Moslem congregants will only travel by foot to worship and so requiring parking spaces to be provided, in often tight cramped inner city sites is equally unrealistic.

But when it comes to church-related planning appeals, curious decisions can be made that do suggest a level of discrimination that results in some planners putting aside their environmental credentials, as in the case of KICC (Kingsway International Christian Centre) . This is a huge church of over 12,000 members from 46 different nationalities, which has been seeking to build a mega church which would seat more people than any existing cathedral in Western Europe. The church had to move from its previous premises to make way for the London Olympics with the promise from the planners that any alternative site would be looked upon favourably. But not so! Since then the church has tried to get planning permission on several different buildings and new sites, whilst its congregation remains fragmented and reduced to holding multiple services in a range of scattered venues. Back in 2009 KICC's application for an 8,000 seater mega-church in Rainham Essex (on the outskirts of London), on an industrial estate was refused. They partly chose this site because there were no near neighbours so they could not be accused of causing a disturbance and being too noisy. This application was refused on the grounds that the site was already allocated for industry, although most of the units remained empty.

The Planning Inspector dealing with the Rainham actually stated that the church would put too much demand on local bus services (isn't that what buses are for?). This is extraordinary in that nowadays transportation planners are obsessed with getting people out of their cars and on to public transport for 'green' environmental sustainability reasons. In the cinema case too, the [new] planning inspector also raised concerns about too many pedestrians being generated, because many of the congregation would walk to church, as well making a range of curious comments about the use of bicycles, local taxis and public transport all being overwhelming for the area (DCLG, 2009). The KICC Christians meant to fly to church on angels' wings? Planners would not apply the same mentality to office or retail development, where (for another set of confused reasoning) they are encouraging people to use public transport and leave their cars at home. As a result of all these problems the KICC saga has been solved to some extent by the church 'leapfrogging the green belt' and moving into more rural premises has now moved to Buckmore Park, Maidstone Road, Chatham, east of London, as well as still retaining churches in Walthamstowe and other satellite locations, <http://www.kicc.org.uk>. People are ferried to and from the new Chatham site by minibus or commute by car, as public transport is not direct, and arguably this has had more impact on the environment than just letting them stay in London.

More broadly, secularised environmental attitudes often disregard the environmental principles already found in many religions, and do not work with faith groups. Both Christians and Moslems have emphasis on being guardians of the earth and caring for it, and Creation stories, so should be encouraged in instilling the young with a care for the environment. Much more so Hindu and to some extent Buddhist religions have very strong emphasis upon protecting the natural world. So it is ironic indeed that faith group members are often picked on for lacking environmental awareness, particularly when many are relatively poor immigrant groups and not part of the mainstream consumer society (Narayanan, (ed) (2015).

6.2 ECONOMIC REASONS

Many churches and other faith groups have been forced to look for accommodation on the outskirts of cities, and have applied for planning permission to use industrial units on business parks. In many cases they have been refused permission because they are seen as taking up space needed for employment even when they have remained vacant for several years. Overall faith groups are seen negatively as having no economic contribution to make to society. But such faith groups often supply social infrastructure and social capital that enables people to work in the first place, especially childcare facilities, local advice and training on employment opportunities and a voice in the community. Larger churches may also provide in-church employment in running bookshops, websites, cafés and food banks and all sorts. In fact The provision of childcare and home support for the workers has been seen as a key ingredient in ensuring that urban regeneration programmes can actually work. More broadly, anthropologists investigating the role of factors that generate economic development in South Asia and Africa, have found that Pentecostal and Evangelical churches can have a positive role, in generating employment, education, local business growth and even health and community wellbeing. This is partly of adherence to scriptural principles regarding saving not spending, reductions in crime, more stable family life and an overall more aspirational approach to life. Because church leaders are local and not part of the ex-pat expert advisor brigade they are likely to have more influence and understand what really works locally. Granted such changes may open local communities to western-style consumerism and rejection of traditional indigenous values, but it is generally found that with time people can reflect on their lives and retain what is good from the past as well as the present (Freeman, 2012).

Likewise inner city faith groups can have a major role in urban regeneration and renewal which is going to be more sustainable in the long term than being dependent on bringing in footloose multi-national companies attracted by the grants, whilst national retail outlet chains often put locally run shops and traders out of business (Brownill, 2000). Patrick Anderson a Christian working with Planning Aid for London, told me sadly, that 'church is not seen as the engine of the economy' by the planners. He also commented that globalisation of production, is the reason that so many reason industrial units remain empty because industry has gone elsewhere where labour is cheaper, and the same global forces have increased immigration to the UK. So it is foolish for the planners to hold on to the industrial units and wistfully wait for traditional industry and business to pick up, and rather they should be encouraging and supporting faith groups, and immigrant groups as a whole, as the new sources of economic growth and urban regeneration.

6.3 SOCIAL FACTORS

As can be seen faith groups can provide a whole range of social goods and social and religious capital which supports and regenerates communities. Pentecostal churches have an emphasis upon the full Gospel of healing, healthy living, prosperity and wellbeing. So one would imagine they would be ideal partners in Healthy city programmes which are often closely aligned to sustainability objectives and World Health Organisation initiatives (Guise et al,2010). Even if the planners take a purely secular view of the value of religion, as Katie Mc Clymont explains (2015) churches have always made a major practical contribution through what she calls 'municipal spirituality' by providing church halls, and other ancillary buildings for use by the community, for crèches, community meeting places, food banks, support groups, emergency accommodation for the homeless and refugees, and also simply quiet spaces in busy cities where people can contemplate and even worship, such as in graveyards, cemeteries and church gardens. But much of this seems to be 'under the radar' of the planners, not least because some of this provision is mainly used by women, those with small children and also the elderly.

Previous research on 'gender and planning' issues (Greed, 2005) found that many essential services and activities essential to women did not register as being relevant to land-use planning. For example childcare requirements generates the need for crèches, day care facilities and nurseries, although they require buildings and have a substantial impact on journey to work patterns therefore should be a major consideration in formulating land use, transportation and locational policies. But planning applications for such facilities have often been refused, and on appeal it has been deemed that such uses are social and therefore ultra vires that is outside of planning law's remit because they are not to be 'a land use matter' (Greed,2004). In contrast Sport, has always been seen as a valid physical land use, especially playing fields for male ball games , for which large areas of land is provided, although arguably sport is also just a social matter. In the same way, religion and all the so-called social facilities it provides have often been unrecognised and therefore rendered ultra vires in the planning process, even when this neglect has major environmental sustainability implications in reducing the availability of local facilities resulting in more journeys outside the area in question.

In addition to planning control, building inspectors seem to have problems with multi-use buildings where maybe there are worship and meeting places, but also offices, communal areas, catering, educational facilities and maybe even cafes and retail outlets. Strict application of rules and controls, never designed for such multi-use buildings, will result in refusal, or in increased costs and lengthy delays. Building control operates separately from planning control with additional sets of rules. An application may be passed around to all the relevant departments such as to the fire department, licensing authorities regarding 'live music', public health and sanitation, and even the police and magistrates. One also needs to consider under environmental issues, policies and controls regarding, noise, disturbance, cooking smells loss of amenity and so forth. For example, there are all sorts cultural issues around whether people accept or complain about religious noises such church bells, Moslem calls to prayer, gospel singing and street evangelism accompanied by music. Noise is a frequent reason (excuse) for refusal, and there are many examples of 'non-traditional' (black) churches being required to install treble glazing.

However, paradoxically, when it suits their needs, governments actually like faith groups when they take some of the burden off the welfare state by providing housing, health, education and social care for free. But this is not translated into acknowledging the need for buildings in which to undertake this work. Whilst they like this 'religious capital' (social capital) that faith groups provide, they are much more wary of their 'religious capital' that is their beliefs, because of fears of fundamentalism and social division (Baker, 2012). As stated although religion is one of the seven categories under equality legislation, it is low on the pecking order and often viewed negatively and as incompatible with other equalities issues, such as gay rights and the need for social cohesion. Yet, many churches and mosques contain people who themselves suffer high levels of discrimination because of their race and yet they are powerless to fight back and find themselves cast as promoters of discrimination, rather than being discriminated against themselves.

Faith groups may receive opposition to their presence in local areas from both progressive groups concerned with equalities (as above) and from more traditional, reactionary groups in society. For example, returning to the KICC saga, in their search for large buildings (before moving out altogether to Chatham), the church put in applications on a range of sites and buildings within London. For example they bought a redundant cinema in Bromley, inner London, near to Crystal Palace, and started using it as a church, in the hope of receiving retrospective planning permission. They were subject to the threat of enforcement proceedings on a whole series of technicalities. As the local press attests, local residents

expressed objections on a much wider range of criteria. In particular they have expressed concern about 'outsiders' taking over the building, thus apparently depriving existing residents of its use, in spite of the cinema being derelict and unwanted for years. Fears were expressed by some local residents about noise, disturbance, increased crime and anti-social behaviour taking place, and overcrowding on the pavement (sidewalk) outside (www.crystal-palace-mag.co.uk). In reality nobody has wanted the building for years, the locality has a substantial and long-established ethnic minority population and members of the KICC church are known for their holiness and good works, and are hardly part of the perceived criminal fringe.

More broadly, this example raises questions as to quite 'who' comprises 'community' and 'local culture' in the minds of the planners. It also raises issues as to what local planning authorities see as valid leisure, entertainment and cultural uses. Many local councils are keen to promote the 'night-time economy' and the 24 hour city. Such policies usually results in over-provision of licensed drinking premises, with attendant noise, public drunkenness and street urination. There is clearly a double standard as many churches are refused permission on the basis of noise and disturbance, although many congregations are likely to be tee total and careful not to disturb the peace. In the end the cinema building was turned into an arts complex, a use which arguably does not reflect the needs of the majority of the local population but that of the metropolitan elite. But culture, media and the arts are far more likely to be seen by the planners as drivers of urban regeneration and the local economy, than religion as attested by many other examples from my research, circus school (SOAS, 2014). Because there is no survey of the actual need for church premises, planners base their decisions on the assumption that there is a drop in church attendance, and thus decline in the need for church premises, and so it is argued that more redundant church buildings should be returned to community use (Branson, 2009). For example, St Paul's Church Bristol, built in 1790 and restored through the Heritage Lottery Fund, which was adapted in 2005 to make space for a circus arts academy. Note this is a majority ethnic minority area where just up the road one can find Black churches precariously holding on to tenancy of industrial units who would have jumped at the chance to be offered such redundant church buildings in the area.

7 CONCLUSION

The planning system does not value religion or the role of faith groups to increasing economic, social and environmental sustainability. Planners either ignore the spatial implications of religion, or relegate it to the wrong planning law categories (Rogers and Gale, 2015; Wickham, 2014) Both ethnic minority groups and women feel particularly discriminated against in this respect. Women ministers of Pentecostal churches felt they were not taken as seriously by the planners than white male vicars (Onuoha and Greed, 2003).

Both attitudinal and procedural measures are required to change the current situation. Both sides: planners and faith groups need to understand each other's viewpoint and goals. Congregations, through the auspices of advocacy and planning-education groups such as Planning Aid, need to learn about how planning operates, and how policy statements and legal parameters delineate what planning can and cannot achieve. Planning, architecture and local politics need to be promoted as careers for young people from faith groups which can reshape the future, as is already being done at the KICC church (Beckford,2000; NCLF, 2015).

But, it is the planners, not the planned, who hold the most power and responsibility. So all development plan-making should include surveys and analysis of the numbers of religious buildings and spaces There should be a calculation of how much need there is, in terms of numbers of existing, vacant, suitable buildings and levels of existing and future demand. A hierarchical model of the different sizes and types, of catchment areas and levels of attraction of different sorts of religious development should be created (along the lines of what is done already through retail gravity models of attraction, catchment area and demand) (Greed,2016).

The implications of religious land-use and development should be related to employment, transport and housing policy. Likewise sustainability policy, economic development policy, and equalities assessments should all take into account the value of religious development which would thus be integrated into high-level, city-wide policy and not treated as an isolated, local-level afterthought. Considerable attention should be given to public consultation and participation, involving faith groups from the start.

At the national level, there need to be changes in planning law, especially in the UCO to ensure that religious development is not lumped in with other competing uses, and that it is given full value and respect. At the local planning level, there should be a more tolerant, less negative, and less judgmental approach to development control, and a more sensitive approach towards applying building regulations and rules which were designed mainly for commercial buildings, not worship spaces. It is to be noted that the Greater London Authority has taken some of these issues on board, including some more positive references to religion both in its main development plan document and its related Supplementary Planning Guidance (GLA, 2007; GLA, 2009, pages 22, 62, 86, 91, 264). If we do all this it will help create sustainable, functional towns and cities, whose populations benefit from a more equal, peaceful and understanding way of life.

In order to integrate religious considerations into the planning process, I have been adapting the 'Women and Planning' principles of the Gender Mainstreaming Toolkit for planning officers (RTPI, 2003; Reeves, 2005) in order to apply it to religion in Figure 1. A fuller version is presented in my research report (Greed, 2017).

FIGURE 1: TOOLKIT TO MAINSTREAM RELIGION INTO PLANNING POLICY

To integrate religious issues into the planning process one must ask the following questions:

1. What organisational resources and expertise is available to the planners on faith and religion?
2. Does the policy-making team include those knowledgeable on religious issues?
3. Who are perceived to be the planned?
4. Who is consulted in terms of ethnicity, class, gender, and religion?
5. Are both leaders and laity included? Both Clergy and community members?
1. 4. How are statistics gathered, are they disaggregated by religion?
6. Is there adequate funding to carry out the work?
7. What are the key values, priorities and objectives of the plan?
8. How is it evaluated? By whom?
9. How is the policy implemented, managed, monitored and managed?

silviaviegas@ces.uc.pt

1 INTRODUCTION

My presentation for the AESOP annual congress falls within the scope of a wider exploratory approach embraced at the launching of the post-doctoral research project INSEHRE 21, focusing on the process of socio-spatial and housing inclusion of African and Middle Eastern refugees and asylum seekers in contemporary Europe, with reference to the reception of Portuguese-speaking African communities in Portugal, from 1975 until today, i.e., after the liberation of most of its former colonies. The aim of this presentation is twofold: to introduce some theoretical authors selected for structuring the INSEHRE 21 investigation; and to confront the key concept of inclusion with the European possibility of constructing responses directed (or not) to the access of these needy immigrants to the Right to the City (Lefebvre, [1968] 2009), both purposes with reference to the current neoliberal crisis in the Western countries, particularly in Europe.

This presentation is organised into three interconnected parts, the first one concerning the theoretical-methodological structuring notion of inclusion starting from the thoughts of four important scholars, such as Michel Foucault, Slavoj Žižek, Henri Lefebvre and David Harvey, seeking to identify the broader meaning of belonging, and its paradoxical significances, and of “spaces of inclusion”, namely its materialisation. The second part refers to the project INSEHRE 21 itself, its principal objectives, description (theme, object of study, questions, methodology and structure) and state of the art, addressing social (self-) production and official production of housing (and urban) space in Portugal and other European countries. The third part discusses the theoretical premises of the project in light of its principal intentions aiming to frame spatial (and intersectoral) inclusion processes in future reflections and to identify new avenues of theoretical and empirical research.

2 THEORETICAL FRAMEWORK

In the late 1970s, the French philosopher and social theorist Foucault ([1977/1978] 2008) defended that, in general terms, the government seeks to include all citizens, according to several levels of partaking in the building of society, so they best meet its policies. In short, for the author, inclusion equals normalisation within the framework of “governmentality”. It means preserving all individuals inside of the capitalist neoliberal system involving them in activities targeting the maintenance and reproduction of its segregating market logics. This contradictory process – inclusion as a path for rejection – implies larger surveillance and state control over the behaviour and wealth of communities. Nevertheless, referring to the crisis of the global system, Foucault (ibid.) also stressed its symptoms, outbreaks and/or forms, e.g., the resistances and counteractions that seek to encourage society as the legitimate holder of its knowledge whilst protecting collective needs.

For the Slovenian sociologist and theorist Žižek (1997: 44), the hegemonic neoliberal globalisation that emerged during the 1990s already had its strings attached to the fiction and/or ideal of multiculturalism tolerance, that is, a condescending ethnocentric approach based on a respectful form of “racism with distance” that asserts one’s own superiority, all the while founding propitious grounds for the emergence of fundamentalism ideologies and xenophobia. The decoding of such a paradoxical process – acceptance as form of rejection – forced Europe to transfer the focus once centred on the clash between cultures to the conflict between opposing viewpoints regarding the coexistence of different cultures (Žižek, 2016). Therefore, targeting “real inclusion”, Žižek (ibid.) advocates the commitment on the quasi-utopia of global solidarity (nearly) as a path for collective redemption and finding.

Regarding the physical expression of conflicting processes in neoliberal context, the French philosopher and sociologist of space Lefebvre ([1974] 2000) discussed, in the mid-1970s, the exclusion/inclusion present both in the spatial practices and in practical spaces, i.e., central to interventions and their material effects, while differentiating public and/or public-private (official) production of political spaces, namely representational spaces with exchange value (commodities), from the (social) production of social spaces, also known as spaces of representation, i.e., spaces of social inclusion regarding their use value. Furthermore, Lefebvre ([1968] 2009) developed the guiding concept of Right to the City advocating one’s complete access to a myriad of rights (housing, infrastructures, urban benefits, etc.) and the construction of citizenship.

Recently, as throughout the peak of the global neoliberal dominant system, the British urban geographer Harvey (2008: 23) reinforced the importance of this fundamental notion by sustaining that this Right to the City is “moreover, a collective rather than an individual right since changing the city inevitably depends upon the exercise of a collective power over the processes of urbanization.” As such, regarding the production of what I designate as “spaces of inclusion”, the author reclaims some vital questioning: ““what kind of humanity [do] we wish to create amongst ourselves,” and “how do we [really] want to create it?”” (Park apud Harvey, 2007: 2). Hence, embracing a hopeful vision, Harvey (2000) also advocates the collective use of the cracks in the system (its inconsistencies) so as to build an alternative, emancipatory and socially just society.

3 RESEARCH PROJECT INSEHRE 21

3.1 OBJECTIVES

The purpose of the study is to identify the strategic guidelines being drawn up by the European Union (after 2015, being a year of pronounced influx of refugees) for the socio-spatial and housing inclusion of these vulnerable and heterogeneous social groups, as well as the more significant consequences of the interventions of certain States, in view of their different border pressures. Moreover, I intend to deepen current policies and instruments in Portugal, being considered a semiperipheral European country with experience regarding the inclusion/exclusion of Portuguese speaking African communities after 1975, where the shortterm arrival of refugees (until 2018) is expected to be of small-scale, as opposed to Germany, the leading European hoster during 2015. Consequently, I propose to follow the interventions programmed by the central government, articulated with local administrations, civil society (more or less organised) and the private sector, seeking to identify contributions for the rise and consolidation of a new paradigm of socio-spatial and housing inclusion of refugees coming from Africa and the Middle East.

On the other hand, considering the ideological-economic division between Member States of the European Union and the most excluding effects of certain (inter)national policies, I also seek to understand if these macro strategies have induced local, complementary or alternative, visions to the current dominant global policies and practices, developed by grassroots communities encouraged by better access to housing, urbanisation and full citizenship. I also want to identify whether the involvement of these immigrants in the production and/or transformation of (their) urban and housing space can contribute to fostering and invigorating European networks of solidarity and transnational support with positive effects regarding their socio-spatial inclusion. At the same time, I intend to identify convergent practices within this network as a starting point for the drafting of an international manifesto aimed at improving the quality of urban and housing life of refugees and their host societies as well, reinforcing Portugal’s strategic importance on the topic of the European response.

3.2 DESCRIPTION

The theme of this research is the inclusion of African and Middle Eastern refugees in contemporary Europe from a socio-spatial and housing perspective, with Portugal as a case study as opposed to Germany.

The critical reading of the past, namely the reception of Africans from Portuguese-speaking countries after the independences (1973-75), synchronous with the onset of political and social instabilities, particularly in Angola, Mozambique and Guinea-Bissau, is a case-control. This allusion helps to understand, on the one hand, the complex processes of self-production of housing space in everyday life as a strategy of access to housing within a specific context of reduced state response regarding the promotion of massive housing. On the other hand, it helps to comprehend the recent public and private-public interventions of (re)housing aimed at controlling the access of these communities to space and accommodation, including the consequences of these different scenarios concerning the inclusion/exclusion of these populations in Portugal.

The research has, as object of study, the access of the most vulnerable immigrants, refugees or asylum seekers, to space and housing in Europe, either through the government of the Member States that follow the strategic directives of a discordant European Union, or through the participation of local agents in the process of production and transformation of the urban and housing space. I refer, in particular, to (1) government policies and practices with greater openness to the participation of these immigrants in the production of space, including in regard to the design of (their) urban and housing solutions, granting greater room for manoeuvre in a more inclusive scenario, and (2) organised civil society (local associations, NGOs, religious congregations, etc.) that, within this flexible governance, articulated with refugees and/or other co-citizens residing in Europe – considering and respecting their origins, rhythms and own experiences –, adopts innovative and (vital)ly emancipatory responses, complementary or alternative to the globally advocated.

The main questions that guide this study are:

1. is the European Union promoting the economic, political, socio-spatial and housing inclusion of refugees from Africa and the Middle East in Europe today?;
2. how can Member States, conditioned by the dominant political and economic environment, through a critical analysis of their past experiences on this subject or similar ones, contribute to the establishment of more inclusive national (socio-spatial, urban and housing) policies?;
3. can local communities, together with governments and other players, including immigrants and/or refugees, contribute to identifying practices that point to larger access to urban space, infrastructured housing, and complete citizenship?;
4. are these national and/or local learnings able to revert politically and operationally in favour of the socio-spatial, urban and housing inclusion of refugees on a transnational scale, thus contributing to the building of an inclusive Europe?

Methodologically, I opted for a qualitative approach. Starting from architecture and urbanism as nuclear disciplines, I will make an interdisciplinary bibliographical review on the scientific, theoretical and empirical knowledge, referring to the two identified models of access to space and housing (via global or local responses), that are the object of study, including synergies, permeabilities and consequences. Then I will seek additional empirical information on the subject, case study (from a historical perspective) and cases for counterpointing in present-day Europe, through fieldwork. This includes conducting semi-structured interviews with privileged speakers, namely members of governments (including of the European Union), grassroots communities and representatives of immigrants from the Middle East and African (including Portuguese-speakers in Portugal), and direct observation in European contexts that represent the problem that I address. The restitution of knowledge will take place through communications in scientific meetings, publications in specialised journals and a colloquium with the participation of the agents that were interviewed, adopting a reflexivity logic. The recommendations will be included in the final report and book, also being disseminated on the project website.

The written record of the oral discourse and of the informed observation of the living space will contribute to illuminate the complex processes of access to space and housing for masses and their effects, such as the role of the various players involved in this dynamic. The construction of an iconographic roadmap, consisting of photographs, drawings and maps, based on interviews and observation, besides illustrating

morphologies, typologies and types of housing, among other indicators, constitutes an additional tool for analysing these processes and their materiality. Thus, I intend to decode the logics of appropriation and selfproduction of the urban and housing space (re)produced by these immigrants under study, as well as the physical expression of some governmental solutions (policies, instruments and practices) aimed at the access of these groups to housing, according to different phases (initial reception, support for installation and inclusion), endeavouring to identify points of contact between different practices (global, national and local) and between these practices and the drawing of responses leading to greater inclusion. This cross-cutting approach will be a positive differentiator in broader international projects-to-be about refugees' inclusion in Europe today, reinforcing North-South research partnerships.

The research is structured in two parts, the first referring to collected experiences namely in Portugal and the second to the problematic, both starting from a theoretical essay on “spaces of inclusion” in contemporary Europe. The first part contemplates two chapters alluding to the lessons of the African diaspora including: (I. 1) the study of self-produced neighbourhoods in other people's soil and/or on private nonbuildable land, and (I. 2) areas of rehousing with low costs, especially in the Lisbon Metropolitan Area. The two points of the second part are about: (II. 1) the present materialisation in space of the refugee crisis in Europe, noteworthy in impasse areas that are part of the most covered routes, such as refugee camps in Greece and/or Hungary; and (II. 2) on (inter)sectoral public discourses and responses being outlined in Europe, aimed at the access of these refugees to space and housing, including its contradictions, taking into account different past experiences. These interventions will be analysed in light of the economic-political and social structures of the countries. I refer, in a comprehensive approach, to Greece and/or Hungary, among other Member States, and, in an in-depth look, to Portugal, being a non-wanted peripheral country that is coming out of a financial recession but that wishes to collaborate on this matter, as opposed to Germany, a central and preferred European destination in economic growth that proclaims great capacity for inclusion. This study finishes with a critical analysis that articulates the initial theoretical framework with its empirical parts, preparing the research for its final conclusions.

3.3 STATE OF THE ART

The current refugee crisis became highly visible in 2015 when over one million people from Africa and the Middle East crossed the European borders seeking to survive (UNHCR, 2015). Besides enhancing the image of the Mediterranean as a geographical and cultural barrier, European structural imbalances have become evident due to the financial-ideological rupture between northern and southern countries (Varoufakis, 2016) and, lastly, between the United Kingdom and the other 27 Member States of the European Union, under the Brexit. Furthermore, the pressure of terrorism and nationalist xenophobia in a continent unprepared to receive these populations and habits have deeply increased (Žižek, 2016). By the end of 2015, Portugal had welcomed 699 refugees from 1354 asylum seekers (i.e. population of concern), contrasting with 316,115 individuals of the 749,309 requests addressed to Germany (UNHCR, 2016: 58-59), the European country with “the proacceptance political flag”, having great expression through that year. In a considerably reduced scale and with no border pressure, by 2018, Portugal intends to receive 10,000 refugees, approximately 13% of its present-day Portuguese-speaking African immigrants (SEF, 2015: 65-69).

The urban and housing effects of this complex scenario are yet unexplored. On a macro scale, space produced in the refugee camps of Europe, as identified by Flinders (2016) in line with Lefebvre ([1974] 2000), illustrates the individual (often survival) strategies of everyday life. Concerning Portugal, the urban areas of illegal genesis (AUGI) and the self-produced neighbourhoods located in occupied lands, in both cases inhabited by Africans since the 1970s, illustrate daily processes as well (Raposo, 2012; Cardoso and Perista, 1994). In the long-term, national governments face many local challenges mostly related to the access of housing, urbanisation and the building of citizenship, as encouraged by Lefebvre ([1968] 2009) and Harvey (2008).

Although the MIPEX (2015) indicates an integration of 75% in Portugal and of 61% in Germany, the OECD/EU (2015) declares that 14% and 6% of their immigrants have reduced living conditions. Past governmental responses fall short of immigrants' needs and of the alleged intentions to overcome them. Regarding Portugal, once the SAAL was concluded in 1976 (Bandeirinha, 2007), only after 1990 did the administration conceive new significant public instruments so as to promote housing space. There is the Law of AUGI (1995), whose reconversions were studied by Raposo (2011), and the PER (1993), with 32%

of its segregating rehousing practices targeting Portuguese speaking African immigrants (Malheiros and Mendes, 2007; Malheiros and Fonseca, 2011: 54), followed by some other unsustainable versions (Amilcar et al., 2011). In some countries of origin, as recognised by Melo and Viegas (2014) and Viegas (2015), massive resettlement and rehousing practices are even more segregating.

The Portuguese government wants to contribute towards the inclusion of refugees in Europe: (1) the Working Group for the European Migration Agenda (2015) anticipates a National Action Plan, (2) the State Budget (2016), despite the weak economic growth, provides for the co-financing of European mechanisms up to € 24M, and (3) the Major Options of the Plan (2016-2019) recommend innovative housing policy, stimulating the public reflection (Pereira et al., 2016; Matias, 2016). Germany, meanwhile, intends to maintain economic development by employing immigrant workers, also by providing the construction of 400,000 homes/year for these refugees (Deutsche Bank, 2015, Reuters, 2016). However, Somerville and Steele (2001) reveal how the limited housing options for minorities favour exclusion. Thus, local responses from civil society have emerged all across European countries whilst trying to accommodate these communities inclusively.

4 BRIEF REFLECTION

The cross-checking of theoretical and empirical issues concerning the strategic guidelines being drawn up by the European countries for the socio-spatial and housing inclusion of refugees (and asylum seekers) must take into account, as underlined by the nominated scholars – Foucault, Žižek, Lefebvre and Harvey – , the hegemonic global neoliberal system we live in, as initiated in the late twentieth century having increased at full steam to these days. Regarding the corresponding policies, following Foucault's thoughts ([1977/1978] 2008), this means that the European governments, either from central (Germany) or peripheral (Portugal) countries, may be inclined to create mechanisms of seeming inclusion for the needy immigrants that, in fact, in the long run, contribute instead to the preservation and/or enhancement of a predatory system that will necessarily neglect them. Žižek (1997) addresses a corresponding deception when unveiling the hidden intentions and consequences of the multiculturalism tolerance in Europe, by defending that separation between different cultures results from taking a discriminatory position towards these immigrants. Of interest for my quest of production of “spaces of inclusion”, i.e., spaces where these poor immigrants may really belong to, Lefebvre ([1974] 2000) identifies that most public and/or public-private spaces are being forged so as to create more value, thus to nourish the market logics of capitalism. In such context, access to housing, infrastructures and urban benefits may be taken into account. Nonetheless, the inclusion of refugees (and asylum seekers) in the production of their space – as a legitimate path for the collective construction of a complete form of citizenship – is lost due to the nature of the process. Harvey (2007; 2008) would surely reject this restrictive approach, also, whereas advocating the Right to the City both as a path and effect of the forging of an emancipated and a much more just mankind. This problem is far more relevant as we are confronted with the necessity to create both inclusive living (housing and urban) conditions for (and/or by) these migrants, in need, and their hosting societies. Countries with less border pressure (e.g. Portugal) and that are deprived of flourishing economies may constitute privileged ground for implementing new experiences and practices.

Perchance lesser controlling local governments articulated with grassroots communities and immigrants are now in a more favourable position to identify and implement more inclusive actions than European and/or national satellite administrations. If so, resistances and counteractions wouldn't have to happen in order to defend society and its vital collective needs, this being an indicator of systemic crisis as identified by Foucault ([1977/1978] 2008). Immigrants and civil society would, rather, participate in the constructing of an innovative European global culture having their necessities as priority. Žižek (2016) corroborates this thought by calling to all our human solidarity as opposed to the indifference of the capitalist system. Following an interrelated philosophy, Lefebvre ([1968] 2009; [1974] 2000) refers to spatial practices of inclusion that point to the production of inclusive spaces taking into consideration its use value. For its part, Harvey (2000) finds in the paradoxes and contradictions of the capitalist system the encouragement to overcome it, materialised in Spaces of Hope, these spaces also being what I would classify as “the right to the inclusion”.

ABSTRACT: Like many other large cities in China, Nanjing central area has experienced a large scale urban regeneration since twenty-first Century, mega-retail-Led regeneration, which transforms the original residential land to commercial land, dominates the process. Large scale and huge volume flagship stores emerge on the regenerated land affected by the commercial building model coming from the developed countries. The emerging space form is also supported by the local government, because it can quickly make the image of the city catch up with the international standard, significantly enhance the level of physical space environment and bring considerable economic income. Nevertheless, more and more attention has been paid to the negative social effects brought by this space form. Taking the central area of Nanjing as the research object, based on 2000-2015 historical topographic maps, this paper reveals the

transformation characteristics of central area space form in Nanjing, it shows that the space form has been transformed from the dispersed, high density and low plot ratio to the concentrated, low density and high plot ratio, in the meantime, it has produced many so-called "public spaces". According to the authors' first-hand survey data, this paper finds that the so-called "public spaces" are just the outdoor spaces separately belong to different commercial flagship stores, and in which there exist obvious spatial injustice. The injustice embodies in two aspects: one is the function simplification, the "public spaces" only bear the commercial and transportation functions, which can not meet the requirements of the central area public spaces to carry a variety of social activities; the other is the environment exclusiveness, the "public spaces" just designed to attract the young middle class with a consumption orientation, which can hardly be used conveniently, comfortably and with dignity by all regardless of age or economic circumstances. This paper also analyzes the production mechanism of space injustice from the aspect of China's land regeneration system, and the local government entrepreneurialism and the capitalization of space production are defines as the root cause. In accordance with the analysis result, this paper suggests the public policy attributes of urban regeneration should be strengthened through the reformation of the land regeneration system and planning-making system, and the improvement of public participation, so as to obtain the realization of spatial justice.

KEYWORDS: Spatial Injustice; Mega-retail-led regeneration; Production mechanism; Central area public spaces; Nanjing, China

1 INTRODUCTION

Public space in central area is an important carrier of urban public social activities, it can promote the social sustainable development better with higher inclusiveness. The experiences of construction in Europe and America in the latter half of the last century demonstrated that, property-led regeneration would lead to privatization of the public space in the central area, and losing the true "Publicness" (He and Wu, 2005; Steel and Symes, 2005; Low and Smith, 2006; Minton, 2006; Madanipour, 2013; Tallen, 2013). At the end of the last century, western scholars combined social justice and space, and put forward the concept of "Spatial Justice" (Lefebvre, 1991; Harvey, 2008; Harvey, 2010; Soja, 2010), which raised the reexamination of the social attributes of public space, such issues as accessibility, privacy of the public space and the right to develop and use of different populations had increasingly become the focus (Mitchell, 2003; Pasaogullari and Doratli, 2004; Varna and Tiesdell, 2010; Gehl, 2011; Németh and Schmidt, 2011; Mehta, 2014).

China's modernization and urbanization are similar to those of European and American countries in the 1970s and 1980s, property-led regeneration dominates the process (He and Liu, 2008), and the central area often has the most frequent urban regeneration activities. Under the regeneration, the quantity, shape, environmental quality and function content of public space in central area have changed remarkably. Nevertheless, like the western countries, the transformation of public space under the economic-oriented regeneration always focuses the improvement of the environment quality so as to attract the consumer groups, and neglect the essential attributes of undertaking social public activities (Yang and Xu, 2011; Zhang and Hu, 2013).

In recent years, with the promulgation of the national planning documents, New Urbanization Plan of the State (2014-2020) and Opinions on Further Strengthening the Administration of Urban Planning and Construction (2016), and the convening of the "Central City Working Conference (2015)", the concept of seeking social equity has been emphasized. Simultaneously, the thoughts of "Space Justice" and "Inclusive City" are introduced to China, and also the "New Urban Agenda", which was issued at the Third United Nations Conference on Housing and Urban Sustainable Development held in Ecuador in 2016, appealing to all the countries to promote the construction of "Inclusive City" and "Shared City", particularly emphasizing the importance of public space (Shi, 2017). Under the influence of these global planning concepts, Chinese scholars begin to pay attention to the social benefits of public goods such as public space, from qualitative point of view, some scholars criticize the lack of public justice in China's public space (Yang, 2006 ; Chen and Ye, 2009a; Yang and Xu, 2011; Zhang and Hu, 2013), discuss the definition of publicness in public space (Yu, 2005; Xu and Semsroth, 2013), social attribute characteristics (Yang, 2013) and responsive solution of privatization of public space (Dai and Xing, 2010; Zhang and Yu, 2010), but lack the quantitative research. Hence, this paper hence takes Nanjing Xinjiekou city centre as the research object, based on the 2000-2015 year history maps and one-hand survey data, and

quantitatively analyses the change of public space form and function, and the social injustice of the current public space and its production mechanism.

2 CONCEPT DEFINITION AND STUDY OBJECT

2.1 CONCEPT DEFINITION

2.1.1 PUBLIC SPACE

Public space, as a technical terminology, first appeared in sociology and Political Philosophy, in the early 1960s, it gradually was introduced to the subject area of urban planning, and appeared in architectural academic works written by Mumford and Jacobs. It has different definitions according to different angles (such as social research, political philosophy, and spatial design, etc.), but they also has something in common (such as accessibility) (Chen and Ye, 2009b). This paper uses the most generalized definition of the concept that public space is the space all the people have the right to approach and visit freely.

2.1.2 SPATIAL JUSTICE

Lefebvre and Foucault first expanded the social attribute of space, from a static perspective to a dynamic perspective, and from "Containers" of social activities to "Space Production" under the impact of social relations (Lefebvre, 1991; Elden, 2016). Under their influence, Harvey, soya and others continue to deepen the theory of "Spatial Justice", and argue that, under the condition of capital operation and political power, there are social injustice phenomena such as unfair distribution and possession of space resources (Harvey, 2008; Harvey, 2010; Soja, 2010). As far as public space is concerned, as social public goods, its spatial justice should be reflected on the fairness of the public space production process and fairness of use right (Madanipour, 2013).

2.2 STUDY OBJECT

Nanjing, the capital of Jiangsu Province, is an important regional central city of the Yangtze River Delta, with a population of 8 million. Nanjing Xinjiekou district is located in the heart of the inner city, because of its important traffic location and commercial foundation, it has been the location of the old city centre of Nanjing since the foundation of the People's Republic of China, taking Zhongshan Road, Zhongshan East Road, Zhongshan South Road and Hanzhong road as the main framework, its general scope is the area extending around the intersection. Since the reform and opening-up, especially after entering the new century, it has a rapid development and has gradually become the most concentrated area of public facilities in the inner city, and also the most densely populated and the most crowded area. The new Nanjing Plan (2013) clearly pointed out that Xinjiekou area will continue to be the city centre bearing the important public activities, therefore this paper selects the most central 1.56 square kilometer area of Xinjiekou as the study object (Fig.1).

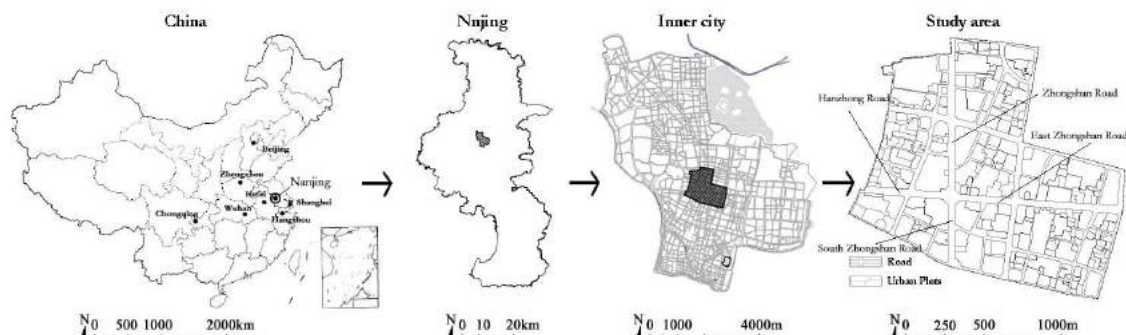

Figure 1 - Study Area Location. (Source: Created by the author)

3 EVOLUTION OF PUBLIC SPACE

3.1 OVERALL SPATIAL EVOLUTION

In order to clarify the process of public space production, we first need to analyze the characteristics of the overall spatial evolution of the central area. This paper divides it into two aspects of land use and spatial morphology.

3.1.1 LAND USE EVOLUTION

Since the reform and opening-up, China's major cities have rapidly changed their development goals from "Productive City" to "Living City", the central area has become the major region for promoting urban economic development, improving people's living standards and improving the quality and image of urban environment, and commercial-office use buildings full of modern international flavor just cater to this demand (Wu et al., 1999; Geng, 1999). Because of the limited financial resources, the property-led regeneration has been perceived as a "panacea" of the local governments (He and Wu, 2005; He and Liu, 2008; Huang and Cao, 2011).

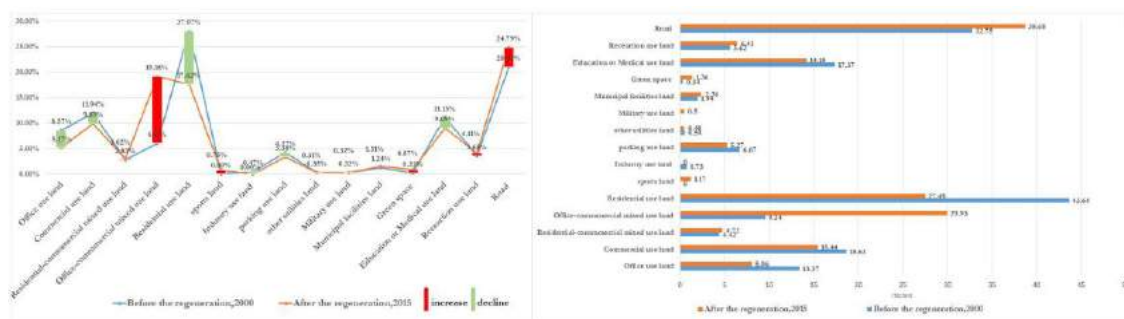

Figure 2 - The Proportion and Area of Land Function Changes. (Source: Created by the author)

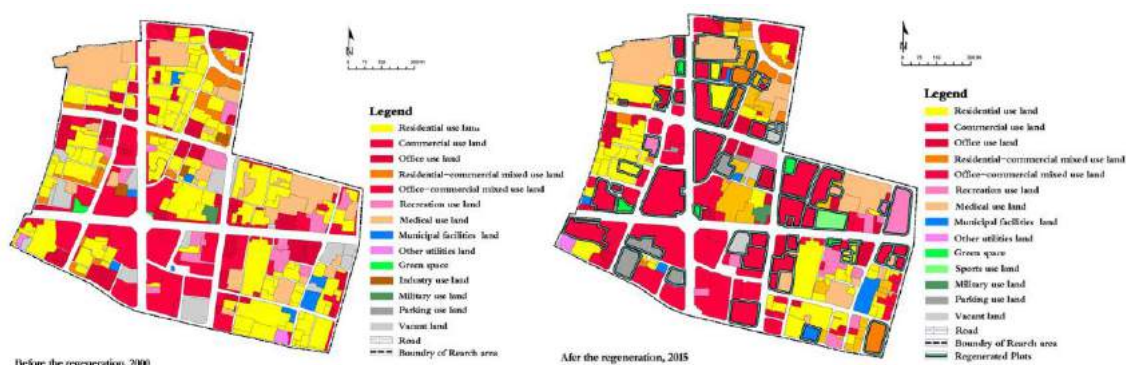

Figure 3 - Changes in the Functional Layout of the Land. (Source: Based on historical topographic maps)

In research area, from 2000 to 2015, the former 0.73 hectares of industrial land is completely cancelled, and the total amount of residential land decreases from 43.64 hectares to 27.49 hectares, and the proportion of residential land drops from 27.97% to 17.62%, the proportion of commercial-office mixed use land increased from 6.11% to 19.18% (Fig.2). Comparing the changes in the past 15 years, we can find that 60 plots are regenerated, accounting for about 32% of the total land area, of which 37 plots have become commercial and office related use after the regeneration (Fig.3).

3.1.2 SPATIAL MORPHOLOGY EVOLUTION

In the study area, the overall plot ratio in 2015 is 3.52 compared with 2.47 in 2000, the plot ratio of new regenerated plots is generally over 4 (Fig.4). The increase in the volume rate will inevitably lead to the

elevation of the building height or the promotion of the building density. Through the model contrast analysis, the overall height in 2015 has obviously improved, the new commercial-office building height is generally above 100m, buildings higher than 100m has increased from 22 in 2000 to 202. In the aspect of building density, most former plots demolished stands houses with higher density and lower height, due to flow distribution needs and urban image considerations, the regenerated commercial buildings need to have enough outdoor space. Through comparison, we can find that the overall building density decreased significantly (the overall building density was 0.44 in 2000, and that was 0.37 in 2015)(Fig.5). This indicates that total amount of outdoor space increased after regenerated, excluding the area increased by the road widening, the actual increase in external space area is 5.8 hectares.

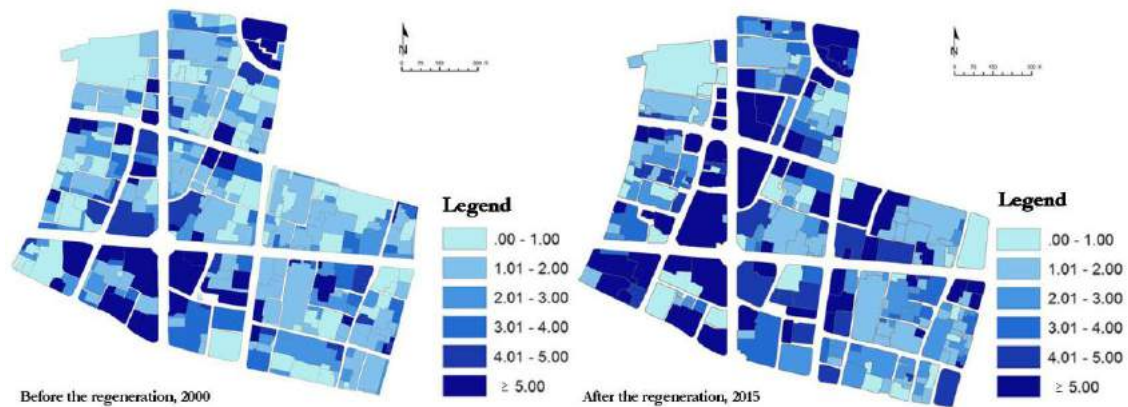

Figure 4 - Plot Ratio Change. (Source: Created by the Author Based on historical maps)

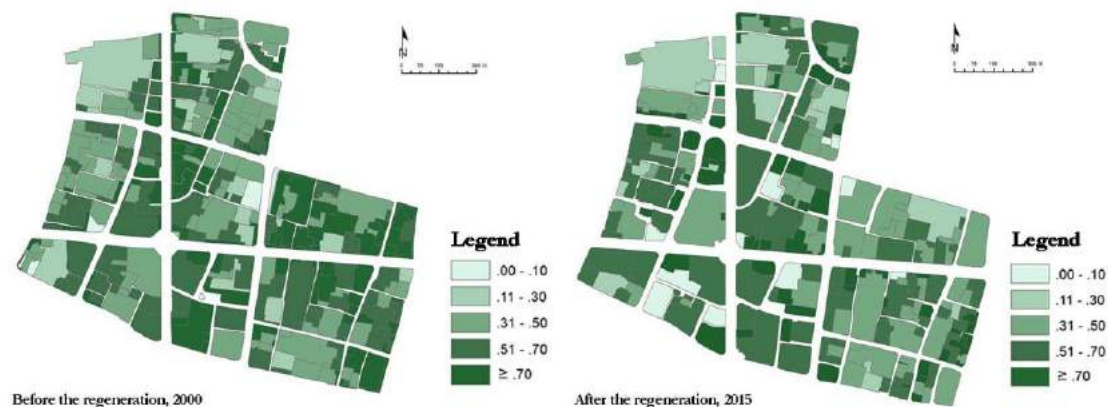

Figure 5 - Building Density Change. (Source: Created by the Author Based on historical maps)

Through the analysis above, we can conclude that the overall spatial morphology variation trend of the central area is from high density and low plot ratio to the low density and high plot ratio. Under this trend, the quantity of outdoor space has been improved obviously, which provides the basic condition for the increase of public space.

3.2 PUBLIC SPACE EVOLUTION

3.2.1 QUANTITATIVE CHANGE IN PUBLIC SPACE

Whether the increase of outdoor space means the increase of public space, we need to judge it according to the definition of public space. Through comparative analysis of regenerated plots accessibility before and after (Fig.6), the new residential areas, hotels, administrative offices and educational facilities are all under closed management, which means that a large amount of the public space has been privatized. As a result, although the outdoor space has increased by 5.8 hectares, but actually inaccessible outdoor space has increased by 3.5 hectares, and accessible outdoor space only has an increase of 2.3 hectares.

Compared with the land use map it can be found that, the new public spaces with high accessibility are all the additional products of public facilities such as commercial, business, office, culture and entertainment use land, especially internal and peripheral areas of office -commercial mixed use land.

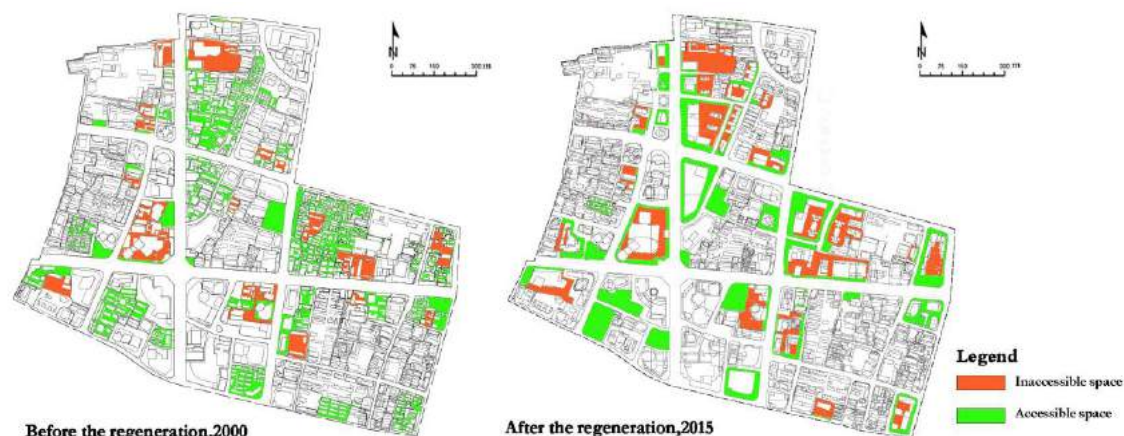

Figure 6 - Comparative Analysis on the Accessibility of Regenerated Plots Public Space.
(Source: Based on Author's Survey)

3.2.2 PUBLIC SPACE MORPHOLOGY EVOLUTION

Comparing the plots texture before and after the regeneration, the public space form has changed remarkably (Fig.7). In aspect of form, the public space shows a change trend from decentralization to agglomeration, from complexity to simplicity, some plots are even completely demolished. In aspect of location, the public space is characterized by the change from the center of the plot to the edge and from the interior to the exterior. Morphological changes, to some extent, will make space loose attraction, and be not conducive to the set the space for stay. The transformation in location, as a result of accessibility, seems to be conducive to enhancing the publicness.

Figure 7 - Typical Plots Texture Analysis Before and After Regeneration.
(Source: Based on historical topographic maps)

4 THE SOCIAL PERFORMANCE OF PUBLIC SPACE

Whether the new public space is more public, and can it embody wider social justice? In May 2016, we conducted on-site observation and questionnaire survey of the new public spaces on the day and night of the working days, the day and night during the holidays, so as to analyze the gender, age, income and occupation of the population and the types of their activities to evaluate the social performance.

4.1 TYPES OF ACTIVITIES IN PUBLIC SPACE

Based on investigation result, it can be found the main types of activities in new public spaces are traffic and business, and there is 6.85 hectares public space only having traffic function, 5.57 hectares of public space is only with business and traffic functions. There are only 2.78 hectares of public space for daily activities such as rest, recreation, sports, landscape and public welfare activities, and these spaces are fragmented and immethodical (Fig.8).

Figure 8 - Spatial Distribution of Activities. (Source: Based on Author's Survey)

Figure9 - Spatial Distribution of Children and the Old. (Source: Based on Author's Survey)

4.2 PEOPLE WHO USE THE PUBLIC SPACE

4.2.1 GENDER

Overall, the proportion of female in the public space use population in the central area is about 64%, higher than that of male. At night and on weekends, this tendency is more pronounced due to the increase of business activities (especially shopping). Spatially, the public space that female use mainly concentrated in the surrounding area of commercial facilities, and the male ratio is higher around the office, hotel, parking facilities, the sex ratio is basically equal in the periphery of culture and tourism facilities. According to the census data of the population sampling survey of Nanjing in 2015, males in Nanjing's permanent population is 4.24 million, accounting for 51.52% of the total, higher than that of female (Table.1).

Therefore, this paper argues that, because of the increase of commercial use land, the public space in the central area becomes more attractive to the female population.

Sex	Working days		Weekend & Holidays		Overall result of the survey	Nanjing population census data
	Daytime	Night	Daytime	Night		
Male	35.95%	33.91%	34.65%	31.67%	35.88%	51.52%
Female	64.05%	66.09%	65.35%	68.33%	64.12%	48.48%

Table 1 – Gender distribution in Public Space. (Source: Based on Author's Survey)

4.2.2 AGE

The population of Nanjing has shown an aging trend since 2000, in the light of the census data of the population sampling survey of Nanjing in 2015, compared with the sixth national census in 2010, 0-14 years old population proportion increases by 0.71 percent, the proportion of the population aged 15-64 decreases 2.27 percent, the proportion of the population aged 65 and over rises 1.56 percentage points. The age distribution of the population using public space in the central area does not agree with that of the city, the age of the population is 15-40 years old, accounting for about 78%, and the population under 15 years old accounts for about 4%, and the population aged 65 and above is only about 6% (Table.2). The spatial distribution of children under 15 years of age is more concentrated in the place around commercial buildings where people are less crowded, they mostly engage in simple recreational activities under the supervision of their parents during waiting for the other relatives. People over 65 years old are distributed in parks, green spaces and the places where is less crowded and there are seats, around business and

commercial buildings, mainly engaged in activities such as fitness, conversation and waiting. So we can find that, spatial distribution of the two age group shows a trend of marginalization (Fig.9).

	0-14years old proportion	15-40years old proportion	41-64years old proportion	Above 65 years old proportion
Nanjing population census data	10.21%	79.10%		10.69%
Research area data	4.12%	78.26%	11.35%	6.27%

Table 2 – Age distribution in Public Space. (Source: Based on Author's Survey)

4.2.3 INCOME AND OCCUPATION

The survey result does not indicate the spatial injustice in public space caused by income, but the vocational differentiation phenomenon is obvious. According to research statistics, population whose monthly income less than 6000RMB accounts for the main proportion (about 68%), that below 2000RMB accounts for 34.12%, and that over 20000RMB only accounts for 4.56% (Fig.10). The results of the occupation survey indicates that students are the main users (30.56%), while the proportion of migrant workers and retirees is low, accounting for 3.12% and 7.89% respectively (Fig.11). Income conditions does not show spatial injustice for two reasons, first of all, student belongs to the group of which monthly income is less than 2000RMB, but their annual consumption is far more than China's annual per capita disposable income, the main reason is that, under the family's indulgence, the only children have abnormal consumer behavior such as blind consumption, excessive consumption, comparison consumption and hedonic consumption (Zeng, 2012); secondly, that is related to the consumption characteristics of high-income group, according to the research of Hu Xiaochun et al. (2010), China's high-consumption group's survival consumption (food and clothing) and public consumption (public entertainment and shopping) gradually reduced, and their development consumption (education, health care) and minority consumption (consumption that seeking privacy and novelty, non-localized consumption) gradually increased. Therefore, they prefer the quiet, natural, healthy and novel places, so the central area public space, dominated by mass and inward consumption, loses its attraction to the high-income group, and it also can not provide fitness, natural health and leisure functions, which results in lower high-income group proportion. The imbalance of occupational categories shows the nature that the public space in the central area lacks the attention to the rural migrant workers and the elderly groups with lower consumption ability.

Figure 10 - Income Distribution in Public Space.(Source: Based on Author's Survey)

Figure 11 - Occupation Distribution in Public Space. (Source: Based on Author's Survey)

5 THE PRODUCTION MECHANISM OF SPATIAL INJUSTICE

The theory of Spatial Justice shows that, the imbalance of social performance is due to the imbalance of space production and governance power. Therefore, this paper analyzes the mechanism of injustice in public space from two aspects: the development mechanism and management ownership.

5.1 THE DEVELOPMENT MECHANISM

5.1.1 THE PROCESS OF PUBLIC SPACE PRODUCTION

China is a country with public ownership of land, and the land belongs to the state or collectives.

After the reform and opening up, the state breaks the original land allocation system, and gradually allows the local government to transfer the use right of land, separating the land ownership and use rights stripped. So the central area land of inner city has become the focus of land transfer because of its significant asset value. In order to regulate and control the transfer market, to achieve the planning objectives of government better, use the land resources rationally and improve land use efficiency (Wang and Yong, 2011), at the end of the 1990s, China began to establish land banking system to manage the regeneration and new development. In this system, the urban regeneration process is divided into three stages: formulating controlling plan, land transfer and formulating constructive plan, so public space construction has the corresponding task in different stages (Table.3).

Stage	Task and related content
Formulating controlling plan	1. In the event of public space under independent construction, determine its location, size, greening rate and specific facilities 2. In the event of public space under non-independent construction, only determine its approximate size by building density, offer construction proposals through flexible design guidelines
Land transfer	The content determined by controlling plan should be embodied as indicators and transfer conditions
Formulating constructive plan	The construction entities carry out specific spatial design according to the transfer conditions, and determine the specific forms, layout and styles of greening, paving, furniture and water

Table 3 –The Task of Public Space Construction in Different Stages. (Source: Created by the Author)

5.1.2 THE ROLE OF LOCAL GOVERNMENT

The government has absolute control power of three stages, its nature should be to protect the public interest, however, under the background of decentralization, marketization and Globalization, the pursuit of economic interests and political interests has become the core of the local government's concern, it presents a significant state of entrepreneurialism (Zhang et al., 2006; Huang and Cao, 2011). Urban spatial resources, as the competitive capital directly controlled by local governments, become the main guarantee for their interests (Fig.12). When the government gets rid of the representative of the public interests and has its own interests, it will inevitably reduce its input and attention to the public interest (Huang and Cao, 2011), so it impute the construction responsibility of public space to the developer and lower the construction standards (Table.4).

Figure 12 - Proportion of Transfer-land Fees in Nanjing Local Government Fiscal Revenue Change Trend, 2000-2015.(Source: Nanjing City Statistical Yearbook, 2001-2016. Available at: <http://221.226.86.104/file/nj2004/njtjnj.htm>)

5.1.3 THE ROLE OF THE DEVELOPERS

As the main body of market capital, developers are seeking maximum benefit as much as possible. Therefore, how to reduce costs and how to create and use conditions for value output is the main consideration. Its role should only be limited to the organizers and implementers of constructive planning, for obtaining more profits, because of capital advantages and the local government's desire for revenues, some large developers can participate in the controlling plan phase, negotiate or exchange conditional with the government to modify design standards and reduce input on public facilities (including all aspects of public space) (Wang, 2014). In the constructive plan stage, taking advantage of the power of the organizer and executor, the developers control the designers and the constructors to make the outdoor space as "socalled public space" to attract the consumers and exclude the other people who belong to "ineffective-use" group. Hence, the public space in the plots constructed by developers is entirely the production under the guidance of the capital, and it will often only have commercial and traffic functions.

Stages	The government shows a disregard for public interests of public space
Formulating controlling plan	Impute the construction responsibility of public space; The indicators of each plot is conducive to commercial profitable, only setting rigid requirements through the building density index
Land transfer	Raise the price of land as much as possible, thus to force developers to do everything to reduce public facilities construction
Formulating constructive plan	Have close supervision on the rigid design conditions, be in a muddle over the elastic demand for the greening, paving, furniture and water

Table 4 –The Role of Local Government in Different Stages. (Source: Created by the Author)

5.1.4 THE ROLE OF THE PLANNERS

Planners are the executors and proponents of controlling plan and constructive plan, and they have the dual identities of the public and the professionals (Zhang, 2004; Wang, 2014). As the public, they have the social morality of pursuing social equity, but they also have the pressure of life, and must to obtain economic benefits by selling their own skills. In fact, planners always have nothing to do with the plots they design, because of the government and developers' monopoly power, in order to gain economic benefits faster, higher and longer, they become "service staff" to meet all the needs of employers (Zhou and Sun, 2006; Wei et al., 2012), as far as public space is concerned, they lose the attention to its publicness. As the professionals, planners should have the ability to provide professional technical advice to realize the public attribute of public space. Nevertheless, under the influence of the government and developers' behavior of concerning the image of public space and the consumption service level only, their professional skills also emphasize the aspects of physical economic attribute, ignoring the social attribute.

5.1.5 THE ROLE OF THE PUBLIC

The public is the largest beneficiary of public interest, so the pursuit of public interest maximization is the only goal of the public, they should have been important participants, supervisors, advocates and stakeholders at all stages, but in fact they have been marginalized. There are two reasons, firstly, because the public interest is made up of different personal interests, in the period of economic rapid development, the public usually pays more attention to their own individual interests and economic interest, but ignores the public interest and social interest (Wang, 2014), residents in the original plots of central area are almost all moved to the other places (Yuan et al., 2010), therefore, the public space in the central area, which is supposed to be completely public, has become the matter has something to do with everyone, but no one cares about it; secondly, because of the monopoly of power and the pursuit of economic efficiency, local governments have neglected the importance of public participation for a long time, which leads to the limitation of the public participation in the three stages. At present, public participation is divided into two forms: elite participation and general public participation. Elite participation means that, in the planning process, experts and scholars are invited to offer consulting, but the local government control the invitation right, in the meantime, experts and scholars are also planners, so to some extent they are dependent on the local authorities (Wang, 2014), and they show mercy at consultative meeting, with care only about the hard bottom line and neglect of the elastic requirements. The general public participation in the planning stage is currently limited to questionnaires, forums, notice of planning results and public comment, although the state has promulgated the policy to emphasize the status of public participation, but that only

enrich the methods of notification, information and consultation (such as media and network), not changing the participation level (Yang, 2011). Since the public does not have the right to make decisions and veto, the true public space can not be realized.

5.2 THE MANAGEMENT OF PUBLIC SPACE

After the construction of public space, to some extent, its management also determines the use of public space (Mitchell, 2003; Low and Smith, 2006; Madanipour, 2013). In accordance with the regulations of “Nanjing Urban Governance Regulations”, “Regulations on the Administration of Nanjing City Appearance” and “Measures for the Administration of the Area in Front of the Buildings in Nanjing”, each operator have the responsibility to keep the ground and the façade clean and facilities neat and orderly within the scope of land that they have the use right, including trees, lawns, furniture and pools. If they are contaminated, damaged or missing, the operator should clean and repair them in time, otherwise the administrative penalty will be imposed. Therefore, in order to avoid unnecessary investment and maintenance costs, the operators often set barriers to keep visitors away from the trees, lawns, water and sculptures, and they also try their best to reduce the seats and the place where activities other than consumption may be carried out. In research area, only the independent-construction public space is managed by the government, in which there are more diverse social activities and population, but of the 60 regenerated plots, only 5 are under independent construction with a total area of 1.3 hectares.

Figure 13 – Public Spcae Management. (Source: Created by the Author Based on the Map of Land Right in Nanjing)

6 CONCLUSION

Through historical evolution analysis and current situation investigation, this paper conduces the qualitative and quantitative analysis of spatial injustice in public space of Nanjing Xinjiekou city centre, and from the aspect of regeneration system and management ownership, the internal mechanism causing injustice is discussed.

In the context of overall spatial evolution, the outdoor space in the central area has increased significantly, but the increase in public space accounts only half of the increase in outdoor space, and most is located at the commercial and office use plots. The public space form shows a change trend from decentralization to agglomeration, from complexity to simplicity, and the location changes from the center of the plot to the edge and from the interior to the exterior. Through the research on the social performance of new public space, this paper finds that new public space has spatial injustice such as function injustice (ignoring social function), gender injustice (ignoring male), age injustice (ignoring children and the elderly) and hierarchy injustice (ignoring migrant workers and retirees).

Based on the analysis of the regeneration system, we find that, the government holds the absolute power of public space development, but its entrepreneurial behavior make it get rid of the role of public interests guardian, and to turn public space a subsidiary product of the pursuit of profit, with no guarantee of its publicness. As for the planners and the public, the former have become the echo of government decisions because of their own income interests, and the latter cannot play a decisive role because of the limited degree of participation.

From the aspect of management ownership, after the construction, most public spaces are managed by the business operator. Under the restriction of the city management regulations, business operators try their best to reduce the social function of public space in order to minimize the investment and maintenance costs.

Through the analysis of injustice and internal mechanism, if we want to improve the publicness of public space and pursue the real spatial justice, we may proceed from four aspects. First of all, the fundamental change in the current injustice is to get the local government out of the shackle of the land economy, making it move back from the enterprising government to the public government; Secondly, we can set up the statutory design guideline of public space, and bring it into the transfer condition of the land; Thirdly, we should reclaim the management right of the existing public space, improve the public space environment and increase social space and facilities; Finally, the degree of public participation in the design and construction should be promoted, and the public should be ensured the decision-making power.

ID 1400|- INTEREST AT STAKE: A NON-SUBSTANTIAL READING OF COMMUNITY

Li Destri Nicosia Giulia¹

1 INTRODUCTION

Talking about community is becoming more and more dangerous, and the reason for this danger is quite simple: the concept of community seems to resonate with the post-political warning emerging from our times (Zizek, 2003). In a post-political perspective, a community is an assemble of individuals who share – more or less explicitly and overtly – a so called “commonality” which can be variously stated: a place, a purpose, a cultural feature, a context, a practice. Thanks to this commonality we can find a certain degree of homogeneity among those individuals, and thanks to this homogeneity we can find a certain degree of compliance through which we can define, or even predict, their actions. What we lose in this frame is the political dimension of community as «the unavoidable challenge of negotiating a here-and-now» (Massey 2014: 140), washed away and reduced to a mere contractual dispute on supply services and management. The (non-obvious) happy end is widely known: government becomes governance, politics becomes administration, class struggle becomes a neighbours' scuffle and, consequently, the space of resistance leaves room for the end of history to unfold (Fukuyama, 2003). The underlying utopia is the emergence of self-regulating subjects who are able to recognize, despite their different interests and needs, the best of all possible worlds: a world where efficiency is simply more advisable. Following this path, it is worth to wonder how we can regain a proper political dimension of the concept of community.

In planning theory, we can find two main ways which can lead to this regainment. On one hand, we have the deliberative tradition of the communicative turn: from this point of view, the community is first and foremost a community of speakers who are able to recognize, through argumentation, the greatest good (though a context-grounded one) translatable in a normative rationality. In this case, the judgement about what is good is no longer emerging from the individual conscience of each subject but rather from dialogue, the means through which the political is unearthed according to the Aristotle's quotation of human beings as “social animals”, who can become proper citizens only in the context of a discursive arena (the agorà).

On the other, we have the radical tradition of critical theorists: here the community is not the ontological place of rationality but the proper milieu of multiple conflicts. Thanks to thinkers like Ernesto Laclau, Chantal Mouffe and Jaques Rancière, just to mention a few, the Marxist class struggle overflows the limits of the economic field to reach the many overlaps of intersectionality (race, gender, social class, age etc.). The community becomes the perfect place of variously articulated struggles for hegemony, that outline different and transversal political subjects through likewise different and transversal logics of equivalence (Laclau, 2008): what we lose in this case is the chance to indicate a unique fundament (e.g. rationality) through which we can describe the core of a proper political action (e.g. a shared purpose reached through

rational dialogues). Rather, and however paradoxical this may appear, the political of the community is the very impossibility of finding a definite and univocal fundament (Rancière, 2007).

Given this frame, many researchers and academics have indicated potentialities and limits for both these attempts to regain the political dimension of the concept of community in planning theory. Even though the deliberative tradition proved a convenient answer as both theory of planning and procedural tool, it is nonetheless susceptible of harsh criticism due to a rationalist naivety in considering the possibility of creating a neutral place where each subject can dismiss his/her relations and positions of power, and just act as a rational subject. At worst, this naivety becomes a real manipulation perfectly fitted with the neoliberal paradigm. Besides, although the radical tradition has inherited from Post-structuralism and Post-modernism a disenchanted gaze, along with a fruitful and incisive ability to read reality as theory about planning, it shows procedural and operational weaknesses in translating its critical interpretation in practical processes of transformation (Roskamm, 2015). So far and for distinct reasons, both these attempts risk a dead end or, at least, a double bind: through their lenses, planning looks like a transformative discipline that is struggling against its own inability to transform reality. On one hand, planning simplifies and reduces this reality to a community of rational beings disconnected from power geometries (Massey, 1994); on the other, it just limits itself to describe phenomenologically those intricate power geometries restraining the concept of community to its ungrounded and everchanging conflictual becomings.

What is the reason to keep talking about (and researching on) community? How can we redress (assuming we need to do so) the post-political tendency which seems to characterize this concept? How can we reframe and represent its political dimension, as well as try to use its transformative potential in the context of a planning practice? What does this use mean to us as researchers?

My assumption is that this kind of questions allows us to consider the community as a dimension of challenge, pleasure and responsibility of co-existing with others, as well as to defy dominant narratives and try to unveil their contextual circumstances and consequences. But, and this is my point, we should do that in order to re-functionalize the semantic field of the concept of community and to make this re-functionalization more than a simple theoretical exercise, rather a praxis which can convey and handle issues, themes and motives to engage with the very political project expressed by the question: and now how are we going to live together (Massey, 2014)?

2 A NON-SUBSTANTIAL CONCEPT OF COMMUNITY

Two starting conditions – closely interdependent – are indispensable for the political dimension of community to emerge. First, we need to renounce any substantialist interpretation through which searching for a “correct” and “authentic” understanding of this concept, as well as its (alleged) factual equivalent. From this point of view, I think it would be much more interesting to put into question the reasons why a specific theory appears more effective and explanatory than others (e.g. for what purpose is this idea of community widely recognized?), in place of wondering whether a theory could provide the best interpretation of a fact (e.g. is this idea of community true?).

Second, this implies an implementation of our work as researchers with a sort of meta-analysis of our position to indicate the conditions of possibility of our speech (e.g. where are we talking from? whom are we talking to? by what means?) (Porter, 2010). Indeed, the need to renounce any substantialist interpretation of community is not only about concepts and theoretical tools, rather it encompasses the very speech of researchers: wondering why a research question and its specific formulation appear more urgent than others is exactly to opt for a clear epistemological position with respect to both the way we consider facts around us and the way we consider ourselves among them.

In this respect, if we want to put aside substantial readings of the concept of community, we should turn down the idea of community as a group of people who share akin features, similar backgrounds and typical behaviors and, if anything, we should look at this concept as a dispositif (Foucault, 2004; Agamben, 2006), on both theoretical and operative levels, which reactivate – in different ways and with different consequences – what we can indicate as a general disposition to live together. The term dispositif (translated as “apparatus” or “device”) means whatever can guide, orient, determine, shape and control behaviors, opinions, thoughts and speeches. Indeed, this does not only include institutions, laws, norms,

scientific statements and moral principles (including the networks of relationships those elements established among each other), but also tools, physical conditions, methods, languages and practices in which we are constantly immersed (as researchers too). For this reason, the attempt to formulate a non-substantialist concept of community cannot culminate in a positive and conclusive definition of it. Rather, we should try to point more toward a field than a proper object of analysis. In other words, we need to define as best we can its coordinates and strategies of autopoiesis, and even more so, we need to understand what is at stake given a specific context. At this juncture, the importance of the context is not only determined by social, political and economic trajectories which crisscross it, but from the conceptual (symbolic, narrative, representational and so forth) products that a specific context has been able to create and put into practice. Ultimately, we should be aware that this conceptual archipelago is not safe by the only virtue of its possible moral merits and standings, especially if what is at stake is still unclear and underestimated.

The consequence of this non-substantial reading of community as dispositif and field, rather than as object and natural fact, is to shift our attention from the concern about the creation of an “us” to the ways in which this “us” has been challenging time after time, becoming the field for new joints, fractures and belongings as always never-end contested processes (Desmond, 2014). In view of this, the research aim will no longer be to define “who we [they] are”, but all those minimum breakpoints which questioned this very definition. By themselves, these breakpoints do not exclude the creation of an “us”. However, in the process of this creation, the focus will be to point to the negotiating aspects of the matter, which are understood as the symbolic, discursive and relational adjustments, deviations and adaptations which express the tension between the production of a collective identity and the production of an interest at stake: in other words, all those different techniques of subjectivation (Foucault, 2016) through which learning to be affected as processes of stakeholderization (Marres, 2005; Metzger, 2013).

At this point, I assume that the political dimension of the concept of community emerges precisely from refusing the idea of community in a traditional and essentialist sense and, specifically, when the very idea of community is being questioned through processes which reframe and redefine the field of legitimacy of this term as well as the use people have made of it in a specific context and under specific circumstances. However counterintuitive this formulation might appear, it has the purpose to rethink (and to operationalize) the concept of community putting aside a series of categories and attributions (such as identities, cultures and traditions) which tend to reduce its meaning to a purely positivistic interpretation, as such univocally definable and traceable, and which can let it fall into the binary logic of inclusion/exclusion. Rather, the attempt is to treat those categories and attributions from an exquisitely relational point of view, trying to understand not only how these elements change by hybridizing themselves with others, but rather trying to highlight the ways in which – in the hybridization – they are questioned trying to “keep the conversation going” (Greenwood, 2007).

So, when I chose Riace as field of my research and moved there in January 2017, the main questions were: could the transformations occurred in this town during the past 20 years have taken place as a process of questioning the traditional meaning of community and redefining its legitimacy? And if so, what are the repercussions of this process on local government and governance? Is this producing an effective link between the satisfaction of human needs and the socio-political capacity and access to resources, especially with regard to both inhabitants and refugees, as well as the precarious socio-economic equilibrium of the area?

3 OVERVIEW ON RIACE

Riace is a small town of the Ionian Calabrian coast, called Locride, in the metropolitan area of Reggio Calabria, south of Italy. As many other towns in southern Italy, Riace has experienced a process of constant depopulation, particularly during the ‘50s with flows to northern Europe, Canada and Australia, and around the ‘70s and ‘80s with flows to the north of Italy. Corruption and mafia influence has brought economy and social tissue to a near standstill, and a massive lack in public services and infrastructures is the main cause of a deep marginalization. Nevertheless, since 1998 Riace has been addressing both the refugee issues and the inland depopulation challenges in Italy, enough to be recognized – by national and international media, as well as leading Italian and European institutional figures – as a “role model” to open up a better future for crisis-struck areas by an integrated practice of refugee hosting.

Like other towns in Calabria, Riace is split into two settlements, with 7km between them: Borgo Superiore (High Borough), located in the mountains, and the so-called Marina (Marine), located on the Ionian coast. Marina is a spontaneous and informal settlement built during the late '70s, and it is generally considered – verbatim – as the “refined area” whose inhabitants have emancipated themselves from the former rural condition finding employment in public administration sectors or leading small building firms mainly. Currently, Riace counts about 2,000 inhabitants, 1,000 of which dwell in Marina and 1,000 in Borgo Superiore. Among them, and more or less equally distributed between the two settlements, 500 are refugees included in CAS (Centro di accoglienza straordinaria, Extra-ordinary Welcome Center) and SPRAR (Sistema di protezione per richiedenti asilo e rifugiati, Protection System for Asylum Seekers and Refugees) projects. CASs are facilities providing for the overcrowded ordinary “first reception” centers in the event of considerable and close arrivals by sea – the so-called Hubs, a kind of “regional sorting centers” where refugees are identified and can formalize their request of residence permit. After this formalization, they enter the SPRAR project, a network of local institutions, in cooperation with voluntary sector organizations, managed by the Ministry of Interior and designed to undertake an integrated “second reception” system. SPRAR provides, in addition to first assistance (as food and housing), complementary services such as legal and social guidance and support, as well as the development of individual programmes to promote socioeconomic inclusion and integration.

The “Riace model” started taking shape in 1998, when almost 200 people, mainly from Iraqi Kurdistan and the Kurdish region of Turkey, were rescued from a precarious barge landed at the coast of Marina. This barge will become a more noble and evocative sailing ship (veliero in Italian) in the narrative construction of Riace’s story, especially in its mediatic representation. This particular shift will be quite meaningful as a paradigmatic example of a certain rhetoric which will characterize the semantic field of this case, as well as the ways in which institutional representatives, writers, directors, voluntary organizations and activists still approach it. Faced with this landing – neither the first nor the last – a small group of Riace’s inhabitants, including current mayor Domenico Lucano, decided to give hospitality to those strangers and to open the door of the Pilgrim House (Casa del Pellegrino) near to the Shrine of Saints Cosma and Damiano, they also strangers who came from the sea. After a short period of time, all the Kurds but one left Riace for northern Europe. However, that experience changed something in the perception of Riace: the idea of a history which could be trace backwards, as the chance of an ill-gotten restitution, unfolds. In 1999, Domenico Lucano became member of the Local Council and the refugee welcome system took the first steps: in 2000 Città Futura (Future City, whose name evokes Tommaso Campanella’s utopian work City of the Sun) was founded as the first organization in Riace whose aim was – and still is – to host refugees, and in 2001 the town joined the PNA (National Asylum Program) which will be renamed SPRAR in 2002. Since then, about 6,000 people have been welcomed in Riace and about 70 of them still live in the town as residents: a very small number – almost insignificant – compared to 6,000, but with a different weight compared to the number of inhabitants. Since 2004, Domenico Lucano has been mayor of Riace (he is currently serving his last mandate) and during these years has received a substantial number of national and international tributes and awards: he was listed as one of 50 most influential leaders by Fortune Magazine and he received the Bern’s Foundation for Freedom and Human Rights Prize in 2015 and the Dresden Peace Prize in 2016, just to mention a few.

There are three main characteristics which make Riace’s hosting refugee system a “role model”. First of all, the so-called “diffused hosting” practice (accoglienza diffusa), through which some of the abandoned houses of Borgo Superiore are rented out by emigrant owners to voluntary organizations which cooperate with SPRAR (and are therefore funded by the Italian Ministry of Interior and EU), refurbished by these organizations and then dwelled by refugees. The “diffuse hosting” practice has been used since 1998 thanks to a bank loan granted by Banca Etica (Italian ethical bank), also thinking about the possibility of employing those houses as facilities for solidarity tourism. At present, this type of activity is not working due both to the considerable number of hosted refugees and the lack of additional habitable houses. In addition to the revitalization of the village, the “diffused hosting” (also practiced in Marina) responds to the need to avoid the creation of ghettos and give refugees the opportunity to live independently in real homes.

The second element of innovation is the use of SPRAR’s funds to create handcrafted workshops for responding to multiple needs: the restoration of antique handcrafted traditions; the creation of job opportunities for riacese people; the creation of exchange and integration possibilities between inhabitants and refugees, since one riacese and one refugee work together in each workshop. In both cases, most of them are women in demanding situations, especially because they are single women with children.

Indeed, these workshops do not have a good production capacity: those who work receive a salary thanks to SPRAR's funds and earnings from the handcraft products, which are not of high quality, are sufficient to cover raw materials and bills expenses. Nevertheless, as pointed out during an interview with a Città Futura's operator, an important feature of the workshops is the curative impact of employment, which affects both refugee and riacese women, especially in terms of confidence, social dignity, and – thanks to the relationship that is being created – ability to recreate a “normal” situation, through which they can share their daily home life (relationship with children, housekeeping advice, etc).

Lastly, the third feature of the hosting refugee system is the establishment of a local currency to cover funding delays of SPRAR project. Also in this case, this tactic meets several needs: this currency allows refugees to independently manage their financial resources, buy their own food and clothes without intermediaries and interact with the social and economic tissue of the town. In addition, with regard to voluntary organizations (which are 7 by now, including Città Futura, for a total of about 70 jobs), local currency eliminates temptations to profit from essential goods for refugees. This tactic should have also increased sales in the small shops of Borgo Superiore but, at the moment, almost all of Borgo's shop keepers have much more trouble in accepting this form of payment due to debts contracted with suppliers. Moreover, Ministry of Interior recently expressed strong criticism on the local currency, considering it unacceptable from a legal point of view. In this regard, and as I will examine, it is worthwhile to note that Riace has a low ranking in SPRAR's evaluation reports drawn by Ministry of Interior because of an excessively anarchistic and not fully-conformed management and conduct.

4 RIACE-DISPOSITIF

After this overview, some questions arise: why has all this happened in Riace? What are the reasons why a small town in Calabria, depopulated and isolated, becomes a reference point for a hosting refugee practice? And yet, although this practice is being spread (not without resistance) in Calabria and Italy, why does Riace continue to be perceived as an exception and guiding light? In other words: what are the elements which create Riace-dispositif, and for what reasons does Riace work as a dispositif? I argue that, to answer these questions, we need to consider at least three levels of analysis: firstly, we need to identify causes closely related to context; secondly, we should understand in which ways media relevance contributed and still contributes to maintain the “Riace model” alive; lastly, we need to understand the relationship between Riace and institutions, especially those involved in SPRAR projects.

As for the causes related to context, it is important to remember that the history of Riace has a repressed origin, so that I have often read articles and listened to verbal reconstructions in which stories mingle with each other and overlap in their details and timings. In fact, in early 1997 (about a year before Riace), a barge carrying refugees landed at Badolato, a town nearby. In this case, municipality – and not a scant group of inhabitants as in Riace - decided to give hospitality to these people. Within a few months, a strong media attention arose on Bandolato (Sasso, 2012). The Town Council proposed the idea of “diffuse hosting” and the Municipality asked for a loan to a local bank in order to put in practice the idea and refurbish houses of the old town. However, after a while, the bank was investigated for mafia collusion, a circumstance which threw the whole project into crisis; moreover, most of refugees left the town and Italy, as happened in Riace after the first landing in 1998. Badolato's experience ended in the worst way, but the underlying idea would have been inherited.

Interviewing both locals and some of the protagonists (social workers, researchers and activists) involved in this experience, it emerged that, unlike Badolato, in Riace they were able to create consensus around the topic of hospitality. Consensus can depend on several factors. A first group of factors can be identified by putting together, on one hand, the small size of the town and the depopulation process which over the years has reduced Riace's social tissue and its relationship's network to minimum; on the other, the symbolic value of the stranger linked in particular to the deeply felt celebration of Saints Cosma and Damiano. Indeed, the patrons of Riace emphasize - through the symbols of the double and the stranger – the transformative and diagnostic function of encounters between communities: in the specific case, the community of Riace and the Calabrian Roma community who, through dances, ritualization of conflicts and barbers, test the “state of health” of intra- and inter-community ties. Moreover, a second group of factors can be traced back to the social and environmental policies promoted and implemented in Riace; to the strong personal assumption of responsibility about transparency and honesty in the management of SPRAR funding; to the will to involve the inhabitants of Riace as much as possible in the practice of

hosting refugee, especially in terms of employment. Compared to these second group of consensus-building causes, the figure of the mayor of Riace plays a crucial and, I would say, personalistic and charismatic role. However, the centrality of this figure does not seem to have only positive effect.

Putting aside the first group of factors, it is worthy to focus on these second elements of consensus-building, especially on the social and environmental policies promoted over the years by mayor Lucano. In the account of Riace, these political choices are lived and described as battles promoted by ideals and “questions of principle”, specifically ideals and principles literally embodied in the mayor’s figure. In this regard, we can see in action a concept of “justice” that overcomes differences between social justice and environmental justice, and shapes the idea that every person, regardless of race, income, culture, and gender has the right to a decent quality of life (Anguelovski, 2015). Among the most important actions promoted and implemented by the mayor, a few should be remembered: the development of a door-to-door separate collection system of domestic waste and the creation of a recycling area, both managed by a local cooperative; the renewal of green areas; the creation of community gardens for inhabitants and refugees; the reduction of water-service costs thanks to an aquifer which makes the town self-sufficient in terms of water supply, and relatively autonomous from private water companies; free school bus and nursery services; free occupation of public land; elimination of first home tax (even when expressed by state laws). Each of these actions must be read and weighted referring both to the context of southern Italy, where waste, water and land policies are strongly mortified (to use an euphemism) by mafia-style management, and to the Italian context in general, where municipalities have inadequate availability of economic resources and use municipal taxes to rebalance this lack of funds. With regard to these policies, the mayor acted personally and almost at the limit of standard procedures, in order to demonstrate the nonsense of slow and intricate bureaucratic iter, which hold back any action of effective change and improvement of living conditions, rather than support it. At the same time, there is a strong symbolic value in support of each of these political choices, a value we can glimpse in Lucano’s words (repeated as a mantra during our encounters): «I am not a perfect mayor, because if I were a perfect mayor I would not do the interests of my community, but those of government» (emphasis added). In other words: if I want to be a good mayor, I do not have to behave like a mayor. These words define one of the key elements of *dispositif*-Riace: an idea of the political dimension of community that could radically put into question a “traditional” model of territorial governance, showing a breakpoint through which meanings and practices can be re-negotiated and foster processes of democratization. However, we should wonder how the symbolic value of policies implemented in Riace is interpreted and operationalized by its inhabitants.

4.1 ELUSIVE OBJECT

More generally, the construction of the symbolic value of Riace has seen engaged over the years, on one hand, some activists and organizations at regional, national and international levels; on the other, mass media which have contributed – through newspapers, reportages and documentaries – to the creation and dissemination of an order of discourse on Riace. As for activists and organizations, their actions developed in the frame of the Italian radical and non-governmental left, particularly committed – especially in the South of Italy – fighting against mafia, helping the “poor”, caring for territorial and environmental heritage, and promoting a concept of development far from capitalist logic. In this case, commitment to the cause was shown mainly through supporting actions, networking and joint initiatives and events. Their strategies would deserve a long discussion, especially with regard to the way they intertwine with the political, economic and social history of the country and the region. For the moment, however, I will examine the media aspects and how Riace-*dispositif* was created for public opinion.

There are two moments in which the history of this town had peaks of popularity: the first one, between 2009 and 2010, during the production and release of *The Flight*, a movie on Riace by German director Wim Wenders; the second one, in 2016, when the American magazine *Fortune* put Domenico Lucano among the 50 most influential leaders in the world. In both cases, Riace stands on an Italian media landscape where migration issues are strongly influenced by an increased number of landings by sea, a securitarian institutional and political reaction, and a growing perception that migration and terrorism are intertwined phenomena. Faced with this narrative environment, Riace shows features of “another possible world” (the utopia of normality, the slogan of Riace) able to keep alive the dreams of those who believe that hospitality, abolition of borders and equality are imperatives. However, there is a perspective that, more than any other, is encouraged by the media narrative: the refugee’s shift from “emergency and problem” to “resource and rebirth”. Although only now the Italian inland depopulation issue is becoming a

trend in public debate, the idea that a small Calabrian town – marginalized and “endangered” – is finding ways to change through “migrant force” appears as a key to understand the migratory phenomenon and to circumscribe two main streams in public opinion: on one hand, the deployment of those who want to feel protected from foreign invasion; on the other, the deployment of those who - in matters of realpolitik, common sense or historical courses and recourses - see in migrants one of the ways to secure a future.

Therefore, the rhetoric on Riace focuses mainly on the following elements: the rebirth of Borgo Superiore, otherwise destined to neglect; the rebirth of a local economy, whose dramatic decline had been the cause of depopulation; the rebalancing between an old-aged local population and young migrant families with children. The migrant-resource becomes the last chance to have access to the former rural past - that of land values, handicraft traditions, a more environmentally friendly life and conviviality. Somehow, Riace opens to the possibility that a lost world may find a chance to rebirth thanks to a bucolic dimension of community where time seems to be magically suspended. However, this understanding contributes to evoke the idea of a traditionalist community, whose sole consequence is to emphasize the false opposition between the two main streams above mentioned. In fact, this idea of community - with its symbolic and nostalgic result - leaves behind any kind of critical understandings of how national policies deal with the issue of migration in general, and the consequences that these policies have on small local realities, as well as on their ability to promote an effective improvement in living conditions thanks to a repopulation process. Indeed, we might wonder: if Riace is a role model, is it therefore the best possible application of the SPRAR project? The answer is no: “Riace model” is perhaps one of the most critical experiences evaluated through the SPRAR project criteria.

Even though the “best practice” of Riace was the main source of inspiration for both the 2001 PNA (Programma nazionale asilo, National Asylum Program) and the 2009 Regional Refugees Act of Calabria Region, at first glance it seems to be an exception to the rule that the law tries to re-absorb and normalize. This normalization is achieved by ambiguous strategies: on one hand, using Riace as a borderline entity to which asking for “breaking the rule” in case of emergency, such as speeding up procedures for giving immediate hospitality to a dozen refugee families (an emergency dictated by the overcrowding of other SPRAR or CAS centers); on the other, criticizing Riace for disregarding rules, such as failing to properly provide required certificates and supporting material for aforementioned procedures. In this game of roles, however, Riace does not have the power to impose itself as an effective alternative to the rhetorical construction of the law, and as a breakpoint that seriously can put into question the securitarian language and perspective through which the phenomenon of migration is treated. Yet, Riace’s significance remains stuck in a mechanism in which the more it shows the flexibility of its “absence of law”, the more the law is strengthened and re-affirmed (Agamben, 2003). The institutional formal accuracy and the anomie of Riace, both entwined with the symbolic value of mayor’s political choices, do not merely contradict (and conflict) with each other, but rather interweave in the frame of a “coherent non-coherence”, undecided and uncertain, in which the truth value of a fact – “the Riace model” – emerges in all respects as an elusive object.

To conclude, according to what John Law writes in his book *After Method* (Law, 2004), when Riace is presented as an alternative model for addressing both the refugee issues and the inland depopulation challenges in Italy, it is simultaneously possible to see how this dispositif creates both a manifest absence and a hidden otherness. In the first case, with regard to the migrant-resource interpretation, manifest absences are refugees in their singularity, with expectations, plans, migratory paths, potentialities and skills, each of them being considered case by case, person by person; in the second case, with regard to securitarian migration policies, what is othered are both the interest at stake of the territory, its transformative potential and future improvement, and the possibility to address its relational baggage into an effective process of democratization of knowledge, learning, and self-managed approach to social change (Greenwood, 2007).

5 CONCLUSION

Has the dispositif-Riace activated a process of questioning the traditional meaning of community and redefining its legitimacy? Has it had the ability to trigger democratization processes involving inhabitants (including refugees) in order to negotiate one or more interests at stake? In the game of roles and concerns that converges on “Riace model” – which shows Domenico Lucano, the mass media which inform public opinion, and institutions as its main protagonists – two actors fail to respond: refugees and

inhabitants, with convergent and divergent potentialities and needs, who daily experience how difficult it is “to be integrated” into the challenge of negotiating a here-and-now. Indeed, although breakpoints and re-negotiation tactics, highlighted through public policies, certainly go towards that direction and contribute to “raise the scale” of citizens’ expectations regarding the actions of municipality, they have not reached an effective critical point to trigger local initiatives able to complement those policies. One of the most obvious consequences is that Riace is likely to shift from a “welcome town” to a “SPRAR town”, a place where the dominant perception – according to both its inhabitants and refugees, and partially supported by material evidences – remains that of the inevitable need to leave after a while. The question is: as planning researchers, is it possible to identify practices by which putting into question this perception and furthering interests at stake to reach a critical point and trigger “a process whereby self-articulated or solicited statements of interest, attachments and points-of-views are translated into stake within a specific process of stakeholderization” (Metzger, 2013: 781-796)? In this specific case, I believe it is essential that this process had the purpose to explicitly define and correlate, even in conflictual ways, different definitions and dimensions of need, trying to go beyond the cumbersome vagueness of the only answer formulated so far: employment.

At present, a spontaneous group of researchers, social entrepreneurs and Riace’s inhabitants (including members of two organizations involved in refugees hosting) has been working on this purpose, trying to operationalize and improve the considerable agropastoral and environmental assets of the area. The group, which I belong to in the frame of my PhD research, is working on re-functionalizing the concept of “productivity” as a much deeper holistic process than its current merely economic equivalent, keeping in mind that talking about agropastoral and environmental assets is far from nostalgically thinking about a past that no longer exists. This means, in both cases, to follow the path outlined by public policies put in place by mayor Lucano and find strategic research paths that can bring together environmental and social justice (Anguelovski, 2014), in order to comprehensively hold together different but strongly interdependent issues, such as land use, workers’ conditions and rights, intra- and inter-specific mutualism, food sovereignty and biodiversity. The creation of this working group, a sort of task force, aims at implementing methodologies of co-production of knowledge which are envisioned to be, as we argue, the most appropriate in order to redefine and put into use the transformative potential of the political dimension of the concept of community as expressed in the context of this article. In fact, co-production of knowledge responds perfectly to the need to move from a substantial approach (eg what is community? who are we as “community?”) to a non-substantial approach (eg what does this concept of community mean? what are its consequences and potentialities?) in framing research, highlighting those processes of subjectivation and stakeholderization through which the matter of fact is put into question. Besides, those processes involve also the academic researcher, equally engaged in a reflexive process in which she can understand her position with respect to both the way she considers facts around her and how she considers herself among them.

In this regard, the most challenging aspect observed so far is to communicate - and translate - the importance of shared knowledge – and envisage methods for this purpose – in order to identify research questions, tools of analysis, actions and criteria to evaluate their impact. Although the circular link between them might appear obvious and automatic, it involves a twofold awareness: first, to acknowledge the importance of recognizing the actual range of possibilities grounded to the context and its resources; second, to acknowledge the importance of shared knowledge with respect to processes of democratization, not only in terms of sharing purposes and results, but specifically in terms of ownership of social change and its impact (Campbell & Vanderhoven, 2016).

1 THAILAND IN AN ERA OF SUPER-DIVERSITY

The borders of the world seem to diminish, as we are moving into the era of diversity or one would consider it to be an era of super-diversity. Against the backdrop of immigrant issues, various countries have to rely on the movement of people for the decades to come. The members of South East Asian are among those countries. In the year 2015, in the aim for stronger economic development in the whole region, they initiated the ASEAN Economic Community to encourage the flow of skilled migrants in the territory. Several national and regional policies were nominated for smoother integration. Thailand who is ranked among the top 15 countries of migrant destination in the world will remain as the major destination in AEC. Unfortunately, the local neighbourhoods that are the area where the host and the newcomer interact were overlooked. They are the places, which have to cope with the impact of immigrant first-hand including more housing and services demands, social tension, diversified needs, etc. To make it worse, immigration studies in Thailand have only been focusing on the issue of illegal immigrant, labour regulation and immigrant health problem related to HIV and infectious diseases. However, few scholars have touched the aspects of socioeconomic development and urban development context as Haguet and Chamrathirong (2012) stated that "Analyses of the effects of migration on the Thai economy have for the most part narrowly focused on the wages earned by migrant workers and have only recently begun to consider migration's impact on the broader structure of the economy.". Researchers in the field of

immigrant integration have been proposing that the diversity in the local community should be adopted as the main solution for immigrant integration. (Bosswick et al., 2007; Dixon et al., 2011; MPI, 2014; Kesten et al., 2015) It is the realm that promote “commonplace diversity” (Wessendorf, 2011). Various studies support that the good-quality physical environments are significant stimulators for diversity, including space for interaction, cultural spaces, public infrastructure. (Jacobs, 1961; Penninx, 2009; Legeby, 2010; Lelévrier et al., 2015) We anticipate that with the proper neighbourhood environment, there will be numerous types of positive interaction that eventually result in better integration.

1.1 CASE STUDY OF WAT-KET, CHIANG MAI, THAILAND

At present, Chiang Mai is the second largest city of Thailand with the area of 20,107 km² and the capital city of the northern province with approximately 1.67 million people populate in the city (170,000 are living in the in city area). It has one international airport, the CNX with 140 flights per week. For the land transportation there are 7 round-trip trains from Bangkok and Chiang Mai per day and dozens of public and private buses and minivans wherewith. Chiang Mai is 720 years old, one of the oldest cities in Thailand with hundreds of temple and cultural heritages. Chiang Mai is already home of 17 consulates including USA, Japan and Italy, etc. Moreover, there are 7 major universities that provide international courses, just merely in Chiang Mai University (CMU) alone, there are almost 400 international students. There are 34,341 foreign license-workers and 263 developers (as of 2011) in the city. Thereupon, Chiang Mai is somewhat dynamic and diverse already. Due to that it is famous not only as a touristic destination but also as the second home for a considerable number of foreigners. Furthermore, there are around 65,000 residences who are from 8 main hill-tribe populations that reside in the city as well as the so-called alien residents from neighbour countries (Myanmar, Lao, Cambodia). And it is certainly possible that Chiang Mai will become even more diverse after the open of AEC 2015 as she is the primary transportation hub of Thailand, and the city will need to accommodate the massive influx of immigrant, likewise the impacts that come along with this phenomenon. Wat-ket neighbourhood locates in one of the special land use area in Chiang Mai (Preserved residential area). It is the area which designated for the preservation of traditional architecture as well as the socio-cultural heritage of Chiang Mai through the primary land use for residential usage. Nevertheless, due to the regulated year of the article (2012), a considerable number of the vernacular buildings are disappearing as it was either consumed by private developer or abandoned by the owners.

Vividly, as illustrated below, the existing building use map displays us the reality that the commercial buildings take up imminently all of the waterfront spaces. The only green space is also in a defective condition. The smaller green spaces are owned by the hotel and are utilized primary for parking spaces. In the inner residential area, there is no public spaces neither. Regrettably, there is extremely limited choice and type of accommodation in this neighbourhood (single family house, row house and condominium). Similar to the whole city, the public transport is not efficient and comfortable (the only bus stop is located at the bridge in the southern direction). Thus the majority need to rely on the private vehicle or taxi (red truck).

Figure 1 - Wat-ket neighbourhood building use map

1.2 DIVERSE NEIGHBOURHOOD DESIGN PRINCIPLE

Ambitiously, the Diverse Neighbourhood Design Principle (DNDP) has been accumulated through the comparative case study of Milan, Italy, Singapore and Kyoto, Japan. In order to extract the key factors that contribute to neighbourhood diversity, we did the Immigrant Citizen Survey (Huddleston and Tjaden, 2012), in-depth interviews and questionnaires with more than 400 participants. Our participants were from more than 15 countries of origin, including China, Thailand, USA, UK, Brazil, etc. Even though there are difference compositions and interpretations because the three cases define their own “diversity” as blended environment, global city and multiculturalism. The empirical evidences indicated that DNDP is integral for all the case study areas. Consequently from the comparative case study, we have proposed 20 factors that are imperative for neighbourhood diversity. For instance, free/ safe/ open public spaces, access to diverse choice of housing, more mixed use cultural spaces (see Table 1). More essentially, we have discovered that in all three cases there are at least 15 to 17 DNDP factors. Therewithal, this DNDP can be utilized at the preliminary of neighbourhood planning process to comprehend with an existing situation and afterward address for all the crucial factor to encourage the concept of diversity and integration in the neighbourhood.

DNDP FACTOR		NON-PHYSICAL CONTEXT
PHYSICAL CONTEXT		
Affordable connection		Appropriate activity promotion
Free/ safe/ open public spaces		Advocator/ mediator
Access to diverse housing choice		Local association
More mixed use		Local stakeholder partnership
Cultural spaces		Civic participation
Local institution		Economic opportunity
Public infrastructure		Flexible permit of stay
Facility for children		Rightly defined diversity
Neighbourhood amenities		Language assistance
Community hub/ centre		Commonplace diversity

Table 1 - Diverse Neighbourhood Design Principle

1.3 EXPERIMENTAL DESIGN

For the research experiment, to begin with, we implemented the DNDP to seek out potential factors as well as missing factors, this was possible through the in-depth interview with 100 immigrants in the neighbourhood and 5 experts from Chiang Mai. Nevertheless, as strongly advocated by several scholars that integration is a two-way process that must include both the local and the newcomer, therefore, we need an implementation method which assist us in participatory planning process. For us to investigate further on the novel method that would encourage both parties to cumulatively plan for their neighbourhood masterplan. A number of studies suggested that the interaction among two counterparts (resident and immigrant), the public-private partnership and the way in which the immigrant integration is initiated in the bottom up manner are crucial for the neighbourhood diversity. While we touch upon this delicate issue of immigration, we came upon the tool of Gaming Simulation (GS) that we believe it has the potential to be implemented as the experimental tool for this research. Particularly, GS can make complex information into more understandable. GS shows higher potential to consider different perspectives on the problem at hand than several other types of media. As stated by Duke “the multilogue, variety of interpersonal interactions (such as persuasion and negotiation) occur quite naturally among game players”. (Duke, 1975) Nature of gaming was extremely helpful when we are trying to create mutual partnerships among a wider variety of stakeholders or participatory activity. Subsequently, using the DNDP as the starting point we implemented role-play gaming simulation to introduce the neighbourhood diversity notion and design workshop game as the medium that bring together 100 participants (50 locals and 50 immigrants) to collaborate in neighbourhood planning activity and henceforward propose the DNDP Wat-ket neighbourhood master plan.

2 APPLICATION OF DNDP IN REAL NEIGHBOURHOOD

Through the application of DNDP and the interviews with our respondents, we comprehended that in Wat-ket there are 10 potential factor including; More mixed use, Cultural spaces, Local institution, Public infrastructures, Neighbourhood amenities, Appropriate activity promotion, Advocator/ mediator, Local association, Civic participation, and Rightly defined diversity. Unfortunately, the rest of the factors are perceived to be either lacking or missing from this neighbourhood. To be more precise, the majority of the expert have cited the cultural spaces of Wat-ket to be somewhat potent as well as the local institutions which several experts believe to be positive asset of the neighbourhood. The lessor ones that our expert spoke of were the “more mixed use” and “rightly defined diversity” contexts of the area. Withal, on the negative side, in the context of the absent DNDP factors, there were 3 factors that three different experts adverted that they are in urgent situation comprise 1. Affordable connection, 2. Access to diverse choice of housing and 3.

Local stakeholder partnership. Following by the issue of free/ safe open public spaces that few of them think that it is lacking. It seems that they generally pointed to the inferior physical aspects in the neighbourhood. Tangibly, according to our research, the DNDP factors in Wat-ket are fragmented, as there are missing a half of them. While they obviously lack the physical factors that relate to basic needs (i.e. diverse choice of housing, affordable connection, economic opportunity). The immigrant in Wat-ket neighbourhood seems to make do with the strong nonphysical factors include, unique advocator which is an elder who is local museum caretaker (he acts as tour guide, educator and advisor for the visitors,

tourists and migrants wherewith) and other three advocators that are the university students, specifically those from CMU that have been exposed to familiar international environment, as well as local associations and local institutions instead. For instance, with the narrow choice of housing they asked for the help from the advocator to find an acceptable one, the participation particular in religion association. Therewith, we have to concede that in Chiang Mai the immigrant would not genuinely need to assimilate themselves to Thai culture, however they do not reach the level of diversity neither. Two parties mutually respect each other. But there are evidences which reflected that there is limited connection and interaction between the two (i.e. lack of place for everyday encounter, limited access to certain places, missing stakeholder partnership).

Generally, on the surface Wat-ket seems to be physically diverse area. Yet underneath that diverse environment there are voids of crucial DNDP factors (specifically, public spaces, affordable connection, community centre) that promote diversity. And this reality has been limiting the interaction among them. Fortunately, these negative narratives at lease gave us the opportunity to learn that several of DNDP factors are related to each other, theses relations include two-way connection (i.e. affordable connection and public infrastructure), one-way connection (i.e. free/ safe/ open public spaces and commonplace diversity), interrelate, a number of them can be substituted by the other (local association and local institution). The best case scenario is that we need the entire set of the DNDP, if we cannot do that the essential needs of the immigrant, interactive spaces, local stakeholder partnership & civic participation and advocator must be fulfilled at the least, in order for the local community to live without massive tension.

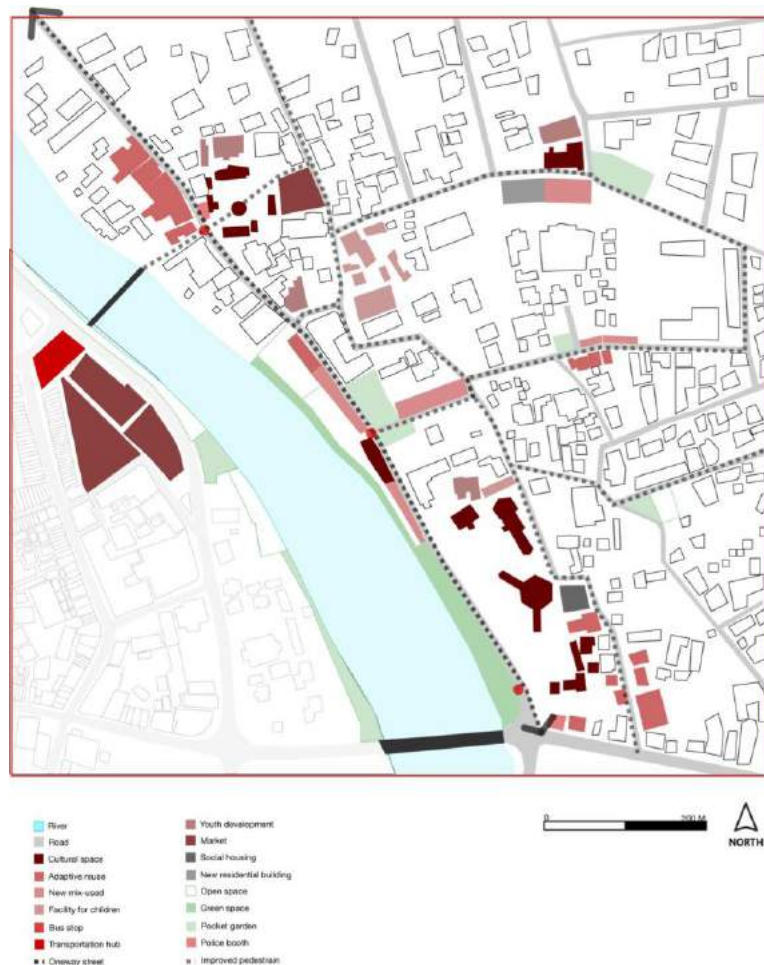

More on the factor correlation, traditionally, temple (cultural spaces) used to be the centre of Thai neighbourhood. Unfortunately, nowadays it is not the same as it used to be in Wat-ket. Obviously, community hub/ centre is also an integral part of neighbourhood-level integration, we need to reinterpret the meaning of community centre. The centre should be able to accommodate diverse ranges of people as well as stimulate them to visit and actively participate. And it should have multi-function facility. The absence of community hub/ centre might also be one of the cause of weak local stakeholder partnership within this area and vice versa. Wherewith, we need certain kind of interventions to reignite the space. As we have found out that the temples have high potential to exert and revert as the major community centre; given that there is an appropriate activity to predispose the local stakeholder together. "The most important thing is how to find an appropriate space, tools and/or activities that can be applied to stimulate the people participation, people perception regarding the local cultural heritage. It is apparent to us that it does not need to be a colossal project from the central government; we just need several small local interventions, however, it can improve the identity of the community, preserve the cultural memory, connect the local people, attract the tourist and then incite the local economic as a result." (Huyakorn et al., 2014)

The investigation might direct us to the perspective that Wat-ket is not such a noble territory for integration. Still, we found out that there are several latent qualities which can be developed, considerable number of them are uniquely discovered only in the area wherewith. There are: 1. the rightly defined diversity that cherish the different character, which blossomed from single socio-cultural route/ aspect of the neighbourhood 2. The robust local religion local associations (4 religion buildings are residing in the same neighbourhood) 3. The complexity of local neighbourhood diversity that otherwise we could not consider of, we have learned that the definition of diversity must be defined by the locals (that must consist of both the host and the newcomer) and the humble definition of diversity; "share of common route or appreciation of the similarity" that is cherished by the general residents 4. Various active local advocators. (such as the local institution which consist of two local universities and T Thailand Creative & Design Center (TCDC), local associations comprise the association for Thai-Muslim, the Sikh institution, the Christian authority and Healing Family Foundation for orphan and disadvantages people) 5. The contribution by external institutions such as universities or government organizations, 6. Several religion spaces have potential to be decent community centre (as it normally is long time ago), it may need a push or an appropriate promoter. 7. Special kind of mixed-use space (Foundation for orphan, art gallery and residential building). Nonetheless, we also learned about certain flaws 1. Only strong local associations and willingness for participation is not mean that there will be a quality neighbourhood partnership, sometime without proper stimulation this only leads to bonding relationship within the same socio-cultural group. Wat-ket seems to lack both the spaces and policy to support these two factors 2. The commonplace diversity and neighbourhood diversity strongly associate with physical aspect of DNDP, for example good quality public spaces, well-connected and universally designed street, facility for children, etc. Therefore, they should be one of the starting area that require emerging consideration 3. The lack of facility for children could lead to the life outside of the area or life confine within their own house (as the families that have children in our

case study) 4. Various neighbourhood amenities do not always determine that there will be access to economic opportunity for the immigrant, in this aspect certain soft measures or policies (including tax reduction, skill training, special permit of stay, incentive benefits) should be implemented. At any rate certain facts are universal though. Without free-safe-open public spaces and right activities promotion, the chance for commonplace diversity will not be enough, thus blocking the diversity in the area. Wherewith, local diversity advocator can foster ongoing dialogues of neighbourhood diversity. Inasmuch, these are the three pillars that keep neighbourhood integration process a conceivable reality.

2.1 POSITIVE RESULT OF THE EXPERIMENT

Follow up after we have accumulated the potential and missing factors of DNDP, we conducted the design workshop with the local stakeholder to conjointly develop the neighbourhood masterplan that integrate the diversity notion as the heart of the plan for the neighbourhood of Wat-ket. The workshops were organized three times with at least 100 participants. The local stakeholders who have been joining our activities are including 1. Resident (both native and immigrant residents), 2. Local government authorities, 3. Local businessmen, 4. Representative from religious groups, 5. Chiang Mai university students, 6. NGOs (such as TCDC, Healing family foundation), 7. Experts, 8. Others. In the scope of bottom up and interactive approach. The design workshop gaming simulation seems to produce fruitful results of participatory planning. Together with the local stakeholders we could put DNDP into use with the real community. Accordingly, the developed master plan is illustrated in figure 2, we will elaborate the masterplan from the gaming simulation activities by dividing it into 4 major diversity hubs and 2 minor hubs. The major ones are 1. The Wat-ket community centre at Wat-ket temple, this hub will be the main centre of the neighbourhood through the direct connection with the new transportation connection, existing open spaces and the market on the opposite side of the riverbank. Likewise, they wanted to have new permanent market space next to

temple, and the adaptive reuse of several buildings that could provide exceeding housing options for this community. The stakeholder also agreed to put the new bus stop and build a new pedestrian which pass through the temple and link the arterial road with the main street as well as the pedestrian bridge.

Figure 2 - Masterplan result of the design workshops

Furthermore, they have the vision for Wat-ket school to open for children from all backgrounds and it will act as the youth development space for Wat-ket neighbourhood too. In order to make it truly operate as the community centre, our stakeholder proposed that they should initiate the local committee that involve all of the member from different socio-cultural groups (Muslim, Buddhist, Christian, Laos, etc.) and local stakeholders (businessmen, local school teacher, resident, immigrant, etc.). The older residents remarked that similar kind of local committee used to exist and they appreciate that it could be revived. 2. The readjusted waterfront area, the consensus is to keep the shabby park but redeveloped it to be inclusive space (improved street furniture, lights, universal design utilization, improved vegetation area), with the new public-access waterfront area we proposed two new mixed use buildings, one of them is the novel AEC cultural centre that act as the museum, library, learning centre, training facility for both the local and newcomer. All the stakeholders reached an agreement that this waterfront project should be financed by the government and the private sector, it should also be managed and taken care by the entire neighbourhood. They would like this to be the flagship public-private partnership project of Chiang Mai. The participant also fond of the idea regarding new multipurpose open space that can be used for weekend market, cultural fair, festival, etc. In addition, the adaptive reuse of the rusty commercial building that should include cultural amenities usages like ethnic restaurant, workshop for traditional crafts, bookstore. They also would like to have new bus stop at the AEC cultural centre. Opposite to the centre, there will be development of the park (owned by the hotel) and another mixed use building along with it.

Additionally, 3. The hub at the First church of Chiang Mai. The church authorities are the only one that grant us the property to be developed as the social housing for the area. They also would like to provide one building for youth centre/ library and another for childcare centre. We will add new bus stop at the park opposite of the church too. Ambitiously, they want to add various adaptive-reuse buildings surrounding the arterial road as well. And 4. The development near the Muslim mosque, in this hub there will be new low-rise residential building complex next to new mixed use building. Beside the mosque, the majority were keen on the idea of new urban farming space that will be taken care by the residents. With better openness, the mosque authorities said that they will try their best to be further open for diverse type of student wherewith. For the minor diversity hubs, A) the first is the space near the Healing family foundation that show great potential as a decent dual cultural space, which has art gallery and orphanage. The local stakeholder agreed with our proposal to include children facility to it. This facility can be the place which are missing from the community; the playground and kinder garden. Moreover, B) this research came up with the new Chiang Mai university outreach (the building is owned by the owner who is working at the university) to facilitate diversity and integration through various language courses, vocational training and volunteer centre.

It could be operated to assist smoother various student exchanges and youth activities in the area. There is likewise the consideration for smaller green spaces. One is the area focuses on re-using of the abandoned plot that will be developed as the petite park. Next to this park there will be both new mixed use buildings and the adaptive reuse of vernacular buildings. Not only that, supplement to those proposals, Wat-ket stakeholder want to develop the community garden that has both green space and multifunction open space in the inner residential part of the community. The main street will have traffic adjustment; it will be one-way street that goes downward from 12.01 a.m. to 12.00 p.m. then goes upward from 12.01 p.m. to 12.00 a.m. to reduce the flow of motor traffic. In addition, we add that they also want to improve the streets as much as possible, especially to make it safer to the kids and elders. The new bus stops will be the outposts for volunteer neighbourhood watch accordingly.

In line with the masterplan and our interaction with the local community we have learned the essential factors of DNDP which are appropriate for Chiang Mai, however, with minor adjustment they are possible to be implemented in other city thereafter. Firstly, the mixed use spaces and building, this is due to the limited spaces and high proportion of older architectures. These spaces/ buildings should have dualability or multiple usages that concern with cultural aspect (i.e. art gallery, craft workshop, ethnic shop, bookstore, etc.). Secondly, the religion building with it high potential of socio-cultural context could be the primary community centre that bring people together, nevertheless there ought to be the way to bring these different groups together for more interaction as well. Thirdly, the main mediator in the local neighbourhood seem to be the university student coupled with the respectable elderly in the community. Importantly, we recommended that they are the principal factors for neighbourhood diversity and we should turn to them since the beginning of integration process. Fourthly, Thai people love the local market (both permanent, weekly and special events) and not only them, in several of our case studies illustrated that this is the main venue for neighbourhood diversity and immigrant integration. Consequently, these

kinds of space should be preserved and promoted instead of the colossal department stores that are growing and consuming vast majority spaces of the city. Lastly, even it seems to be the basic issue but there are the needs for better quality and more public open spaces and pedestrian connected street.

2.2 FRAMEWORK FOR NEIGHBOURHOOD DIVERSITY

Thereby, from our exploration in the research case study. With our optimal attempt, this figure is our endeavour on the Diverse Neighbourhood Design Principle to extract and cluster the key factors as well as to conjugate the relating factor for the expedient implementation in other area.

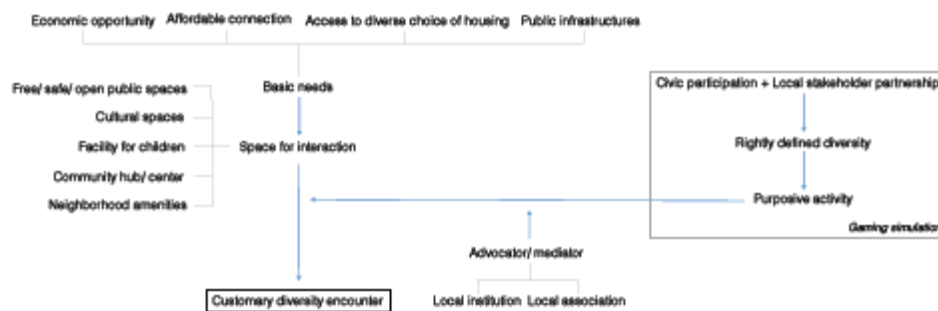

Figure 3 - Framework for neighbourhood diversity

In order to achieve the “customary diversity encounter” in urban neighbourhood area, there are mainly 6 indispensable elements that we need in the local community. Firstly, the basic needs that must be fulfilled including affordable connection (i.e. public transport, well connected pedestrian way), access to diverse choice of housing; from low to high price, several tenure options, building types, the rights for social/ affordable housing etc., universal public infrastructure (in particular, the healthcare facility and educational facility) and accessible economic opportunity, both formal and informal types, protected rights for everyone, fair and transparent job recruitment. Ideally, the neighbourhood should be developed in a mixed use (residential& retail, education & commercial) manner, it could help solving these issues in-one-go.

And while these needs are specifically important, it is generally for individual integration. For preferable integration in the whole community context, the spaces for interaction would be the major stimulator. These spaces will be different according to the socio-cultural aspect, believes, environment factors; climate, topography, availability of free spaces. Nevertheless, there are also diversified spaces from various cases that we found similar to each other. The spaces we are referring to consist of free/ safe/ open public spaces; from tiny pocket garden to massive urban park, from publicly own to semi-private open spaces, multipurpose area to more-specific-function. In addition, we also recommend that cultural spaces, for instance religion building, art gallery, ethnic shop/ grocery are the attractive areas for interaction. Forasmuch, as cited by all the major literatures, the facility for children (i.e. school, playground, kinder garden) can encourage exposure to diversity in an extremely friendly environment. In certain cases, there is also the place where the people deem to be the community centre/ hub such as youth centre, neighbourhood centre or even temple. Lastly, the neighbourhood amenities that are loved by both the locals (native, immigrant residents) and visitor, these amenities include local gastronomies (café, pub, bar), market place and local commercial spaces. Ordinarily, there are not only favourable for integration but also function as the main economic lifeline, economic opportunity provision and attraction for plenty of local communities as well.

In parallel with the upward physical factors, there is also the need for both local initiator and initiation for neighbourhood diversity. Firstly, we require strong local stakeholder partnership (between public and private body, NGO and government or all of them altogether) and civic participation (which all the resident take part in actively and willingly) as the spearhead of nonphysical factor. For the integration policy to work these two notions should be present in the neighbourhood. In accordance with the two, the local community must be the one to arbitrate on their own definition for diversity. With the rightly defined diversity (the definitions we have encountered were “blended environment”, “global city perspective”, “multiculturalism” and “share of common route”), the purposive activity will follow by shortly. The effective activities consist of cultural exchange, local festival, parenting support, free language courses, job related

skill training, gaming simulation activity, university field visit, etc. In this research, we likewise demonstrated that gaming simulation tool can play a colossal part in the stimulation for this nonphysical aspect of DNDP. Finally, local people with the help of local advocator/ mediator; the youth, NGO, elder, local association and local institution can organize these initiations within the space for interaction and simultaneously lead to customary diversity encounter. Substantially, this can be the prominent prototype framework through participatory approach for other community in Thailand and hopefully other nations in AEC accordingly.

2.3 EPITOME

In essence from what we have cultivated from the case of Wat-ket neighbourhood in Chiang Mai, the DNDP factors seemed to be disunited. It is understandable that it is lacking in the factors that relate to government provision and policy, including affordable connection, access to diverse choice of housing, free/ safe/ open public space, facility for children, and much more. Also, the collaborations among different stakeholders are perceived to be lacking. Which is why a certain of older residents are reporting the growing tension and feeling of “otherness” within the area. Against this backdrop, Wat-ket neighbourhood also consists of high potential factors, few of them are uniquely found in this community. Wat-ket are developed more in the mixed building use aspect, that is why there are a few buildings that host various space that to certain-degree contributed to neighbourhood diversity. Theses spaces are including the attractive cultural spaces that are temple, museum, church, art gallery. Wherewith there are several neighbourhood amenities such as café, restaurant, pub and bar. There are wherewith an exceeding number of advocators in the area.

Our respondents likewise pointed out to uniquely defined diversity. The researcher also found one-of-akind diversity advocator who is the museum caretaker/ local educator. Supplement to these advocators there are various cultural festivals and the majority of the residents seem to be truly eager for participation. These two factor also help foster the notion of neighbourhood diversity and everyday positive interaction. In our research setting, DNDP combining with gaming simulation tool is proved to be a reasonable median for neighbourhood immigrant integration, through its key ability to improve the people perception and its flexibility, the significance of the initiation of appropriate integration projects locally. Wherewith, the potent property to encourage bottom-up participatory planning, one of the better communicative tool that can translate difficult and complex information in to easier message. As well as the way it could provide the opportunities for “learning by doing” and “multilogue conversation” for the players, facilitator and observer in such a playful and cordially environment. Hopefully, we can somehow fill the missing link which is preventing the government from developing the successful integration policy and project that varied studies have been advocating.

If we take a look at the resulted neighbourhood masterplan, the decent starting point for Chiang Mai neighbourhood diversity could be the adaptive reuse of vernacular/ historic building that focus on multiple usages (especially cultural amenities), green open spaces and quality pedestrian street that seem to be diminishing in Thai major cities, the religious space as the cultural centre that adopt the notion of neighbourhood diversity, the love for permanent/ seasonal market and importantly the nifty and active diversity mediator in Chiang Mai context are the university students and elder figure in the local community.

2.4 LIMITATION AND WAYFORWARD

This research strives to introduce and illustrate the concept of diversity and its possible implementation in AEC context. For this research, it follows principles of an interrelate-mixed methods study to broaden the concept of diversity from socio-economical disciplines into a broader multidisciplinary research on one aspect. And to strengthen the notion and understanding of diversity and immigrant integration in scope of the urban complexity on the other. By stating this immigrant integration and to certainly respect the notion of diversity we intend to cover as several types of immigrants as possible. Even still this multidisciplinary approach can help the study in accumulating significant relevant factors, we do not plan to extend it to all facets and integrate those aspects into one single research. We neither will not be that ambitious off stating that this research would be comprehensive in all angle of immigrant integration, however our study is mainly considering crucial determinant that related to urban planning/ design for immigrant integration.

Though, we might not be able to comprehend several other issues such as the complex physiological notion of immigrant integration, social security in terms of terrorism may not be an integral part of the study and healthcare/ contagious disease, nor we can cover all the aspect of diversity such as religions, believes and LGBT. Moreover, we do not claim that the result of the diverse neighbourhood design principle will be able to cover all of the different kind of neighbourhoods in AEC. Considering the limited time frame of the research, the study put higher degree of attention on consolidating the urban planning policies and neighbourhood design factors that promote immigrant integration and diversity concept into a diverse neighbourhood design principle that can insure the livelihood improvement both for the local resident and migrant together in same neighbourhood and flourishing the positive urban development by the AEC in the future.

With more time and larger group of sampling, we could project the essential factor of DNDP, by understanding what kind of immigrant (i.e. country of origin, income range, family type) can effect particular needs for housing, services, local association/ activity, etc. which in our research we could find certain patterns. For instance, migrants from the country of Myanmar, Lao, Cambodia tends to prefer to live in more-affordable type of housing (in particular flat/ apartment) and the main activity they love to do in public open space are more inner group activities. As per the people from USA, they are likely to rent a single house or townhouse type of housing, they also incline to interact with other social/ ethnic groups and do active activity such as sport. Thus, the majority of them demand more bicycle mode of transportation. For the group of Japanese, the majority are living in the house that they have purchased, more of the socio-cultural related activities (such as festival, cooking, art) are what they prefer to do in the public open space.

On the other hand, this research result setting left us with numerous issues that oppose to existing study about neighbourhood diversity and immigrant integration. In the majority of the cases (i.e. London, Budapest, Singapore, Milan, etc.), the integral factors that dictate the immigrant's neighbourhood choice for migration are diverse choices of affordable housing and access to decent quality transportation. However, in Wat-ket case as we presented, these two factors were reported missing within the area, and the migrants chose to reside here anyway. The one from more developed countries have enough money to ignore this fact, those who were from the under-developing countries do not have any other choices. Therefore, the thorough study into the different complexity of these immigrants is eminently needed.

Diverse Neighbourhood Design Principle can also be improved and we encourage other study to pick it up and further explore. Given more time and budget we would like to cultivate further factor. For example, we can focus deeply into one single factor of cultural space; its relation with the number of immigrant population and how they feel integrated. Or try to understand how much space of the free/ safe/ open public spaces is needed per one immigrant. It is possible as well to supplement the principle, forasmuch we know for certain that it is not possible for us to cover all of the enormous aspects. DNDP can be integrated with other principle and tool including GIS, Nationwide survey, LEED ND too.

Looking back to the participatory activity, GS (combining with DNDP) is an excellent communication tool due to the mechanism of the game that let the players put themselves in other peoples' shoes, and in our case the role of immigrant and resident. Likewise, the sessions produced the environment of the interaction in relaxing and friendly atmosphere. With decent mechanism, it cans make the majority of Thai native residents understand the difficulty of being immigrants themselves, subsequently they started to consider more about the immigrant. And as stated by numerous literatures that immigrant integration is a two-way process and need to be done mutually by both the migrants and the receiving local entities.

Therefore, with it efficacy in positive communication stimulator, immigrant integration policy in other scope should keep this expedient tool in mind ditto.

As strongly value by Duke (1974) and Rizzi (2011), gaming simulation cans possibly be an alternative language for urban planner/ design, which in the case of this research the communication has not stopped after the game session but it has been continuing and growing. A group of the residents even chose games as the way to communicate about diversity in the neighbourhood, specifically with the kids and younger generations. This impact of gaming simulation requires to be deeply studied further, in order for us to clarify and understand the phenomenon of these non-direct impacts of gaming simulation better.

Hopefully in the near future, the dynamic of gaming simulation could be put into better use, our research expands the understanding of it application and it seems to have an extremely elevated potential for urban

planning and design context wherewith. Regardless, in this new era of diversity, several nations will require collective policy planning in the local community level. Neighbourhood planning is the best arena that urban policymaker and immigrant integration initiator should start implementing this tool. Unconventionally, GS could be an enchanting instrument to achieve neighbourhood diversity and refined integration process concurrently. Due to its diversified potentials as Huyakorn and his colleagues have unearthed that “one of the most notable attributes of gaming simulation as a tool for immigrant integration and co-existing diversity is that it can stimulate the mutual understanding and concerted respect among the resident. This is one of the ways that we can move beyond the clichéd stigma of dissimilarity, let it be the socio-economic age or sexual difference and truly pursue the notion of diversity.” (Huyakorn et al., 2016)

Possibly, with more understanding and less negative stigmas in the local neighbourhood, there will be greater attention and pressure to the government in term of the immigrant (especially, those who are less fortunate) rights protection law, immigrant integration policy and regulation improvement. Aloud what the MPI has advocated that “If integration efforts are to succeed, extensive investments of political, financial, and intellectual capital—and dedicated and prolonged attention from policymakers—will be needed for the foreseeable future.” (MPI, 2016) The public should change the perception toward migrants and admit that they are crucial to our urban development today and the future to come therewith. As a number of scholars started to believe that migration can; with proper policy development would benefit the destination country and host country as a whole. Swing believes “Countries with migrant-friendly policies are more likely to prosper.” (Swing, 2016) These benefits are such as ethnic shops, revitalization of aged neighbourhood and immigrant entrepreneurship because the migrants are not the substitution but the booster of both local and nation economic as suggested by Nallu “A surprising number of migrants and refugees have been able to cross the city’s physical and psychological divisions, breathing new life into its dying neighbourhoods.” (Nallu, 2016). Despite that the journey ahead for neighbourhood diversity and immigrant integration might not be downright bright. Conversely, in these negativities we have subsequently found various possibilities for better inclusive community in the era of super-diversity which is approaching.

ID 1403 | ETHNIC HOUSING SEGREGATION AND THE ROMA/GYPSY POPULATION: A PORTUGUESE PERSPECTIVE

Sónia Alves¹

¹Instituto de Ciências Sociais, Universidade de Lisboa
sonia.alves@ics.ulisboa.pt

ABSTRACT: Questions of spatial segregation and over-representation of ethnic minority groups with weak connections to the labour market are central to the political and policy agenda across Europe and academic studies in the fields of housing and urban regeneration. In some countries, the spatial concentration of ethnic minorities is considered in itself an indicator of socio-spatial disadvantage, accentuating pathological discourses related to ethnic communities but in turn providing more resources for these areas. In other countries, where policies have a less preventive character and only intervene during phases of advanced urban decline, the existence of ethnic enclaves and concentrated poverty has led to housing demolition and rehousing, in many cases with controversial results. The relevance of the link between ethnic segregation and integration is known. On the one hand, people create and modify places, on the other hand, spaces in which people live and work affect their social relations, and individual fortunes (eg educational attainment, income levels, reputation). The over-representation of ethnic groups in some areas has been considered a problem where it hinders opportunities of social integration, and when it amplifies processes of stigmatization and the inter-generational transmission of disadvantage. However, it has also been recognized that the concentration of ethnic communities may actually be an advantage for developing relationships of solidarity and the preservation and affirmation of cultural identities. This paper aims to contribute to this debate. It focuses upon the ethnic housing segregation of the Gypsy/ Roma population in Portugal, and asks if ethnic clustering on a number of housing estates is the result of a voluntary impulse towards aggregation (therefore perceived positively by residents), or the result of a lack of choice (thus an 'institutionalized' or deliberate political choice to put the Gypsy/Roma people at distance). In the first part, I review the literature on the factors that underlie the social construction of ethnic segregation; in the second part, I review literature that presents the empirical results of research conducted in different locations of Portugal but has in common processes of rehousing of the Gypsy/Roma population in urban areas. I compare these results with those I obtained in field work in Porto where I interviewed Gypsy/Roma people regarding their preferences given models of concentrated housing relocation or more dispersed neighbourhoods. Focusing upon the Portuguese case, I offer some answers to the following research questions: Is the spatial segregation and concentration of the Gypsy/Roma population on a number of housing estates a voluntary choice or a of lack of choice given institutionalized political decisions taken by local authorities or bureaucrats? How does the Gypsy/Roma population feel about segregation and concentration? Do they wish to live in segregated areas, have they been able to choose between more concentrated or dispersed patterns? What are the consequences? Do they believe that spatial segregation reproduces inequality and separation?

KEYWORDS: housing policy, Gypsy/Roma population, ethnic segregation, Portugal.

1 LITERATURE REVIEW: ETHNIC MINORITIES, HOUSING POLICY, AND ETHNIC SEGREGATION

There is a vast literature on socio-spatial segregation, housing policy, and ethnic minorities that sees ethnic segregation as a socio-spatial product of social relations marked by inequality in power relations.

The increasing concern and debate over ethnic minority concentration and segregation in cities, with heightened attention paid to their perceived, positive and negative, effects (Powell, 2013), has been developed from a socio-spatial perspective, and recognizes that social relations are frequently correlated with the spatial organization of social groups in the residential structure, influencing social interaction and community cohesion (Alves, 2017a).

The degree to which two or more groups live separately from one another, in different parts of the urban environment, along lines of social class and ethnicity, etc. (Andersen et al. 2000), is relevant because social distances can be seen making intercultural dialogue more difficult while the place where we live is likely to influence access to public and private services.

The over-representation of ethnic groups in some areas, and their underrepresentation in other areas, has been discussed from the perspective of their causes and effects. Voluntary or forced causes of ethnic segregation have been at the centre of the debate, with segregation being explained as:

- a deliberate or voluntary choice of aggregation, related to preferences for class, religious or ethnic affiliation, and preservation of networks of social support and aspects of cultural or religious identity (Schnell and Ostendorf, 2002);
- a matter of resource constraints: of financial resources (eg income, security of income, and capital assets), cognitive (education, and knowledge of the housing market); political and social power, related to the contacts people have that might help to influence decisions, for example to access housing in certain areas (Fortuijn et al. 1998);
- a matter of (more or less) subtle forms of racism and discrimination by host society/ institutions towards people perceived as belonging to different racial or ethnic groups (Peral and Ramos, 2014), for example in the private and social rented housing market.

While the first explanation emphasizes the preference for living close to people who are like ourselves, while avoiding other specific groups, the second and third emphasize the lack of choice in housing markets, the latter emphasizing institutional practices and ethnic or cultural discrimination.

Knox and Pinch (2010) claim that segregation is the result of mechanisms involving the market, the state, and civil society: "(patterns) reflect hostility among the wider population, discrimination in employment and housing markets, and clustering for defence, mutual support and cultural preservation" (Knox and Pinch, 2010: 185).

In a paper entitled "Neighbours: determinants of whom Europeans want to keep a distance", in which Peral and Ramos (2014) examine the individual (eg social values, trust, threat perceptions) and the contextual (eg national economic performance, immigrant flows) determinants of social distance, prejudice – which is defined as an average or hostile attitude towards a person who belongs to a group simply because they belong to that group- is identified as a key reason for the negative social attitudes of host societies towards immigrant or minority groups.

In his analysis of the connections between class, ethno-racial division and state policies (eg police staff, welfare offices, housing authorities etc.), Wacquant claims that in an era of triumphant neoliberalism, in which the structure of social space has been objectified in the built environment, the spatial concentration and stigmatisation of poverty is in itself a factor that reinforces inequality and disadvantage (see Wacquant et al. 2014 and Wacquant, 2014). This argument is further developed by Powell (2013) for the case of Gypsy-Travellers whose spatial confinement in marginal sites (in the UK, as in Portugal and other European countries) has limited everyday social relations and encounters.

The segregation of ethnic minorities and migrant groups has also been explained by the characteristics of housing policies and markets, in terms of the condition of housing tenures, for example in terms of price levels, vacancy rates, and allocation rules. Andersen et al. (2013) identify several specific elements of national housing policies to explain housing patterns of immigrants in four Nordic capital cities. One

important conclusion of this study is that “the ethnic tenure segmentation of these housing markets is only partially explained by their income segmentation, existing elements of policies that have special consequences for immigrants, along with the effect on income groups” (Andersen et al. 2013: 40). The unequal distribution of incomes and processes of discrimination would explain the filtering effects of housing markets.

The context-dependent nature of segregation is also emphasized by Malheiros (1998) who has interpreted the spatial organization of immigrants and ethnic minorities in southern European cities. Regarding the metropolis of Lisbon, his work has shown (Malheiros and Vala, 2004) that, on the one hand, until the 1990s ethnic minorities largely relied upon the informal housing market and, on the other, they showed a strong suburbanization pattern, “comparable to some French metropolises, especially Paris” (ibidem: 130).

Hoekstra (2017) has also shown that: “migrant policies – and other urban policies – are informed by broader and locally specific understandings of the real and imagined city that shape what (and who) is perceived as a policy problem and how it can and should be addressed” (ibidem: 15).

A good illustration of the way in which (explicit and implicit) understandings of urban reality inform policy discourses and practices is how housing and land-use planning policies deal with questions of ethnicity and social class.

In countries where the concentration of less well-resourced families is seen as a factor hindering opportunities for social integration while favouring processes of urban decline (such as Germany or the Netherlands), governments have formulated and implemented strategies of social mix to prevent or reduce spatial segregation. These strategies have varied significantly in their rationales, purposes, modes of implementation and territories of intervention (Rose et al. 2013), inviting different kinds of criticism (Markovich, 2014). In other countries, such as Portugal, where the spatial concentration of immigrants or minority groups is not considered a problem per se, housing policies and urban planning, have not sought to prevent or break up concentrations of poverty, but have reinforced processes of socio-economic and ethnic segmentation of housing tenures and housing estates. A paradigmatic example of this claim is the Special Rehousing Programme (PER) created in 1993 to relocate residents of shanty towns¹ living in the metropolises of Lisbon and Porto. The construction of new housing estates for the rehousing of families, reproducing the socio-economic and ethnic composition of original areas, has led to the concentration of citizens with high economic needs in large suburban social housing estates.

For Mustafa Dikeç (2011), urban politics as has been the case in France, has contributed to the political construction of the periphery as the periphery-as-urban-outskirts. By designating the suburbs as separate territories and their inhabitants as different, French urban policy has consolidated an unjust spatial order and a source of stigmatization.

While Piketty (2014) also emphasizes the importance of the social composition of areas of residence, as regards opportunities of social mobility and dynamics of socio-spatial inequality², the empirical investigation conducted by Alves (2017b) in critical urban areas in Porto demonstrates that political discourses and strategies have reinforced processes of social and spatial segregation (or of ghettoization) that are precisely part of the problem of marginalization of these areas and their occupants.

Discrimination against the Gypsy/Roma, also called ‘Romaphobia’, has been discussed in various ways. While Kabachnik (2013), Greenfields (2008) and Greenfields and Smith (2010) criticize the adoption of political discourses and practices that aim to repress the nomadic ways of Gypsy/Roma families, Sigona

¹ The shanty-towns' expanded dramatically during the 1960s and especially the 1970s following the independence of ex-Portuguese colonies, when the return of thousands of Portuguese families and Portuguese-speaking African immigrants (from Cape Verde, Angola, Guinea Bissau, and Moçambique) led to the construction of slum-like neighbourhoods on the periphery of Lisbon and Porto (Alves 2017b).

² Piketty argues that, in addition to the level of education and parental income, the chances of social mobility among children are substantially dependent upon the average income of areas of residency. He also argues that the chances of school success depend more upon the quality of classmate than the quality of teachers, especially at the basic and secondary levels. “Sending a trained teacher to a difficult neighbourhood does not greatly improve the chances of school success. On the other hand, sending pupils from the suburbs of difficult districts to a Parisian school can considerably increase their chances of success” (my translation) (Piketty, 2014: 98).

(2011) and van Baar (2011), address the discriminatory attitudes that have impeded or delayed this population's ability to settle, and Slaev (2007) and Kovács (2015) that have confined them to the least desirable social/public rented housing. Van Baar (2011) claims that the nomad theory, which argues that Gypsy/Roma are 'nomads' who can only survive in segregated camps" (van Baar 2011: 207), isolating them from mainstream society, has contributed to marginalize or even dehumanize this population. He points out that they have been the object of centuries of exclusion and mistreatment which has limited opportunities of social integration and social mobility. This is an opinion shared in Portugal by Castro who affirms that nomadism is: "one of the most publicized stereotypes about the gypsy population" (Castro, 2013b: 52). According to Castro (2013b) nomadism serves to support specific options in terms of habitat (eg nomadic shelters) which aim to reject the right of Roma families to housing. The very creation of nomadic shelter parks outside the urban perimeter seeks to avoid conflict and prevent clandestine camps near the city.

2 FINDINGS OF OTHER STUDIES CONDUCTED IN PORTUGAL

Empirical studies carried out in Portugal on the preferences of gypsy families in relation to housing (typologies, social relations in the neighbourhood context etc.) stress that, in general, the living standards of the Roma are well below those of the rest of the population. They often live in dwellings of poor quality in segregated areas, sometimes without basic services (such as indoor toilet, bath, or shower).

Whilst in Portugal there are no official statistics on the numbers of families/individuals of Gypsy/Roma origin, as the Portuguese constitution allegedly does not allow citizens to be accounted for according to race, colour, or religion (therefore census data are not broken down by ethnicity), surveys and studies conducted by Castro (2013b: 41) estimate that the number of Gypsy/Roma in Portugal is around 40,570 individuals, of which about 40% still live in non-classical housing (ibidem: 43).

In 2008, a survey carried out by the municipal housing company of Lisbon (GEBALIS) counted 760 families, composed of 3,296 individuals of Gypsy/Roma origin living in social housing in Lisbon. Whilst this is a relatively small number, accounting for only 4.3% of the total population inhabiting the Gebalis housing stock, which totals 80,000 residents, due to unequal spatial distribution of these families across the housing estates (as they are represented in only 38 out of a total of 66 housing estates), in some neighbourhoods they are considerable over-represented, equivalent to 1/3 of the total population (Santos, et al. 2013, Pereira and Rebelo, 2013).

The main explanation for such uneven distribution, and that "Gypsy/Roma families are often kept in substandard housing and degraded or dispatched to the urban peripheries" (my own translation) (Reis, 2001: 76), are strong, negative prejudices towards Gypsy/Roma (eg claiming that they are asocial, involved in criminal activities, or unwilling to integrate), leading to discriminatory practices towards them:

The hypothesis of rehousing the Gypsy/ Roma in a scattered way in the urban fabric is seen as "problematic" [...] because the proximity between Roma and non-Roma is seen as threatening" (my own translation) (Castro, 2013b: 49).

Some of the families in my unit of observation were able to live in one of the less stigmatized and stigmatizing social districts of the city of Porto, despite subtle manifestations of displeasure by the population living in the neighbourhood." (my own translation) (Casa-Nova, 2009: 120).

3 AIMS AND RESEARCH METHODS

The literature review shows that there is a deficit of studies inviting the opinions of Gypsy/Roma concerning their preference to live in more or less segregated areas (Schnell and Ostendorf, 2002), and of studies examining the effect of different patterns of residential segregation on Gypsy/Roma social and economic prospects and well-being.

The aim of this paper is to fill a gap in the international literature on the preferences of Portuguese Gypsy/Roma families regarding more concentrated or dispersed models of rehousing, envisaging that the

findings presented here will be of interest to urban planners, sociologists, public housing managers, and local housing authorities.

The findings presented here are predominantly drawn from a research project conducted between 2007 and 2011 scrutinizing the effects of area-based initiatives that targeted different neighbourhoods (centrally located and peripheral ones) on vulnerable social groups in Porto (Alves 2010). Whilst the initial research did not focus upon families with Gypsy/Roma backgrounds¹, the fact that the São João de Deus neighbourhood (hereby SJD) targeted for demolition was well represented by Portuguese of Gypsy/Roma background and these were object of evictions and forced displacements (Alves 2017a), justifies the focus of this paper.

In terms of data collection, the results here presented are based on 8 semi-structured in-depth interviews, which lasted between one and two hours, with residents, NGOs, and public officials. An additional interview was conducted in March 2017 with a mid-level public administrator who works in Domus Social, the municipal agency responsible for the provision and management of the stock of social housing in Porto². The aim of this additional interview was to inquire if the spatial concentration of the Gypsy/Roma population in some social housing estates (such as Cerco, Lagarteiro, Aldoar), after the forced displacement from SJD, was the result of a voluntary choice by these families or the result of a lack of choice given institutionalized political decisions taken by local authorities or bureaucrats. In short, this interview sought to access stakeholder views regarding the hypothesis of segregation as a result of a range of discriminatory behaviours based on prejudice and negative stereotypes towards the Gypsy/Roma population.

All the interviews were digitally recorded with the permission of each interviewee and subsequently transcribed. The theoretical foundations for the analysis of interviews were generally located within realistic evaluation and social constructivism that sees discourses, as discussed by Manzano (2016), as statements that incorporate judgements, ideologies, and ideas.

4 THE GYPSY/ROMA POPULATION AND THE SJD

SJD is a peripheral neighbourhood, which, like other social housing estates built on the outskirts of Porto, “was born poor” in terms of urban planning, social occupation, and location. The neighbourhood was constructed in a marginal area, with an incipient urbanization process and very low or nonexistent economic and social opportunities (such as jobs, social and private services, etc.) (Alves, 2017a: 385)

In 2000, the population of the SJD was officially estimated at 2,600 inhabitants, 34% of which were of Gypsy/Roma origin. The history of the SJD developed in phases. The first housing blocks were built in the 1940s, while in the 1970s, in a context of housing shortages related to population growth and rural-urban migration, expansion of the neighbourhood occurred with the construction of shacks (barracas). In the 1990s a project funded by the National Programme against Poverty, and funded by national and local resources, enabled the eradication of illegal housing and the construction of 12 new blocks of multi-family housing - in total, 270 dwellings, as well as the construction of equipment and services for youth, the elderly, and the unemployed. At the end of the project, disagreements between the representatives of the municipality's housing department and the person in charge of the project (a local priest), regarding the way the rehousing had been carried out resulted in abandonment of the area.

The residents stopped paying rent and private and public spaces were not managed, leading to increased drug trafficking and abuse, with increasing numbers of people entering the neighbourhood to buy/sell drugs, which in turn led to a spiral of social and physical decline. Relationships once characterized by trust and solidarity gave way to tension and internal division, for example, among the Roma/Gypsy community between: “families who sell drugs and had more financial resources, and those who live from work at fairs,

¹ In 2011, the Gypsy/Roma represented 34% of the total population, while 7% were of African background.

² Domus Social manages 12,617 dwellings distributed among 48 social housing neighbourhoods, and where 29,221 individuals live.

which were less profitable than the former" (Mendes, 2005: 59). In December 2001, the election of a new mayor and a right-wing political party in the municipality led to demolition of the neighbourhood. Between 2003 and 2005, and in a context of pronounced police intervention, 25 blocks of multi-family housing were demolished (a total of 562 housing units), leading to 162 forced evictions and the displacement of 430 households to other social housing neighbourhoods.

Alves (2017a) shows that the effects of displacement and relocation were not the same for all sub-groups of the population. Two significantly divergent positions were identified. On the one hand, a group reporting high levels of satisfaction regarding the new housing conditions, in terms of housing quality and dimension, and the state of the neighbourhood, namely in terms of crime and conflict. On the other hand, a group of tenants experienced limited opportunity to negotiate with the housing authority and new housing, like the neighbourhood, worsened in terms of size, quality, and infrastructure. The right to housing was denied to many Roma/Gypsy families, contributing to their further marginalization and impoverishment, and creating new problems such as isolation of the elderly and an increase in the school dropout rate among the Roma community.

5 THE PREFERENCES OF GYPSY/ROMA FAMILIES

To more fully convey the experiences and perspectives of respondents concerning models of concentrated or dispersed rehousing of Gypsy/Roma families, direct quotes from longer verbatim narratives are presented in Table 1. The main aim of presenting direct quotes is to allow respondents to speak in their own words and the reader to get a better idea of the arguments presented by respondents regarding the question above.

The qualitative information collected during interviews revealed the presence of positive aspects in the SJD, such as the presence of networks of reciprocity and friendship between the Gypsy/Roma population and non- gypsies, as well as the resilience shown by residents facing tensions and dilemmas related to the long-term institutional abandonment of the neighbourhood.

In general, the results show a heterogeneous Gypsy/Roma population regarding preferences and discourses related to more concentrated or dispersed models of rehousing. However, there seems to be a general consensus that the concentration of ethnic communities has not been voluntary, as Gypsy/Roma families have been channelled onto the least attractive housing estates, locations refused by others.

Whilst residents, NGOs, and public officials recognize that living in the vicinity of close relatives is a factor influencing the choice of Gypsy/Roma families that seek to provide support to their senior relatives and children, they consider that the patterns of segregation of Gypsy/Roma families is mostly unwelcome, as large concentrations of Gypsy/Roma families in the same area does not favour social integration and may feed the intergenerational transmission of disadvantage and processes of social and territorial stigmatization.

As explained by one respondent, a senior Gypsy/Roma individual, more balanced Gypsy/Roma residential distribution may be an advantage for integration, since it would prevent unwanted social conflicts between opposites while preserving cultural traditions:

"My advice is that there should be one, two in each neighbourhood so there is no confusion. For example, one in each block, so that there are not many together, because it is better for integration, for conviviality. If we get together at weddings, I invite my friends and we have eight days of partying, that's ok, but living together every day does not work. We are very united in the gypsy community. We have many positive things like all of us gathering at the door of the hospital when someone is sick, or parties. But when there are clashes between 'contraries', no one should be involved in or be blamed for what others do" (R1).

Other interviewees commented on the problem of school segregation, as children of Gypsy/Roma families tend to go to schools located near their 'ghettos', the residential concentration of Gypsy/Roma families tends to create school segregation, that is seen as a factor that produces poor school results, reduced

opportunities of social interaction with children from other cultural backgrounds, and therefore, the delay of social integration and opportunities (eg in the employment market) of families of Gypsy/Roma origin.

6 CONCLUSION

One of the key challenges in planning and housing policy today is social polarization and social segregation, with institutional and individual discrimination raising several issues concerning social justice and human rights. While this paper seeks to raise public awareness of these matters, it also attempts to present some empirical findings related to the segregation of Gypsy/Roma families in contexts of rehousing. Some general results emerging from this study are as follows.

Whilst patterns of residential segregation in a city can be attributed to a range of processes, such as individual preferences for certain dwellings and locations, or for certain types of social composition (eg. for social homogeneity vs. heterogeneity), individuals or social groups lacking economic resources are more dependent upon structural conditions, such as those related to prejudicial attitudes and behaviours inscribed in state planning and housing policy towards socially endangered groups.

Considering that systems of housing and urban planning have a remarkable impact on the spatial ordering of social relations in cities, conditioning opportunities for different ethnic and socio- economic groups, the social composition of neighbourhoods, therefore opportunities for everyday social interaction, it is important that deliberative democracy in the form of collaborative planning favours the construction of more harmonious societies, embodying more just principles and outcomes.

When making planning decisions, planning practitioners and housing administrators should bear in mind that large concentrations of Gypsy/Roma families on some social housing estates do not match either this group's preferences and expectations, or scientific knowledge and recommendations for the improvement of policies (Castro 2013a). Also, as pointed out by Le Galès and Therborn (2009), more powerful social classes are the motors of spatial segregation, as they have more resources to oppose the mix of social classes and ethnicities. While the majority tend to be defensive regarding minority groups, namely towards the Roma/Gypsy population, putting pressure on public officials to keep them at a distance, minority groups develop processes of creative adaptation to local living conditions. It is important that public officials and policy-makers work closely with local Roma/Gypsy and non-Roma/Gypsy families, aiming to develop processes of learning, dialogue, and exchange of knowledge, so that policies ameliorate socio-economic and spatial inequality and create healthier, more inclusive spaces that favour the integration of minority groups.

ACKNOWLEDGMENTS

I am grateful to the interviewees for their contributions. This research would not have been possible without their time and insight. I am grateful to the financial support of the Portuguese Fundação para a Ciência e Tecnologia for research grant SFRH/BPD/75863/2011, POPH/FSE. I also wish to thank my colleagues, involved in the project 'exPERTs – Making sense of planning expertise: Housing policy and the role of experts in the Programa Especial de Realojamento' (funded by FCT PTDC/ATP-EUR/4309/2014) for valuable debates and discussions.

1.1 TABLES

R1	"The dispersion of the gypsies into various neighbourhoods is bad for the parents and good for the children, and is a form of integration for the children of today because tomorrow they will be divided. This change will be good for the integration of the Roma in the future." (71-year-old, pensioner of Gypsy/ Roma origin).
R2	"I understand this is very beautiful when we are 20, 30, but then we come to 50, 60 we need someone close. I think that the gypsy tradition is to have, at least, the son or the father nearby. With the rest, it is indifferent." (60-year-old, pensioner of Gypsy/ Roma origin).
R3	"The rehousing should be better done, sending the direct family, parents, children, siblings from the same neighbourhood, unless the person says I do not want to. But usually most want, most of them..." (48-year-old, security guard, of Gypsy/ Roma origin).
I1	"There are gypsies who do not like to live near gypsies. However, they all have a conception of life and habitability a bit different from ours. They need ample spaces. Of course, there are some of them who have adapted perfectly to our habitat and like it. I am convinced that the majority like to live in a gypsy community." (resident of the SJD, public official in local parish, of non-Gypsy/ Roma origin).
I2	"There was some cohesion among the gypsy community, but the relationships ended up being very tenuous, the illegal activities of the neighbourhood eventually weakened the relationships - the conflicts were mostly related to the businesses that existed between them, and with power relations." (social worker, ONG in the SJD, Fundação Filos).
I3	"There were many conflicts within the community, fights, gunfire, and misunderstandings among them associated with trafficking. There were even gypsies who said they did not want their children in classes with gypsies. We tried to make them see that things could not be like this, but they are extremely spiteful." (teacher at local primary school, the SJD).
I4	"The city council do not know, did not know, and do not want to know anything about the gypsy community. It creates a discourse that the gypsies are all the same [...] The gypsy community is favourable to the social mix in order to produce cultural interactions, and social integration. Dispersion would not be a problem and would be accepted by the community, but the gypsy population is obliged to submit to poor dwellings, low rents. Gypsies are cantoned in segregated peripheries." (psychologist, researcher at the university of Gypsy/ Roma origin, and representative of the Roma Community in Porto/União Romani).
I5	"There are divergent views on the issue of aggregation or dispersal of Roma (to integrate or separate them?). This is the big debate; should you make neighbourhoods for gypsies? This is considered shameful and discriminatory. There are strong conflicts and contrasts with normal lifestyles, but should we put them apart? Are we creating ghettos of gypsies?" (civil engineering, public official in Porto municipality).
I6	"In general terms, those who obtain access to a dwelling have been on the waiting list for longest, but displaced tenants are given priority over regular house seekers. Based on the match with housing size, income, we make them several offers that they will accept or not. If they turn down three properties in a row, they have their priority status displaced. The stock of social housing in the city of Porto is small when compared to demand. In 2017, the Domus social waiting list comprises 1,050 families. On average, 400 dwellings of social housing are allocated per year, which means that we cannot answer many on waiting lists. [...] We are more concerned for the principles of equal treatment and equal responsibilities and rights, irrespective of the ethnic features of the tenants."

ID 1420 | ANALYZING A GLOBAL SENSE OF PLACE BY USING COGNITIVE MAPS: A STUDY OF AFGHAN IMMIGRANT WOMEN IN AUCKLAND

Roja Tafaraji¹

¹The University of Auckland
rtaf006@aucklanduni.ac.nz

1 INTRODUCTION

Sense of place, according to the literature (Hummon, 1986; Lewicka, 2008; Proshansky et al., 1976; Raymond et al., 2010; Relph, 1976; 1997; Tuan, 1980; 1975), is the characteristic and meaning of a place derived from the experiences that people as individuals or within a group have in the place. Places are,

therefore, spatial settings which gain specific characters from people's experiences in a particular time. Places are conceived and sensed "in a chiaroscuro of setting, landscape, ritual, routine, other people, personal experiences, care and concern for home, and in the context of other places" (Relph, 1976, p.29).

Globalization is widely argued as the process of economic, political and socio-cultural change since it has been associated with worldwide flows of migration and mobility (Berner, 1997; Castells, 1991; Massey & Jess, 2003 [1995]; Pile et al., 1999; Pries, 1999; Steger, 2003). Cities are not excluded from this global change. Their meanings and identities constantly change according to the different experiences of different people over time.

This paper explores the meanings of places in the global city of Auckland according to everyday life experiences of Afghan immigrant women who live in Auckland. In order to discuss the meanings of different places for Afghan immigrant women in Auckland, firstly, I provide an overview of the meaning of everyday life experience in relation to the developing sense of place in the era of globalization. Then, along with offering a critique of the essentialist approach to the place and its meaning in the globalization era, this paper suggests cognitive mapping as a method to explore the meanings of the place in the global city. This paper discusses the findings of the fieldwork study that I undertook for my PhD research project in Auckland from 2014 and 2015. This fieldwork study was on eight Afghan immigrant women from two generations of immigration (1st and 1.5 generation) who live in Auckland. By focussing on cognitive maps which were drawn by these women, this paper, finally shows how these Afghan women conceive, perceive, use, and present different places in the global city of Auckland. As a concluding mark, I suggest that cognitive mapping can be applied as a method compatible with the fluidity of everyday life experiences of different groups of people, especially groups of minority, in the place of majority of global cities like Auckland.

2 EVERYDAY LIFE AND A DEVELOPING SENSE OF PLACE FOR IMMIGRANTS IN THE GLOBAL CITY

Researchers, who are interested in the subjective existence of people in place, acknowledge the importance of the everyday life experiences of people in developing a sense of place, belonging and identity in a city (Altman et al., 1980; Buttner & Seamon, 1980; Lefebvre & Levich, 1987; Marcus, 1992; Perkins & Thorns, 2012; Rapoport, 1976; Relph, 1976; Tuan, 1974). Piotr Sztompka (2008) clarifies the concept of 'everyday life', as the observable manifestation of social existence, the cyclical and rhythmic events over a variety of time periods, the ritualized and habitual engagement with others to participate in activities, as having a certain temporal duration, as the semi-conscious/unconscious event "following habits and routines of which the actors are not fully aware" (Sztompka, 2008, p. 32) and finally as being localized in particular spaces. In his distinguished book *The Practice of Everyday Life*, Michel de Certeau (1988) considers everyday life as the ordinarily practised activities in the city, most importantly walking. Furthermore, Henri Lefebvre (1996a; 1996b) focuses on everyday life as the opportunity for people to use and participate in decision-making processes as their right to the city. Inevitably, therefore, everyday life involves interactions between people and places.

Everyday life experience in the globalization era, as is argued by a number of thinkers (see Hall, 2003 [1995]; Massey & Jess, 2003 [1995]; Pratt, 1999; Rose, 2003 [1995]; Sibley, 1999; Smith, 1999), influences the shared meanings between people and the (socio-political) context. These thinkers and researchers refer to a global sense of place as a developing sense and conception influenced by different aspects of everyday life experiences of people in the global place. Therefore, in the context of globalization, a sense of place is considered as a system of meanings for immigrants shared between them and the place where they experience their everyday life.

The practice of everyday life in the global city makes different groups of people as locals and immigrants interact with their different and sometimes conflicting conceptions and images of the place. Meanwhile, these people share some of the images and meanings during their everyday life experiences in the city. In the scale of immigrants from different ethnic groups and communities, there is considerable chance of developing a sense of community within ethnic communities if their cultural representations are recognized within the host society. Globalization initially has brought "a geographical imagination of a world without borders" to the real geographical world (Massey, 2002, p.293). Here the importance of 'imaginary

geographies' (Said, 1990) becomes meaningful in that this leads the research to study individual and collective images of the places in the global city which are shaped through everyday life experiences of immigrants.

International immigrants, whether they return to their countries of origin or not, make links between their places of departure and places of arrival (Massey & Jess, 2003 [1995]). Research indicates that these links create a sense of being here and there for immigrants at the same time in one place (Massey & Jess, 2003 [1995]). Doreen Massey (2003 [1995]) suggests that this being here and there is obtained through the process when immigrants (re)build their territories and home environments so as not to feel alienated in their new living places. This process leads to (re)conceptualizing of places in global cities in which immigrants resettle.

Once immigrants, particularly first generations of immigrants, were living in their countries of origin (before migration), they were experiencing their places including all the components of the place such as cultural, socio-economic and environmental aspects of the place. Therefore, each place had a specific character and identity which was the after effect of the elements and features which could be experienced in the place. Continuous experiences of immigrants in the place over time, also, support their sense of attachment to the place. However, when migrants leave their places and resettle in another place, they bring all the memories of past life experiences with them to their new living place. These memories contribute to their perceptions of their new living place and lead them to use this place based on their formed expectations. Since people from different countries with different socio-cultural backgrounds have different memories of their past life experiences and therefore different expectations of future occurrences in the new place, it is inevitable that there will be different ways of appreciating this new place based on different perceptions and conceptions of different groups of immigrants within places in the global city.

Massey (2003 [1995]) argues that immigrants' different appreciations of place change the singular identity of those places in global cities over time. It is in this way that local identity is threatened through the globalization process. David Harvey (1989b) also considers this as an end to the feeling of spatial stability and a sense of coherence in a place. Harvey believes that discourses on the need for settled places are part of exclusive nationalism, regionalism and localism which oppose diversity at any scale (Harvey, 1989a). Therefore, by focussing on Afghan immigrant women as a group of minority in the global context of majority of Auckland, this paper explores the meanings of places for them by investigating their everyday life experiences in the host society of Auckland. The everyday life experiences of those people are sources of their (social, emotional, physical) connections as individual and within communities with their living place.

2.1 CRITIQUE ON ESSENTIALIST APPROACH TO THE PLACE OF IMMIGRANTS IN THE ERA OF GLOBALIZATION

Different perspectives on the concept of place have been reviewed in refugee studies and studies on immigration and displacement (see Brun, 2001; Kibreab, 1999; Malkki, 1992). One perspective considers place as an essential concept for the identification process. From this point of view, which emerged after World War II, refugees are looked at as displaced people who are taken away from their roots and morality (Brun, 2001). Therefore, they are people with no culture, no morality, no power and no identity. This attitude to refugees and displaced people brings about particular policies to solve their displacement problem (Brun, 2001; Den Boer, 2015; Kibreab, 1999). By regarding refugees as being 'out of place' and 'uprooted', these policies have set up exclusive strategies which lead to two possibilities for refugees: they either become absorbed into the culture of the new place or return to their place of origin. Another strategy, 'the right to remain at home strategy', is concerned with helping displaced people in their place of origin in order to prevent them from being "uprooted" (Brun, 2001; Kibreab, 1999).

The above-mentioned perspectives in immigration and refugee studies result from an essentialist approach to place which strongly advocates the fixity in the meaning and identity of place. An essentialist approach attempts to solve the problem of identity through looking at place as a unique, unchangeable, independent and fixed entity even over a time period. Therefore, relationships between people and places as well as represented cultures are also fixed and localized. This approach may not be responsive to the co-existence of cultural differences in global cities because the phenomenon of socio-cultural diversity in a

place is not easily understood through this essentialist approach. Critics of this approach argue that mobility is an inevitable fact of the current world and that refugees do not lose their identities through their immigration process (Malkki, 1992).

The critics of the essentialist approach to place present another view through looking at refugees as active agents who are able to develop meanings of their new places. This view is characterized by deterritorialization or reterritorialization (Gupta & Ferguson, 1997; 1992; Malkki, 1992). It is associated with the globalization process in which different trends of mobility and displacement necessitate new ways of conceptualizing space, place and the relationship between people and places. In this view, place must be experienced to obtain meaning. Place is a product of socio-cultural construction, not a fixed entity. This is in accordance with Doreen Massey's understanding of place as the setting for social interrelations (1991; 1994a; 1994b). Massey sees place as a meaningful product of the intersection and interaction of different identities (Massey, 1994b). According to her understanding of place, the place of immigrants and refugees is the intersection of different and even conflictive identities of different communities. From this point of view, different communities with different interests, norms and values coexist in the same place. As a result of the participation of each community in the reterritorialization process, different power relations are expected to govern over the place at the same time. While this may cause conflicts and tensions between different communities, these conflicts create the possibility of negotiation between those communities, which affects the way that each community appropriates the place. Therefore, it can be argued that refugees' conceptions of their new place are not only influenced by their past life experiences, but also by their present experiences and interactions in the place. That is why a specific community develops different identities in different places (Brun, 2001). Interaction is the key in the construction process of identity.

In the following sections of this paper, I will discuss how cognitive maps represent the everyday life experiences of immigrants with focussing on the experiences of Afghan immigrant women in Auckland.

3 COGNITIVE MAPS AS THE REPRESENTATIVES OF THE LIVING ENVIRONMENT

Cognitive mapping has been used by research on people's perception of place in order to simplify the complexities of people-place relationships and interactions (Golledge, 1999; Golledge & Stimson, 1997). Studies in the field of environmental psychology define cognitive maps as abstract representations of people's feelings, beliefs, thoughts, and ideas which are structured on different aspects of (individual and social) identity in the context of their everyday life experiences (Cohen, 1985; Downing, 1992; Kaplan, 1973; Kitchin, 1994; Proshansky et al., 1976; Spencer et al., 1989) and the way they orient themselves within the place (Golledge, 1999; Lynch, 1960). Maps as sources of insight (Jacobs, 1996) illustrate significant forms of representation in the place. Cognitive maps, therefore, generate specific information about daily activities of people in the city which are not necessarily mentioned in their verbal narratives. Maps are able to represent a socio-cultural system that in a global context can be used as a representation of mainstream discourse (Ristock & Pennell, 1996). They show how the power relations in the global context control and define the geographic boundaries which lead to creating social boundaries for people's activities in the city (Harley, 2009). According to the developing sense of place in the era of globalization, I apply cognitive maps of a group of Afghan immigrant women in order to obtain an understanding of the sense of place in the global city of Auckland.

3.1 AFGHAN WOMEN'S COGNITION OF AUCKLAND AS REPRESENTATIVE OF THEIR (PERSONAL) EVERYDAY LIFE EXPERIENCES

This paper uses cognitive maps as representatives of the living context of a group of Afghan immigrant women who live in Auckland supported by a number of quotations from semi-structured interview with these Afghan immigrant women. Founding on the collected data from my PhD project, I asked eight Afghan immigrant women, who were the participants of the study, to draw a map of Auckland representing the city in which they live. In their drawings of Auckland, I asked them to include the places that are important to them during their everyday life experiences such as their living place, their working or studying

places, and places of interests or landmarks of the city. The scale of the details in their maps was not specified, so they were to decide about the scale of their maps, from neighbourhood, suburb or city. They were insured that the scale of their drawing and the area which is shown in their maps do not matter as long as their illustrations of the important places in the city match their daily preferences. The shape of Auckland was another aspect of cognitive maps which were asked to be presented in their drawings.

Participant Afghan women represent their imagination of the city according to the elements of the city to which they have become familiar during their everyday life experiences. Kevin Lynch (1960) defines these elements as elements of legibility, which help people to understand and read the city. They include nodes, pathways, landmarks, districts, and edges. However, interpretation and explanation of all of these elements in cognitive maps of Auckland are beyond the scope of this thesis. Nodes and pathways are two elements that I analyze in cognitive maps of Auckland in order to obtain an understanding of how participant Afghan women spend their daily time in the city, and get access to places in the city and appropriate them. Through analyzing nodes, I inspect the important activity locations that participants refer to in their maps. Also, the pathways in the maps are the ways through which participants visualize the access between their important activity locations in the city.

3.2 DISCUSSION AND ANALYSIS OF COGNITIVE MAPS

In this section, I analyze the ways that participants imagine Auckland as their context of everyday life experiences. I support my analysis of the cognitive maps by the data I collected during the interview meetings with my participants. This analysis assists me to discuss the sense of place for the participants in different places of the global city of Auckland.

I explain everyday life experiences of the participants in different places of Auckland based on an existing classification of activities in public life of the city. This classification helps me in analyzing everyday life experiences of participants according to the type of their activities in different places of the city. Jan Gehl (2011), who has focused on the quality of urban life, discusses types of human activities in public spaces. He distinguishes between necessary (functional) activities, optional (leisure) activities, and social activities. Necessary activities, according to Gehl (2011), are everyday tasks – almost compulsory – which take place regardless of the quality of the place, whereas optional activities highly depend on the quality of the place and the potential that it provides for people to spend more time in it. Social activities can happen spontaneously with other activities and highly depend on the presence of others in public places. Greetings, playing, and collective activities of any kind are known as social activities in public places. I begin the analysis of the cognitive maps with the younger group of participant Afghan women who belong to the 1.5 generation of immigrants and have been in New Zealand for approximately 15 years¹. In the cognitive maps presented by Zahra and Meena, who are cousins, a technical element concerning their cardinal directions in Auckland² appear to be common (Figure 1). This shows that both of them think of the links between their important places in Auckland as links between four cardinal directions through the central part of the city (CBD). These links reflect means of access for them between those places. This is clearly shown in Zahra's cognitive map in which she draws a train and car as means of transport and annotates them with "train" and "motorway" to show her means of transport from the city to those places. She clearly stated this in the interview, when I asked her about her frequent means of transport in the city:

“Roja: What is your frequent means of transport in Auckland?”

Zahra: Emmm, my car and train, yeah.

Roja: Which one do you use more?

Zahra: I use just train.”

¹ In this research, I studied on 8 Afghan immigrant women as the research participants in Auckland. Participants are introduced based on their generations of migration: first generation and 1.5 generation. According to the official report published by Department of Labour of New Zealand in 2008, the first generation immigrants are “immigrant youth2 who were born overseas and arrived in New Zealand after the age of 12”, and the 1.5 generation immigrants are “immigrant youth who were born overseas and arrived in New Zealand by the age of 12”² (Ward, 2008, p. 4). This categorization, although not a fixed categorization, is based on immigrants' age of arrival² and their place of birth which are considered influential in the identification process of migrants in the host society (Ward, 2015).

² However, this can be explainable by the fact that I interviewed them together in the same place and it was Zahra who first drew her cognitive map while I was interviewing Meena. Therefore, Meena might have had the chance to look at Zahra's drawing copied the pattern in her drawing. However, I asked them to only rely on themselves and the way they imagine Auckland including its important places for them as individuals.

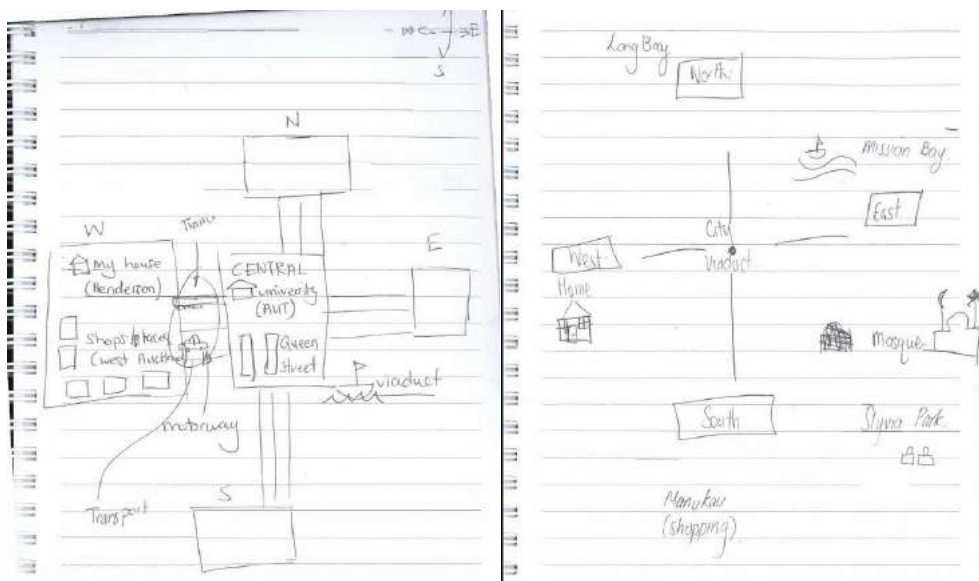

Figure 1. From left to right: Zahra's and Meena's cognitive maps of Auckland

Meena, however, does not clearly show her means of transport in the map. She imagines the city in four cardinal directions. These straight lines between important activity locations are representative of perceptual links between those places since she does not do necessary activities in the central part of Auckland, unlike Zahra who studies in the CBD. Therefore, Auckland is perceived as a whole entity, not as fragmented zones. However, in her interview, Meena noted that she drives her own car as her most frequent means of transport and uses the train as a means of public transport if she wants to go to CBD to do some necessary activities like studying:

Roja: Okay, what is your frequent means of transport?

Meena: Driving.

Roja: Driving?

Meena: Yeah.

Roja: So you have your own car?

Meena: Yeah.

...

Roja: Okay. So you don't usually use public transport. Do you?

Meena: Emmm, no unless I come to see... you know, for studying like I'm going to study next year in the city, so yeah I'll train. But emmm, other than that no...

However, her decision not to use public transport is supported by her mother who thinks of the bus as not a "safe" place to be in:

"Meena: ...When I was younger as well, my mum didn't..., she was not against... she was against public transport, like she... she thought it wasn't safe, so she would hate me going on public transport as well, so it's like, you know, you get your own transport, you know.

Roja: Aha...why did she think that it's not safe?

Meena: She was just like ...you... you see all sorts of people, you just never know what they could do, you know?... And so yeah.

Roja: Aha.

Meena: Yeah, and I was younger as well, and you know wearing scarf it was kind of difficult as well.

Roja: Aha.

Meena: So yeah, she... she would just like watching us."

The perception of Meena's mother about public transport in a global city has made Meena avoid using public transport during her daily life. It is clear from the above quotation that the perception of Meena's mother is based on the unfamiliarity with people of whom "you just never know what they could do".

The above quotation demonstrates the importance of the influence of the family, particularly mothers, in the daily life experiences of young Afghan women like Meena. This influence contributes to Meena's different appreciation of a place, which is based on her experience as a Muslim woman in the global city of Auckland. In this regard, Doreen Massey (2003 [1995]) argues that immigrants' different appreciations of places change the singular identity of those places in global cities over time.

Sadjida, a 26-year-old Afghan woman, refers to her living area as her most preferable place in the city. She shows this in her cognitive map. The following figure is her cognitive map of Auckland (Figure 2). In

her cognitive map, Sadjida allocates half of the page to the Lynnfield area and places around her living area. The big circle on the map represents that she imagines important places within the Lynnfield area as connected with each other and she includes access ways within the immediate vicinity of the circle including May Road. There is another circle shaped area that Sadjida annotates as "City" in the map. It includes the University of Auckland, AUT, IMAX and Queen Street. She shows the connection between the former circle and the latter one with connector lines, which resemble streets. While she was drawing those connector lines, she mentioned to me that the longer one is Dominion Road, which according to her is the main link between her living area and the city.

Figure 2. Sadjida's cognitive map of Auckland

However, Sadjida does not acknowledge cardinal directions in her map and this causes confusion in understanding her imagination of the city because Lynnfield is located southwest of the city centre area of Auckland, while she locates the Lynnfield area north-east of the city centre in her drawing (Figure 2). This means that she does not imagine the location of different places in relation to each other in a bigger picture of the city. This is reflected in her explanation of choices of preferred places in Auckland. Most of her preferred places are located within the boundary of her living area, including the YMCA gym, the Coffee Club in May Road, and the Countdown shopping area in Mount Roskill, among others. In addition, in her interview, Sadjida stated that the bus is her main means of transport in the city and she relies on this mode of public transport to access places in the city:

"Roja: What is your frequent means of transport?"

Sadjida: Um, frequent would be bus."

Sadjida's daily life in Auckland is divided into two main parts of home and university and this division is clearly presented in her cognitive map. However, she illustrates her cognitive map by focusing on each node and the potential activities in each of those places. Hence, for Sadjida, the connection is not as important as places themselves. This shows the importance of activities for her in each of the places she illustrates in her drawing rather than accessibility to these places and the links between them.

Taiba, one of the young participants, represents her cognitive map of Auckland in a rectangular shape, which embraces important activity locations for her as shown in the map below (Figure 3). Her main link between those locations is clearly noted as "Motorway (20)"¹ in the map. It affirms that she is clear about her means of access, which is car.

¹ By Motorway (20), she means State Highway 20 (SH20), which is known as the Southwestern Motorway in Auckland.

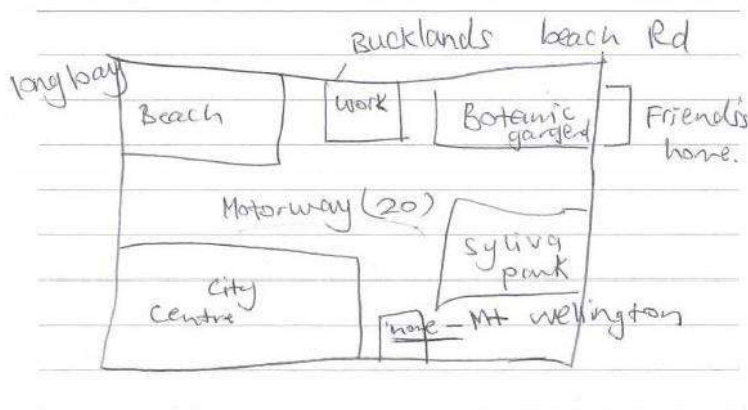

Figure 3. Taiba's cognitive map of Auckland

The following extract of the interview with Taiba highlights this:

Roja: So ...what is you frequent means of transport?

Taiba: I drive.

Roja: Do you drive?

Taiba: Yeah, now I do. Before I used to catch the train and the bus."

Taiba, also mentioned that having a car is not her preferred choice of transport. However, she has no other choice since public transport is not reliable in Auckland:

"Roja: How do you feel about in-city travels and transport in Auckland?

Taiba: You always have to have a car, otherwise (chuckles)... otherwise you can't depend on public transport, it's hard."

Henna, who is a university student at Auckland University of Technology (AUT), presents her cognitive map of Auckland as a route map, which shows places in a route between her home and the university. In the following map (Figure 4), Henna draws Auckland in a linear shape that extends from south to north. Congestion of annotated places in the eastern side of Henna's cognitive map is indicative of locations of her main activity zones in East Auckland. However, the locations of places in Henna's cognitive map do not match with their real locations in Auckland. It shows that Auckland, for Henna, is perceived according to her daily life experiences.

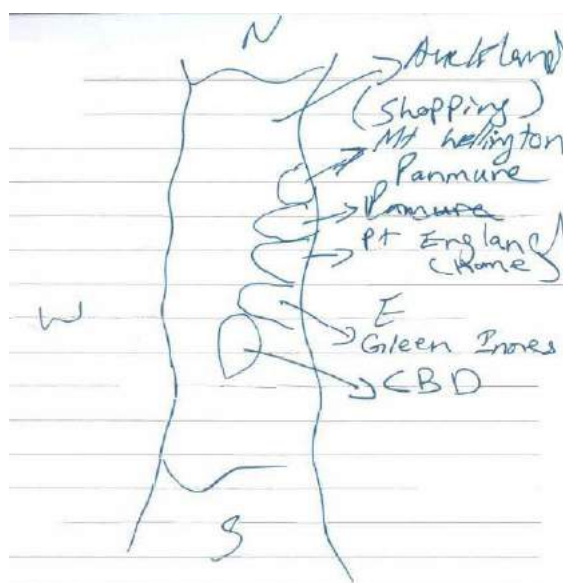

Figure 4. Henna's cognitive map of Auckland

In the interview with Henna, she pointed out that a train is her main means of transport, particularly during her routine daily life on weekdays. In her cognitive map of Auckland, this is clearly confirmed by the way that she defines her route map according to train stops during her journey:

*"Roja: What is your frequent means of transport?
 Henna: Train."*

However, in her interview, Henna mentioned that her preference of using a train is not because of the efficiency of trains or any other public transport in Auckland. She would prefer to drive her own car if she did not have a problem parking in the city.

*"Roja: Do you feel more comfortable in using public transport or your own car, just generally?
 Henna: I would be happy to use my car, but I won't be able to find a parking.
 Roja: Aha, so is it just because of the parking?
 Henna: Eh yeah.
 Roja: If it was enough parking in the city, you would bring your car?
 Henna: Yeah, yeah. Because coming by train takes a lot of my time."*

She is also a train person when she wants to go to shopping, as is annotated in the map in the Mount Wellington area. Again, this is highlighted by showing Panmure as a node between her home place (Point England) and shopping place (Mount Wellington).

The following cognitive map belongs to Sophia (Figure 5). She patiently illustrated her cognitive map consisting of symbols, shapes, and annotations. Sophia shows the location of Auckland CBD properly at the centre of the map, which is represented by drawing the landmarks of Sky Tower, and the University of Auckland in the city campus.

Figure 5. Sophia's cognitive map of Auckland

However, Sophia's cognitive map does not reflect cardinal directions since she does not picture her cognitive map of Auckland from a bird's-eye view. She illustrates her important activity locations with the aid of symbols and shapes such as trees, humans, and buildings. Therefore, connections between these places are not according to reality. Two main access ways, which are distinctly shown on the map, are Queen Street and Tamaki Drive. In Sophia's cognitive map, Queen Street links "Work" to "Shopping" and "Home", while Tamaki Drive is framed with trees on both sides and defined as a connection provider between "beach" and Mission Bay. In the following extract of the interview, Sophia explains her reason for preferring Tamaki Drive in Auckland to other streets and routes:

"Sophia: Probably more like the Mission Bay and Tamaki Drive area. Because it was like close to my area, nothing to worry about, you know, in terms of transport or carpark or whatever... you know? It was more relaxing."

Therefore, the close proximity between her living place and that area gives her a sense of comfort without having to worry about transport and parking. The interpretation and analysis of this type of illustration of access-ways in the cognitive map could be that Sophia is either a bus or a car user. However, her level of details in her cognitive map (e.g. trees and buildings) show that she is more of a bus user that she could captured more details on her way between home and work. This is confirmed by her interview as below:

*"Roja: Ohum, eh, what was your frequent means of transport in Auckland?
Sophia: Ehhh if I went to town, it was mainly by bus."*

However, Sophia insisted that her daily life and stage of life influences her preferences of means of transport:

"Sophia: It depends on time... like when are we talking about? Like [during] uni time, I was always bus person. Yeah, but after uni, when I got a car and I worked and stuff, I was more a car person, yeah."

The two following maps are the cognitive maps of Banoo and Soraya (Figure 6 from left to right), who are two participant Afghan women from the first generation of immigrants in Auckland.

Figure 6. From left to right: Banoo's and Soraya's cognitive maps of Auckland

The generation of immigration results in a notable difference in the illustration of cognitive maps of Auckland. Other studies have also examined and found that length of residence affects the attachment of people to their living environment (Cuba & Hummon, 1993; Hernández et al., 2007). In this study, Banoo and Soraya who have been in Auckland for three years, depict their important activity locations in Auckland in and around Queen Street. This is firstly because they both live in the CBD area and secondly because they have not had many experiences outside of the CBD in Auckland according to their length of residence in Auckland. Their linear maps are indicative of the importance of Queen Street in their minds when thinking of Auckland as their living environment. The role of connection is more important in their maps compared to those of other participants from another generation of immigrants. Indeed, Queen Street is not perceived as a pathway¹; rather, it is represented as the whole district or zone in which they live and think of Auckland.

¹ According to Kevin Lynch (1960), pathway, district, node, landmark, and border are five elements of legibility with which one imagines his or her living environment. A multitude and variety of these elements in a cognitive map are indicative of a legible living environment.

Since most of the activity locations in Banoo's cognitive map are placed in or around the vicinity of Queen Street, it is expected that she walks to her destinations. This is confirmed by the following extracts from interviews with her:

(Translation from Farsi)¹ "Roja: What is the most frequent means of transport for you here in Auckland?"

Banoo: I mostly walk."

Additionally, Banoo indicated that proximity of Queen Street to most of her important places in Auckland is the main reason for her to like it. This is quite clear by looking at Banoo's cognitive map and realizing that the importance of Queen Street has made her depict Auckland around Queen Street:

(Translation from Farsi) "Roja: What do you like about Queen Street?"

Banoo: I like it, coz it's nearby my place. English classes are close, my GP is close to me, the bank is close to me, many things are close and handy in Queen Street. If I don't have things to do, I can wander around the street, and have a walk."

Studying the cognitive maps of the participant Afghan immigrant women along with their interviews shows that there is a correlation between length of residence in Auckland and the illustrated details of their living environment in their cognitive maps. Participants of the first generation who have been living in Auckland for three years have fewer details with which to annotate their cognitive maps than the others of the 1.5 generation of immigrants who have been living in Auckland for more than 10 years.

The difference between the cognitive maps of the participants is also related to the location of their living places as well as their other activity locations in Auckland. The participants' stages of life, such as their age and their occupation, are highly relevant to the way they illustrate their cognition of Auckland.

4 CONCLUSION

This paper discussed that the meaning and sense of place is not fixed and stable while differences are increasing in the global city. Meanings and sense of place are influenced by multi-layered differences inherent in everyday life experiences of different groups of people in the place. In order to understand the developing and changing sense of place, this paper studied the different everyday life experiences of a group of immigrant women from Afghanistan who live in the global city of Auckland. Application of cognitive mapping as a method provided this study with an opportunity to explore different meanings and functions of places in Auckland for participant Afghan women who live in Auckland. The different meanings and functions of places in Auckland explored in this study are not necessarily mentioned in interview quotations of the participants. In this paper, I used cognitive map as a method for explaining the diversity of appropriation, perception, and presentation of the city of Auckland by a group of Afghan immigrant women who live in Auckland. The results of this study showed that participant Afghan immigrant women imagine Auckland according to their context of everyday life experiences in the city. Similarities and differences between the presentations of their cognitive maps, also, refer to different layers of their identity including gender, ethnicity, religion, age, as well as stage of life and so on. Additionally, the results of this study show that participant Afghan women living in the global city of Auckland are influenced by different power relations of the context of globalization. These influences lead them to imagine and define social boundaries for themselves during their everyday life experiences in the global city.

In conclusion, this study suggests that the study of everyday life experiences of different groups of people in the era of globalization helps academic and practitioner planners to understand different layers of identification in the place. It is beneficial in the process of plan and policy making in terms of the sensitive and subjective approach that it considers in understanding difference in the global city. The application of cognitive mapping, I suggest provides a situation of taking a discursive approach in the research. It recognizes different layers of identification in the place in order to understand different senses of place in the era of globalization.

¹ Interviews with 2 participants were conducted in Farsi according to their preferences. Therefore, the interview transcriptions are translated from Farsi to English.

ID 1429 | THE 'FOSTER CITY': THE DIFFERENT STRATA OF URBAN DIVERSITY IN A NEWLY-MIXED TOWN

Dana Shevah¹

¹Technion- Israel Institute of Technology
shevahd@gmail.com

ABSTRACT: In the past several decades, an expeditious internal migration process is evident in Israel. Israeli towns which were established during the 1950s and 1960s have attracted Ultra-Orthodox communities and Palestinians who are Israeli citizens. This process stands in contrast to the Nationalist-Zionist ethos, which has aimed to plan and populate new towns in the peripheral areas of the new state, mainly for secular Jews. As a consequence, population groups who are considered as 'others', share the urban space with the local population. Against this background, tensions between the different population groups arise, turning the city into a contested arena, where struggles over public resources, public services, local identity and urban image proliferate. This paper highlights the different strata of urban diversity in the context of planning, asking how urban management and planning deal with a city that becomes mixed and is characterized by multiple conflicts. Karmiel, a newly-mixed town in Israel, was selected as a case study. This paper is based on a PhD research that focused on three planning events which differ in scale and represent the conflicts within the urban realm, resulting from and intensified by increasing urban diversity in terms of religious inclination (secular vs. ultra-orthodox Jews), ethno-national identity (Jews vs. Palestinians who are Israeli citizens), and socio-economic inequalities (high socio-economic status vs. low socio-economic status). The methodology combines multiple sources of knowledge and information: historical knowledge (archival documentation); planning knowledge (statutory plans, municipal board-meetings' protocols, court verdicts, interviews with municipal officials and planning practitioners); local knowledge (in-depth conversations: local residents, social activists, local NGOs, building contractors, business owners, national and local press, the civic discourse in Facebook groups); quantitative data and information (Israeli central bureau of statistics, The Ministry of Housing publications, Israeli Tax authorities, Israeli Knesset research center). This approach has produced integrative knowledge about contemporary urbanism, stressing the unique urban dynamics within cities that are becoming mixed. This paper offers a new conceptualization- 'the Foster City'. Ultra-Orthodox Jews and Palestinians, who are Israeli citizens, are compared to 'step-inhabitants'- they are not an ideological product of the Nation-Zionist city. The Israeli urban reality is characterized by growing heterogeneity, subverting the Israeli planning policy which strives for absolute social, cultural and spatial separation between Jews and Arabs and between secular and Ultra-Orthodox Jews. This abnormality challenges the existing order, eroding the utopian ideal of the homogeneous Nation-City. The 'Foster City' highlights the intermediate situation of newly-mixed cities, not only in Israel, but is germane to the European context as well. It emphasizes the complicated conditions of population groups considered as 'others', in two central aspects: alienation and temporariness. In the 'Foster City' the struggles over symbolic and spatial demands echo everywhere: at home, in the streets and neighborhoods and in the entire city. Nonetheless, the 'Foster City' is an enabling space, providing for marginalized groups an opportunity to fulfill their civil rights: it reduces the supremacy of ethnic, religious, and socio-economic status, while allowing civic belonging to sprout.

1 INTRODUCTION

The scope of international immigration is rapidly growing in the last several decades. Many population groups are forced to relocate to other countries, whether as a consequence of war, political insecurity, famine or severe lack of sources of income. However, immigration processes are also derived from a personal choice, in search for better occupation conditions or in order to improve quality of life. The movement of population groups from one country to another has a significant impact on cities worldwide, making them more diverse and heterogenic in terms of religion, social and cultural composition, and economic characteristics (Wood, 2015).

The World Migration Report (IQM, 2015) has asserted that immigration is in its essence an urban matter. By the end of 2015, the amount of immigrants in the world was estimated by 232 million people, 50% of them dwell in Australia, Canada, United-States, France, Germany, United-Kingdom, Russia, Saudi Arabia and United Arab Emirates. In Sidney, London and New-York, immigrants constitute over one-third of the total population, and in Brussels and Dubai immigrants constitute more than half of the total population (ibid). Due to extensive international immigration processes, diversity has become one of the most prominent characteristics of cities. Diversity comes into play in many different ways: status, language, gender, age, sex, race, religion, life-styles, sexual preferences and world-views (Watson, 2006). Media reports all over the world document struggles between different population groups, turning cities into a contested arenas, where struggles over public resources, public services, local identity and urban image proliferate.

Israel is not a popular destination for international migration, mostly because its borders are closed up against foreign immigrants. However, during the 1950s and 1960s, Israel absorbed major international immigration influxes, exclusively of Jews, which have dramatically impacted the urban space. The Israeli case is unique because these massive immigration influxes of Jews to the new state have gained embracing support, both from the officialdom and the public. To date, immigration of Jews is perceived as a legitimate process which the state and its Jewish citizens have encouraged. Bringing Jews from all across the world to Israel has fulfilled a vital role in the establishment of a Jewish state in the land of Israel. For this reason, the immigration process of Jews gained inimitable label: "Aliya". In 1990s, Israel has absorbed over million immigrants from the former Soviet-Union countries, but ever since the Jewish immigration influx is relatively low and slow.

Nevertheless, in the past several decades Israeli towns are facing similar challenges, as other cities in the western-world are experiencing. Recently, in several Israeli towns and cities, urban conflicts between different population groups arise due to an unprecedented internal migration, mainly of Ultra-Orthodox Jews and Palestinians who are Israeli citizens to secular cities. This process stands in contrast to the National-Zionist ethos, which has aimed to plan and populate new towns in the peripheral areas of the new state, mainly for secular Jews. Israeli towns have become more heterogenic, subverting the organizational conception of Israeli space, as can be observed in the absolute spatial and social separation between Jews and Arabs and between secular and Ultra-Orthodox Jews. As a consequence, population groups who are considered as 'others', share the urban space with the local population.

This paper illuminates the different strata of urban diversity in Karmiel, a town in the central Galilee region in Israel, which was chosen as the case study. Karmiel is one of the last two development towns in Israel. Its intended purpose was to break the continuum of Arab settlements in the area and replace them with Jewish settlements (Falah, 1989). Its political agenda of "Judaizing the Galilee" was the reason for expropriating the lands of four Arab villages in 1976. Although officially planned for a secular Jewish population, mainly Jewish immigrants and veteran Israelis, over the years the town has attracted both Arabs from nearby Arab settlements and, recently, a sizable population of Ultra-Orthodox Jews.

An examination of the different strata of urban diversity allows better understanding of contemporary urbanism within towns and cities that are becoming mixed. It sheds light on the different aspects of the ongoing debate within urban planning and urban studies, and challenges the theoretical discourse that deals with mixed-cities, demonstrating how the incorporation of planning perspective illuminates the difference between mixed and newly-mixed cities by offering a new conceptualization: the 'Foster City'.

2 DIVERSITY AND CONFLICTS WITHIN THE URBAN SPACE

The theoretical thinking about urban diversity has evolved in numerous disciplines: Geography (Amin, 2002; Amin & Thrift, 2002; Fincher & Jacobs, 1998; Valentine, 2008), Sociology (Sennett, 2001), Political Science (Boyd, 2006; Putnam, 2007), and Urban Planning (Bollens, 2008; Koutrolidou, 2012; Sandercock, 1998; Soja, 1999; Van Leeuwen, 2014a), with a specific focus on urbanism and relationships between different groups in the urban space. Planning and Urban Studies literature deals mainly with the dynamics between population groups in public spaces. For example, research publications from Europe and U.S focus on the relationships between veterans and immigrants (Askins & Pain, 2011; Bailey, 2011; Besemer, Brameley, & Livingston, 2015; Wilson & Taub, 2011), whereas publications from Canada and Australia focus on the relationships between the local population, which has emigrated from Europe and other western countries as part of imperialism and colonialism, and the native population (Bloch & Dreher, 2009; Gyepi- Gabra, Walker & Garcea, 2014).

However, two contradicting approaches can be identified. The first includes researchers who opine that urban diversity is one of the most valuable assets of cities (Bollens, 2007; Sandercock, 1998). It is argued that diverse street life enable positive interactions between different groups, which can assist in handling prejudice and even eradicate it (Wessel, 2009). For others, urban diversity is perceived as an instigator of social problems (Koutrolidou, 2007; Van Leeuwen, 2010, 2014b). Putnam (2007) expressed his concern from too close of a social contact, stating that:

"The more we are brought into physical proximity with people of another race or ethnic background, the more we stick to 'our own' and the less we trust the 'other' " (p. 142).

Empirical evidences show that public spaces turn into struggle arenas between groups, hence, aggravating social tensions (Amin, 2002; Van Leeuwen, 2014a). Spatial separation, language differences, mistrust and anxiety result in disrespect and intolerance (Dirksmeier, Helbrecht & Mackrodt, 2014). The prime source of conflicts between population groups in cities appears to be a competition over urban resources (Bloch & Dreher, 2009; de Souza Briggs, 2007), for instance: over worship places (Beebejaun, 2012; Sandercock, 2000), and over religious schools for minority groups (Bugg, 2013).

Empirical reports illustrate that religious and ethno-national diversity constitute a fundamental barrier for perceiving diversity as a potential. Nieuwenhuis, Volker & Flap (2013) found that the more religious diversity exists in cities, neighborly relationship will probably be negative. Similarly, the research of Bloch & Dreher (2009) from Sydney, Australia, indicated that the larger the Muslim population in the area, feelings, such as: fear, anger, and threat, were stronger even amidst people who expressed support in social diversity. Bakker & Dekker (2012), and Gundelach & Frietag (2014), found that as a minority group increases, it is probable that the majority group would feel that their social, cultural and economic privileges are at stake.

The complexity of urban diversity has raised many debates in regard to the ability of planning to balance between different spatial demands, to bridge and reconcile between groups and implement participatory planning processes that include the opposing parties. Theory suggests that the ability of urban planning to properly deal with urban diversity depends upon the recognition of the 'deep differences' between population groups (Watson, 2006), and their 'conflicting rationalities' (Watson, 2003).

3 METHODOLOGY

The research examined three planning events in Karmiel, which differ in scale and represent the conflicts within the urban realm, resulting from and intensified by increasing urban diversity. The first planning event focused on a struggle over elementary school buildings, which had evolved between the secular residents of an old neighborhood and an Ultra-Orthodox voluntary association. It emphasizes urban diversity in terms of religion inclination, and focuses on a conflict between secular veteran residents and newcomers Ultra-Orthodox Jews in one of the oldest neighborhoods of Karmiel. The second planning event followed the daily life of 'the other'- a Palestinian who is an Israeli citizen that has moved recently to Karmiel. The personal narrative opened up a discussion in regard to the dynamics of social relationships between Jews and Arabs in Karmiel, which are characterized on the one hand by discrimination and exclusion, and on the other hand, allow the organization of political-civilian actions which strive for a shared and respectful

city-life. This event emphasizes urban diversity in terms of ethno-national identity, and focus on the overt and often rampant conflicts between the Jewish residents of Karmiel and the town's Palestinian residents. The struggles over local identity, public services and urban image are manifested all over town, impacting the entire region.

The third planning event examined the master plan of a new neighborhood in Karmiel. It focuses on the interplay between physical and social aspects in neighborhood planning, and compared the way in which this interplay was reflected in the town's original planning and how it currently comes into play. Against the social vision raised by the city's leaders, the analysis relates to the spatial coding and the social message conveyed by it. Three spatial components are addressed in specific: housing mix, transportation planning scheme, and land use. This event highlights urban diversity in terms of socio-economic inequalities, and indicates on a potential conflict between the future residents of the neighborhood: those who are characterized by high socio-economic status versus those who are characterized by low socio-economic status. It is expected that the new neighborhood will offer alternative accommodation for the middle-class Arab sector, and like other neighborhoods built earlier, will most likely attract Arab residents from nearby Arab settlements.

The research approach utilized multiple sources of knowledge and information: (1) historical knowledge: books and archival documentation about Karmiel and its planning history; (2) planning knowledge: review of statutory plans, municipal board-meetings protocols, court verdicts, interviews with municipal officials and planning practitioners; (3) local knowledge: in-depth conversations with local residents, social activists, representatives of local NGOs, building contractors, local business owners, review of national and local press, and a follow-up review of civic discourse conducted in Facebook groups. The research tools include: interviews, conversations, observations and documents' review, which were processed by discourse analysis. Quantitative data was another valuable source of information, which was retrieved from the Israeli central bureau of statistics, Policy publications of The Ministry of Housing, documentation of real-estate transactions, as reported to the Tax authorities, and publications of the Israeli Knesset research center. The quantitative data served as a complementary source of information which was analyzed by descriptive statistics. Triangulation of the findings from the three different planning events was also conducted.

4 URBAN DIVERSITY IN ISRAEL

Inter-group tension in Israel's urban context stems both from global immigration processes and from internal migration. It is commonly discussed in terms of the ethno-national political dispute over national territory and resources (Falah, 1989; Kipnis, 1984; Peled, 2005; Rabinowitz & Monterescu, 2008; Soffer, 1991; Tzfadia, 2008; Yacobi, 2002; Yiftachel, 2009). Struggles between Palestinians and Jews are performed in varied contexts: over housing policy (Chiodelli, 2012), over infrastructure (Nolte & Yacobi, 2015), over holy places (Jabareen, 2006; Shmueli, Collins, Kreiner & Ben Gal, 2014) and over shared urban space (Jabareen, 2009; Kallus & Kolodney, 2010; Yacobi, 2002, 2013). Social dynamics between Jews and Arabs in Karmiel are characterized by extreme fluctuations. On the one hand, callous discrimination in the housing market, excluding institutional actions, and racist expressions in public places are highly prominent. On the other hand, a growing civic organization, representing both political and social actions, seeks to promote shared and respectful city-life.

Israeli scholars have outlined two distinct, yet complementary, theoretical perspectives: the first intends to contribute to the ongoing debate on multiculturalism and the way in which it is implemented in practice (Tzfadia, 2008); the second relates to the existing tension between the representation of the city as enabling space and the representation of the city as preserving and securing socio-national stratification (Marom & Yacobi, 2013; Yacobi & Tzfadia, 2009). Reality in Karmiel reflects the city as a situational place, where social relationships are not stabilized nor fixed, but rather in formation.

Lately, Israeli scholars have indicated on a burgeoning process of which a growing number of young Palestinians move to Jewish towns (Alfasi, 2014; Monterescu, 2011; Rabinowitz & Monterescu, 2008). Three fascinating trends can be identified as the major push and pull forces of such a process. The first trend stems from lack of planning in the Arab settlements in Israel, which has led to a severe housing shortage. The second trend relates to the significant improvements of the Palestinian population in Israel in varied aspects of life: education accomplishments, rise in employment rates, and social mobility,

processes which attest on the growing Palestinian middle-class sector in Israel. The third trend is connected to the second trend, in that mostly young, educated and economically stable Palestinian families in Israel search for a better quality of life than exist in their settlements of origin, combined with a relatively new and overt wish to move away from the nucleolus family and the traditional way of life.

Nevertheless, inter-group urban tensions also exist within the Jewish population. A growing migration of Ultra-Orthodox religious groups to secular urban neighborhoods has lately increased such tensions (Hason & Gonen, 1997, Shevah & Kallus, 2015). Although the secular and Ultra-Orthodox Jewish communities share the same faith and ethnicity, de facto, they are very different in terms of religious commitment and inclinations (Shilav, 1998), as well as in their spatial and social practices (Fenster, 2011). In the past several decades the Ultra-Orthodox population undergoes a salient expansion process. This process is characterized by massive departure from the 3 main Ultra-Orthodox centers: Jerusalem, Beney-Barak and Ashdod (Cahaner & Shilav, 2012), to distant peripheral cities, mostly located in the southern and northern parts of Israel. A combination of sharp increase in housing prices along with demographic pressure in these Ultra-Orthodox centers has caused the Ultra-Orthodox community to search for other accommodation alternatives.

Urban tensions between secular and Ultra-Orthodox Jewish communities are often over urban resources that are increasingly in demand by the fast-growing Ultra-Orthodox population; and this takeover of urban resources is often considered by the secular communities as interfering with their spatial patterns and use, and a threat to daily life. In addition, recent institutional policies aimed to confront and resolve the housing crisis in Israel have led to a contemporary trend of massive construction projects for building new neighborhoods largely distant from the urban core. Modern building standards and profit considerations fall short in addressing the need to enlarge the housing stock of affordable housing, hence raising additional tensions based on socio-economic characteristics.

4.1 CONCEPTUALIZATIONS OF CITIES WITH SIGNIFICANT URBAN DIVERSITY

Cities across the world, remarkably diverse in terms of population composition, have become a major focus of research. Alongside the discourse on how to deal and manage urban conflicts under the circumstances of growing diversity, the literature offers conceptualizations of such cities. The typology of diverse cities suggests three types, differing by character and history of the relationships between different groups in the urban space.

The category 'divided city' addresses the relationships between ethnic-groups in a city in which a spatial separation is most obvious, whether by physical means such as: walls and fences, or by distinct residency areas for each population. This category includes cities, such as: Beirut, Nicosia, Sarajevo, Mostar, Belfast and Jerusalem, which were all divided as a result of national disputes (Allegra, Casagila & Rokem, 2012; Bollens, 2002; Kotek, 1999; Marcuse, 1993; Mitchel & Kelly, 2010; Van Kempen & Murie, 2009). Lately, it is also discussed in other geographical contexts, for example: the Middle-East (Silver, 2010), and China (Madrado & Van Kempen, 2012).

The 'Dual city' is another conceptualization that describes relationships between different groups in cities, on the basis of economic differences. It was developed during 1990s, in light of the capitalist reality, emphasizing the difficulties arising from extreme economic rifts between wealthy and poor people (Marcuse, 1989). A third type, which is the most germane to the Israeli context, is known as the 'mixed-city'. It describes cities in which two different ethnic groups share the same urban space. The term mixed-city refers to cities which were historically populated mostly by Arabs, however as a consequence of 1948 war, their inhabitants were expelled or escaped. As a result, Arabs who remained have become a minority group within a significant Jewish space. The 5 Israeli mixed-cities are: Acre, Haifa, Jaffa, Lod, and Ramla, which later have been labeled by Rabinowitz & Monterescu (2008) 'depopulated colonized mixed towns'.

Three central aspects differentiate the Israeli case from the international debate in regard to urban diversity. Firstly, whereas the theoretical planning discourse on 'cities of difference' (Fincher & Jacobs, 1998) emphasizes the tensions between different ethnic groups derived mostly from cultural and economic differences, in the Israeli case, it is the regional dispute that produces and exacerbates tensions, therefore the socio-political dimension is substantial. The Israeli mixed-city is part of a historical process in which the Israeli territory, including Arab cities, have been Judaized, first by 1948 war and later through the policy of

population distribution (Yacobi, 2002; Yiftachel & Yacobi, 2003). Secondly, the international literature deals with urban diversity under the conditions of massive immigration from third world countries to western countries, while urban diversity in Israel is currently derived from internal migration processes of Ultra-Orthodox Jews and Palestinians who are Israeli citizens from their hometowns to secular Israeli cities. Thirdly, the international literature stresses a univalent correlation between minority groups and low socio-economic status and political power. Conversely, in the Israeli case, this correlation is not significant. The Ultra-Orthodox population is indeed ascribed as having low socio-economic status, compared to other groups in the Israeli society; however, this group holds a considerable political power, at the national as well as at the local level. Similarly, Palestinians who are Israeli citizens, constitute a significant minority group in the Israeli society, however, those who choose to immigrate to secular Israeli cities, are mostly highly-educated and with high-income, representing the growing Israeli-Palestinian middle class.

Given the above, in order to better understand the current urban reality, it is important to inquire the different strata or urban diversity in cities that become mixed, especially in Israel, in which this trend has recently intensified in Karmiel, Beer-Sheva, Hazer-Hagliliit, and Nazarat-Ilit, turning them into newly-mixed cities, however not yet recognized as such by the state or by their local municipalities.

5 THE 'FOSTER CITY'

This paper addresses the internal-migration of Ultra-Orthodox and Palestinians who are Israeli citizens, to Karmiel. From a planning perspective, Karmiel challenges the theoretical conceptualizations on cities characterized by significant urban diversity. The 'Foster City' is a new conceptualization, in which the new immigrants are analogous to the city's 'step-inhabitant'. The 'step-inhabitants' are not an ideological product of the nation-city: they were not born nor raised in it. The duality in the 'Foster City' (i.e., on the one hand, conflicts between different population groups; on the other hand subversive actions for promoting shared and respectful urban space) symbolizes the difficulties of adjusting to the new reality and accepting the new order. The 'Foster City' illustrates the complexity of dealing with urban diversity in places that are not in line with liberal-western democracies (Watson, 2014). Its abnormality represents the cracking of the National-Zionist project which aimed for social, cultural, political and spatial separation between different population groups. Therefore, at least in the urban scale, the 'Foster City' undermines the theoretical 'ethnocratic' approach (Yiftachel, 1999; Yacobi & Yiftachel, 2003). The intermediate situation of the 'Foster City' reflects struggles and confrontations against the new reality in two central aspects: alienation and temporariness.

Civic discourse against the internal-migration processes are an evident of the newcomers' strangeness and alienation. The political power and the profound foothold of the Ultra-Orthodox community within the municipality raised a firm objection of the veteran residents against the municipality, but were not directed against the Ultra-Orthodox community. However, the Palestinian internal migration is being perceived as an infiltration into the Jewish urban space. The terminology that is being used as part of the public discourse represents the city as a battle field, distinguishing between the 'threatening group' and the 'threatened group'. Ultra-Orthodox tendency to separation and introversion: dressing codes and separation in the educational institutions are characteristics that emphasize their strangeness and alienation. Unlike the Ultra-Orthodox community, the aloofness of the Palestinian residents in Karmiel is forced upon them. The lack of public services for the Palestinian residents of Karmiel: in education, leisure and religious services, force them to divide their lives between Karmiel and their hometowns. This creates a phenomenon that can be labeled: 'double urban citizenship', which enhances their strangeness and alienation.

Although it seems as if the 'step-inhabitants' are here to stay, it is possible to assume that in case better conditions in terms of housing supply will be created in the future, the Ultra-Orthodox community would prefer to return to the three main Ultra-Orthodox urban centers: Jerusalem, Beney-Barak and Ashdod. It is also possible to assume that a substantial investments in developing Arab settlements in Israel (e.g. suitable housing, public services and open public spaces), that would meet the needs of the growing Palestinian middle-class, they would prefer to return to their hometowns. Yet, this temporariness is far from being certain, since immigration of families is very different from immigration based only on occupational conditions (which characterizes the international migration processes). Therefore, limiting it is highly unlikely (Orgad, 2015).

lucia.martinez@ulpgc.es

1 INTRODUCTION

This paper collects some of the looks and thoughts arising within the framework of the project "Inter-university cooperation in the management of sustainable tourism between Cape Verde, Mauritania, Senegal and the Canary Islands". It is an activity that took place in the framework of the European project of "University institutional strengthening of the Canary Islands and Africa (Senegal-Mauritania - Cape Verde) space: SEMACA", which belongs to the European programme of cooperation transnational Madeira-Azores-Canary Islands (MAC 2007-2013). We will focus in the case of the city of Saint-Louis in Senegal, at the mouth of the Senegal¹ River, since its planning combines a historical past with strong French influence, with an urban morphology in grid and a building typology that has been awarded the recognition of world heritage of the UNESCO in the year 2000, in contrast to a peripheral urban growth out of the heritage area, where there is little control on its evolution.

The city of Saint-Louis has experienced an exponential growth in its population in recent years, which has generated a rapid urbanisation where the coalescence of buildings is completely uncontrolled. It urban crisis, reflecting an economic crisis and a crisis in the finances of the state, is marked by a decline in socio-economic indicators and a deterioration of living conditions and the health of its inhabitants, in a country where the management of cities is influenced by the predominant role of the State and its leader, standing over local authorities.

Our research is orientated towards the theory and technique of the transformation of the anthropogenic transformation of space based on spatial planning, which includes tourism, sustainability and landscape, understood as necessary elements for achieving social, economic and environmental balance.

¹ Senegal gained internal autonomy within the French West Africa (AOF) in 1958 becoming the Islamic Republic of Mauritania, and achieved independence in 1960.

2 TERRITORIAL ADMINISTRATION

To understand better its development, it is necessary to know some data of this African country, with 706 kilometres of coastline bathed by the Atlantic Ocean and an extension of 196.722 km² located in coastal West Africa, into the depression known as the basin Senegal-Mauritania, between the parallel 12 ° 30' and 16 ° 40' North and the meridians 11 ° 30' and 17 ° 30' West. It borders to the North with Mauritania, to the South by Guinea and Guinea-Bissau, and to the East by Mali. It has the feature to be flowed through this West State of Gambia supported on the river of the same name.

As for the territorial organization of the State, Senegal has inherited a very centralized structure. Despite this, progressively since the 1970s, and especially following the 1996 Decentralization Act, to avoid that, administrative political measures have been applied. Currently Senegal is organized according to the French model of territorial administration in regions, which are divided into departments, and these in turn are subdivided into districts (called as well if they are urban centres) and communes (called this way if they are rural communities).

The Region of Saint-Louis¹ is one of the eleven administrative regions currently comprising Senegal. It lies to the North of the country, forming the border with Mauritania, and is divided into 3 departments, 7 districts, 20 communes and 18 rural communities². The three departments of the Region of Saint-Louis in Senegal are: Saint Louis, Dagana and Podor. Of these three, the Department of Saint-Louis is the most densely populated, with a density estimated of 310 inhabitants/km², opposite the regional average density of 44 inhabitants/km². And within the Department of Saint - Louis, lies the town of the same name, the city of Saint Louis of Senegal, which we can say that it is the fourth most populated of Senegal, with 172,000 people surveyed in 2013, after Dakar (2,682,000 inhabitant), Thiès (282,000 inhabitant) and Kaolack (182,000 inhabitant).

The city of Saint-Louis in Senegal is located at the mouth of the Senegal River that runs through the city from North to South³, and its topography is characterized by a coastal plain to the West, bordered by the Atlantic Ocean, which is rising slightly eastward, toward the Mainland. While its strategic position make that Saint-Louis has the characteristics of a sea and River City, the presence of the river and the Ocean has been a constraint to its urbanization, since the place is subject to frequent flooding.

We can say that the city of Saint Louis is fragmented by the presence of the River into three parts: "la Langue Barbarie" westward, constituted by a spit of sand of 300 meters wide that separates the River from the Atlantic Ocean, which takes contact 25 Km more to the South, and it settled districts of fishermen (district of Goxxumbace, Ndar Tout and Guet Ndar); "the island of Ndar in the Centre, it is the current island of Saint-Louis in Senegal⁴, a narrow island just 2 kilometres long by 400 meters of width that is formed naturally by sedimentation, it is the heart of the old colonial city, owner of the heritage value of UNESCO; and "island of Sor" to the East, even though it is located in the continental area, receiving the nomination of island because it is surrounded by tidal marshes in times of flooding of the river Senegal.

¹ Currently, 10% of the country's population is concentrated in the Saint-Louis region.

² At the head of each Region there is a Governor and a Regional Assembly, and at the head of each Department there is a Prefect. The State maintains the supervision of all levels of the administration. The 1996 Decentralization Act reinforces the responsibilities and competencies of local communities and organizes the Senegalese territory in 11 regions, 60 departments, 43 districts and 320 rural communities.

³ The Senegal River is about 1,790 kms. long and was born in Guinea, in the Fouta Djallon plateau, with the name of Bafing River. After joining the Bafing with the Baoulé River, it is when already receives the name of Senegal.

⁴ She was baptized with this name by the French, in honor of the King of France "Saint Louis" and also, by being his ancestor of the reigning sovereign Luis XIV. 2

Figure 1 - Bird view of Saint Louis fragmented into three parts by the presence of the Senegal River at its mouth

It is in these lands where sits most of the population of Saint-Louis (districts of Sor Nord, Darou, Balacoss, Diamaguere, Leone-HLM, Eaux Claires/Diaminar, Ndioloffene Sud and Pikine) and where the city grows without hardly a planning intervention. New neighbourhoods (barrios of Khor, Bango and Ngallele) that have settled in the Mainland firm, where do not have reach the river floods have also emerged in recent years.

The island of Saint-Louis in Senegal holds an exceptional urban heritage value awarded by the Organization of the United Nations in the year 2000, on the basis of II and IV criterion. And the Langue de Barbarie and the border area with the Island of Sor beside the river are considered protected areas.

Figure 2 - Delimitation of areas classified by the UNESCO: the red zone is the area of heritage value, and the Orange area is protected area.

The Commission of the UNESCO determined that it deserved inclusion in the World Heritage list because "the historic town of the city of Saint-Louis exhibits an important interchange of values and influences on the development of education and culture, architecture, handicraft and services in much of West Africa" (criterion II), and because "the island of Saint-Louis ancient capital of West Africa, is an excellent example of colonial city, characterized by its particular natural environment, and illustrates the development of the colonial Government in this region"(criterion IV).

But better to understand the growth and the urban transformation of the city of Saint-Louis, it is necessary, as if it were a palimpsest, reveal about the current city, and the evolution from its origins. It is occupation and colonial origins.

3 MATERIALS TO ANALYSE

Its location has always had a great interest for Europeans a logistical point for trade in slaves with Cape Verde. Initially it was occupied by the Portuguese, then by the French, although on several occasions and

temporarily it happens to be occupied by the English, but the island definitely becomes French colony, and the French, who built in 1659, are the first "Fort of Saint Louis". Therefore, that date is regarded as the founding of the city.

A morphological analysis of the city of Saint Louis, following the social events and demographic growths that have driven the rate of urban growth, will allow us to reason about the phenomena that have led to the development of its evolution and landscape and urban entities by stage of growth.

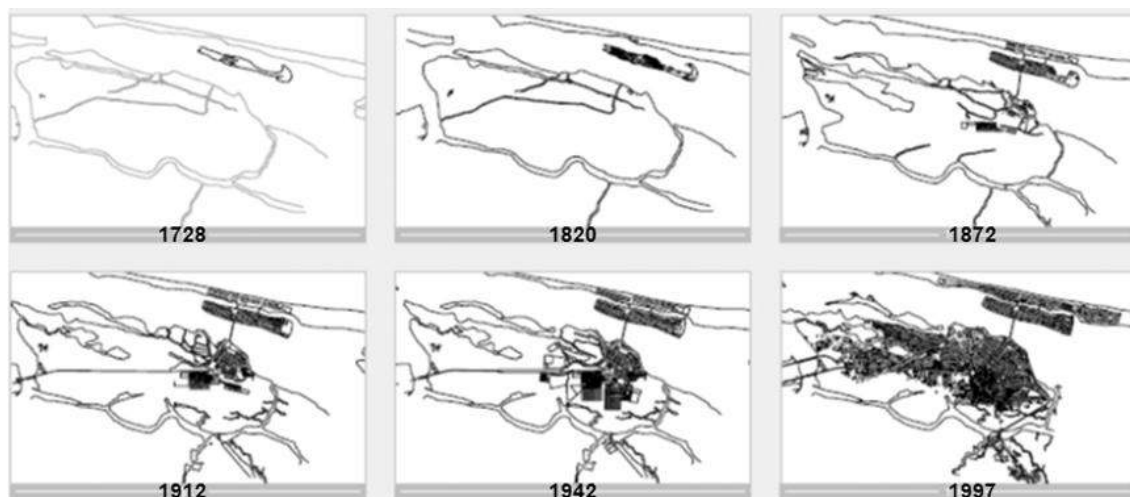

Figure 3 - Evolution of urban growth of city Saint Louis of Senegal. (Source: Inventory of the Architectural and Urban Patrimony of the island of Saint-Louis of Senegal. École d'Architecture de Lille)

Since the mid-17th century to the middle of the 18th century, the island is characterized by urban growth environment to military construction¹, which is the main solid construction of the island, being bordered North and South by domestic buildings organized according to a regular grid and built mostly with straw and reeds, and only some few in masonry. To the East and West of the military construction space will be free of buildings, located to its West, the Plaza de Armas (the current Plaza Faidherbe)². By that time, the city of Saint Louis consists of only a score of houses and it is inhabited by around 5,000 people.

The city of Saint-Louis lives the golden age of the colonial administration during the nineteenth century. After being occupied again by the English, between 1809 and 1817, the island definitely becomes a French colony. The city of Saint Louis is located, in those moments, has not already only military equipment, but also of public and religious facilities, and gradually will occupy a greater extension of stable land on the island of Saint Louis. With the first abolition of the slave trade, in 1815, the island of Saint-Louis changes its initial commercial activity by the trade of arabic gum, which will play an important role, over commercialization of leather, wax, ivory from the islands of Ivory Coast or gold from Galam.

The Senegal River makes this city an important port centre for the Atlantic trade and a natural departure gate. In general, the Senegal River is navigable at all stations in 175 kms. stretch from his contact with the ocean to the small town of Podor³ and at times of high water, around three months of the year, to Kayes, 975 kms. from the mouth. All this favours an important colonial trade with an increase in the transit of ships. This new commercial activity generated an increase of the local population, while growth is slow and irregular. 5,000 inhabitants in 1790, it passes to the 12,000 in 1848, representing a population increase of only 7,000 people in 58 years (in more than half a century). This slow population growth is due to the epidemics of yellow fever, which often decimate the population.

But already in 1829, the administration consider that is necessary to regulate the growth of the city through the drafting of the first "alignment Plan" of the island of Saint-Louis, although only became partially applied. This fact makes a great wave of urban works with the need to build public services such as the layout of

¹ This military construction will continue to be expanded throughout the eighteenth century.

² Louis Faidherbe was formed as a military engineer and served in Algeria and Senegal before becoming the colonial Governor of French Senegal between 1854-1861 and 1863-1865. He is considered the founder of the colonial empire of France in Africa.

³ It is located 215 km east of Saint Louis, and with 10.173 inhabitants registered in the year 2006

streets and discharge zones. The buildings will begin to run already in solid form, and even many of native dwellings, which were initially built with straw and reeds, are replaced by new constructions executed with masonry.

Figure 4 - Plan of alignment in Saint-Louis de Senegal, 1829. (Source:gallica.bnf.fr)

At this time, the small size of the island, 2 km long and 400 meters wide, forced the population to leave their physical limits and to occupy the edges of the Senegal River, thus forming the first suburbs of the city. The suburbs of N'Dar Toute y Guet Ndar in the Langue de Barbarie, where fishermen were settled and the suburbs of Sor Nord y Diamaguène in island of Sor, on the Mainland. All of them were connected with the island of Saint-Louis through three bridges, which were built between 1856 to 1865. The Moustapha Malick Gaye bridge and the Geôle bridge (which currently only support struts) connecting the island of Saint-Louis with the tongue of sand of the Langue de Barbarie, and casting Faidherbe bridge will allow the expansion of the city towards the Mainland. This bridge, built in steel, is also recognized as UNESCO World Heritage. The grounds of the Langue de Barberie were occupied by the fishing community, given that this spit of sand located on the border between the Atlantic Ocean and the River, makes it the ideal place to develop the artisanal fishing, most important economic activity of the city, and that both women and men are engaged. The fishing community of Saint Louis is one of the most important in West Africa and currently comprises more than 4,000 crews. Guet Ndar is the District of fishermen where today more than 36,000 people live in overcrowding on a narrow spit of sand, which develops a dynamic and energetic activity: the fishermen arrive with their catch while dozens of trucks waiting to buy fish and transporting it to inland as to Kaolack, Mali and Tambacounda. Another part of the catches are given to women who are engaged in smoking-drying fish on the shore. Construction and repair of boats and fishing nets, activity also takes place on the beach in Saint Louis, where it is possible to see almost all the stages of construction of the Senegalese fishing boats.

Figure 8 - The typically Senegalese scene in which women engage in dry fish along the shore. (Source: personal picture)

Another important fact that will have impact on the expansion of the city of Saint Louis and its growth toward the continental zone (sister island), is the construction of a railway station that will connect various parts of the colony, allowing travel and transport materials in much shorter time. This is the way how it has created an infrastructural continuity as strategic point and location for the supply of goods to and from the island of Saint Louis. On the outskirts of this point, Sor-Nord district and station, which is located at the entrance of the Faidherbe bridge, where will focus higher density of population, that constituting the District of Diamaguene¹. On the other hand, should take into account that, in those moments, the French were doing great works of engineering world in order to expand his empire, such as the opening of the Suez Canal in 1869, promoted by Frenchman Ferdinand de Lesseps.

The installation of large railroads and the expansionist desires of France, led to build in 1885 the railroad which connected Saint Louis with Dakar, and subsequently Dakar with Niger². The construction of this railway subtracted the role of main road of transport and communication, which had been so far to the Senegal River. The city of Saint Louis, well equipped in infrastructure and very well communicated, becomes political, economic and intellectual capital of Senegal and Mauritania. Head of a hierarchical network of military posts and lines of communication, Saint Louis experienced a considerable growth in 1895, becoming the capital of the French Africa-occidental³.

In the 20th century is produced a demographic expansion and modernization of the city⁴. The progress of medicine involve a population growth which is reflected in the decrease in the infant mortality rate and an improvement in sanitary and food conditions. Between 1930 and 1940, the population has now reached the figure of 36,000 inhabitants, and will continue to growth despite the significant number of men sent to the front during the second world war. In the year 1942, it writes by L.H. Hoyez, "Plan for Expansion, development and improvement of Saint Louis", in which projected paths of the last large areas of the continental zone. However, from 1957, the competence of Dakar as the new capital of Senegal is felt to the detriment of Saint-Louis, who undergoes a small demographic decrease, compared to Dakar, whose population is quadruples.

In 1970 the perimeter of the city has multiplied by three, and the continental zone, given that it has the necessary land, has become the main area of growth of the city, despite the bad conditions of this muddy field. Saint Louis is a city that already has 81.204 inhabitants, in contrast to the 36,000 who had in 1940. This growth is due to migration flows and the strong rural exodus that throughout the 1970s intensifies drought and the limits of the city makes more spontaneous than volunteers.

While the "Plan Director of conditioning and planning" is written in 1975 (Le Schema Directeur d'Aménagement et d'Urbanisme [SDAU]) to manage the development of the city, this will not have any impact on the management and regulation of the territory. This Master Plan proposed an increase of the extension of the communal perimeter of 12,800 hectares and an urban extension to Ngallèle, but the growth of this town is at the moment little accepted.

4 DETERIORATION OR DISAPPEARANCE

In the 21st century the city of Saint Louis will experience an exponential increase of its population growth, bringing together at the edges of the city constructions without any control of their growth, as opposed to the regular tracing inherited from the colonial era.

¹ See the dissertation of Daye Mamadou Sow, "Les transformation urbaines dans les villes du sud;" «L'exemple is Saint Louis du Sénégal». (2005) Université de Toulouse - Le Mirail

² The railway network in Senegal, in the beginning very developed, has been deteriorating gradually and there are now only two lines of travelers: the Dakar-Thies autorail and the commuter train, which offers a regular service between the station of Dakar and Rufisque. This train is known as "the little blue train".

³ Between 1895 and 1958, the French Africa-occidental (A.O.F.) was a Federation of eight French colonies in West Africa, with the aim of coordinating the colonial occupation of France on the African continent under the same authority. It was formed by Mauritania, Senegal, French Sudan (now Mali), Guinea, Côte d'Ivoire, Niger, Alto Volta (now Burkina Faso) and Dahomey (now Benin).

⁴ In the 20th century, Africa enters a phase of conquest and Saint-Louis becomes Centre military from all over West Africa, materialized by its main square and bordered by the most important military buildings of the city.

Zones	Equipment and urban facilities
Island of Saint-Louis	52 %
Langue de Barbarie	13 %
Continental zone (Sor)	35 %

Table 1 - Equipment and urban facilities. (Source: Plan Directeur d'Urbanisme (PDU) de Saint-Louis 2000-2025)

For a correct analysis, it is necessary to oppose the "urban facilities" look, the existing in each of the area's population burden:

Zones	Population in 2000: Inhabitant	%
Island of Saint-Louis	14,022	9 %
Langue de Barbarie	36,652	25 %
Continental zone (Sor)	98,806	66 %

Table 2 - Population in 2000. (Source: Department of Public Safety (DPS) de Saint-Louis)

The low population of the island of Saint-Louis (with only 9%) accompanied by the highest percentage of equipment is explained by the unemployment of many buildings that are dilapidated, and fundamentally, by the fact that in this area the majority of the buildings are administrative buildings or have commercial use, when they are not the second homes of senior officials who have their primary residence in Dakar, and which do not come to be regarded in the population census of Saint-Louis.

Urban growth, combined with poor flooded and swampy terrain, translates into an explosion that fragmented the continental zone in 11 districts (2/3 of the 16 total).

Zones urbaines	Quartiers	Population	Superficie (ha)	Densité
Langue de Barbarie	Goxxumbacc	9680	22,37	434
	Ndar Toute	7576	15,70	482
	Guet Ndar	18685	15,85	1179
	Ensemble	35.941	53,92	667
Ile de Ndar	Nord	8768	39,65	221
	Sud	4115	12,87	320
	Ensemble	12883	52,52	245
	Sor Nord (Diawling/Marméal)	9557	41,97	228
	Darou	6553	22,52	291
	Balacoss	4902	29,21	168
	Diamaguène	8976	27,13	331
	Léona-HLM	12717	60,13	211
	Eaux Claires/Diaminar	6933	39,66	174
	Ndioloffène Sud (Médina-Courses)	12176	136,12	89
	Pikine	30820	184,11	167
	Ensemble	92634	540,85	171
Périphérie	Khor	1996	24,45	82
	Bango	3473	38	91
	Ngallèle	1015	19,46	52
	Ensemble	6484	81,91	89
Ensemble (Saint-Louis)		147942	729,20	203

Table 3 - Population density of Saint Louis City. (Source: Agence de Développement Municipal (ADM) de Saint-Louis)

The density of each neighbourhoods shows the unequal distribution of the population in the urban space. As the urban front moves, the grounds of the continental zone are increasingly more inhabited, complying to the East a peripheral semi-corona on the island of Sor, which is characterized by irregular occupations that are built on areas that are inundated by the flooding regime of the Senegal River, which begins in July and which are greatest in October and November producing floods around 1.35 meters above the sea level.

Table 4 - The average monthly flow in m³/s for a basin of 268,000 km², measured in hydrological station of Dagana.
(Data obtained from the periods 1903-1974)

On the contrary, during the great drought, the flow is so low that, sometimes, it may even to wade the river. It is when the population without access to housing, raised in these areas improvised housing units that are destroyed by water when the river returns to its maximum runway. The problem financial and mortgage security prevents access to housing many families without resources, which self- construction their homes on land that just calls them the river. Currently, these floods are partially controlled thanks to the construction of the Maka-Diama dam, built 150 Kms. up and waters at an altitude of 1 meter above the sea level, on the border between Mauritania and Senegal, near the mouth to the sea, which prevents access from saltwater upstream, which caused the sterilization of the agricultural soils when they flooded¹.

5 DISCUSSION AND CONCLUSIONS

The truth is that the urban crisis, a reflection of an economic but also financial crisis of the State, is marked by a decline in socio-economic indicators and a degradation of the conditions of habitability and health of their inhabitants, in a country where the management of cities is marked by the predominant role of the administration of the State, against local authorities.

It is very important to remember that Senegal is a presidential Republic and although it works democratically, being in this regard recognized as one of the countries with more successful and rooted in African culture, the local administrators are appointed and accountable to the President², and representatives of the State will continue under responsibility at all levels of the territorial administrations.

It can be said that the territorial organisation of the State has inherited a very centralized configuration, in which there is a high degree of administrative centralization in the management of the public sector, both at the level of financial resources and the realization of all kinds of tax procedures (administrative charges, opening of premises licences or other facilities, etc.) also contributes to what the fact of the spatial concentration of foreign companies in the Dakar-Thies environment.

It is very important to remember that Senegal is a presidential Republic and although it works democratically, being in this regard recognized as one of the countries with more successful and rooted in African culture, local administrators are appointed and accountable to the President, and representatives of the State will continue stewardship at all levels of the territorial administrations. However, gradually, from the 90's will be to produce a series of institutional reforms in Senegal, which will lead to the decentralization of the State, strengthening the management capacity of local institutions. Although the economic resources of Saint-Louis in Senegal are still based in coastal fisheries, livestock and agriculture, and despite the efforts of modernization, the primary sector remains, today, very little productive.

¹ The river has two large dams along its course: the dam of Manantali in Mali, built on the Bafing River between the years 1981-87 as a reservoir (Lake Manantali, 477 km² of water surface); and the aforementioned Maka-Diama dam.

² In the spring of 2012, there were presidential elections of Macky Sall was then victorious. This election, peaceful and democratic, were greeted by the EU (among others) as a sign of maturity, since its opponent (former President) Wade wanted a continuity of dubious legality.

Coinciding with the 90's (under the rule of the Socialist Party of Diof) a new era of urban management will start in the city of Saint Louis, propitiated by the new powers which acquire regions (so far only in State hands), and among which is the responsibility of the urban management of its territory, which will foster citizen participation through the new local authorities. In this sense, the "Programme of strengthening and support to the development of these neighbourhoods" initiated the development and implementation underway a "Plan of development of neighbourhood" (PDQ), which marks the priority projects and acts as a pedestal from which, the actions of development are identified, to be subsequently performed.

However, the reality is in the case of Saint Louis, as well as in many other communities, the room for manoeuvre they had on their territory was shoestring, lacking the financial, human and technical resources to deal with new responsibilities, mainly those derived from the management of their territory. It should not be forgotten that one of the basic characteristics of the Senegalese economy is one that is called "informal" with a basic structure which is composed of an average of 2.9 workers, usually within the same family.

According to a survey conducted by the "Directorate of Economic Statistics and Compatibility", this economy is formed by 48.8% of the active population (working 2,216,617) that supports the 35.8% of all non-agricultural production. Own Saint Louis resources consist of the revenue that it can raise through local rates, which are decreasing due to the impoverishment of the population. But to this fact, it must be added to the absence of a fiscal cadastre allowing measuring the potential benefit of taxable activities and that they could improve municipal revenues, since many taxes are not always collected¹.

On the other hand, we must be aware that while the communes acquired new skills, also assume the costs of its operation. If you look at the investment of your budget, we appreciate how between 70-80% per year goes to the performance of his administration, making it impossible to invest in equipment or basic urban infrastructures, and even has no ability to maintain in good condition the existing. This is due, inter alia, not only a poor management but a weak local financial capacity and remarkable retardation of transfers from the State. The consequence is that, despite programmes of decentralization and the existence of local financial organizations supported by State, competences transferred to the regions in spending are notoriously inadequate and scarce, which, moreover, gradually decrease down between communes and rural communities, who are obliged to tip over towards the informal economy.

What does highlight do, before the concept of "decentralization" of recent years, there has been an awareness citizen participation, and the creation of a "Cell of coordination, information and entertainment for Local development" (CCIADL), which has become the "Agency of communal development" (ADC), and the creation of the "Programme of strengthening and support to the development of neighbourhood"(PRADEQ)², and in the "Program of animation Social urban" (PASU), which aims to fight poverty (improving the living conditions of the population of the districts), support the self-promotion initiatives at work in the neighbourhoods of the city and involve all relevant partners and associative movements in the management of this neighbourhoods.

However the reality is that due to its weak economic engine, the commune of Saint-Louis runs out of capacity investment, and needs the help of State investments or foreign partners. Should be noted serious deficiencies in infrastructure, both of a general nature: progressive isolation, poor accessibility, poor conditions on roads, disappearance of the railways and its airport downtime, as in the urban nature: widespread poor health, inadequate sanitation and supply of electricity and water, etc. And, in the aspect of human capital, lack of programs both basic and professional education at all levels, inadequate level of training and lack of development of marketing actions in activities that, like the tourist, could mean an improvement substantive for the population and its own habitat.

Ultimately, there is a lack of State investment as well as lack of local financial autonomy that runs the risk of becoming endemic. Therefore, the fact that "The communes acquired new skills in the management of its territory, favoured by a decentralization", it is nothing but a fallacy, given that it has no power to act.

¹ According to the program of development community (PDC) 1998-2008, "in the absence of a precise knowledge of the available resources, the budget of the commune represents less than 1% of the wealth produced by the local economy, valued around 58 million CFA francs".

² Programme de Renforcement et d'Appui au Développement des Quartiers

In this situation, the existence of a heritage of UNESCO, and even a few natural resources likely to regain a significant role of this commune, this city, and even the island of Saint Louis, seems to have a difficult prognosis¹. The recovery of a historical heritage worth to be taken into account such as the island of Saint Louis, suffer the negative consequences of a very negative economic and social context. In part, as mentioned, by factors exogenous, characteristic of the political and economic organisation of the country and, in part, by endogenous factors, such as the progressive degradation of the urban heritage that sustains a population without resources. Buildings in ruins, streets without the minimum necessary infrastructure, low-income housing and very limited equipment. All this suggests what policies would be necessary apply for the restoration of a heritage of humanity gradually sinking into oblivion, well by the resources of the country and through international cooperation programmes.

ID 1492 | THE STREET FOOD MARKET, TO BE OR NOT TO BE? A STUDY OF DIFFERENT GROUPS' INTEREST DIALOG BEHIND INFORMAL URBAN SPACE

Mingming Zhu¹; Siyuan Tang¹; Qixuan Wang¹

¹Tongji University

fzhuquangfu@163.com ; 1244557321@qq.com

ABSTRACT: Street food market was the major business form in Shanghai, in which food, vegetables and fruits are sold. But by the end of twentieth Century, after the government management is centralized and moved indoors, the street market within urban area mostly disappeared. But before long, street food markets of all sizes came into being again, creating a typical irregular space in Shanghai. Especially in the bustling city center, there are still many street food markets despite of the prohibition. This phenomenon is attracting more and more attention from media and public. Why can the street market exist in a contradictory status messy, traffic impacting but full of vitality and natural livelihood? Why is the street market loved by some on one hand, and is despised by others simultaneously on the other hand? Whether the government should extinct the street market or let it be? This paper selects Taiwan Road food market, located in the East Nanjing Road Commercial District in the city center, as an example, focusing on the interests of the game behind the street food market. First, the market's physical space is surveyed, and the

¹ Another highlight is that Senegal and Mauritania have put their efforts in common and created a Board of protection and conservation of the delta of the Senegal River, in the years 1970 to protect its rich flora and varied fauna, resulted from the many marshes and Islands that make up the mouth, where there are several natural parks which currently form a great refuge for birds. In the area we find the National Park of the birds of the Djoudj, located about 60 kilometers north of Saint-Louis; the Diawling National Park, on the other side of the river and the border with Mauritania; and in the same mouth Senegalese national language of Barber Park is now also.

interrelationship among the location background and surrounding facilities is sorted out; secondly, the social association inside the market is emphasized and analyzed. Through interviews with the four types of people related to the market from interest aspect---customers, vegetable vendors, residents and management, the links between these people and the street market is analyzed. Furthermore, their attitude towards the market and its consequence is analyzed as well, to deduct the source reason for why the street market never extinct. Through combing the benefit gaming between these four types of people, the necessity and positive influence of urban irregular space represented by street market is pointed out. Meanwhile, facing the negative urban influence brought by the street market, suggestions are made for the future development of the city street food market.

KEYWORDS: Street food market; city center; informal space; stakeholders; dialog

1 INTRODUCTION

The street food market in China refers to the outdoor commercial space composed of different vendors along the streets where there are many people living. Because of the variety and flexible price, The street food markets is quite popular. However this kind of informal space also brought some problems to the city, such as the traffic and environment problems.

The street food market in the cities originated very early. Initially, farmers outside the city picked up vegetables and meat into city for sale every day. Different vendors got together along the streets and then the early street food market was formed. With the increase of population in the cities, there was an urgent demand for basic fixed markets. Then the government introduced the municipal management pattern of modern western cities, collecting certain rental fees from the vendors and providing them with fixed booths. The first official food markets appeared with the form of street fairs. However, the place where the vendors gathered was not limited to the trading area set by the government. The vendors would take over and try to expand their territory as soon as there was an open space, even the main roads or the civic center where there are many tourists and residents. As a result, problems such as obstructing traffic and affecting city appearance were becoming more and more serious. The government has issued a decree banning Street farms or transferring indoors to improve road conditions and environmental quality.

The street food market was the mainstream form of Shanghai food market. In the end of twentieth Century, the street markets in the urban areas almost disappeared after two years' rectification movement. But before long, they began to appear again in all kinds of streets, especially in the central city. Today, there are still many street food markets fighting with the prohibition. From the beginning of 2015, Shanghai launched a large-scale movement of streets rectification movement, making the street market concerned again by the media and public attention.

This paper selects Taiwan Road food market, located in the East Nanjing Road Commercial District in the city center, as an example, focusing on the interests of the game behind the street food market. First, the market's physical space is surveyed, and the interrelationship among the location background and surrounding facilities is sorted out; secondly, the social association inside the market is emphasized and analyzed. Through interviews with the four types of people related to the market from interest aspect---customers, vegetable vendors, residents and management, the links between these people and the street market is analyzed. Furthermore, their attitude towards the market and its consequence is analyzed as well, to deduct the source reason for why the street market never extinct. Through combing the benefit gaming between these four types of people, the necessity and positive influence of urban irregular space represented by street market is pointed out. Meanwhile, facing the negative urban influence brought by the street market, suggestions are made for the future development of the city street food market.

2 CASE STUDY

This context selects the Shanghai Taiwan road food market as a case study, which is located in the central commercial area of Shanghai, three minutes walking distance from the famous commercial street, East Nanjing Road, and is also the largest a street food market in the surrounding area. Taiwan road food market is located in the remained old settlements along Taiwan road surrounded by these commercial

areas. Taiwan Road, a total length of no more than 200 meters, has now developed into the most important informal vegetable distribution center in the northeast of Huangpu District.

Figure 1 – The Location (Drawn by Author)

There are several considerations for selecting this case: firstly for the media attention. As a kind of informal economic place, the street food market should be banned according to the regulations, but many of them have not only disappeared, but also become the most closely related places with the people's lives. Secondly, the sharp contradiction, along Taiwan road there is the bustling metropolis and exquisite commercial center on the one side, while the filthy road street markets at the same time, causing a great gap in the environmental quality and landscape image. What's more, the views of different groups of people on the road food market are very contradictory. Consumers are pouring here for the convenience and good price but the nearby residents suffered a lot from the noise and dirty and crowded street. Thirdly for the typical meaning, Taiwan road Market is a typical case of urban village renewal in urban central area in the city center land area, to retain or eliminate the food market, which will affect the interests of the crowd? How to balance the contradiction between the needs of the original residents and the development of the city?

The development of Taiwan road food market has gone through three periods: (1) after liberation period: small commodity market. Before liberation, there were fixed stores on both sides of Taiwan road. After liberation, sporadic mobile traders began to set up stalls on the streets. After the renovation movement around 1959, there were no signs of itinerant traders on the Taiwan road. (2) 1990s period: vegetable street. There is an emergence of mobile vendors, gradually increasing the size, forming a neighborhood vegetable street, which is the prototype of Taiwan Road food market. (3) Latest ten years: the street food market is still repeated. The relevant departments in recent years has carried out several campaigns and raids, the results were obvious but did not last long, the street market emerged again and again.

Figure 2-4 - Three Periods of Taiwan Road Food Market

Taiwan Road food market street is "L" shaped narrow strip space, with a total length of about 135 meters and the width of 6 - 6.5 meters, of which 2 meters on both sides are occupied by stalls. the middle passage is left just about 2 meters for transportation. People are only allowed to walk through the road. There are three entrances and exits. The flow line is single and clear. On the one hand, it is convenient for customers to browse all booths. On the other hand, it is easy to cause traffic congestion because the pathway is so long and narrow. There are 63 stalls totally along the street divided into six categories. Generally speaking, different types of stalls are mixed and arranged, to some extent, avoiding competition from similar stalls.

Figure 5-7 - Three Periods of Taiwan Road Food Market (Drawn by Author)

3 ANALYSIS ON FOUR GROUPS OF STAKEHOLDERS

Understanding the spatial distribution of the road food market, this paper began to study the different interests behind that. In such a stage of urban grassroots such as customers, vendors, residents and managers, each of whom have their own necessity and problems. "who benefits, who suffered?" What's the relationship of them? This chapter is divided into the following four parts to analyze the four stakeholders. We hope to understand the positive and negative effects of the food market from the perspective of the four groups, and understand the real needs of people.

3.1 CUSTOMERS

In this study, we recorded the number of customers in Taiwan Road food market in three periods of a day: during 6-7 am, there were 1062 customers; from 10 to 11 o'clock, there were 682 customers; and during 3-4 pm, there were 782 customers. On average, there are a lot of customers and the business is in good condition.

What are the main drivers for consumers to come to this food market? A total of five factors, included the price, distance, freshness, Messy condition and familiarity with vendors, were selected for the attractiveness of a multiple regression analysis. The available survey sample was 136 and the results were as follows(Tab. 1):

Coefficients ^a					
Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.
	B	Std. Error	Beta		
1	(Constant)	1.885	1.474	1.279	.221
	Distance	-.140	.066	-.373	.054
	Price	.734	.403	.271	.091
	Messy condition	-.278	.230	-.234	.241
	Freshness	.441	.361	.133	.241
	Familiarity	.207	.141	.182	.169

a. Dependent Variable: Satisfaction Score

Model Summary ^a									
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	更改统计量				
					Adjusted R Square	Adjusted F	df1	df2	Adjusted Sig. F
1	.946 ^a	.895	.855	.52896	.895	22.230	5	13	.000

a. Predictors: (Constant), the price, distance, freshness, Messy condition and familiarity with vendors

b. Dependent Variable: Satisfaction Score

Table 1 – Multiple Regression Analysis (Drawn by Author)

$R^2 = 0.855$, It shows that the equation has a high degree of fit and a significant coefficient of $Sig = 0.000$, and the correlation is good. We get this equation:

$$Y = 1.885 + 0.734X_1(\text{Price}) + 0.441X_2(\text{Freshness}) - 0.278X_3(\text{Messy condition}) + 0.207X_4(\text{with vendors}) - 0.14X_5(\text{Distance})$$

According to the equation, the evaluation of the customers on the food market is the most closely related to the price, followed by the freshness, sanitary condition and so on. Among them, the attractiveness of the street market is positively related to the price, freshness and familiarity with the stall holders, while the time required for the food market and Messy condition are negatively related.

Although the customer and the road market is a win-win relationship, there are hidden dangers here as a result of the popularity. Because Taiwan road food market area is limited, with the increasing number of customers, on the one hand it makes people constitute more complex and brings instability to the security; On the other hand, excessive flow will affect the evacuation, when the accident occurred, the emergency evacuation of more difficult to implement, immeasurable!

3.2 VENDORS

Vendors are mostly jobless and unemployed migrant population, concentrated in the age of 40 years old, some young and old, operating time in about 10 years, so they have a certain perennial Shentan sense of belonging.

Where the threshold is low, is one of the few outlets of the vendors, and provides a low threshold for employment marketplace atmosphere, poor supervision of Taiwan Road market just for these unemployed and retired personnel etc.. Taiwan road around the old Chengxiang residential area, population density, low living standards, lack of supporting facilities, roadside stalls commodity prices more in line with the level of consumer spending, so vendors have considerable sources of interest. Huangpu District city center prices high, but the Taiwan Road market stall rent is quite low, especially compared with the surrounding normal farms, low rent and excellent location to attract more vulnerable groups lack of funds to set up here.

An important part of the market, vendors are important service people but also the problem makers. On the one hand, they bring some positive effects, such as making up for the lack of formal indoor markets, and providing the convenience for residents to buy food, at the same time, improving the Taiwan Road market visibility and competitiveness, some residents or tenants also seize the employment business driven traders joined the camp, activity area. On the other hand, the negative effects are also very obvious: the first is the general vehicle illegal street stalls, with stacking goods everywhere, making the original narrow road more difficult to access. And customers cause serious traffic problems in the market. Secondly, the large amount of garbage, noise and smell produced by the vendors make the environment nearby quite messy, and the behavior of obstructing public facilities and occupying public land can be seen everywhere.

In summary, the positive significance of vendors determines the importance of their existence, while its negative impact also determines the urgency of regulating the street food market.

3.3 NEIGHBORHOOD RESIDENTS

The attitudes of surrounding residents towards the market are complicated. On the one hand they enjoy the convenience, while suffer the negative impact on the other hand. Even some residents often complain and report to the management, which mainly focus on the traffic jam, poor environment and noise etc.. (Fig. 8-9)

Residents of the way to buy food is mainly divided into walking and non motorized vehicles. Stalls next to storage batteries, bicycles, motorcycles parked at random, affecting the passage of pedestrians. Some dealers transport tricycles to the goods parked in the trunk, the goods piled up in the residents of the import and export channels, traffic congestion will expand the scope of more. In addition, the key health problem is also plagued residents, we collect three large garbage Taiwan Road market operation of the manufacturing source: 1. vegetable stalls, this kind of garbage left by most vendors, daily life often leaves after withdrawal stalls with the garbage bin nearby. 2. fruit stalls, similar to the former one, the putamina number is larger in need of cleaning. 3. aquatic products stalls, the whole Taiwan Road food market, the sale of aquatic products stalls accounted for the total operating booth 1/6. The stalls for aquatic products are very humid, and the fish floor is the most important cause of flies and mosquitoes. From the business perspective, to solve the problem of aquatic products and health food category is relatively difficult.

Figure 8-9 - Space Occupation And Poor Sanitary Conditions (Photo by Author)

From the attitude of the residents, we can see that the residents living in this neighborhood are the most clear-cut groups on the stand of exclusion from the street food market. They obviously have a lot to complains on the problem, but their ability is not strong enough to change much. Compared with what they lose, the benefits form Taiwan road food market is very limited. In response to the higher authorities repeatedly, the confusion still can not be resolved. The inhabitants were expected to receive the due compensation, but failed to achieve it, which intensifies the contradictions between the residents and the vegetable stalls.

3.4 NEIGHBORHOOD RESIDENTS

The administrators Taiwan Road food market mainly for three departments: (1) Community neighborhood committee - the Bund Street Dongfeng residents committee, responsible for handling the public affairs and public welfare undertakings of residents in their residential areas, mediating civil disputes, assisting in maintaining public order, and reflecting the opinions, requests and suggestions of the residents to the government organs. (2) Urban management brigade -- Huangpu District city administration law enforcement team. They carry out the relevant laws, regulations and regulations on urban management, and have maintained and maintained the order of urban management, and are responsible for the guidance, co-ordination and organization of the administrative law enforcement of urban and administrative supervision. (3) City appearance Bureau - the Bund Street Municipal Administration Joint Meeting Office. They exercise the power of administrative punishment within the limits of the authority of this Municipality, and to supervise and inspect the city's environmental sanitation in accordance with the law.

According to residents, related management action in the treatment usually lags behind and finish with no results and the communication and cooperation between departments is not enough. Every department holds different views of the market problems and it's hard to reach the common sense. In addition, the management costs are getting higher and higher so that it's harder to keep remediation and the effect can not last so long. Repeated assault remediation have only achieved temporary achievements. When the managers leave, the vendors comes back. Even worse, Surrounding residents' shopping needs persist and the formal indoor food markets are not enough, street food market becomes a vital supplement. At the same time the interview found that there are interest relationship between vendors and managers, vendors and stores along the street. Some managers even take a laissez faire attitude. The management and fairness is difficult to guarantee.

4 DISCUSSION

4.1 THE POSITIVE INFLUENCE OF THE STREET FOOD MARKET

1. Convenience: Taiwan Road market is in large scale with various vegetables and other goods and located in the old residential area, where there is a large number of residents. The street market makes up the lack of formal markets and fits with the local consumption level.
2. Reputation: after years of operation, Taiwan Road market gain a good reputation around, coupled with the Taiwan small commodity market history, has brought the huge popularity. Even some tourists come here.
3. Employment: The limitation of having a stall here is small, providing good employment opportunities for those unemployed, retired and migrant people and improving the economic development and social stability.

4.2 THE NEGATIVE INFLUENCE OF THE STREET FOOD MARKET

1. Congestion: limited space and narrow roads coupled with the large flow of people make the road become very congested. Traffic will also affect the effect of emergency evacuation.
2. Disturbance: smelly garbage, air pollution as well as a variety of noise pollution have brought a lot of interference to the local residents, which is also part of the main reason for the complaints.
3. Security: the internal management is not, do not pay attention to the security market itself is very poor, people disputes to be resolved in a timely manner, residents not to respond to and deal with market chaos is not timely supervision, the negative impact is not stopped.

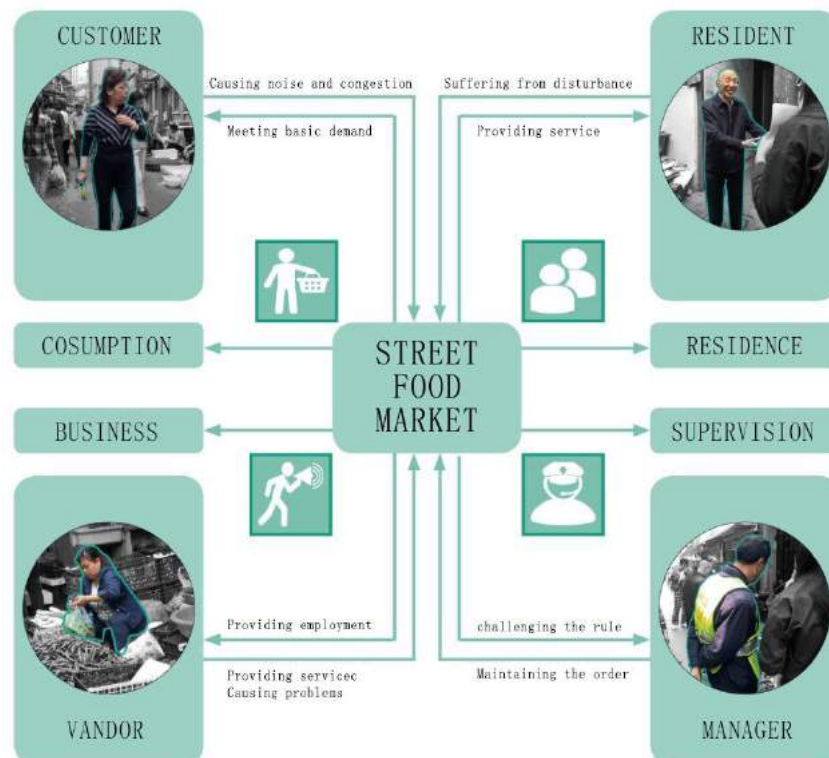

Figure 10 – Relationship In The Four Stakeholders of Street Food Market (Drawn by Author)

4.3 REFLECTION ON THE INFORMAL URBAN SPACE

The street food market is one of typical urban informal space, formed naturally in the process of urban development. In the current process of urbanization and urban governance, it is often regarded as a negative object. But the existence of the street market also shows the true need of people, reflecting the living culture from the bottom up and it gathers people together to create the vitality which is poor in big cities. Besides, the street food market also promotes the communication of different parties in the community, which is particularly precious in modern city. Therefore, we should treat this kind of informal space dialectically and allow it to exist and develop within a reasonable range.

5 CONCLUSION AND SUGGESTION

Shanghai Stall Guideline was issued in 2007, making Shanghai the first city in China trying to delegate powers to lower levels on the management street vendors. Compared with the past, urban management is becoming more and more people-oriented. But the street food markets are also completely banned and that's not the best ideas.

Therefore, the recognition of the legitimate status of mobile vendors is the prerequisite and basis for good governance of street food markets.

Through combing the benefit gaming between these four types of people, the necessity and positive influence of urban irregular space represented by street market is pointed out. Because of the necessity, street food market is reasonable to be reserved with a strong supervision and management. We suggest to establish the consultation mechanism in which relevant departments, community representatives, business representatives, consumers and market vendors can participate together to make their voices heard. They can search countermeasures for various negative impacts and disturbances, such as sewage, smell, noise and so on, and carry out effective managements. By improving the environment and broadening the existing space reconstruct Taiwan road to a pedestrian street, with the current market reputation and popularity, it is going to be a good place for daily shopping and leisure.

ID 1535 | BOUNDARY-MAKING AROUND A “TRANSGENDER GHETTO” IN A NEIGHBORHOOD: A CASE IN ALSANCAK, İZMİR (TURKEY)

Özlem Arslan¹; Fatma Şenol¹

¹İzmir Institute of Technology

mim.ozlem@gmail.com

ABSTRACT: This study inquires how a transgender community negotiates and re-identifies its living and working space against the socio-spatial boundaries drawn by urban planning decisions, media images and policing strategies. It develops as a case study in Alsancak, a central-city neighborhood in İzmir, known as "the tolerant city" in Turkey. Alsancak is notorious for housing a transgender community most of whom are sexworkers. In the "sexed city", the sexual codings of the urban spaces and the populations associated with them demonstrate the modern societies' conflicts and contradictions (Knopp, 1995). This study assumes that social identities and differences are established through constantly negotiated power relations, at which space plays a major role. Identities have spatial dimensions which are "constructed together and constructed through interaction" (Massey, 1994). Urban planning, policing strategies and media images are part of the dominant power relations that draw socio-spatial boundaries around marginalized groups as "others". However, boundary drawing is not only an act of control by the powerful but also an act of resistance by the weak (Pratt, 1999). Through their everyday practices, individuals and communities (here, transgenders) can produce, negotiate, and re-define such socio-spatial boundaries through social interaction, social conflict and social struggles. Despite the prevailing stigmatization, criminalization and policing of transgender people in Turkey, Alsancak neighborhood with its diverse socio-economic, religious and ethnic groups, and commercial and service uses (with a vivid night-life) appears as a safe space for the transgender community. Transgender community lives and works in the inner streets of the neighborhood, which they call the "transgender ghetto". They experience significant social consequences ranging from discrimination to violence, even in this relative "safe space". Through archival research on urban planning decisions and media images about this transgender ghetto and in-depth interviews with local associations (including a LGBTI association), this study compares the socio-spatial acts of boundary drawing by the powerful and the weak. The findings of the study will be interpreted for developing urban planning decisions for an "inclusive city".

1 INTRODUCTION

This study, as part of a discussion about diversity is about how the socio-spatial boundaries are formed around the living space of the transgender community in Alsancak neighborhood in İzmir. The part of the neighborhood where they live and engage in sexwork is referred by the transgendered as their "ghetto". Transgender ghetto in Alsancak is an appropriated space, formed as the transgender community negotiates and re-identifies its living and working space against the socio-spatial boundaries drawn by urban planning decisions, policing strategies, and media images.

Cities are often described and studied as sites of difference (Young, 1990; Massey, 1994; Eade and Mele, 2002; Valentine, 2008). Coexistence of different cultures and different lifestyles in the cities is deemed to

bear the potential of merging, and creating hybrid cultures, thus difference in the city is often celebrated. However living with difference in the practice is often left undescribed. Contact with difference, instead of changing values and promoting a general respect for others, might result in the hardening of the values and attitudes. Many communities living in close proximity to one other maintain “series of parallel lives” which co-exist without really touching each other (Valentine, 2008). We argue that this is the case in the Alsancak neighborhood, where diverse social groups including some of the city’s transgender sexworkers reside. Transgenders are the common ‘others’ for multiple social groups in Alsancak. The otherness of transgender sexworkers, as gendervariant individuals engaged in the immoral act of prostitution, is likely to produce polarization and division instead of an inclusion. Furthermore, overall process of othering them might result in their further marginalization. In an overly heterosexual ‘masculine’ society (Efe Güney and Demircioğlu, 2015), difference signified by gender identity and sexual orientation is unlikely to be regarded affirmatively.

Massey (1994) argues that “identities have spatial dimensions which are constructed together and constructed through interaction”. Whereas power constitutes both identities and spatialities. Act of drawing boundaries by different groups determine continuous processes of inclusion and exclusion as group identities rely on the recognized similarities between members and recognized distinctions with the members of other groups. Normative mechanisms, such as shared understandings of contextual codes and social practices emphasize boundaries between social groups Cohen (1985) (as cited in Jackson and Benson, 2014). Like identities and difference, spatial boundaries are negotiated, defined and produced through social interaction, social conflict and struggles between different groups (Gotham, 2003). In Alsancak, the most significant conflicts and struggles exist between the transgendered sex workers and the ‘decent’ residents of the neighbourhood. Power relations between these groups are exhibited as both claim the neighborhood as their living space. While media images and policing strategies openly take sides against the transgendered, institutions of urban planning concerned with the area disregard their existence completely.

Relating to the studies about the relationship between planning and diversity, as well as gender, sexuality and sexwork, this study examines the processes of boundary making around a transgender ghetto in Alsancak neighborhood. Inquiring into the subject; we intended to find out the role of urban planning, local communities, media images, and policing as well as the transgender community in the formation of these boundaries. Interrogating the existence of the transgendered and the sexwork, as well as the problems and safety concerns in the Alsancak neighborhood, we intended to portray the making of sociospatial boundaries. In the following section, overview of the concepts related to gender variance, sexwork and the place of sex, sexuality and sexwork in the discipline of urban planning is given, followed by the description of the site and the methodology of the study. In the next section, the study findings are discussed on the basis of queerness of the Alsancak neighborhood, the situation of sexwork and the formation of sociospatial boundaries.

2 LITERATURE REVIEW

Sexual diversity and freedom, an urban phenomena arising out of the density and cultural complexity of cities, results in the development of minority sexual subcultures, communities and social movements linked to them in the cities. Nevertheless, concentration of these subcultures and movements in the urban space makes it easier to both stigmatize and control them in an attempt to protect majority cultures. Eventhough, the sexual codings of cities, districts within cities and the populations associated with them are complex, they demonstrate the conflicts and contradictions of the modern societies. Furthermore, these codings are associated with power relations, therefore they are deeply contested (Knopp, 1995).

Hubbard (2000) refers to the spaces dominated by heterosexuality as ‘moral geographies’, and states that judgements on the acceptable types of peoples, behaviours and practices are made daily in different settings. Moral approval of the forms of acceptable heterosexual behavior is sustained by social and legal regulations which discipline those who violate this moral order. Sexual dissidents are excluded from the public spaces which are constructed around particular notions of appropriate sexual comportment due to a citizenship based on heteronormality (Hubbard, 2001b). Civil society is both a heterosexual and a patriarchal concept determining the acceptability in the public realm, making it very difficult for those whose sexualities are considered immoral to enter into the public realm. The rights of the individuals who do not fit into dominant sexual standards are almost erased as they are tagged as ‘sexual others’, who are

denied of proper citizenship. These individuals often experience social stigmatization for being unable to fit into the definition of a 'good citizen' becoming "second-class citizens not only by the state but also by 'decent', 'respectable' sexual subjects" (Hubbard, 2000). Transgenders and sex workers are among the sexual dissidents who experience stigmatization and othering (Knopp, 1995). They are viewed as they need to be spatially contained hence they are excluded through the construction and maintenance of spatial boundaries (Laing and Cook, 2014).

GENDER VARIANCE AND SEXWORK IN SOCIOSPATIAL BOUNDARY MAKING

Transgender as a collective term signifies individuals who do not perform or identify with their assigned gender and have taken some steps to present themselves in another gender (Valentine, 2003, pp.27-28). Hence, transgender describes an individual who cross the boundaries of gender defined by culture (Bockting et al., 1998). The 'transgender community' refers to a broad range of gender variant people not necessarily including information about their sexual orientation or their views on gender reassignment surgery (Salisbury and Michael, 2016). The transgender population is one of the most vulnerable and marginalized populations in the city as they often experience significant social consequences ranging from discrimination to outright violence for transgressing gender norms (Doan, 2007). When trans people look for shelter even within queer urban spaces, they are tolerated but not always welcomed warmly (Doan, 2009). Challenging gender norms can provoke acts of violence, which is called gender bashing. Especially transwomen who live full time as women become potential targets for harassment, abuse, and violence (Namaste, 1996).

Transgender individuals face serious discrimination and lack legal protection when they do. They might be refused as tenants or as employees just because of their gender identity (Doan, 2001a). Unconventional gender presentation makes it difficult for transgender individuals to find or maintain employment. As most transgendered individuals are forced into sexwork, they work at risk of substance abuse, unprotected sexual experiences, and various mental health problems (Cochran et al., 2002). The internalization of the social stigma in the transgender community results in the suicides and attempted suicides (Doan, 2007). Moreover, safety of the transgenders is systematically dismissed from the general legislations, sustaining the violence and crimes of hatred against this group which might result in killings (Doan, 2001b).

Transgendered individuals experience the gendered nature of space as what Doan (2010) refers as "the tyranny of gender" which begins when certain individuals entitle themselves as "heteronormatively constructed gender enforcers in public spaces". The policing behaviors of these individuals are often accompanied and exacerbated by the silent but supportive watchers. Transgendered individuals are regularly profiled and approached by the police in public spaces for the "crime" of being transgender hindering them from moving freely and existing in public spaces (Doan, 2010). Difficulty in finding and maintaining employment forces the transgenders to sexwork (Doan, 2007). They usually choose to work on the streets which comes on the expense of more exposure to violence as well as more pressure from the local communities and the police. Street-based sex workers are exposed to high levels of violence, intimidation and corruption. Instances of extreme violence, including murder are reported frequently on the media. All sex workers experience occupational stigma and discrimination, however the negative effects of sexwork related stigmatization and criminalisation are deepened for sex workers who are members of visible minorities. Because of their visibility and gender identity transgender sex workers face exacerbated stigmatization and violence. Sex work related stigma adds to the stigma of the gender variance in shaping the interactions of the transgendered sex workers with the police and the community. Consequently, they are often displaced both for their marginal gender identity and for being a sex worker. If displaced, transgender sex workers, who usually work in specific locations, where regular and new clients can easily find them, are pushed to the more marginal urban spaces where they potentially face more violence (Krüsi et al., 2016). Furthermore, transgender sex workers, usually experience harassment, abuse, and violence with little protection from police (Nichols, 2010). Studies on transgender sex workers show that they are routinely subjected to violence, public humiliation, and, not infrequently, to murder (Brooks-Gordon, 2008).

SOCIAL CONTROL OF SEXWORK

Sexwork, commonly an urban phenomenon takes place in a variety of indoor and outdoor settings in the city (Laing and Cook, 2014). Street sexwork, mainly in residential areas forms the most visible and

controversial form of sexwork (Hubbard, 1997). Sexwork is frequently referred as a 'nuisance', as something that should be isolated from the 'mainstream' society, moved away from residential neighbourhoods and prime city spaces. It is viewed to disturb neighbours, passers-by, and potential investors. The location, actors, and the outcomes of sexwork cause conflicts. Inherent territoriality of sexwork is influential in setting physical and discursive boundaries which determine what can happen where (Laing and Cook, 2014). Street sexwork has been viewed as inevitable while being simultaneously condemned as immoral and sickening. Therefore, commercial sex is a contested realm often subjected to the politics of NIMBYism (Hubbard, 2001).

In heterosexually ordered cities, the sight of the sexed body of the sexworker in the public realm disturbs the moral expectations about sexuality. The eroticisation of the public realm they cause by their outlook and behaviour provokes legal and moral response. The state, the law and the 'good' sexual citizens start to police the limits of spaces of sex work in order to hinder prostitution from spoiling the public realm (Hubbard, 1997). The stigmatization of sex workers is central to the constitution of the social order as they are viewed as a risk to the society for threatening family values. Consequently, spatial displacement from the urban landscape by law enforcement or community protesters has been the most common method of the social control of sex work (Krüsi et al., 2016).

As one of the instruments of social control, the role of the media in identifying sex work and sex workers as a threat to the society cannot be ignored. Since sexuality is frequently used to define acceptable social behaviour, the conflicts related to the sexuality are usually presented in the media provoking sensations, thus leading to 'moral panics' about certain individuals and groups. Resultantly, Sex work and sex workers often appear in media causing moral panics (Hubbard, 2000; Hubbard, 2001b). As fears of otherness are a, whereas many unreported lesser physical assaults are also common (Harcourt et al., 2001).

magnified in the context of the city, media becomes instrumental in shaping the daily encounters with those who are considered as potential threats providing support for the exclusionary urban policies (O'Neill, 2008).

LOCATION OF SEXWORK

Moral geographies assume that the visibility of sexworkers is more acceptable in some spaces than others, therefore street sexwork is often only tolerated in the areas reserved for it. Street sexwork is mostly confined in certain, notorious inner city districts where the vice police controls it while simultaneously keeping it away from neighborhoods where it might have caused most controversy and dissent (Hubbard, 1999). The control of sexwork is primarily aimed at reducing the 'nuisance' experienced by people living in areas of street sexwork, justified by the "the right of the normal decent citizen to go about the streets without affront to their sense of decency". Therefore, the judicial system considers sexwork as an offence against standards of public morality and decency when it is visible in the public realm (Hubbard, 1997). Neighbourhood nuisance concerns, closely linked to sex work related stigma and policing, affect the working conditions of the sexworkers as they confront residents, neighbourhood watch groups and security guards. These interactions are determined by an understanding which focuses on the riskiness of the existence of the sexworkers in the neighborhood, not by concerns about their safety (Krüsi et al., 2016).

Spaces of sex work are shaped by continuous struggles between sex workers, neighbourhood residents, businesses, and the police (Hubbard and Sanders, 2003). Imbalanced powers are involved in these struggles since the complaints of the neighborhood residents are prioritized over protecting the working conditions, health and safety of the street-based sex workers (Krüsi et al., 2016). Simultaneously sex workers themselves also actively shape the spaces of sex work as they resist the interventions against them, negotiate the use of space and have private property rights (Laing and Cook, 2014).

POLICING OF SEXWORK

Sex workers and sex work spaces have been targeted by a wide variety of interventions and policies (Laing and Cook, 2014). Dominant policy approach to sex work has been criminalisation and police enforcement, which have increased the risks of violence (Krüsi et al., 2016), and stigmatization for sexworkers (Hubbard, 1997). Policies regarding sex work target repressing the spaces of street sex work

as techniques of governmentality and surveillance are used to contain, exclude or control sexworkers (Hubbard et al., 2008).

Boundary maintenance with regard to sex work and related social problems is seen as a task of the police as well as the courts. As policing controls the sexuality via surveillance and punishment, what public space is, how it should be, and when, where, how and by whom it can be used, is in a way determined by the police. Sexworkers from all segments and their clients have been targeted by police interventions (Laing and Cook, 2014). While the legal regulation of sexwork reinforces the exclusion of the sexworkers, repression and containment are the common strategies used in policing of sexwork which is a spatial process sustaining the marginalization of sexworkers (Hubbard, 1998). The police tolerates, though seldom encourages sexwork in “unofficially designated areas” therefore policing of sexwork determines the creation of sexwork zones by making it impossible for clients and sexworkers to meet somewhere else (Hubbard, 1997).

Stigmatisation, criminalisation, and labour conditions impinge the rights of sex workers for police protection and legal recourse. When sex workers seek police protection, they often face inaction of the police justified by the understanding that their experiences of violence are an inherent part of selling sex. Since sex work is viewed as inherently dangerous and sex workers are seen as victims, blame for sex work related violence is appropriated to sex workers as the police free themselves from the task of protecting sex workers. This process increases the structural vulnerability of sex workers since they are stripped off the societal protections that other citizens normally have (Krüsi et al., 2016). Moreover, there are occasions when officials exploit and victimize sex workers by forcing them to sex acts, extorting bribes, and harassing. Assaults, physical harassment, being beaten, being arrested without evidence are common forms of police violence, and even incidents of group rape is reported. Furthermore, in fear of further arrests or fines, the negative experiences with the police also might hinder sexworkers from going to police when they are the victims of crime. Consequently, many incidents of harassment, assault, rape, and kidnapping among sexworkers are not reported to the police. Complaints of the sexworkers are often not registered, or when they are registered the perpetrators generally are not convicted (Nichols, 2010).

COMMUNITY RESPONSES TO SEXWORK

The assumed incompatibility of the sex work with the space of the neighborhood community has been used to justify exclusionary actions against sex workers. Media discourses stress that sex work harms the neighborhoods by restricting the accessibility of streets to residents at night. In some instances campaigns to remove sexwork from ‘their’ streets are initiated by the residents using street patrols or pickets (Hubbard, 1998). Often backed by the local press, such campaigns sometimes result in the displacement of sex work (Hubbard and Sanders, 2003). Community responses to street sexwork range from a state of no tolerance to empathy. Some levels of sympathy towards the sexworkers exist, but the tolerance to sexwork tends to be low. While views on sex work and sex workers are usually mixed, some residents stress the impossibility of coexistence and insist that only visible police activity could address the issue and result in their removal from residential spaces. However, moral protesters of sex work often do not represent the whole community. Opinions and attitudes of residents who are more tolerant about sexwork are often not voiced either in Tensions between sex workers and other residents in public spaces present issues related with balancing the needs and interests of different groups. Common complaints linked to street sex work include visible sex acts in public, traffic, noise, littering, clients' harassment of female residents, physical altercations, and the health risks presented by discarded condoms and needles (Hubbard, 1997; Weitzer, 2009). For the majority of the neighborhood residents sex work is an issue related with the overall quality of life. Street sex work in the neighborhood affect the use of public space negatively as some residents feel unsafe walking home especially at night. Many sex workers also indicate concerns about the perceived safety of some areas as they regard certain public spaces as dangerous (Pitcher, et al., 2006). The prevalence of nuisance, its impacts on the reputation of the area, lack of control of street sex workers by authorities, lack of control over public and private spaces, and the emotional impact of living in areas of street sex work are listed by residents as main concerns about the quality of life (O'Neill et al., 2008).

URBAN PLANNING ON SEX, SEXUALITY AND SEXWORK

Sex and sexuality has been inquired geographically since it is accepted that space, fundamentally influenced by the dynamics of human sexuality, exposes how sex is represented, perceived and understood (Knopp, 1995, p.149). Intersections of sexuality with race, gender and class determine how certain populations are targeted for displacement in the neoliberal city. Therefore, city is not a neutral stage for sexual relations, but is an active actor in creating sexualities by promoting heterosexualities while repressing others (Seitz, 2015).

The decisive role of the city in determining sexualities and connected relations, locate issues of sex and sexuality in the field of the planning discipline. Planning has been conventionally viewed as a means for creating an “orderly urban environment” (Fainstein and Fainstein, 1971). On this commonplace objective ascribed to planning, Doan (2011) remarks that definition of the “orderliness” is made in a “narrowly heterosexist” sense, “favoring white, male and heterosexual conceptions of orderliness”. Therefore, planning has a significant power to heterosexualize space (Hubbard, 2011). Urban spaces, weaved with moral values encourage and naturalize heteronormativity, in which particular acts and individuals are marginalized as immoral, while the mainstream is often defined on the ideals of family, with the assumed heterosexual orientation and a related gender. Heteronormativity of planning ensures that spaces of commercial sex representing sexual and moral disorder are monitored and controlled by the state and law. Therefore, different sites of commercial sex, including places of street sex work are causes of controversy in planning (Hubbard, 2001).

In theory, planning might be instrumental in mediating controversial views about the place of sexwork, whereas in practice, since sex-related businesses are not recognized as a land use category it is not the campaigns or in the press (O'Neill et al., 2008).

possible for planning to identify places for commercial sex. Nevertheless, the criminal laws along with the policing keep pushing away street sex work from the city. Zoning ordinances prohibit adult entertainment facilities and land uses related to commercial sex near residential areas, schools and religious facilities, confining sex consumption to the industrial districts. In some instances, local authorities designate a rather safe sex work zone away from residential areas, making sure that no annoyance was caused to the public. But these places, which are tolerated and not encouraged, are basically allowed in order to protect the social and economic value of certain land uses which might be effected by the negative impacts and externalities of sex work. Though often misleading, commercial sex in neighborhoods, is often associated with adverse effects such as increases in crime, decreased property values, and neighborhood deterioration (Hubbard, 2001). When planning and licencing bodies work to determine the location of sex work, planning resembles policing as both are instrumental in creating ‘moral geographies’ by deciding what is permitted where (Laing and Cook, 2014). Furthermore, current planning and licencing practice is inclined to favour the rights of residential property owners over the rights of sex workers, by locating commercial sex in places where it is not safe or profitable. In most situations, it is not clear if planning powers like zoning and licensing respond to the community concerns about sexwork or they serve the interests of profit seeking developers who want to take advantage of ran down areas of sexwork. Since street sexwork does not have a legitimate land use status in terms of planning, it can be subject to displacement by means of urban redevelopment (Hubbard, 2001; Hubbard and Whowell, 2008).

Policies intended to regulate or eradicate places of sexwork may have a negative impact on the livelihoods of the marginalized transgendered individuals, who have limited employment options (Doan, 2001). Though planning is instrumental in the urban governance of sexwork, its capacity to act in a rather ‘socially and sexually liberatory manner’ is controversial since it is expected to protect dominant, mostly heterosexual, moralities. Whereas, in order to make socially-just decisions, the views of those who are offended by sexwork should be balanced with the views of those who benefit from it. Therefore, the claims and rights of sex workers should be incorporated into the debates on sexwork and given prominence in the planning process (Hubbard, 2001) in order to understand the exclusionary spatial practices they go through as they face abuse, harassment and violence (Hubbard, 1997).

3 STUDY SITE AND METHODOLOGY

Alsancak is a neighborhood in İzmir, the third largest city in Turkey. İzmir is one of the most important metropolitan centers in Turkey with a rapidly increasing population and urban area (İmar ve Şehircilik

Daire Başkanlığı, 2015). The city has a cosmopolitan culture linked to being a port city historically (Gökçen Dündar, 2010; Kaya, 2010). İzmir today is known as the 'tolerant city', probably connected to the influence of its historic cosmopolitanism, which have generated a rather tolerant social environment and an alleviation of the conservative culture of İslam (Efe Güney and Ayhan Selçuk, 2016). Alsancak, situated right between the envisioned new center and the traditional center of the city, is part of a larger district which provisions major commercial and service functions in the city. It is a completely built up, lively center which contains more commercial uses than residential in its intertwined modern and old buildings (İmar ve Şehircilik Daire Başkanlığı, 2015).

Alsancak neighborhood differs from the other parts of the city with the social mix of its residents. Historically, it has been the 'Frank (European) quarter' (Zandi-Sayek, 2012) of the city, so eventhough most have moved out to 'better' neighborhoods, the neighborhood still has remaining local non-muslim residents who are very old. Some middle-class, and upper-middle class households who inhabit flats in better quality apartments still reside in the neighborhood, eventhough they complain about the degeneration and decline in the neighborhood. The neighborhood with its central location and its proximity to many commercial and service jobs as well as major art and culture facilities is a choice of residence for young professionals. It is almost impossible to see children on the streets which imply rare-existence of families with children. Alsancak is also notorious for housing some of the city's sex workers, most of whom are transgenders. As a result, certain inner streets of the neighborhood in certain hours (as the night sets in) are used for sex work mostly by transgender sex workers living in the neighborhood which is a nuisance for other residents.

These presumptions about Alsancak neighborhood are inferences from a pilot study conducted in the area in August-November 2016. This pilot study involved semi-structured indepth interviews directed to the key informants including the headperson of the neighborhood, directors and members of the LGBTI association Black Pink Triangle, and residents of the neighborhood. In addition, short interviews were made with the businesses which contribute to the daily life in the neighborhood. These interviews as well as personal observations and trials of mapping provided general information about the current state of the neighborhood. After the pilot study, media images and reports about the problems, safety concerns, existence of the transgenders and sex work in the neighborhood were searched online and documented. In April-May 2017, a second set of in-depth interviews were conducted. Five interviews were made with transwomen living and/or working in the neighborhood. One of them was an activist in the LGBTI association of Black Pink Triangle, and other four were sexworkers or former sexworkers. The directors of Black Pink Triangle and Alsancak Movement Association, and planners from the planning departments of the Konak District and İzmir Metropolitan Municipalities which are responsible for the spatial plans of the Alsancak neighborhood were also interviewed. The focus of the second set of interviews was the existence of the transgenders and sexwork in the neighborhood, interrogating community and group relations and safety concerns in the neighborhood and prospects of neighborhood change.

4 STUDY FINDINGS

Alsancak neighborhood is referred as 'mixed' as it contained families, singles, businesses, sex workers and transgenders. Despite being affordable, the area was chosen by sex workers due to its proximity to many entertainment facilities. There is a transgender community in the neighborhood, who know, support and watchover each other. They get together especially in cases of significant events like protests, deaths and suicides. Most of the transgenders are sexworkers and they are ghettoized with other social groups who can tolerate living with them (Demet and Erdem from Black Pink Triangle, October 2016).

The neighborhood is associated with sexwork in the local press and other media. The existence of sexwork is a common nuisance for most residents due to morality, safety and the quality of life concerns. Though, most residents have remarked that if sex work did not exist, the transgendered in the neighborhood would not be that much of a problem. The safety and quality of life concerns about the neighborhood were also stated by the trans women sex workers, but trans women sex workers face pressure and threats from the community of residents and the police besides the shared disturbances in the neighborhood. Some have moved out, or thinking about moving from the neighborhood due to the community and the police pressure. There have been numerous neighborhood campaigns voicing the complaints of the neighborhood residents about sex work which were reported in the local and national press.

ALSANCAK NEIGHBORHOOD AS A QUEER SPACE

Many points from the interviews with the members of the LGBTI association Black Pink Triangle and trans women comply with the characters of the queer spaces defined in the literature. According to Yavuz, Erdem and Demet from the LGBTI association Black Pink Triangle (2016); Alsancak, popular for being the center of the city and for being a center of art, culture, entertainment and night life in the city, is a breathing place in İzmir. It is more democratic and more political compared to other districts of the city. Being easily accessible, it is a meeting point, convenient for being organized for political action and activism including LGBTI politics and activism. Alsancak is a place open for performance and presentation of the programmed behavior and exhibition of the existential situation regarding gender. It is an “acquired place” where transgenders have gained considerable visibility and acceptance. It is an entry point for transgenders who come to live in the city of İzmir. It is a “safezone”, a rebel zone for LGBTI individuals and a living space, a habitat, for the “others” of the society. It is a more humanistic, less religious and less conservative relative freedom zone in the city.

Inline with these comments, Alsancak has been identified as the “queer” neighborhood in İzmir for being the preferred neighborhood of residence by LGBTI individuals where they feel comfortable (Efe Güney et al., 2014). ‘Queer’, once an epithet directed to the people who do not conform to the conventions about gender and sexuality such as gays, lesbians, bisexuals, transgendered people, and others, has been appropriated by these people in order to revise its potential to hurt and to reclaim their identities and to empower themselves (Bell and Valentine, 2008). Reports of the interviewed transwomen (May 2017) also picture Alsancak as a queer neighborhood as they state that their reason to choose Alsancak to live and work was that there was an established transgender community in the neighborhood. They refer to the neighborhood as an entry point to the city and state that there is a circulation of the transgendered individuals in the neighborhood, where newcomers are rented rooms and worked in the bawdyhouses of those who are already settled.

Alsancak has been appropriated by the transgender community for almost three decades. The neighborhood embodies a “transgender ghetto” on streets where bawdyhouses and street sexwork is concentrated. Eventhough it is embraced as a living space by the transgendered, they face continous discrimination, exclusion, harrassment and violence in the neighborhood reminding Doan’s (2007) remark on the controversies about the inclusiveness of the queer spaces when transgendered individuals are concerned. Incidences of transgender murders and suicides in the neighborhood are reported in the media. Transgendered sex workers live and work under surveillance, pressure and occasional threats from the police varying in frequency and intensity. They continuously confront the neighborhood complaints and occasionally they become subject to neighborhood campaigns which intend to displace them from the neighborhood (Aylin, Rüya, Fulya, Sezin, personal communication, 2017). Police control is intensified on the occasions when these complaints and campaigns are reported in the local media. Also when the new responsible police chiefs are appointed in the city, police controls get more strict and frequent (Demet from Black Pink Triangle, personal communication, 2017). Media representations of the transgender existence in Alsancak, take sides with the neighborhood campaigns, meanwhile, the voices of the transgendered are only heard in the few publications belonging to the LGBTI associations which have limited followers.

It is also evident from the interviews that Alsancak is not safe either for the transgendered or for other residents especially at nights. While the residents mostly complain about sex work, the sight of sex workers, apparent scenes of bargaining, and noises of the kerb crawlers, both residents and the sex workers complain about the existence of pickpockets, hijackers, drug dealers and users, and gangs of outcasts in the neighborhood. These people, however, mostly target the lone trans women sex workers at night. Events of crime are not rare in the neighborhood, nevertheless residents state that the streets of sex work is unsafe, whereas trans women sex workers think the neighborhood is completely unsafe.

SEXWORK IN ALSANCAK

The situation of trans women sexwork in the Alsancak was reported by local newspapers as the ‘problem of transgenders’ reporting the complaints of the residents and the aggressive reaction they received from the trans women when they voiced their complaints. Residents blamed the use of alcohol and drugs by both transgenders and their clients for behaving aggressively. They stressed the anxiety they felt on the streets at nights and stated that they avoided the streets where sex work took place. Sexworkers are blamed to make disturbing offers to the “normal” citizens who were not interested in buying sex. The

residents added that it was not the existence of the transgendered in Alsancak, but witnessing them soliciting disturbed them. Stressing their frustration by the inaction of the local authorities and inviting them to take action, they complained about the association of 'their' neighborhood, which was once the most decent and the most beautiful neighborhood in the city with sexwork. Neighborhood residents were reported to demand to get back the old 'safe and peaceful' Alsancak. After the local press report about the transgender sex work in the neighborhood the police forces made strict controls on the streets where sexwork is concentrated. This intensified police surveillance and patrolling has also been reported in the same newspaper as "the police gave an end to the transgender occupation in the neighbourhood" (Yeni Asır, 31.10.2016).

In the local press, realtors' comments on the decreasing property values due to sexwork was also reported. They noted that some houses were rented to the transgendered at exorbitant prices to be used as bawdyhouses and some were rented on an hourly or daily basis. Stressing the "moral dimensions" of renting houses to the transgendered, realtors stated that decent residents of the neighborhood were constantly selling out their houses for lesser prices than they worth and moving out because of the "transgender terror".

FORMATION OF SOCIOSPATIAL BOUNDARIES IN ALSANCAK

Transgender community in Alsancak neighborhood can be viewed as a minority sexual subculture. Since majority of them are sex workers they are stigmatized both for their gender identity and for being engaged in sex work. They experience an othering due to the moral panics of the decent residents which are provoked by the media images. In this situation, diversity and difference seems to present a division, polarization, and further marginalization instead of an inclusiveness.

Social boundaries are constructed and maintained through geographical ones that signify distinct ways of life (Pratt and Hanson, 1994). The drawing of socio-spatial boundaries is a political act, it is a demarcation of difference that helps define and label what is 'same' and what is 'other'. The drawing of boundary lines can be either an act of control by the powerful or an act of resistance by the weak (Pratt, 1999). Similarities and distinctions, here gender identity, sexual orientation, and morality determine sameness and otherness precisely. This absolute distinction define social as well as spatial boundaries, where some parts of the neighborhood, particularly some streets are reserved mainly for different groups. But as mentioned by Jackson and Benson (2014), these spaces are not completely segregated enclosed zones but they intersect, traverse and overlap each other, especially at particular times of the day.

According to the local press and interviews, sexwork in Alsancak is concentrated mainly on the 2. Kordon, Şair Eşref Boulevard, Bornova (1469) Street but spreads to 1416, 1454, 1456, 1457, 1460, 1464, 1467, 1469, 1485 streets. These streets are monitored at night by the police with intensified controls especially after the neighborhood campaigns and media reports about the campaigns (Aylin, Rüya, Fulya, Sezin, personal communication, 2017). Neighborhood residents report feeling anxious and uneasy about using these streets at night because of the existence of sexworkers, their outrageous apperance and sights of bargaining. They are mostly concerned for women and children being on these streets (Ahmet from Alsancak Movement Association, personal communication, 2017). Not only these streets, but most other streets in the neighborhood, are viewed as unsafe by the trans women sex workers who face acts of harrassments and violence from the clients as well as from the strolling hijackers and outcasts. Added to this, trans women sex workers confront assaults, threats and pressure from the neighborhood residents and from the police. They report that, eventhough Alsancak is "their territory" they only feel comfortable and safe on the streets in the company of fellow trans women who they refer as "the gang" (Aylin, Rüya, Fulya, Sezin, personal communication, 2017).

Demet from the Black Pink Triangle (2017) reported that she and her trans women friends frequent cafes and bars owned or managed by women or LGBTI individuals, and they avoid cafes and bars owned by male chauvinists where they feel harrassed. A point that came out of the interviews with catering businesses is that the transgendered are not welcome in some cafes and bars on the drawbacks that they might cause trouble by behaving improperly. It is reported that they will only be welcome on the condition that they behave properly. Some residents speak of them in a tone of tolerance as they point out that they greet them, and they treat them kind "eventhough they are not like them" (Berna, personal communication, 2016) reminding Valentine (2008) as he interprets 'tolerance' as a signifier of an unequal relationship.

Trans women sex workers face discrimination and social and spatial exclusion as they are often rejected as tenants. Even when they own flats in the neighborhood they report being unable to inhabit them due to the threats of the neighboring families. Aylin (personal communication, 2017) could only move to her first flat in the neighborhood five years after buying it. Now, as the owner of six flats in the neighborhood, she has a prerogative to choose who will live in her proximity. On occasions, discrimination against the trans women extends to the highest ranks of bureaucracy. As one of the governors of the city of İzmir called for the home owners in Alsancak, not to rent their properties to the trans women sex workers who are bad examples for the society spreading fear and disease (Vali Göksuya Ayrımcılık Uyarısı, 2004).

Urban planning has no involvement in management or regulation of sex work in Alsancak, since sex work is not recognized by any means in Turkish planning system. However, it might be indirectly influential on the transgender existence in Alsancak, as their first noticeable visibility in the neighborhood coincided with the implementation of new spatial plans in the area in 1985 (İmar ve Şehircilik Daire Başkanlığı, 2015) which resulted in the degradation of the residential quality of the neighborhood. This implementation plan made it possible to have miscellaneous commercial uses in the neighborhood which led to the opening of many businesses which were not quite compatible with the residential uses. Some of these uses, related with night life and entertainment, attracted new residents to the neighborhood. Consequently, many better off households moved out of the neighborhood as the properties they left became accommodation options for the newcomers, some of whom were trans women (Former Director of the Department Of Development in İzmir, personal communication, October 2016).

5 CONCLUSION

Divisions in urban space marked by boundaries reflect patterns of social difference and inequality, as they reinforce existing social and structural divisions in society (Joseph, 2008). Difference signified by gender identity or sexual orientation is not regarded affirmatively in the masculine society. The otherness of the trans women sex workers in Alsancak, as gendervariant individuals engaged in prostitution, produces a polarization, division and further marginalization instead of an inclusion.

The appropriation of a part of Alsancak Neighborhood and labelling it as 'Transgender Ghetto' can be viewed in terms of challenging the straight space as Hubbard (2000) asserts. Nevertheless, Doan's (2007) remark about queer spaces that they offer only partial protection for gender variant people seems to be true for Alsancak. Though queer spaces are considered as safe spaces for sexual dissidents, they are not free from harassment and violence because of their gendered nature. The inclusiveness of the queer spaces are questionable particularly when transgendered individuals are considered.

The coexistence of the transgendered and others in Alsancak mostly presents a 'parallel lives' situation which does not promote any sincere interchange (Valentine, 2008). In Alsancak, spatial proximity has caused defensiveness and the bounding of identities and communities as Young (1990) suggests. In line with Valentine (2008) the close proximity of the transgendered and other residents in Alsancak bears the potential of "reactions out of intolerance" ranging from rudeness, to discrimination, violence and even to hate crimes. Even behaving in a civil or decent way in public does not testify being free from prejudices and judgements, therefore does not lead to respect for the other. Tolerating the other, stresses an unequal relationship, in which a dominant, or more legitimate group may choose whether or not use tolerance (Valentine, 2008). Processes of exclusion, "by which those who claim belonging to the place define themselves against what they are not" (Butler and Robson, 2003) work in the making of Alsancak neighborhood.

After a long period of neglect concerning the needs of the minorities, there has been an acknowledgement that inclusion and diversity should be the among the main concerns of the planning (Healey, 1997; Sandercock, 1998). This is not yet the case for Turkish planning practice which neglects sexual minorities along with the other disadvantaged. Hence, spatial plans in Alsancak are made without any social analysis of the area. On the other hand, the need for voicing the claims and rights of sexworkers (Hubbard, 2001a), as well as LGBTI communities (Doan, 2001b) is stressed in the decision making for planning in order to have a true understanding of their circumstances in the city, for socially-just, inclusive and safer cities for all.

ID 1586 | MAPPING INFORMALITY: THE CASE OF STREET FOOD IN THEWET, BANGKOK

Sirirat Sornprasit¹

¹Department of Urban and Regional Planning, Faculty of Architecture, Chulalongkorn University
sirirat.se@chula.ac.th

1 BACKGROUND OF STUDY

Street vending are the most primitive form of informal trade which nowadays, continuously playsthe important role in economic and social capital in many countries, especially in the developing world. Street vendingoffers the easy access to get cheap food and commodity as well as job opportunity with low investment. Moreover, street vending vibrates public space and activate urban livelihood through the exchange and trading.

Bangkok is a prime case where street vending play considerable role in many dimensions. According to the previous study on the emergent role of Bangkok street vending in response to the changing urban context due to socio-economic change, technological change, and climate change resulting more frequent and severe urban flood disaster (Sereerat, 2013). The study revealed the informality of street vending is the mechanismdriven by 3 performances: flexibility, mobility, and resilience, in providing access to food and necessity to citizen both in everyday life as well as during crises. Street vendors as a result is a resilient urban element that can meet inclusively the basic needs of all citizen. In social aspect, street vendor's informality and inclusiveness also maintain vitality during critical condition through the reciprocal help. This finding could be apply to the more resilient urban design and planning for the future urban Asia.

While the importance of street vending and its potentials is increasingly widely acknowledged through, development studies, socio-economic studies, architecture, planning, urban design and urban studies, there is considerable disparity on how they should be defined and approached as elements in urban study. As the informality of street vending also have negatively driven both socio-economic and environmental problems such as the chaotic growth, out of law, traffic congestion, dirt, pollution, privatization of public space, image of poverty. Street vendor are considered as an unwanted urban element for Bangkok public sector policy makers, urban designer as well as a part of citizen.

Under the supervision of the Bangkok Municipal Administration (MBA). Bangkok is one city trying to fix chronic problems due to the street vendingactivities for several decades in order to modernization and beatification the city. Which has used several measures such as formalization through licensing, clearance, allocation to new arable, space management, and latest measure was the clearance without correctly public participation process. However, the results in many such cases street vending area in Siam Square, Silom, or Bobea were not successful as expected. Or in some cases the clearance and allocation had done successful only in a short period and not standing still. As can be seen from the return to vending space. Moreover, illegal street vendors are still increase dramatically. The study shows top down management, use of force to suppress or forced allocation without public partition process of understanding together to find solutions together to reflect on the context and the needs of the public, including households with street vendors. The Participatory planning is a tool that has been widely accepted and used in the planning of the development and widespread. Because the process of discussion is important in helping to coordinate incompatibilities, conflicts and work together to find solutions that lead to a common agreement among the stakeholders (government, private and public), however, bringing the discussion to organize street vendors cannot be applied directly. Due to the characteristics of street vendors in Bangkok by a trade system that is linked to the informal network of other related benefits, both directly and indirectly. The structure of the stakeholders are complex and difficult to get cooperation to reveal his identity to contribute to discussions.

2 RESEARCH GOALS AND OBJECTIVES

The goal of this research is to redefine the research framework on street vending aiming to understand how street vending eventually related to urban system. In order to achieve that goal, the empirical study

would be conducted in urban network perspectives. Accordingly, the objective of the research is to examine the relationship between informal and formal activates occurring thoroughly the process of illegal vending on street.

3 RESEARCH FRAMEWORK AND METHODOLOGY

According to reviewing literature on street vending, most of studies usually narrow research framework into some specific dimension such as poverty and labour, public space, informal economy, crimes, urban environment, urban sociology and so on. For public sector as well, street vendor is considerate as problem maker on sidewalk and public space, not traders, or other perspective.

In order to understand how street vending really effect to urban system. It would be re-investigate street vending as a whole process and systems that need time and mobility to operate the trade using supply chain analysis approach as a tool. This study will focus on food street vending that have a cooking process but each of activities were operate not in one place or kitchen, in many location within the city. As a consequence street vending would not be study only on street vending area alone, but also the co-related places such as goods resource place, stock place.

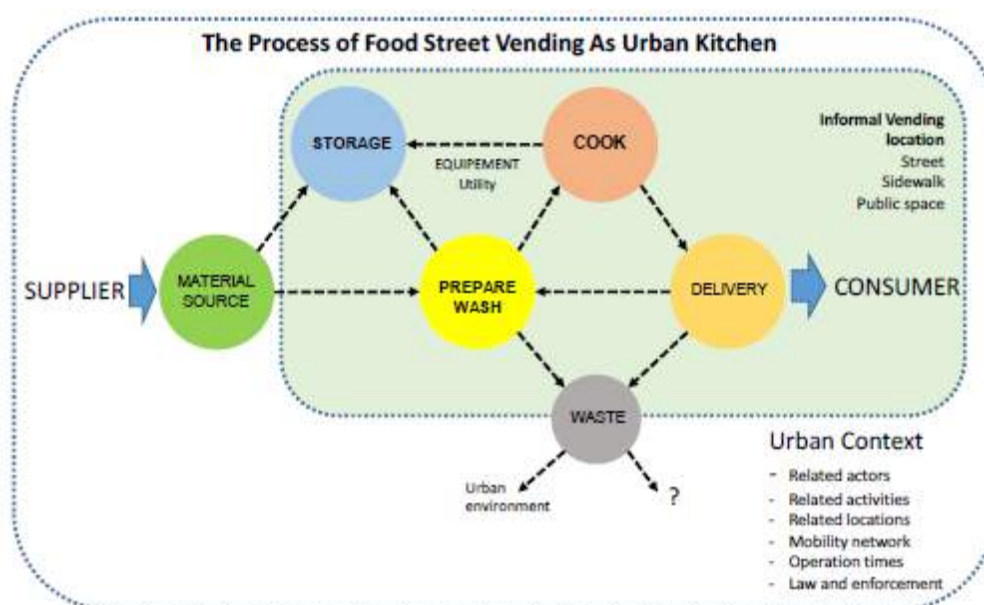

Figure 1 – Research framework

4 FIELDWORK AND MAPPING

This empirical study used food street vending areas around Thewet Market as its case study, and site investigations were conducted in January of 2013 (Sereerat, 2014). Quantitative data was gathered through the spatial surveys and qualitative data was gathered through interviews with street vendors. The data gathered from fieldwork were collected in form of cartography in 2017 presenting the process of street vending in relationship with time and place within urban network.

1. Survey of Street Vendors (previous study)

A preliminary survey was conducted in order to define the nature of street vending activities in this specific context in the time-space dimension. The surveys were conducted at three intervals during the day, according to the uses of the sidewalk by street vendors on weekdays as well as weekends. Notes, drawings, photographs and videos were collected on-site to provide related spatial context data such as the number of street vendors divided by gender, spatial typology, vending mobility, and items sold. The collected information was then mapped together with the surrounding context such as road networks and accessibility, buildings and land-use characteristics.

2. Interviews with Street Vendors (previous study)

A quasi-ethnographic interview approach was used as the research instrument for collecting data from the street vendors. Convenience sampling was used to conduct interviews for gathering information about street vendors in two dimensions: the socio-cultural dimension and the time-space dimension. Questions were formulated on the basis of key questions and the hypothesis derived from the literature review and research objectives. About sixty potential respondents were screened for a controlled distribution of age, gender, mobility and items sold. Potential respondents were then identified and, when the purpose of the study was explained, nearly all those invited to participate were willing to do so and a total of 50 data sets were collected.

Regarding the structure of the questionnaire, the questions were categorized into two main parts. Questions in part one were related to socio-economic data, time of use, type of goods and services provided, form of employment (full-time, part-time, etc.), equipment provided for selling the goods, customer attraction, effected laws and regulations, social behavior, environmental morality, and happiness and well being. In part two, the questions focused on the physical attributes of street vending such as stall type, mobility, selling space dimensions, supplementary equipments, work environment, customer attraction and identity.

3. Mapping street vending activity

According to Laguerre 1994, the mapping and marking the informal activities became a means for exploring the definition of informality. It appeared that the existing activities resisted the formal systems, structures and intentions of the space. Laguerre recognizes this resistance of the informal but states that the informal emerges in two directions, "either through the intentionality of the actor, or through the external construction of 'informality' by the audience". This study as a consequence would apply mapping as a tool for exploring the system of street vending using the street vending in Bangkok as a cases study. Using the data from survey and interview recorded in 2013, there were 27 cases valid for mapping from 50 interviewed cases.

5 STREET VENDING AROUND THEWET MARKET

Thewet is a well-known old commercial district located in the inner city (old city) area. This area was named after the old palaces, Wang (Palace) Thewet and Wang Thewawet, constructed in the Rama V period (BE 2416-2458). Thewet Palace now is being renovated and Thewawet Palace has become a part of the National Bank of Thailand. There are also several important temples around this area such as WatThewarat, Wat (Temple) InthraWihan, WatBenchamabopit and WatNoranatSuthirkaram. Since Thewet has a long history of settlement, there are old communities attached to the fringe of the temples mentioned above. Markets and shophouse rows are situated along the Sam-Sen Road and Phadung Krung Kasem Canal. Before the 1990s, Thewet and Bang Kun Prom (an area well-known as a dress-making district and recently an area for street vending opposite the National Bank of Thailand) abounded with commercial activities. However, after urbanization began to spread outside the old city, the small shops and restaurants along Sam-Sen Road drastically decreased. Only the markets and some of the shops and eating places have remained active until this day.

Street vending in the Thewet District overall presents a strongly local feel. The visible features of street vending in this district produce a very conventional image of street vending, or an image that can be found in other places in Bangkok as well since the 1990s. Vending sets, which include pushcarts or stands with parasols that can be both mobile or stationary, are the prominent element of the Thewet street configuration. This image of street vending is similar to that found along Phahurat Street, which can be defined as parasitic urban elements in a reciprocal social system. However, according to survey, the identities of street vending in Thewet were found to be more diverse than its image suggests.

In terms of the spatial context, there were two main factors related to street vending. First, Thewet Market is an old market located just next to the interchange hub for several important bus routes as well as the ChoaPraya ferries (ThaThewet-Thewet Pier). Second, Thewet Market is surrounded by shop-houses, several governmental offices, state enterprises, places of education, and temples. The mix of land-uses in

this area has resulted in street vending also becoming varied in accordance to the vendors' main customers.

Figure 2 – Thewet district, 2013

Figure 2 – Map shows the distribution of street vending in Thewet district, 2013

6 FINDINGS

Street vending in Thewet is well known for creating a food street hub where local people and workers can come to purchase foods and have meals, especially at dinnertime. Street vending in Thewet generally accumulate near the markets, connecting bus stops and workplaces. Spatial observations revealed the use of traditional forms of intervention, such as pushcarts with parasols, their mobility and the items sold for everyday use. The analysis revealed the contextual influences on street vending identity. They were rich in the sense of locality and reciprocity, but were mostly vulnerable, poor and not very well educated.

The results from interview revealed that most of the street vendors earned incomes higher than minimum wage, more than half earned more than the starting income for employees with a bachelor's degree.

However, their working hours were also relatively longer than that of formal employees. There were also street vendors who earned high incomes; most of them had started their businesses with very low incomes and had emigrated from rural areas.

The typical type of street vending found in Thewet was street vendors selling food in pushcarts or stands with parasols. However, they were mostly static and sold in the same place. Some of them had two to three regular vending locations. They usually lived near their workplaces, in shared rented houses in old communities near the temples or slums. There were also street vendors who lived far from the Thewet district, however they had started off living in the Thewet District and had moved out because their rental places had been destroyed. Stall-type vendors selling non-food items were mostly found in front of workplaces, and the form of vending showed the relationship between income and spatial organization; higher-income vendors tended to be static, making high investments in strategic vending spaces. Interviews with food street vendors revealed the self-organization and reciprocity among them. However self-organization was rarely found in the younger generation of street vendors. Systematic, easy and fast installation allowed the possibility of reuse of urban spaces at multiple intervals during the day. This spatio-temporal identity could be defined as the “overlapping territorial identity” of street vending. The spatio-temporal identity in this area was quite unique, and could be defined as a “weekly cycle of overlapping territorial vending spaces.” Because there was only one vending interval, but there were different vendors in the same vending lot during the week.

Hawkers or mobile street vendors were also found in this area; most of the hawkers were engaged in the hiring system with patrons who provided their job and accommodation. This type of vendor usually worked as a street vendor seasonally, when they had free time from rice farming in another province. It can therefore be concluded that the role of street vending is to form an exchange between the urban and rural cultures.

Case study	Thewet
Urban context	Local
Spatial context	-Inner city -Old commercial district -Administrative zone -Interchange bus stop, bus terminal
Land tenure (sidewalk)	-Public -Bangkok Metropolitan Administrative (BMA)
Permit for street vending	-Temporarily Permitted Area (TPA) at specific days, times
Street vendors	Conventional
Items sold	Street food and low-end product
Market awareness	Passive
Working hours	Long
Employment status	Vulnerable
Entering to SV	Come from rural areas
Income (Net)	Low income Avg. 20,000 Bth/m Min. 3,800 Bth/m Max. 100,000 Bth/m
Education	Low education level
Social relationship	Reciprocal system Close relationship
Roles of street vending	
Economic	-Informal -Local economy -Urban inclusive
Employment	-Migrated from rural areas -Automaticity -Seasonal job
Market place (Shopping place)	-Local market place -Gathered around market -Food, fruits, groceries, cheap clothes -Cheap price - Orange juice 15 Bth
Customers	-Local people -Bank officers, Administration -Military workers, students
Social	-Reciprocal system -Urban surveillance
Culture	Urban-rural cultural exchange

Table 1 - Summary of street vending in the Thewet District

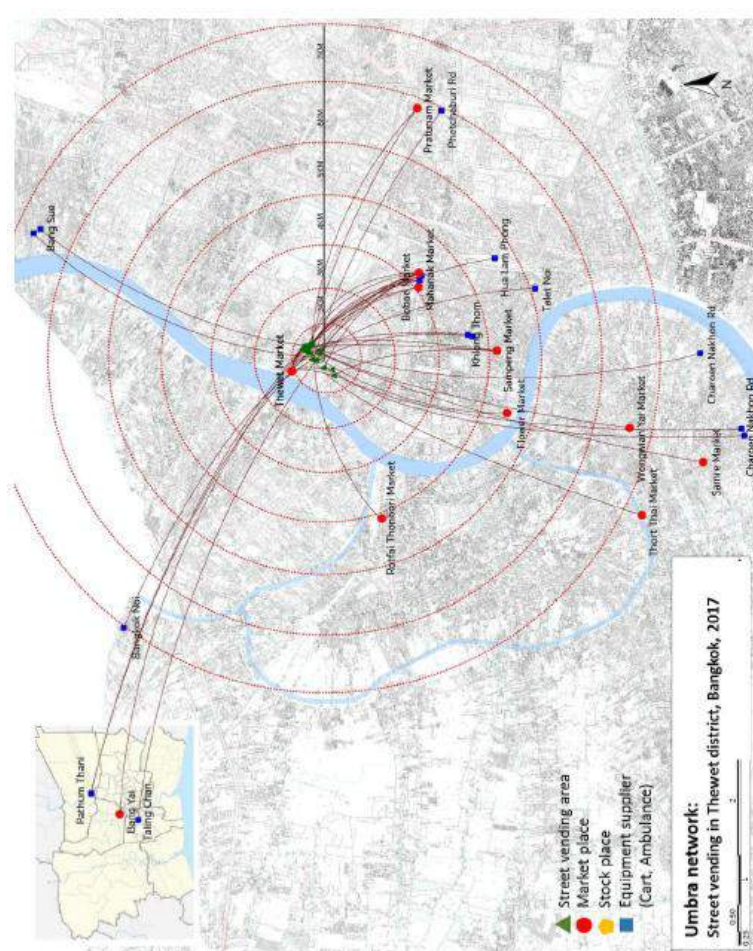

Figure 3 – Map show the umbra network of 27 examples street vedings that connect to other urban network both fomally and informally ways, 2017

7 CONCLUSION AND DISCUSSION

Mapping street vending activities reveal the more clearly that street vending activities performs informally but in a systematic trading process in which connected to urban network.

The use of shading devices such as parasols or plastic sheets was a commonly adopted mechanism in street vending in this area. These shading devices usually overlapped with one another and, side by side together, they unionized all the small vending units into one linear system connected to the building nearby. This could be called the parasitic element. The “umbra network” is a soft urban network line stretched along urban networks temporarily and informally. The term “umbra network” also expresses the living-in-the shadow culture due to local climate and the vendors’ reciprocal social relationship, as well as their shadowy economic features. These umbra networks are an important informal and temporal urban element that should be taken into account in the Asian urban morphology.

In Thewet, “self-made” public spaces also emerged through informal urban elements; this included the flow of users, activities and objects, and included street vending as a key element. These spaces provided a unique feel to the area and could imbue a given public space with liveliness and a spatio-cultural identity. A cross-cultural analysis revealed the complexity of this system as informal elements merged into public space, territories were blurred, public space became the private space of passageways to another shop, and public spaces were occupied by street vendor stalls. These result affirmed that Asian streets are rich in the multi-layering of space and time. They also proved that these kinds of streets have a two-sided characteristic of simplicity and complexity.

ID 1588 | THE ANTHROPOLOGY OF MODERNIST MASS HOUSING: A TOOL FOR URBAN PLANNERS

Giulio Giovannoni¹

¹Università degli Studi di Firenze, Dipartimento di Architettura
giulio.giovannoni@unifi.it

ABSTRACT: Although the modernist failure myth largely descends from Jane Jacobs’ work, many of its advocates abandoned the observational method on which the American author grounded her work. Not only generalizations about the alleged failure of modernist architecture ignored non-environmental factors and disregarded the differences which characterize modernist public housing neighborhoods, but also they were unable of getting direct knowledge of how real life works in them. If we assume that each modernist public housing neighborhood is unique and different from all the others, as it is certainly the case, then we need to get first-hand knowledge of how it works. Starting from the review of anthropological research on modernist mass-housing in different countries this section of the course will discuss the implications of such research for urban planners.

work because they lack in everyday life. According to Newman (1972) such deficiency – and the crime which descends from it – depends on the way such neighborhoods are physically designed. Although Newman certainly demonstrates the existence of a correlation between physical design and propensity to commit crime, the relative relevance of the physical design factor in explaining the alleged failure of modernism is largely overestimated. Furthermore, the peremptory and final manner in which the whole modernist movement has been dismissed by Newman, Jencks, and many others, diverted scholars' attention from studying the inevitably complex social life that, for better or for worse, modernist neighborhoods undoubtedly host. Even in Pruitt-Igoe – that is in the paradigmatically badly conceived settlement according to crime-prevention-through-environmental- design criteria – a small number of interviews with former residents unveils an unexpectedly rich tapestry of memories and experiences. Before the intricate economic, social, and political conditions of postwar Saint Louis drove it to failure, a warm sense of family and community existed among its residents, as recounts Jacqueline Williams: There were friendships and bonds formed there. Perhaps these lasted a lifetime. I know a lot of bad things came out of Pruitt-Igoe, I know they did, but I don't think they outweigh the good, I really, really don't, because at first Pruitt-Igoe was just a wonderful place: it was wonderful! All former residents interviewed by Friedrichs provide an excellent account of their first years in the Pruitt-Igoe 'hell'. What is mostly significant about their memories is not only the emotional content, which can be easily distorted by time and by adolescence idealization, but the way space appears in their descriptions. It is in fact more difficult to reinvent or even to distort the way space was used. As an example, for Sylvester Brown Pruitt-Igoe "was a place we played hard right up and down this long breezeway, and up and down the steps, and running around. And so it was a place where kids could really re ally have a chance to play hard". In the memories of Valerie Sills, all that even produced a strong sense of safety: Pruitt-Igoe was a safe place for me, I mean I don't care what people said about it. They lived outside it. If you didn't live in there you thought it was a bad place, but growing up in there was ... you knew the people and you were never alone. I have to say you were never alone because somebody crossed the house, somebody down under you, somebody up over you, there's people here, there's lights here, there's life here, and so I'm not alone and I'm not afraid.

If then we move from Pruitt-Igoe – and from the intricate economic, social, and political conditions of postwar Saint Louis – the situation is even richer and more variegated.

The few studies which have been carried out on everyday life in modernist neighborhoods show very interesting results. The anthropological research undertaken by Jean-Françoise Augoyard (2007) in the 'Arlequin' neighborhood of Grenoble, France, and that conducted by Noël Jouenne (2005) in the Corbusian neighborhood of Firminy-Vert, also in France, will be reviewed here. They both highlight the limits of approaches – such as crimeprevention- through-environmental-design – which attribute to space and to build form itself a deterministic power over people and their social experience.

3 L'ARLEQUIN NEIGHBORHOOD IN GRENOBLE: EVERYDAY WALKS AND THE DECONSTRUCTION OF DESIGNED SPACE

The Arlequin neighborhood belongs to the so-called Villeneuve (New Town), a modernist settlement built between the mid-1960s and the mid- 1980s straddling the municipalities of Grenoble and Échirolles, in Rhône- Alpes, a south-eastern region of France. The Villeneuve was developed according to a schéma directeur, which envisaged six neighborhoods of 2000 apartments each, located around a large central area for community services and facilities. The Villeneuve project had a strong resonance in France and entailed the coordination among a number of central and local authorities. The whole program was based on the following design principles: mixture of land uses; simultaneous realization of public services foreseen by the plan and of other residential uses; centrality of public transport; creation of a certain number of working districts close to the Villeneuve.

Apart from the unitary design of the major service and infrastructure elements envisaged by the schéma directeur, each quarter of the Villeneuve is largely different from all the others, having been built in different times and according to various design criteria. The Arlequin neighborhood, built between 1971 and 1977, is one of the three neighborhoods belonging to the municipality of Grenoble, together with the Olympic Village (1965-1971) and with the Les Baladins quarter. It is a sinuous north-south-oriented 1.4-kilometers-long structure, with 120-degrees-inclined branches stemming from it at regular intervals. The building-

height varies from six to twelve stories. The whole structure is raised on pilotis, its ground level hosting an unusually long uninterrupted pedestrian gallery. The name of the neighborhood is due to the polychromatic facades of the building. Beyond being a representative example of modernist architecture, the Villeneuve project was the subject of an important research conducted by Jean-François Augoyard (2007), which clearly demonstrates the complexity and subjectivity of the relationship between designed space and human behavior.

Augoyard's research is based on a simple but seminal insight: by walking in one's neighborhood people express their own personality. Therefore, the way a neighborhood –as well as any other living environment– is 'walked', changes from person to person. But since there are countless ways of tracing paths in one and the same space, people's walks can be studied and analyzed in the same way as a language. However, one's personality is manifested according to a 'linguistics of walking' which can't be simply decoded by observing and recording the paths traced through space. Each single walk corresponds in fact to a complex experience which is, in many ways, unique and not replicable, consisting at least of a sensory dimension, of a socio-relational dimension, and of an imaginary dimension: only verbal language can reveal its complexity.

In the light of the above, the analysis method is based on the reconstruction through narration of these 'walking experiences' done in the Arlequin neighborhood by a sample of its inhabitants in different moments of the day and of the week. In fact, in the words of Augoyard (2007, 19), «oral expression ... has appeared to us to mimic quite closely the act of strolling. Like the latter, it is fluid, prone to digressions, capable of forgetting what is apparently essential and of lingering over details. Is it not another expression of an identical way of being?»

In the act of walking there are always a proactive component and a passive component, as there are in the act of reading: «The analogy with graphic expression is unendingly striking. Just as a book is read in company with a motionless (re)writing and is written at the same time that it is read for oneself and for others, walking resembles a reading-writing». If daily walks are a form of expression, a walking rhetoric exists which is «the translation of both the organization of the styles proper to each inhabitant and the correlations among these styles within a shared space» (p. 26).

The first observation that can be made before studying the inhabitants' walking rhetoric is that designed space does not exist as a whole in lived experience: «ignorant of spatial totalities, the inhabitant can exclude without refusing. This is the exclusion of an unrecounted, un-lived territory, which is equivalent to a pure absence» (p. 28). It is important to stress that as pure absence the excluded territory is neutral to the inhabitant's experience and therefore does not pose a problem to the inhabitant.

Inside the space which he actually uses, the inhabitant materializes his walking practice through a multitude of rhetoric figures. Different personalities and various styles of inhabiting express themselves starting from the elementary 'figures of avoidance': paratopism, that is the form of ambulatory practice that proceeds via substitution of one path for another (p. 29); and peritopism, that is the variation of a path through a multitude of variations. The same architectural/ urban spaces take on completely different meanings not only when walked by different subjects, but also when traveled in different moments by one and the same person. This is for example the case of the mezzanine – a passageway internal to the building that doubles the unusually long ground floor gallery – which is simply avoided by some inhabitants, while being looked for by others for its quietness, for a temporary pause for thought, or even for an ambulatory night experience in a space which is imagined as a fascinating labyrinth.

The complexity of meanings that the architectural designed plan takes on in everyday walks is expressed by what Augoyard calls 'polysemous figures': ambivalence, occurring as the meaning of an element ranges between two opposite poles; staggered polysemy, happening as an element takes on several meanings which are similar and interconnected; bifurcation, describing one's behavior in correspondence to a choice point along a path; and metathesis of quality, occurring as «the repeated traveling through one and the same site can accidentally change in quality via nothing more than the effect of a difference in one's everyday chronological cycle» (p. 48). This body of figures shows that in everyday life designed space loses its functional and monumental monosemy: «the variety of usages ruins its beautiful clarity as a finished product» (p. 41). The figures which have been described up to this point are elementary figures, for they apply to single paths. The figures of redundancy and those of symmetry, instead, are combinatory figures which are noted at the scale of whole trips and of complexes of walks. The figures of redundancy

introduce in the act of walking the irrational element of pathos. The metabole is used to describe the various 'tones' (e.g. ironic, poetic, or playful) with whom a walk is carried out. The anaphora describes a walk featured by a centripetal dynamic around an attractive element which is mainly symbolic. The hyperbole denotes a deambulation which is overloaded with meanings that translate themselves in 'exaggerated expressions' (as when the verb 'to scale' is used to describe a walk up the mound in the park).

The figures of symmetry describe the way paths are combined and organize the orientations of one's walks. The properly called symmetry presides over all alternations in one's trip. Dissymmetry is produced mostly by accident when, after the departure toward a specific site, the return trip does not happen to occur as foreseen and another route is then taken. Asymmetry may be observed in all cases where a trip is affected as a whole by multiple and divergent variations. This body of figures shows the way designed space is disorganized and broken, often in unpredictable ways, in everyday uses.

The two last rhetoric figures of walking described by Augoyard, synecdoche and asyndeton, operate on the level of the relationships between the parts which make up the whole trip. The synecdoche concerns the relationship between whole and parts, when the part stands for the whole or the whole stands for the part: as in the case of a specific portion of the park, described as "the park" tout court; or in the case of a space which is identified by reference to one of its specific elements («Often, I go into the space that is dirt-covered ... toward the dragon, voilà!»). The asyndeton, instead, describes the links through which every element of expression (part of a route) follows another one of them in the constitution of the expressive whole. Augoyard's thesis is that ambulatory expression is grounded on an absence of connections. Walked routes would be made of basically discontinuous fragments. This is the major structural difference between the literary text and the text produced by the act of walking.

The afore-described rhetoric figures of walking are used by Augoyard to study the different ways space is appropriated by the inhabitants of the Arlequin neighborhood. These seem to reconfigure designed space in almost infinite manners, so to make us look almost irrelevant its capacity of conditioning the ways of appropriating space by its inhabitants. As an example, whilst for some of them the space which is perceived as 'domestic' shrinks up to coincide with their bedroom, for others it broadens up to include a wide portion of the gallery. The difference in the ways the neighborhood is appropriated are reflected in the language which is used to name places, which changes in different groups and sub-groups, and makes us appear the frequentation of a space as inseparable from the process of naming that characterizes that space. The notion of boundary gets fluid, being there no appropriation «that would have a definitive meaning or that would be established once and for all» (p. 16). Finally, ambulatory practices are enriched by an imaginary dimension which disproportionately broadens the possible meanings which one and the same spatial element may assume.

Conclusively, the decodification of the walking rhetoric performed by Augoyard makes appear dangerously reductive Oscar Newman's and Jane Jacobs' environmental determinism, and allows us to extend Bristol's observations from 'Pruitt-Igoe myth' to the whole 'modernist-failure myth'. Once again, environmental determinism legitimates the architecture profession by implying its capacity of solving social problems, and shifts the attention from the real causes of public housing problems. To Bristol's observations, we should add that the modernist-failure rhetoric also prevents us from appreciating the variety of social and physical situations which modernist neighborhoods have, and which necessarily require very specific policies in order to be managed. The Corbusian unité d'habitation of Firminy-Vert, which was studied by anthropologist Noël Jouenne (2005), provides us a good example of the kind of policies which would be necessary to make these housing complexes correctly run.

4 FIRMINY-VERT: EVERYDAY LIFE AT "CORBUSIER"

The unité d'habitation of Firminy, built between 1965 and 1967, is the last of the five unités – among the thirty globally designed by Le Corbusier – which have been ever realized. It is located in the modernist neighborhood of Firminy-Vert, built after 1953 thanks to the commitment and to the resolution of Eugène Claudius-Petit. This important French politician, who served as Minister of Reconstruction in French government 1948-53, gave up his national political career in order to realize his urban planning ideas as a mayor of Firminy. The neighborhood, designed according to Athens Charter principles by a group of modernist architects, hosts twelve residential buildings of different lengths and heights, a tower-building,

the Corbusian unité, two shopping centers, and several community equipments. Two of these – the Maison de la culture et de la jeunesse (House of youth and culture) and the church – were also designed by the Master.

The work by Noël Jouenne is exclusively related to the Corbusian unité d'habitation. This is a big rectangular north-south oriented building 130 meters long, 21 meters large, and 56 meters high. It is the biggest of the five realized unités, containing 414 apartments (against Marseille's 337) for a population of up to 1800 inhabitants. The building was designed following the same principles adopted in Marseille, such as the elevation on pilotis, the façade libre, and the location of common services on the roof terrace (school, swimming pool, etc.). However, it was built with a quarter of the budget used in Marseille, giving up the realization of underground parking areas and economizing on many things, from insulation to finishing works. The apartments, of different sizes and typologies, are located on seventeen floors, organized on seven internal passageways. Most of them cross the building and face both west and east. The whole construction was designed using a Modulor 2.26 meters high and 1.83 meters large.

The research, based on anthropological methods, entailed observations and interviews over a period of one and a half years. One of the first questions which it tries to answer is: "How did people come to live to Corbusier?" Obviously enough, people moving to the unité d'habitation can be divided into two major categories: that of the ones moving by necessity, and that of the ones moving by choice. The second of these categories is the most interesting to our purposes. Among the factors which appear to be determinant of that choice is the positive image which is conveyed by the name of Le Corbusier, and by the idea of the Ville Radieuse: as in the case of a man reminding his father while driving close to Firminy-Vert and saying: "Here is the Ville radieuse!"; or in the case of a woman, who talks of "an element of utopia" guiding her housing choice. This fact is consistent with Pinson's (1996) observation that «the exceptional character of the Corbusian unités prevented them from being trivialized» as it happened, instead, in cases such as le banlieu and other similar modernist developments.

What is interesting about the myth surrounding Firminy-Vert's unité d'habitation, is not only that it attracts many people, but also that it conditions the administrative behavior of public housing managers. Applications to the local public housing authority for apartments at Corbu were often supported by covering letters written by the mayor. "Obviously, says the Mayor of that time, if we wanted to fill up Corbusier with immigrants that would have not been a problem. But Corbusier would have become a ghetto, and so Claudius-Petit tried, as well as I did, it shouldn't be said, to maintain a certain quota, because beyond that life would have become impossible for all of us". So in a sense, the image which by Le Corbusier is conveyed acts as a corporate brand, guiding people's behavior in many different ways. It is in this way that the unité becomes a socially mixed neighborhood, hosting not only low-wage families but also many teachers, architects, youths, and other middle class members.

The distinction between the ones who chose the unité by necessity and the ones who moved there by choice is somehow reflected in two distinct patterns of behavior concerning the duration of their stay. Although to the forty percent of the inhabitants Corbu represents an ephemeral 'habitat' which lasts up to a year, to a fifth of them it is a stable living environment which is inhabited from ten up to thirty years. But although the positive image conveyed by the architect's name is certainly influential on such a choice, other important factors also come into play. In fact for many families the long permanence at Firminy-Vert is part of a wider life project aimed at gaining access to the property of a house. This is made possible by the low cost of public housing rents.

Some of them are young people, as it is testified by the case of this former resident: Personally I lived at Corbusier and when I left I moved to a small single-familyhome development. In fact on my wage I couldn't afford to build one. I bought "turnkey" and it wasn't too expensive... But honestly, if I had the means to build a house my own way I would have inspired myself a bit more from the home which I knew at the unité d'habitation. Strictly related to long-term permanence at "Corbusier" is the social practice of apartment changing. This is made possible by at least three factors: the high number (at least thirty) of apartment typologies designed by Le Corbusier; the elevated turnover rate of apartments; and the relatively high vacancy ratio. These three factors provide an interesting kind of flexibility which allows families to easily adapt their dwellings to their changing needs.

It is also interesting to consider one of the main problems perceived by people inhabiting the unité: that of noise disturbances. The intricate manner in which apartments are composed means that each of them has

a high number of adjacent neighbors. Most of them gain access to their apartment from different streets and never meet each other. This makes the presence of an acoustic insulation one of the major requisites for the quality of everyday life. As we have seen, initial budget limitations determined significant cuts exactly on that item of expenditure. However, it is also interesting to notice how strongly the perception of noise disturbance changes across different cultural and ethnical groups: whereas to some northern-Africans noise appears to be synonym of life, to other inhabitants it is mostly a source of annoyance. These cultural differences would have significant implications for the way these estates should be managed.

5 CONCLUSIONS

In concluding this essay at least two orders of considerations are possible. The first regards the opportunity of substantially reviewing the narratives which condemn modernist architecture per se. Such opportunity is supported by two reasons. The first reason is that such narratives don't take into the right account the many and complex factors which determined the failure of some modernist architectures. This conclusion, strongly supported by the review of Pruitt-Igoe case, is also confirmed by the cases of Grenoble's Arlequin and of Firminy-Vert's unité, which are in fact examples of correctly working modernist neighborhoods. The second reason is that such critiques are grounded on environmentally deterministic approaches which appears to be, if not completely fallacious, at least substantially reductive in the light of the complex and unpredictable ways in which the living environment is being appropriated by different users. In both l'Arlequin and the unité the one and the same environment allows completely different lifestyles and relationships to space. Although some of Newman's arguments on the correlation between crime and physical design are certainly strong, it is time to fully reconsider their relative importance in explaining socially unsuccessful architectures. The necessity of reviewing the aforementioned narratives becomes particularly strong if we consider, as argued by Bristol (1991), that one of their effects is that of concealing the major causes which determined the failure of many mass housing projects.

This leads us directly to our second order of considerations which concern the major feature of modernist mass-housing buildings: complexity. Buildings conceived to host thousands of people, such as Firminy-Vert's unité and l'Arlequin's apartment blocks, are incredibly complex "machines à habiter" which require to be designed, built, and managed as such. Although Le Corbusier was a master in managing complexity, the way Firminy-Vert's unité was built and managed didn't take complexity into sufficient account. A cut in the budget for acoustic insulation could significantly alter the environmental comfort of inhabitants. Even an apparently insignificant change as that of the colors of passageways could have the significant effect of making difficult to many children orientation in passageways. This leads us to the final conclusion that modernist mass housing neighborhoods can work great if the resources which are invested in their construction and management are adequate. Although this conclusion may appear obvious, politicians, planners, and public housing managers are only rarely aware of that.

rolee.aranya@ntnu.no ; hilde.nymoen.rortveit@ntnu.no ; david.smith@ntnu.no ; eli.stoa@ntnu.no

ABSTRACT: The paper presents preliminary findings from the first phase of a research project that is aimed at investigating the policy for decentralised local centers (commercial and transport hubs) in the city of Trondheim and an expressed goal of creating inclusive spaces at sub city level, while achieving a reduction in transport related greenhouse gas emissions. We use the case of social integration of refugees in the city of Trondheim to examine the potential of the planned local centers in achieving the expressed goal of creating a sustainable and inclusive city. We situate ourselves in the debate on social integration in the spatial domain viz. social mix versus segregation (Cole and Goodchild, 2001, Fincher et al, 2014 etc.) and the value of creating spaces of encounters (Fincher et al. 2014, Gressgård and Jensen 2015) to study the patterns of interaction among refugee groups in the city and their use of space in the local neighborhoods/ centers for such interactions. We relate these preliminary findings to the plans and policies of the Trondheim Municipality - both spatial and social welfare policies, to contribute to the debates on the role of spatial planning to promote social integration in increasingly diverse medium size cities in Europe. Municipal policy on integration of refugees in Trondheim is limited to the formal and structural aspects of society, while leaving the relational, interactional and cultural aspects to unplanned arenas and self-initiative by the refugees. There have been some efforts to represent the cultural diversity of the city through food and cultural festivals, with limited outcomes. As is illustrated by our preliminary investigations, most informants experience a sense of alienation and isolation, and interactions are limited to people of similar cultural backgrounds and other refugees, mainly in central locations. One of the main findings discussed in the paper is that refugees experience a sense of isolation in the neighborhoods they are housed in by the Municipality, raising questions to the efficacy of the policies of social mixing followed in Trondheim. We also find that spaces of social encounters in the local area have only limited potential to facilitate long lasting contact between the refugees and the host population, unless more targeted efforts for social network building is undertaken. The window of opportunity of the first five years of the 'Introduction program' of the Municipality are critical owing to the close contact refugees have to State

authorities. Disregarding the importance of the living environment and social links and bonds in the local community, is a shortcoming in the integration efforts of the Municipality, one which can be easily addressed. In conclusion, the paper raises questions for scholarship on the spatial dimensions of social integration, some of which will be investigated further in the current project.

1 INTRODUCTION

To develop more attractive local shopping- and service centers, is a strategy towards a more sustainable development in Trondheim. Based on a detailed analysis of the distance from where people live and their access to shopping, the Municipal Development Plan for Trondheim evaluates public transport and possibilities for densification in relation to existing and planned local centers¹. This strategy is largely based on environmental objectives since it is assumed to reduce the need for transport and to minimize urban sprawl. In the development plan, there is also an underlying argument that local centers will become arenas for social and cultural encounters and thus contribute to a more inclusive and diverse city, (Trondheim Kommune 2010). Sustainable urban development means, in a broader sense, a commitment to create an inclusive and diverse city where everyone has equal opportunities to participate. Social sustainability includes, according to Bramley et al (2009; 2010), both the notion of 'social equity' and 'sustainable communities'. While 'social equity' implies that everyone should have equal access to employment, affordable housing, and services such as education, health, recreation areas, and public transport, the term 'sustainable communities' addresses senses of belonging, opportunities for social interaction, safety / security, perceived environmental qualities, experienced house quality, social stability, participation and involvement (Bramley et al 2010).

This working paper discusses the first phase of a research project, addressing questions raised in dialogue with Trondheim town planning office and IMDi (The Directorate of Integration and Diversity), on how to facilitate a more holistic view on the challenges related to the settlement and integration of refugees within Trondheim². Whereas the responsibility of settlement and integration of refugees is organised under the health and welfare office, the town planning office has the responsibility for providing and ownership of social housing. In order to foster a comprehensive sustainability perspective for urban development, it is beneficial to see these sectors together. Further, the potential challenges related to settlement and integration of refugees are seldom explicitly addressed in long term planning strategies (see e.g. Hauge et al, 2015). IMDi stated an interest in learning more about how and in which ways the city is used by refugees, and in which arenas integration actually "happens". Since these being complex questions that are challenging to research, the project uses the local center development plan as a starting point for discussing the unclear spatial policies regarding inclusion and diversity in Trondheim. One important aim of the project is to explore the ways refugees experience and use their neighbourhood and the city, and thus gain insights into how social sustainability issues such as the settlement and integration of refugees could become an integrated element in the local center development. As of now, the plan for local centers is based on the goal to reduce greenhouse gas emissions, while aiming to create inclusive local neighborhoods/areas without any clear idea on how this might be achieved.

The first phase has included a literature review on social integration processes and theoretical frameworks for understanding social integration as experienced in and framed by urban space. Further five student groups (altogether 20 Master students) have carried out mapping exercises and interviews to investigate how refugees in five selected local areas in Trondheim use their neighbourhood, the local centers and the city as a whole. They subsequently discuss how housing, neighbourhood and local centers may facilitate or hinder social integration processes.

¹ In the development plan, local centers are defined as urban areas or neighborhoods with an identifiable center where the population can get access to their daily requirements for shops and services within walking and cycling distance from residential neighborhoods and workplaces (Trondheim Kommune 2013; 2014). Local centers should have a density of minimum 6 dwellings per hectare within a radius of 1-2 km, and should have at least 5-7000 residents and employees in order to justify a feasible provision of goods and services.

² The research project, "Lokalsenterutvikling som strategi for bærekraftige byer – besetting og integrering av flyktninger i Trondheim kommune", is financed by Husbanken (The Norwegian Housing Bank), and runs from September 2016 to December 2017. Professor Eli Støa is leading the project.

In the paper will first present theoretical perspectives on urban planning in the context of integration of migrants focusing on two main approaches, social mix and places for encounters. We will then continue with presenting discussions on integration that we believe will be useful in our further research. Finally we will present some of the main findings from the student work and based on this raise some preliminary questions for discussion. The limitations of using student work should be acknowledged, since we have limited control of the empirical data and the analysis of it. The student assignments are therefore mainly useful as an input, together with a review of relevant theoretical perspectives, into a discussion of issues and questions for further fieldwork within the project. The aim with the paper is to identify challenges related to the role local centers and housing may play in integration processes and to discuss how to pursue the research before we carry out our main fieldwork during spring / summer 2017.

2 THEORETICAL PERSPECTIVES ON ADDRESSING SOCIAL INTEGRATION IN A SPATIAL DOMAIN

Urban planners have to a varying degree addressed challenges due to immigration and (the lack of) integration. Vitello (2009) notes from an American context that while European countries have established a tradition of social planning, including national integration programs, the Anglo American planning tradition struggles to accommodate cultural difference. Planners have engaged with immigrant communities, typically in advocacy roles, but mostly community development has been done by community workers not planners. In European cities, immigration and integration have become a pressing question due to the refugee crisis and fear of terrorism. As often discussed in relation to a concern about the increased segregation of ethnic minorities in poor urban neighbourhoods, integration of immigrants is approached as a 'spatial problem' of uneven distribution of resources, welfare and a general 'good' living environment. Since 1990s, therefore, European countries have seen a shift in both policy and academic discourse from a dominant conception of poverty to "a focus on social exclusion, signifying a significant redirection of emphasis from the material deprivation of the poor towards their inability to fully exercise their social, economic and political rights as citizens" (Geddes 2000, p. 782-783, see also Andersen 2001). This shift in European policy has been followed by "a wide range of efforts to promote community participation in deprived, immigrant-dense areas of the city [...] to encourage immigrant engagement so as to create a shared sense belonging and speed up integration (Gressgård and Jensen 2015, p. 2). Often known as integrated area based initiatives, a cross-sectoral approach to area-development seeing physical upgrading and community engagement as equally important, so-called deprived, immigrant dense urban neighbourhoods are undergoing regeneration to combat social exclusion and facilitate integration.

Fincher et al. (2014) and Gressgård and Jensen (2015), have identified three main theoretical approaches that have informed urban planning debates on integration; the 'right to the city' and 'social justice', planning and 'multiculturalism' or 'pluralism', and a newer discussion related to 'social capital' especially in relation to the above mentioned regeneration approaches towards poor urban neighbourhoods. The concept of 'right to the city' has been central to critical debates in urban theory (e.g. Lefebvre 1968, 1996, Harvey 1973, 2008, Mitchell 2003, Marcuse et al. 2009). When linked to urban planning practices, 'right to the city' suggests a consideration of the power structures present in the city and in urban planning practises, facilitating or hindering, in the present case, refugee's influence on their use and rights over urban spaces especially those shared with the host society. 'Multiculturalism' is a concept with many meanings; "at once a philosophy of the nation and nationhood, a set of public policies, and a democratic reality in many countries and cities in which ethnic and racialized variations exist in the population" (Fincher et al. 2014, p. 3). Fincher et al. (2014) employ the term to discuss the ways planning engages with ethnic and racialized difference, and as such 'multiculturalism' can be seen as a more specific term than 'pluralism' which is the concept that Gressgård and Jensen (2015) prefer in their review on very much the same topic from a Scandinavian context¹. Within planning theory and urban studies, 'pluralism' often refers to the pluralist-elitist debate from the 1950s and 60s (see Allmendinger 2002, and Harding 2009), and has been developed as a perspective that encompasses difference, both in (cultural) values and in power and access to decision-making. Though we in the following chose to use the term 'pluralism', we acknowledge that both 'multiculturalism' and 'pluralism' are ambiguous concepts. For example How (2013) argue for the

¹ Gressgård and Jensen (2015) do not state clearly why they prefer using the term 'pluralism', however in a Norwegian context multiculturalism might be associated with the (quite polarized) debate on whether integration of ethnic minorities has failed or not, where critics of the Norwegian integration policy sees the multicultural society as a potential threat towards values they see as 'Norwegian'. As such, 'pluralism' might be understood as a less politically charged concept.

use of 'transculturalism' as a less static concept, that better capture the processes of intercultural exchange and cultural transformation that take place in urban spaces.

'Social capital' is a concept that increasingly has entered the debate and understanding of integration of immigrants, in addition to concepts such as 'community cohesion' or 'social cohesion' (Gressgård and Jensen 2015). 'Social capital' has been developed as a conceptual framework by scholars such as Bourdieu, Coleman, and Putman (Sullivan 2009, see Portes 1998 for a review), however especially Putnam's (1995, 2000) conception of social capital as an inherent quality of a well-functioning civil society has proven to be attractive for policy directed towards 'excluded' and 'marginalised' communities. The assumption is that people living in deprived neighbourhoods have limited access to so-called bridging social capital which encompasses more distant social ties, and that "living in mixed-income communities may provide opportunities to interact with people who have more diverse social networks, and in turn auxiliary benefits from such interaction" (Arthurson et al. 2015, p. 439). As such, 'social capital' is associated with trust between different social groups and citizens' ability to participate in the wider society. Hence, 'social capital' is also linked to a well-functioning participatory democracy, and suggestions that the quality of governance and outcomes will improve with increased social cohesion and the citizens' participation as 'co-producers' in governance (Sullivan 2009).

As for Norway, ethnic segregation was until the 1990s treated as a question of class mobility and economic redistribution through the welfare policy (Holt-Jensen 2009). The debate on ethnic segregation as reinforcing the old spatial divide between rich and poor emerged, however, throughout the 1990s, and moved in the 2000s towards a fear of 'ghettoization' and 'parallel society' if a concentration of poor ethnic minorities in less attractive parts of the city were allowed to develop further. The focus on integration thus entered Norwegian policy and planning with the focus on area development, to a large degree inspired by integrated area based approaches to urban renewal in other European countries, especially the UK, Denmark, and Sweden (Brofoss and Barstad 2006, Lund 2014). In these approaches, participation as community empowerment partly building on arguments in line with the idea of 'social capital' is often a central strategy.

The theoretical approaches discussed above are, perhaps except from theories on 'social capital', not easily translated into urban planning practices. From a study of eight multicultural metropolis, Fincher et al. (2014) identify two main approaches to urban planning practices to support integration. The first approach, social mixing, target interventions on residential space. As noted by Cole and Goodchild (2001), the assumption of a mixed society as a more 'balanced' and 'harmonious' society is a normative idea with long traditions within planning. The idea was for example a prominent aspect of the British garden city movement before the First World War, and became systematically adopted into the housing and New Town programs of the 1945-51 Labour governments. While criticized from the 1950s for underestimating that segregation might also be a positive factor in developing a strong sense of community, the idea of social mix re-appeared in the New Labour housing policy from 1997, directed towards the housing estates from the 1950s and 60s. Hence, the current focus of attention on social balance "lies in projects designed to promote neighborhood renewal and social inclusion rather than, as before, on the principles of comprehensive planning" (ibid.:345). Fincher et al (2014) discuss the shift in focus in social mix planning in Europe, from being an explicitly class oriented project to become the "dominant solution to managing the segregation of internal and external undesirable Others in [ethnically] diverse cities" (ibid. p. 23) (see e.g. Lees 2008 and Arthurson 2015 on critical discussions on social mix strategies).

The second approach, planning for spaces for encounters, concentrates more on the design and use of public space. This approach involves "the creation of opportunities for interactions between ethnic communities in the hope that contact will reduce prejudice and social conflict" (Fincher et al. 2014; 43, emphasis in original). Since public space is connected to normative understandings of what is accepted as "appropriate" or "inappropriate", the production of public space is often analysed in relation to theoretical debates on 'right to the city' (Fincher et al. 2014, Gressgård and Jensen 2015. See e.g. Mitchell 2003). Of relevance here is both the 'visual manifestations' of migrant minorities in the public sphere, and regulations of the use of public space – both formally and informally. Further, the assumption that encounter can "produce any kind of change beyond the time/space of the encounter itself is increasingly being challenged" (Fincher et al. 2014, p. 43, see e.g. Valentine 2008). In addition, there is a growing body of scholarship that point to the fact that encounters across cultures are likely to take place at sites beyond those that are usually discussed among planners, such as in schools, libraries, workplaces and everyday neighbouring practices like gardening and eating (ibid.).

Though both social mix approaches and planning for encounters in public spaces often come together in regeneration programs targeting immigrant dense neighbourhoods, e.g. the Saupstad-Kolstad area development program in Trondheim (Trondheim Kommune 2013), social mixing is not really discussed in planning strategies that encompass the city as a whole – such as the potential for densification and local center development in Trondheim – other than in the regulation of mixed housing according to size and type of ownership. According to Legeby and Marcus (2011), therefore, the focus on residential segregation and social mix limits the potential of the build environment for integration. They argue that the potential for interplay that develops as people share public space is equally important for integration processes as the residential mix.

3 INTEGRATION AND SPACE IN NORWEGIAN POLICY AND PRACTICE

Several researchers have emphasized the importance of housing for integration. E.g., research on reception centers for asylum seekers suggests that low standards of housing counteracts integration (Hauge et al, 2016). It is generally agreed that a high turnover of residents in an area tend to negatively influence people's feeling of safety and interaction between neighbours (see also Vacher 2007 immigrants experience from social housing in Denmark). Further, studies from Norway have found that the refugee's ability to obtain housing without help from municipal authorities (so-called 'self-settlement') may contribute to empowerment and a feeling of autonomy (Røe, 2015). However, there is a fear that self-settlement will reinforce to the increasing segregation of immigrants in marginalised areas, a situation believed to counteract integration (Valenta and Bunar, 2010; Røe, 2015). At city level, therefore, the idea of social mix is an important strategy when providing homes for refugees. This is true also for Trondheim, as the Health and Welfare office responsible for the housing of refugees seek to avoid concentration of ethnic minorities in certain areas, especially around Lademoen, which is a former working class neighbourhood close to the city center, and at Saupstad housing estate planned and built in the late 1960s and early 1970s (fig 1). Saupstad is today one of the most immigrant dense neighbourhoods in Trondheim, with around 30 % of the population being either immigrants themselves or having parents that are immigrants.

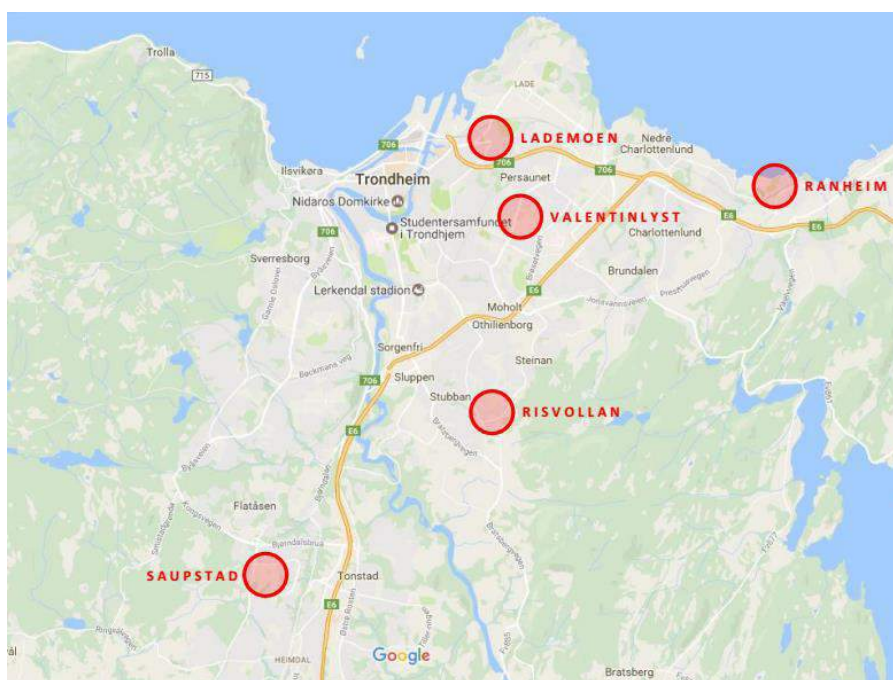

Figure 1: Map of Trondheim with five selected local centers at neighbourhood level. Source: Google Maps.

Because of the relatively high amount of immigrants and low score on statistical indicators such as education, employment and health, Saupstad is part of an integrated area based development program. The development is a cross-sectoral initiative seeking to facilitate cross-cultural meetings and networks among the residents, in addition to a physically upgrading of the local service- and shopping center, schools and public spaces.

According to the Municipal Development Plan (2012-24), Trondheim wants to continue the densification and localisation policy by reinforcing the existing built structures- having the right business at the right place, rejuvenation of the existing local centers, and retaining and developing the blue/ green structures. It also aims to reinforce the existing public services and preserve cultivable land and ecologically sensitive forests (Trondheim Kommune, 2012;b). The densification policy also aims to serve other purposes, such as to reduce the need for expansion of transportation and a better utilisation of existing infrastructure (Trondheim Kommune, 2012b). This coupled with the choice of environment-friendly transport, can also provide a greater degree of diversity and accessibility (Ibid). This resonates with the argument that densification and transformation of the city could help refugees to be more interactive with locals. Therefore, the context of transforming local centres in Trondheim can potentially create a proactive space for an inclusive meeting and exchange with locals for the refugees. Beyond what is outlined in the Municipal Development Plan are the efforts to develop local centers into diverse and inclusive meeting places. Although the plan states this objective as part of the goals of the local center development, currently no concrete measures or means to achieve this have been identified. Refugees are not per se identified as a 'target group' by the plan although the societal development plan (kommuneplanens samfunnsdel) states the goal for inclusion and diversity for the city.

4 ON INTEGRATION (AND METHODOLOGY)

Integration is a complex and somewhat controversial concept (Ager and Strang, 2008). The understanding of integration ranges from an assimilation perspective, which implies an expectation that refugees should adapt to the host society so they eventually will not stand out, to a multiculturalist perspective in which everyone's right to keep their cultural and religious identity is recognized (ibid). Today, most reject assimilation as a measure of integration and accept that the arrival of refugees will involve a greater degree of cultural diversity and hence a gradual change in our own society at both the local and national levels. For the purpose of this project, we lean on Ager and Strang (2008), who developed a conceptual framework for approaching integration of refugees and immigrants. The framework builds on previous work developing indicators for evaluating integration in the UK, in addition to fieldwork in environments of refugee settlement and analysis of survey data. Ager and Strang define ten core domains of integration and divide them in four categories (see Figure 2). The authors insist the domains are interdependent and all significant for integration, with no primacy of one over the other. However, Valtonen (2004) points out the difference that a strong welfare state might provide, and that strong social rights of settling refugees can occur alongside weak labour market status, bringing out features of 'differential exclusion', peculiar to settlement in this particular context' (2004: 71).

Figure 2 Ager and Strang's core domains of integration (2008: 170)

There are however other approaches to integration. For example the Efms INTERPOL (2006:18) defines social integration as “a generations lasting process of inclusion and acceptance of migrants in the core institutions, relations and statuses of the receiving society”, stressing the interactive process between migrants and the receiving society in which the receiving society has much more power and prestige (see also Esser 2000). Hence, integration might both refer to normative aspects of what characterises an ‘integrated’ immigrant, and an experience of inclusion or exclusion among the immigrant population. Methodologically, we first map the policy and practice on integration in Trondheim municipality that so far seem to concentrate on facilitating language and cultural knowledge, and access to housing, employment and/or education, and health services. Interviews have however revealed an understanding among municipal actors of the role of social networks and a general feeling of being included for integration to be ‘successful’ (i.e. partly covered by the social connection domain of the Ager and Strang 2008 framework). For this purpose, the municipality works closely with NGOs’ such as Red Cross. Second, we are in the process of performing in-depth interviews with refugees living in different parts of the city to explore their experiences of belonging and inclusion (or not) to their home, neighbourhood and the city as a whole.

5 A SOCIALLY SUSTAINABLE CITY?: PRELIMINARY FINDINGS FROM THE FIRST PHASE OF THE PROJECT

Among the 13 local centers identified in the local center development plan, five were selected for the mapping exercise carried out by students of the master program in Urban Ecological Planning during fall 2016 (see Figure 2). Of these, the centers at Risvollan and Saupstad represent the development of housing estates in Trondheim in the early 1970s. The local centre at Valentinlyst was established in 1975, in relation to expansion of housing in the area. Lademoen and Ranheim stand out as not being clearly defined centers today. All local centers serve a population between 4300 and 5700 residents, and had between 58-185 refugees settled in the surrounding residential neighborhood in 2016. Saupstad has the largest share of non-western immigrants, with 30 %, while Ranheim has a small non-western population of 2,8 %. Based on qualitative observations, informal talks, interviews, focus groups discussions and workshops, the students explored how the refugees use and relate to their neighbourhood, the local center and the city as a whole¹.

Most groups struggled with finding relevant informants. They found it difficult to approach people directly at the local centers since it is hard to know who are refugees and who are just Norwegians of foreign origin or other kinds of immigrants. They therefore approached established arenas where refugees meet, such as language cafés, the municipal qualification program, churches, sports clubs and other meeting places for immigrants. Three of the groups managed to find a sufficient number of informants within ‘their’ local center, the two others came in contact with refugees living all over Trondheim but still asked them about how they use the city and their neighborhood. All together they interviewed 44 refugees either individually or in groups, in addition to several more with whom they asked brief questions. Some groups also interviewed other actors (social workers, representatives from housing cooperatives etc.)².

5.1 THE LOCAL CENTERS: SPATIAL QUALITIES AND THE ACTIVITIES OFFERED

It seems from the student investigations that the local centers only to a limited degree work as arenas for social encounters between the refugees and the host community. Most informants express that the city center is perceived as more attractive as a social meeting place, a place for ‘hanging out’, than the local centers. Moreover, the local centers often do often not offer activities which the refugees need, such as language cafés, opportunities for volunteering, sports, religious activities etc. Even when it comes to shopping, refugees do not necessarily prefer the local shops. They mainly go shopping where the prices are lowest, which is often in larger shopping malls such as City Syd, City Lade etc. Many also join the free bus to Sweden and do their shopping at Storlien.

¹ Trondheim municipality defines refugees as those who have received asylum in Norway and has lived in the city for less than five years. Among the questions the students asked, were: 1) What are your everyday activities? Where? When? With whom? How do you get there? 2) What kind of spaces/which spaces do you use in the neighborhood/city/city center/local center? 3) What are your most important social networks and why? 4) Describe a normal day/week

² For a more thorough description of main findings from the 5 student groups, see Appendix

As expressed by several informants in almost all the groups, the value of sports and volunteerism as a potential for social interaction among and between groups – immigrant and Norwegian, should not be underestimated. Volunteering functions both as a means for increased interaction, increased familiarity of the cultural and social norms as well as a 'grapevine' for information on employment opportunities etc. The language cafes also perform similar functions. Sport and training was mentioned by several informants as their only means of recreation and interaction with others, albeit mainly other refugees from similar cultural backgrounds. Religious activities were also seen to perform a dual role – of maintaining a sense of identity through one's religion as well as a meeting space for social interaction. Although not all local centers can feasibly provide all such facilities, the local of volunteer centres, sport facilities and religious centers should be part of the discussion on local centers at the city level.

The reasons for not using local centers are however not only lack of the 'right' activities and reasonable prices on grocery and other goods. The centers moreover tend to be perceived as boring, lacking attractive public spaces for 'hanging out' without having to buy something. In some neighborhoods (e.g. Ranheim and Lademoen) there are no defined and visible center at all, which makes them even harder to relate to.

5.2 LACK OF VISIBILITY – AFFECTS SENSE OF BELONGING

According to the students, refugees (and other non-western immigrants) are generally not visible in (most) local centers (with a possible exception of Saupstad-Kolstad). This may be because these groups prefer other places. With the relatively small numbers of refugees living in each neighbourhood, it is hard to influence on and participate in the local everyday life. In most areas there are also a lack of visible 'symbols' of multicultural population, such as mosques and other aesthetic elements. Lack of visibility may affect the process of developing a sense of belong, assumed to be important for social integration (e.g. Efms INTERPOL, 2006).

5.3 SOCIAL ISOLATION

Few informants state that they have Norwegian friends. Informants in Ranheim, who were mainly single male youth, expressed a sense of hopelessness and isolation in the local area where they were accommodated. Their only comfort was in being able to interact with others from their own community in sport facilities located in other areas. In this sense we may draw the conclusion that they are not yet very well socially integrated. Time is probably also an important issue. The informants in this study have lived in Trondheim for less than 5 years, many of them for less than two years. It not only takes time to find new friends. Also achieving a sense of belonging or feeling at home in a neighbourhood and local center takes time. Informants state clearly that the main issue for them at this stage is to learn the language and to get work, this is important in order to be integrated in the long run.

Refugees are not a uniform group. There are obviously cultural differences, as well as issues related to gender and life situation. Young, single and most often male refugees move easily all around the city and seek places and activities where they can meet other refugees, often with similar cultural background as themselves. As was observed by the group of students that worked in Saupstad, it appears that female refugees with families and children are more frequent users of some of the activities offered within the local neighborhood. Here, women of immigrant/refugee background do come in contact with women of Norwegian origin, in for example the knitting group organized by the local volunteering centre but these interactions do not result in 'deep' ties beyond the immediate interaction. As they are conceptualized now, local centers are mainly seen to be shopping centers with some community functions such as the library in Risvollan and Saupstad. The value of interaction that these functions afford may not satisfy the ultimate aim of creating local inclusive neighborhoods.

5.4 HOUSING

Only few informants mention their residential situation as important for their everyday life. This may be due to how students asked their questions (housing was not emphasised in their assignment). But it is worth

investigating closer, since 'housing first' is one of the main slogans in Trondheim's strategies towards integrating refugees (ref?). We also know from research on other vulnerable groups that housing is important for how people perceive themselves as part of a society (dignity, empowerment, identity, privacy etc) (e.g Hauge et al 2009) and for the integration process (e.g. Røe, 2015).

6 RAISING QUESTIONS FOR FURTHER INVESTIGATION

At this stage in our research, we do not have sufficient empiric data to draw any substantial conclusions. We would still like to use this opportunity to raise some preliminary questions for discussion.

Integration of refugees in the first 5 years of their residence in the Trondheim Municipality is the responsibility of the Health and Welfare division of the City Council. This is facilitated through their accommodation in social housing combined with an obligatory 'Introduction Program' (Kvalifiseringssenter for Innvandrere INN) that qualifies refugees for entering the job market – defined as a certain level of language skills as well as basic school education. As stated by the representatives of the Health and Welfare division in a project related meeting, the focus is mainly on 'systemic integration' which can be evaluated through 'measurable indicators' such as attainment of a certain level of education, access to welfare services and integration through paid and gainful employment. Both the representatives from the Town Planning division and the Health and Welfare divisions acknowledged the need to understand and address social integration but expressed the gap in knowledge on the needs and functioning arenas for social interaction and integration. As expressed earlier, this project attempts to fill this gap in knowledge, and will do this by looking into for the role played by the local centers and neighbouring areas.

With reference to the frameworks for integration discussed earlier in the paper, municipal policy on integration of refugees in Trondheim is limited to the formal and structural aspects of society, while leaving the relational, interactional and cultural aspects to unplanned arenas and self-initiative by the refugees. There have been some efforts to represent the cultural diversity of the city through food and cultural festivals, with limited outcomes. As is illustrated by our preliminary investigations, most informants experience a sense of alienation and isolation, and interactions are limited to people of similar cultural backgrounds and other refugees.

The feeling of social isolation perceived by our informants might be an indication of a worrying implication of the lack of focus on social integration as opposed to systemic integration. These young people first come in contact with the local culture and community in their residential neighborhoods. Although they are all obligated to follow the Municipalities education programs in order for them to be qualified for the job market, their sense of alienation in the host culture can possibly have far reaching implications for their role as future citizens. The window of opportunity of the first five years of the 'Introduction program' of the Municipality is critical owing to the close contact refugees have to State authorities. Disregarding the importance of the residential environment and social links and bonds in the local community, is a shortcoming in the integration efforts of the Municipality.

The next level of our analysis relates to the spatial policies of the Municipality and their potential to address social integration. In the urban development strategies of Trondheim Municipality that may be relevant for social integration of refugees, we recognize both social mix approaches and an emphasis on developing spaces for encounters in the local centers. The way refugees are accommodated all around the city with relatively small groups in each area may be due to pragmatic reasons (that's where the available housing is), but it seems that it is part of an overall strategy to avoid an accumulation in certain neighborhoods. We also see from the municipal paper on local centers (Trondheim kommune, 2012a) that there is an underlying assumption that strengthening the local centers will provide social and cultural meeting places. Still it seems from our preliminary findings that neither of these strategies so far have supported social integration between refugees and the host community. One can also raise questions regarding the policy of social mixing itself. Unless it is followed up by initiatives for social integration in local areas it may lead to the kind of isolation expressed by our informants.

From the first phase of investigation in the project, we can raise the following questions that will be explored in the next phase:

1. What are the functioning spaces of social encounter for refugees and how do these encounters have a bearing on relational, interactive and identificational aspects of integration (Ager and Strang, 2008; Valtonen, 2004; Efms INTERPOL, 2006)? How do the refugees perceive this relationship?
2. To what extent do these social encounters take place/facilitated by space in neighborhoods and local centers?
3. Which role does the home play, and the relationship between private and semi private arenas and public spaces in the local areas play for social interaction between refugees and the host community? What qualities of the various spaces and the relationship between them facilitate social encounters that may have consequences for social integration?
4. Is there a visible dimension to the integration process, and if so – how does it come to expression at a local level in Trondheim (and where?)

We hope that knowledge developed through looking more into these questions, will give insights that may be useful in a further discussion on the organization of policy domains and implementation structures in the Municipal administration when it comes to the broadly framed objectives set out in the local center strategy.

adriana.diaconu@univ-grenoble-alpes.fr

1 INTRODUCTION

Planning traditions in European countries have generally either ignored settlement patterns of underprivileged migrating populations or tried to control them through imposed settlement actions or population redistribution (Desage et al., 2014). Urban integration of immigrants or of poor nationals in a migration situation (such as rural population attracted by employment opportunities in the city or returning expatriates from former colonies, etc.) has been generally addressed by providing specific or standard public housing or by implementing social mix policies. In this paper we address integration patterns by focusing on the characteristics of a "welcoming" territory or its "hospitality", i.e. a territory that offers opportunities for integration and that showcases its social diversity. We further question the importance of morphologic configurations of metropolization and of governance arrangements characteristic of metropolitan planning for successful incorporation.

New comers to the city claim space and make place. In regard to these processes, we ask several questions: what settlement and place-making patterns of migrants, chosen or imposed, are associated

with metropolization in different world contexts? Can suburbanization be considered an advantage for integrating a new population, and under what conditions? How do city and suburban administrations, be they fragmented or federated in metropolitan governance institutions, respond to these processes of settlement?

In order to address these questions and see how metropolitan urban areas can use take advantage of their suburban morphology and of immigration we have studied U.S. examples of successful “gateway” metropolises of the 21st century. The choice of the North American example was based on the fact that morphological characteristics of metropolization have their origins in the U.S. and that we find in the American scientific literature successful stories of immigrants’ incorporation that contribute to economic and territorial development. In addition to the US theoretical model we have studied two contrasting European cases of metropolitan pilot projects concerning immigrant and minority integration: that of Grenoble, in France, and of Cluj, in Romania. These two very different contexts in Western and Eastern Europe are put together here in regard to integration patterns of a similar population, impoverished Romanian in majority of Roma ethnicity. Highly excluded from the labor market and from formal housing, suffering discrimination and marginalization in Romania (Vincze, 2015), they are low-skilled and very poor immigrants in search of a better life. In France they often live, at least for a period of time, in very harsh living conditions in improvised and informal settlements such as slums and squats, from which they are often evicted.

In regard to this population, we give here the term “minority” a wide meaning that reflects not only a quantitative difference from the “majority” based on objective and/or subjective criteria, but especially a dominated position due to social and economic exclusion, and to forms of marginality (such as informal or illegal occupations and housing). We focus on the movement of these populations, chosen – such as their economic migration to western Europe – or imposed – such as resettlement after forced evictions – that makes them “new comers” with low resources in a territory where they aim to settle and make a living. In the American literature on migrations and cities, different types of immigrants (high and low skilled, with high and low human and social capital, etc.) are considered together as complementary in their settling and integration patterns. However, the different examples show that generally highly skilled workers have always been more easily integrated, whereas “poorer and less-skilled immigrants – who are often the backbone of the service economy – have met more resistance” (Singer et. al., 2008: 155).

1.1 METROPOLITAN PLANNING

Concerning the European cases discussed in this paper, the term “metropolitan planning” stands here for several types of processes that affect at present suburbs and urban areas. We will mention here three of them. Firstly, there is a territorial morphological change similar to the metropolization processes in the United States that challenges the traditional structure of European cities (Leroy, 2000). In France, for example, a continuous organization of buildings is conventionally defining a city or town. A new understanding of economic and everyday life relations between different territories imposes to consider the networking of urban core(s) with neighboring towns, villages and sprawling areas (Ascher, 1998). This organization generates a discontinuous and heterogeneous structure that alternates higher and lower densities and secondary centralities. The networking of urban, sub-urban or péri urban areas through an increased connectivity – that becomes more important than proximity – increasingly erases the importance of hierarchies between centers and peripheries. These new territorial arrangements, present in certain parts of Europe since the 1970s, are no longer reserved to metropolises or greatest cities but increasingly affect conurbations of less importance, in which most economic activities are relocated in the suburbs.

A second aspect of metropolization concerns administrative reform following this morphologic change. This process is marked in Europe by decentralization of decision-making from the State to the local level. In this process the metropolitan scale is often considered to be the most appropriate for local policy making (e. g. in housing and spatial planning). Encouraged at the European Union level, these reforms are put into practice at different pace and in different ways in European countries. In France, metropolitan governance has been reinforced especially since 1999 (Chevènement Law) and the decision-making power of Metropolitan administrations in spatial planning and housing issues is increasing. In Romania where “metropolitan associations” of town halls are only currently emerging on a voluntary basis and do not have any primacy over municipal authority in regard to specific competences.

A third aspect, “metropolitan planning” aims to give a tangible form to cities’ ambitions for distinction in the global competition between them. In relation to the economic dimension of a metropolis metropolitan developments and regeneration strategies generally aim to bring in innovation, specialization and cutting-edge technologies in order to foster economic dynamism. In this quest for excellence, metropolitan projects aim to attract specialists, highly skilled and creative people and in return they should find here good living conditions. Therefore metropolitan planning contributes to the homogenization of the metropolitan territory by reinforcing connectivity and developing or regenerating derelict areas left behind in the growth process, most often trapped as “gaps” in the metropolitan urban structure. In this way it contributes to raising the potential value of all properties regardless of their location, distance from the urban core, proximity to former industries of railway infrastructures, etc. From this point of view, metropolitan planning signifies injecting resources for the recapture of these forgotten territories in a quest for densification, intensification of urban life and distinction.

1.2 METHODOLOGICAL APPROACH

The American model serves here as a theoretical background for the interpretation of the two European case studies. The latter two have been studied in detail (through field observation, discussions with decision-makers, institutional and NGO representatives, analysis of planning documents, of policies and discourses, etc.). However, difficulties in studying together the three examples arise from different paradigms on integration of immigrants and minorities in the three national contexts (Escarfré-Dublet, 2015).

Fundamental differences appear between the ways countries like the US and Great Britain, on the one hand, and France, on the other, incorporate their long histories of immigration in the conceptual construction of society (Noiriel, 1988; Lapeyronnie, 1993). France has developed a universalistic model of integration in which the individual foreign origin has to be kept in the private sphere and become increasingly invisible in the process of assimilation. In this model, ethnic communities are considered to be antagonistic to the integration in the national social body. In the American pluralistic model, personal origin can be made visible in public space and can be claimed by ethnic communities. Communities can thus be recognized as initiators or stakeholders in local development, and as place makers that inscribe their identity in space. This is not the case in France, where ethnicity (and ethnic communities) are not considered as stakeholders in decision-making and in planning (Escarfré-Dublet, 2015).

Romania is a country that recognizes national minorities (such as Hungarian or Roma). Their presence is related to the multiethnic historical composition of the society, to the important movements in territorial borders in the region and to late formation of nation states. However ethnicity is mostly related to cultural aspects and to the preservation and promotion of these cultural specificities.

A relevant example of differences and incompatibilities arising from different paradigms for minorities’ inclusion in France and Romania is that of the reactions produced in the two countries by the EU Framework for National Roma Integration Strategies up to 2020. To the Commission’s request that all member states design integration strategies for Roma living on their territories, France has expressed the impossibility to adopt such a strategy on the basis of its universalistic model that does not recognize ethnicity and cannot assign advantages on the basis of this categorization¹. On the other hand, Romania – the European country that is the most affected by the marginalization and poverty of its important Roma minority – proposed mostly cultural measures for their integration².

2 THE THEORETICAL MODEL OF GATEWAY CITIES IN THE U.S.

Northern American researchers have studied the way immigration affects cities and the changing patterns of these phenomena especially at the end of the 20th and the beginning of the Twentieth century (Price and Benton-Short, 2008; Singer et al., 2008). Using statistics on the percentage of foreign-born in the

¹ Une place égale dans la société française : Stratégie du gouvernement français pour l’inclusion des Roms dans le cadre de la communication de la Commission du 5 avril 2011 et des conclusions du Conseil du 19 mai 2011.

² Strategia Guvernului României de incluziune a cetățenilor români aparținând minorității rome pentru perioada 2012-2020.

overall population Audrey Singer has theorized a typology of gateway cities based on the historical evolution of urban immigrant settlement in the United States throughout the last century.

In addition to the “established gateways” of the 20th century, that are still attractive to immigrants (such as New York and Chicago), new gateways have emerged. They are called “twenty-first-century gateways” and are places where immigrant population has been rapidly rising since the 1980s (“emerging gateways” - e. g. Atlanta, Dallas-Fort South, Washington) or even more recently, since the 1990s (“preemerging gateways” - e. g. Raleigh, Durham, Austin). Finally, among these new destinations there are cities that had been attractive to immigrants one century ago, and that are now “re-emerging as immigrant gateways” after a period of lost drawing power in the middle of the century.

It is important to note that all these destinations that successfully incorporate immigrants experience overall population growth, and not only an increase of their foreign-born population. This dynamic shows that they have strong economies and that these territories are overall attractive (Singer, 2008: 12). Immigrants are drawn to these areas because of employment opportunities and their presence further contributes to the regions’ overall economic growth.

Singer shows that the settlement patterns in these “twenty-first-century gateways” have changed from previous ones in relation to the “restructuring of the U.S. economy, the decentralization of cities and the growth of the suburbs as major employment centers” (Singer et. al., 2008: 5). Suburbanization was accentuated by morphological transformations of suburbia towards denser and more heterogeneous landscapes that can be described as “suburban metropolises – decidedly not cities, but for the most part large, loosely bounded, lower density, sprawling, auto-dependent metropolitan areas (Ibid. : 15). In these areas new comers can find a series of opportunities such as: jobs, affordable housing, possibilities to establish small businesses and easy access to communication corridors.

2.1 FROM THE ‘ETHNIC ENCLAVE’ MODEL OF THE CHICAGO SCHOOL TO THE ‘ETHNIC COMMUNITIES’ OF THE 21ST CENTURY GATEWAYS

The assimilation model described by the Chicago School of sociology in the interwar period has dominated urban studies research on the settlement patterns of immigrants, both in the U.S. and in Europe, ever since. This model gives a particular role to “ethnic enclaves” situated in devalued areas near the city center and that were offering to new comers cheap housing, often in overcrowded and low quality buildings, and the proximity of employment opportunities. Therefore, as an arrival place of installation for the first generation of immigrants, the “ethnic enclave” represented a resource for integration offering the support of social networks of co-nationals or other immigrants. However, the enclave represented a temporary phase, since more economically prosperous or second-generation immigrants were moving out to the more valued suburbs where better quality housing could be found. Once they or their children had acquired linguistic proficiency, and integrated economically, first or second generation immigrants could easier integrate the mainstream population in the new living environment, further away from the city center (Park et al., 1925). Immigrants’ settlement patterns in “twenty-first-century gateways” are different. Unlike in the Chicago School model, many immigrants settle in the suburbs immediately upon arrival and do not go through the intermediary phase of the “crowded inner city immigrant enclave” (Hardwick, In Singer, 2008: 45). This pattern applies especially to immigrants with high human and social capital who can chose to settle in more desirable parts of an urban area. In addition, the establishment in the suburbs rather than in central cities of high-tech and bio-tech corporations and other firms that employ highly skilled and educated foreignborn staff are linked to these settlement patterns of the more privileged immigrants. However, less skilled and poorer immigrants follow the same pattern by settling in suburban areas where they find affordable housing in apartment complexes from the 60s and 70s or smaller homes, less desirable for the local population living in the suburbs. Sometimes overcrowding affects these housing environments, in a similar way as in the central enclaves mentioned before.

Furthermore, dispersed suburban settlement – instead of concentrated enclaves close to the city center – generates new types of communities and new models of integration. 21st century ethnic communities are rather inconspicuous and difficult to identify and delineate in the cultural landscape. For this reason they have also been called invisiburbs (Skop and Li, 2003). Invisibility however does not necessarily signify losing community cohesion and giving up the support community networks offer immigrants. According to Zelinsky and Lee, urban transportation and communication networks, as well as the use of instant

communication technologies (cell phones, e-mail, etc.) allow dispersed populations who lack residential propinquity to connect regularly and to construct and maintain ethnic communities (Zelinsky and Lee, 1998).

These connections, both virtual and physical, constitute the foundation of heterolocalism (Ibid.), as social presence in metropolitan space. 21st century ethnic communities thus differ from “ethnic enclaves” especially in terms of lack of spatial concentration and sometimes of spatial identification that makes them invisible. In addition, “although the most conspicuous heterolocal communities involve the relatively privileged, the model is also valid for certain lower-status groups whose economic survival relies upon movement and transactions over long distances while retaining or creating a sense of peoplehood.” (Ibid.)

2.2 DRIVERS OF SETTLEMENT PATTERNS IN 21ST CENTURY GATEWAYS

The most important rationale for the suburban settlement patterns of immigrants in emerging gateway cities in the U.S. is the presence of affordable housing, as we have mentioned before. Housing in the suburbs is of better quality and more affordable than in areas closer to city centers (when these centers exist).

In addition, the presence of good schools and the proximity of places of work or of major public transport corridors offering rapid connections to places that concentrate job opportunities moreover guide settlement choices.

The location of new economic activities further from urban cores, sometimes in addition to the restructuring of territories from small agricultural towns to high-technology corridors for example, plays a key role. These employment opportunities concern highly skilled foreign-born workers, but they also have an effect on low skilled immigrants who can find facilities in these areas for establishing small businesses. Such opportunities offered locally can be for example “a large number of older business properties on smaller lots (less than 1,500 square feet) that are ideal spaces for small family-run businesses”, as in Annandale (Singer et al., 2008: 153).

These settlement patterns further contribute to increasing densities in suburban areas that become more dynamic, as well as to increasing their diversity. Many places do not have any majority racial-ethnic group and become truly multiethnic places.

Over time edge gateways have developed a local identity as places where immigrants can find housing, transportation, jobs, and goods and services that cater to them. It can be argued that many edge gateways are performing the same functions as early twentieth-century enclaves provided. Some of these gateways may evolve into a more familiar pattern of either distinct ethnic communities or ethnic enclaves. Yet it is also possible that a different pattern of immigrant settlement is being realized in suburban Washington, and possibly elsewhere, one in which clusters of immigrants are not easily organized into distinct ethnic communities but live in a more multiethnic context (Singer et al., 2008: 138).

However, in regard to local existing minorities, researchers have noticed that residential preferences of immigrants are often determined by avoidance of black neighborhoods, even if in these areas rents are low (Singer et al., 2008: 156).

2.3 RECEPTION AND LOCAL POLICY RESPONSES

Even if legislation concerning migration is adopted at federal level, by having to respond to the inflow of new foreign-born inhabitants local administrations have a key role as policy makers in immigrant's incorporation. Thus cities become de facto policy makers in regard to immigrants' socioeconomic and spatial integration (Price and Benton-Short, 2008: 18). They make policies that respond to the needs of new comers in access to housing, education, health care, etc. and those consenting to activities that allow immigrants to claim space and visibility in the suburban landscape (Singer et. al., 2008: 74).

However, not all local government institutions seek to assist or to include the foreign-born, and especially the poorer and less skilled immigrants. Especially the responsibility of local government for immigrant welfare sometimes meets resistance. In many cases adopted local law and ordinances that are designed to control immigrants concern housing regulations (such as zoning, restrictions against overcrowding, etc.) and employment policies. They are mostly directed at undocumented immigrants, but “the public debates surrounding them are socially divisive and contribute to the unwelcome environment for all immigrants” (Singer, 2008 : 4).

The most worrying facts for local communities are related to the visibility or hyper-visibility of groups of poor migrants. For example the installation of places where poor immigrants gather such as Labor Day sites stirs debates and contestations. In a similar way, concentrations of immigrants following the so-called “cousin syndrome” have a segregative effect pushing away locals:

As a locality in the suburbs becomes known for affordable housing and good transportation, a complex web of immigrant social networks draws in still more immigrants. [...] At the same time, it is possible that large numbers of diverse immigrants settling in a place may make it less attractive for native-born residents who relocate and thus allow room for more immigrants to settle.” (Singer et al., 2008: 157)

3 THE FRENCH CITIES AND IMMIGRANTS

In France, “hospitality” towards immigrants is conceived first of all as a public service (Gotman, 1997). In line with the universalistic model, integration of immigrants is treated as a social inclusion problem. In this country which has a traditional strong position of the State and of non-profit organizations in the welfare and housing system (Esping Andersen, 1990; Kemeny, 1992; Ghekière, 2008) and a large stock of public housing of about 17,4% of the total housing stock (Pittini et al., 2015), hospitality towards immigrants equates to their affiliation to the basic statutory status of nationals (“le droit commun”). Specific measures or services that are especially designed for immigrants (e.g. special residences), actually show the non-access to regular public services, and constitute a “palliative hospitality” (Raffestin, 1997).

Secondly, the claim of space associated with immigration awaits a “gift” of space in a welcoming city. In the context of a strained housing market in most periods of the 20th and 21st centuries this reception has not been without difficulties in France. This un-welcoming city caused the emergence of informal housing clusters (slums) at different moments throughout the 20th century.

Since the 1990s, economic migrations from Eastern European countries (mostly from Romania and Bulgaria) have caused the re-emergence of this phenomenon in France. But from a quantitative standpoint, the phenomenon is a lot inferior to the 1960s slum problem: 12,000 to 15,000 people nowadays, living in about 450 informal settlements in France¹ compared to about 80,000 in 1960 (Olivera, 2011: 13), out of which around 46,000 in the Paris region alone (Barou, 2002: 17).

However today’s precarious settlements of poor immigrants have a different relation to urban areas than those from the 1960s, even if their locations are very similar. For example, Portuguese slums from the 1960s near Massy in the south of the Paris Region were rising almost in the same areas as Romanian ones, 40 years after, in the beginning of the years 2000 (as shown in José Vieira’s documentary « Souvenirs d’un futur radieux »). However, the present metropolitan organization makes them more visible, since they are not situated at the city margin anymore, but in “gaps” of the continuous metropolitan area. In this new landscape, informal settlements are less tolerated especially since all derelict areas that can host them need to be integrated in the metropolitan design through a strategy of “urban recapture” that all major French conurbations go through. (Oliveira, 2011: 13).

Since 2010 State legislation concerning “illegal settlements” of immigrants has been to encourage systematic evictions by local authorities, together with a social evaluation of the situation of the different families starting with 2012. The most important effect of this policy has been the dispersion of poor immigrants following the dismantling of their improvised settlements. However researchers have shown

¹ DIHAL, 2015. In addition to these European immigrants there were about 7,000 to 14,000 extra European migrants (mostly war refugees) in informal settlements of Northern France.

that informal settlements are not only places of marginalization and rejection, but also a resource for integration by creating social propinquity networks allowing to make a living and to access education, health care, and other services (Bourgeois et al., 2015).

3.1 METROPOLITAN EXPERIMENTS FOR EUROPEAN POOR MIGRANTS IN GRENOBLE AREA

The metropolitan area around the city of Grenoble, called Alpes Grenoble Métropole (AGM) comprises 49 administrative units (cities, towns and villages) and about 440 000 inhabitants. It has a legal status that has been evolving since the 1990s in line with the national decentralization policy. Increasing administrative power has been transferred to it both from the State and from the local administrations of the component localities. Since 2012, the number of European Union immigrants in AGM in a precarious dwelling situation (living in squats, slums or hosted in public shelters or in hotels by the public administration) has been quite constant, of maximum 700 people, out of which almost half were children. Most of these immigrants are Romanians, in majority Roma ethnics, having suffered from poverty and marginalization in the Romanian society.

Since 2013, temporary housing solutions provided by the local administration diminished. This caused an increase in the number of informal settlements, making them more visible in the urban and suburban landscape. More than half of these settlements were situated in the localities that neighbor the city of Grenoble (Table 1), on derelict sites or in locations waiting for regeneration and development. These settlements are continuously threatened by evictions (in average 1 or 2 per year per person) and these evictions engender a constant dynamic of dispersal and clustering in new settlements of variable size (from one family to several hundred people for the biggest ones). However the total number of people living in precarious conditions has remained rather constant, with the ones that access stable housing and employment being replaced by other new comers.

	Beginning of 2013	End of 2013	Evictions during the year 2014	End 2014	of	End of 2015	September 2016
Grenoble	8	10	7	10		13	7

Total	18	22	15	22		24	17

Table 1 – Number of settlements per locality in AGM counted at different periods and number of evictions during one year. Source: MOUS Bilan d'activité, Roms Action.

View this distribution of informal settlements in AGM, the local administrations of the localities in AGM decided to develop a common pilot program for integration, to which the different localities could adhere. This program is specific for EU immigrants living in informal settlements (mostly Romanian Roma), who have the legal right to work in France. The program is based on the partnership and coordination of the different participants who contribute to its different aspects (the AGM, the local administrations of all the localities, their social service agencies, the department administration, the prefecture representing the State, non for profit organizations offering guidance on different aspects of inclusion, education, training, etc.) Starting from existing framework measures for access to housing, this pilot program called MOUS (Maîtrise d'ouvrage urbaine et sociale) as a special procedure for integrating a part of the immigrant EU population. It was officially implemented in December 2013, after one year and eight months of trial. This inclusion program is based on offering access to standard housing for free, or for a very limited financial contribution according to family resources, in addition to a reinforced guidance for training and access to employment. The program is highly selective: in 2016 it had attained a capacity of 22 families in independent apartments (12 families comprising 57 persons by the end of 2013). Once a family can leave the program, a regular income offers it access to standard public housing a new one is selected and integrated the program.

The selection is based on a series of eight criteria that aim to evaluate the “capacity” to integrate. An assessment after the first five years of the program (2012 to 2016) counts a total of 24 families (117 persons) that have participated in the project. The objective was to attain independence through stable employment and access to public housing after 18 months in the program.

Since the apartments used in the program had been offered for free by the different local administrations they were located in different parts of the metropolitan area. This contributed to the dispersion of the families that would contribute to making “Roma” ethnic communities invisible in the local landscape. Moreover, this principle corresponds with general housing policies in France that encourage social mix by distributing public housing evenly in the different localities of a metropolitan area. Such dispersion procedures are applied in urban renewal of existing apartment complexes from the 60s and 70s that concentrate public housing (Lelevrier In Desage et al., 2014). However, in the case of the families having integrated the MOUS program we could observe a perpetuation of community ties with the people still living in the informal settlements.

The good results that the program had, based on its high selectivity, are intended to constitute a stimulation for a more global and systematic intervention strategy for the integration of underprivileged immigrants. However, even if the coordination of the numerous participants from public administrations and non for profit organizations was fruitful, it was difficult to achieve and triggered some compromises (e.g. in the selection criteria). Moreover, this program cannot be applied directly to a different population, such as non EU refugees who need legal residence and work permits. Since this program was based on a voluntary participation of the different localities in AGM and on financing mechanisms that are not guaranteed for a long period of time, especially since the costs are quite high for a limited number of participants, it is very likely that such integration mechanisms will not expand and perpetuate.

4 ROMA MINORITY MARGINALIZATION IN THE ROMANIAN CITY OF CLUJ

For historical reasons, the morphology of Romanian cities from the north-western part of the country was characterized by a high density and a clear separation of the city from its surroundings. In addition to the traditional form of Transylvanian towns, a state policy from the 1970s against urban sprawl and implemented densification of already urbanized areas (Diaconu, 2013). Even if suburbanization accelerated starting with the 1990s, especially by the creation of new residential areas for the middle class extending the existing urban structure or densifying neighboring villages, the separation between urbanized and non-urbanized territories is still very clear today.

Following European directions and incentives, a feeble administrative reform has started in 2001 (Law 351/ 2001, than laws from 2006 and 2008) in order to create an administrative form of cooperation at metropolitan level. Such Associations between towns, cities and county administrations were created on a voluntary basis in the 12 biggest cities in Romania including the capital, in order to create “growth poles”. The main objective of this national strategy was to strengthen the role of these urban areas as drivers of regional economic growth and reinforce urban-rural relations contributing to reduce territorial disparities. In addition this type of metropolitan planning in line with EU recommendations was potentially allowing to access more EU and other international funding for implementing metropolitan projects. Created in 2008, the Cluj Metropolitan Association (Asociația de Dezvoltare Intercomunitară Zona Metropolitană Cluj) - CMA is made up of one city, the county administration and 19 villages on a radius of 30 km around the main city, as specified by the Law from 2001. The area had 413,761 inhabitants in 2011.

Cluj, one of the few cities in the country that experience population growth and that attract a large number of students suffers from the limited housing stock that is also in a general bad condition. This pressure on the limited housing market and on building areas creates inflation in housing prices, making housing unaffordable for the most vulnerable.

Concerning welfare policies, the liberal state that followed the communist regime diminished progressively social protection. Romania has nowadays the smallest stock of public housing in Europe (1,12% of the existing housing stock according to the 2011 census) and the highest rate of severe housing deprivation in Europe: 23% compared to 5.2% European average (Pittini et al., 2015). In addition, the selection criteria for accessing public housing are not in favour of the most vulnerable (Adorjani et al., 2016).

After the structural changes in the Romanian economy since the 1980s and the diminishing of the Welfare State since the 1990s, the Roma minority has been increasingly excluded from the formal labor market and assigned in a marginal social and territorial position: “they are pushed to the social and spatial margins of the local societies, i.e. into positions of unemployed on the formal labor market, and/or towards housing areas that do not benefit of developmental investments.” (Vincze, 2015 : 18). This situation encourages “local entrepreneurs and mayors [...] to exploit their poverty and dependence on social welfare or on underpaid day laboring” (Vincze, 2015 : 20).

4.1 SEGREGATION PROCESSES AND GOVERNANCE IMPLICATIONS OF THE METROPOLITAN TURN

In addition to the structural factors mentioned before and to the strained housing market in Cluj, the planning strategies of the city’s public administration encouraged gentrification and produced progressively the displacement of the most underprivileged inhabitants, mainly Roma ethnics from rather central locations to the margin of the city where they created informal settlements. The clustering of about 300 families (more than 1000 people) in an isolated area near the landfill in Pata Rât progressively transformed this process into a public problem. This peripheral settlement suffers from pollution, from all the nuisances brought by the propinquity of the landfill, from isolation (1,5 kilometers from public transport lines) and from extreme deprivation etc. (Dohotaru et al., 2016; Rat et al., 2012).

Forced evictions by local authorities from informal and public housing, without housing alternative or with forced relocations in the same marginal area further contribute to the clustering of marginal communities (Ibid.). The relative dynamic economy of the city of Cluj, especially in comparison to other areas, also attracts poor internal migrants from neighboring towns and villages that can only find shelter in this marginal area. The only resources for making a living in this area are informal work on the landfill – selective sorting activities – in which many Pata Rât inhabitants are involved (Rat et al., 2012) and underpaid day laboring.

In addition to the mobilization of activists concerned by the humanitarian problem related to ethno-residential segregation in a polluted and deprived area, the visibility of the cluster of informal housing near the landfill is increasingly acknowledged as a problem by the local administration because of its propinquity to the local airport. A pilot program funded by the Norway Grants for reducing social and economic disparities in Europe was launched in the end of 2014 (and ended in 2017)¹. This program for social integration and de-segregation of the communities living in Pata Rât was created by the Cluj Metropolitan Association (CMA). Even if there is a partnership with the local administration of the city of Cluj, there is no direct involvement of the municipality through co-funding or direct participation in the project implementation. Since CMA does not have an administrative and decision-making competence, the transmission of this problem from the municipal to the metropolitan level can be interpreted as an opportunity to access funding and to move the problem from the city to a higher i.e. metropolitan level. This practice is in line with the common opinion that social problems should not be treated at local (city) level and that national and EU resources are necessary. This attitude is also based on the discriminatory way of considering the underprivileged population as not belonging to the city, but rather to the rural areas where they should resettle. Both this imaginary of hierarchy between urban and rural in line with social hierarchies and the power subordination of the metropolitan administrative level to the city level are contrary to the principles of metropolitan planning.

5 CONCLUSIONS

We have addressed in the beginning of this paper the conditions under which metropolization constitutes an opportunity for immigrant incorporation in the U.S. The two European pilot projects have further allowed to analyze in which way the metropolitan turn in the administrative reform of European territories can

¹ The program is entitled Social interventions for the de-segregation and social inclusion of vulnerable groups in Cluj Metropolitan Area including underprivileged Roma (“Intervenții sociale pentru desegregarea și incluziunea socială a grupurilor vulnerabile în Zona Metropolitană Cluj, inclusiv a romilor defavorizați”) <http://patacluj.ro>

constitute an opportunity of coordination for the implementation of social integration programs for underprivileged immigrants and minorities.

In the U.S. model, the most important factors for successful inclusion of migrants are a dynamic economy, easy access to affordable housing and to transportation, propinquity with good education facilities and a non-hostile environment. In such successful “twenty-first-century gateways” immigrants are allowed to make place and contribute to the densification, local differentiation, economic development of the suburban metropolis. We can argue that there is more available space and that regulations are looser.

In the two European case studies immigrants and minorities are not allowed to take part in place making, especially in visible parts of the metropolis. Reinforced control over space is established through actions of dispersal (enforced evictions in both cases), marginalization (imposed resettlement in Cluj) and an overall policy of making the impoverished communities invisible in the metropolitan landscape. However metropolitan growth patterns and metropolitan planning make the territorial “gaps” of informal settlements increasingly visible.

In France in addition to access to space, access to employment and to affordable housing (public subsidized housing) are also highly regulated. In these conditions, underprivileged immigrants need increased support in order to integrate in society, that only measures that fall under “the basic statutory status of nationals” (“le droit commun”) cannot offer.

In France, the emergence of metropolitan administrations offers the possibility of implementing pilot projects (such as MOUS) that offer this reinforced assistance for social inclusion through employment and housing. They are based on the coordination of an extended number of stakeholders and decision makers interfering in metropolitan governance at different levels and of specialized organizations (in professional training, support on different aspects of integration such as language training, access to healthcare, etc.). However, stakeholders participate only on a voluntary basis and negotiations trigger compromises in the program principles (such as in the criteria for the applicants’ selection). This program matches the community dispersal objective through social and territorial mix. In the same time this politics does not appear to be contrary to maintaining immigrant communities when heterolocal functioning is made possible by an increased connectivity of the metropolitan area.

The high costs and the voluntary basis of this pilot project are obstacles for extending this kind of program to non-EU economic migrants and refugees, and for insuring its permanence. In the Romanian metropolization can hardly be considered an opportunity for the incorporation of minorities. The administrative metropolization is still at its beginnings and only offers city administrations the possibility to pass the embarrassing problem of informal settlements and of marginalization that it contributed to producing to another different administrative level. This tendency is very common among local administrations in different parts of the world that try to disengage from ensuring basic services to poor immigrants and minorities considering that it’s an issue that should be treated at State level (or federal in the US), or even at the supra-national (i.e. European) level. In Romania the Metropolitan Association does not have any real decision-making power and the coordination of players is limited in the absence of a political commitment from the real-decision makers and especially from the city administration.

The questions addressed in this paper should be explored further in order to understand how European territories are affected by migrations and what are the potentials and opportunities they offer for incorporating immigrants and minorities successfully.

ID 1702 | PLANNING, PLURALISM AND RELIGIOUS DIVERSITY: THE SPATIAL REGULATION OF MOSQUES IN ITALY

Francesco Chiodelli¹; Stefano Moroni²

¹Gran Sasso Science Institute; ²Polytechnic University of Milan

francesco.chiodelli@gssi.it

1 INTRODUCTION: PLURALISM, RELIGION, AND URBAN PLANNING

In recent times, regulations governing religious practices in European cities have generated widespread debate in many countries. In fact, the growing religious diversity in many cities has significant consequences on the urban environment, and primarily the new spaces that it entails (e.g. places of worship and burial grounds) and new forms of expression in public (e.g. types of dress connoting a particular religious conviction, such as the Islamic veil or the Sikh turban). These spaces and forms of

public expression engender complex problems of regulation, including specific questions related to urban planning.

In these circumstances, the otherwise abstract issues of cultural pluralism and religious freedoms suddenly become concrete and urgent within specific urban contexts (Moroni and Weberman, 2016). Consider, for instance, when a religious minority applies to the local council for planning permission to build a place of worship: in many cases, in several European countries, such applications run the risk of encountering forms of resistance – for instance, by local authorities, politicians or grassroots movements – in which the objection to the proposed scheme is framed in terms of planning issues (for some examples in different countries, see for instance: Dunn, 2001; Gale, 2005; Gale & Naylor, 2002; Germain & Gagnon, 2003; Isin & Siemiatycki, 2002; Jonker, 2005; Kuppinger 2011, 2014a, 2014b; Landman & Wessels, 2005; Qadeer and Chaudhry, 2000; Saint-Blancat & Schmidt di Friedberg, 2005; Torrekens, 2013; Vahed and Vahed, 2014; Villaroman, 2012).

Many planning theorists have attempted to untangle the complex web of issues surrounding urban pluralism and diversity in Western cities, sometimes doing so with specific reference to religious diversity (Burayidi, 2000a and 2015; Binnie et al., 2006; Dwyer, 2015; Dwyer et al., 2016; Eade, 2011; McClymont, 2015; Murtagh and Ellis, 2010; Qadeer, 1997 and 2016).

The main aim of this paper is to contribute to this debate on planning and (religious) diversity in the field of planning theory. In particular, it stresses the importance of focusing theoretically not only on positive action, but also on the role of planning and building rules, which is sometimes neglected in the discussion of many planning theorists on questions of pluralism. The starting point of our discussion is the case of a new planning law governing the construction and location of places of worship in the Lombardy region, Italy¹. Although the issue concerns various religious minorities, this article will focus on Islam and hence on the construction of mosques, which in Italy (as elsewhere) is a frequent target of local government opposition. What concerns us here is not so much the current legislation of the Lombard authorities per se as the example that these regional regulations furnish for a critical rethinking of some fundamental issues currently affecting several Western countries and cities. In fact, the planning restrictions introduced by the Lombardy region are similar to restrictions in force in other Western countries (see for instance Gale, 2005, on the UK, Kuppinger, 2014, on Germany, Torrekens, 2013, on Belgium, and Villaroman, 2012, on Australia).

This article is divided into four sections. The first briefly describes the characteristics of religious diversity in Italy and its spatial repercussions. The second focuses on the case of the regulations governing the construction of places of worship in Lombardy, Italy. The third section contributes to the field of planning theory, with reference to ways and means of guaranteeing pluralism in cities through the tool of planning rules, suggesting some theoretical guidelines for reforming the planning system in order to promote and protect (religious) diversity. The last section draws conclusions.

2 THE FACTUAL AND LEGAL CONTEXT: RELIGIOUS DIVERSITY IN ITALY

2.1 IMMIGRATION AND RELIGIONS IN ITALY

Unlike other European countries, Italy is quite new to the phenomenon of immigration; it was not until the 1970s that the country began to see a flow of immigrants, an influx that peaked in the 1990s (Bonifazi, 2007). In 1971 the number of immigrants residing in Italy stood at around 120,000 (barely 0.2% of the population). In 1991 this figure was 356,000 (around 0.6% of the resident population). By 2015 the proportion had risen to 5,014,000 (8.2% of the overall population) (ISTAT, 2015)². According to projections by ISTAT (2011), the number of immigrants in Italy will significantly increase in the coming years: the

¹ A very similar law has been recently approved (April 2016) by the Veneto Regional Council, Italy (Regional Law 12/2016).

² These data do not account for migrants illegally present in Italy: according to Caritas and Migrantes (2012) today these number around 500,000.

proportion of immigrants will rise to 14.6% in 2030: that is, 9.5 million immigrants out of 63.5 million residents¹.

This increase in immigrants coming to settle in the country also brings to Italy customs and religious beliefs that differ from the traditional Catholic ones. According to Caritas and Migrantes (2012), 32.9% of migrants in Italy are Muslims (1,650,000), 29.6% are Orthodox Christians (1,482,000), 19.2% Catholics (960,000), 4.4% Protestants (223,000), 2.6% Hindus (131,000), 1.9% Buddhists (97,000) (on this topic, see also ISTAT, 2015). Hence, Italy is today characterised by a stable population of non-Catholic residents, for the most part immigrants (Allievi, 2000a, 2000b), including a sizeable number of Muslims. Islam is not only the religion practised by a third of the immigrants in Italy; it is also the country's second religion after Catholicism (Introvigne & Zoccatelli, 2013)².

The fact that, in recent years, Italy has experienced a shift from a Catholic majority to a tapestry of diverse religions (Pace, 2013a) is inevitably causing radical changes in the Italian social fabric, since Italy for centuries was a staunchly Roman Catholic country (and Catholicism continues to be the principal religion practised by those born in the country).

2.2 THE URBAN DIMENSION OF RELIGIOUS DIVERSITY IN ITALY

The significant and permanent presence of non-Catholic immigrants in Italy has major consequences also on the urban space. One of these consequences is the emergence of new places, some of which are specifically assigned for religious purposes (e.g. places of worship and burial grounds), while others are related to a particular practice influenced by religion (e.g. halal butchers). Further novelties include new patterns affecting both individual behaviour (dress codes like the Islamic veil or the Sikh turban), and collective ones (such as collective rituals linked to religious practices or calendars) in the public sphere and space, as well as the appearance of temporary spaces characterized by the codes or sensitivities of a specific religious minority – for instance, an area of a park where a group of Muslims gathers regularly at certain hours of the day (Agrawal, 2008; Allievi, 2000b; Becci et al. 2016; Chiodelli, 2015; Gökarıksel, 2010; Knott & Vasquez, 2014; Knowles, 2013; Kuppinger, 2014c).

In Italy, Islam in particular is having a significant impact on the city's spaces. One of the principal Muslim spatial 'markers' affecting the urban landscape is represented by Islamic places of worship (Chiodelli, 2015)³. In Italy there are two main types of Muslim places of worship. The first type is the purpose-built mosque (or formal mosque), usually in the classic form of the building, complete with a dome, minarets and Arabic script or symbols. The second is the informal prayer-hall⁴, which is usually smaller, sometimes temporary, often arranged in former warehouses, private apartments or shops (Allievi, 2010b). The informal prayer room responds to the Muslim's everyday liturgical needs, but does not achieve the critical objective of establishing public recognition and visibility of Islam in the public arena, as would the construction of a purpose-built mosque (Metcalf, 1996).

Precise data on the number of Muslim places of worship in Italy are lacking at present, though today they may amount to around 1,000 (Chiodelli, 2015). It is worth noting that the informal prayer-halls account for almost all Islamic places of worship, and that there are fewer than a dozen purpose-built mosques in Italy. Lombardy's situation is paradigmatic: although around half a million Muslims reside in Lombardy (Menonna & Mirabelli, 2013), there is only one single purpose-built mosque in the region – that is, the small mosque (around 100 sq.m. of surface) of Segrate, near Milan.

One of the main reasons for this lack of purpose-built mosques in Lombardy (as well as in the rest of Italy) is the opposition by local population and authorities.

¹ Obviously, these data do not take into account the so-called 'second generation' (immigrant children who are born and grow up in the receiving country). Nowadays, second-generation immigrants in Italy are not significant from a quantitative point of view. However, their number is increasing rapidly (Caritas and Migrantes, 2012; ISTAT, 2012).

² A certain number of Italian non-Catholic worshippers must be added to non-Catholic immigrants. However, their number is not significant from a statistical point of view: for instance, Italian converts to Islam number about 70,000 according to the Italian Union of Islamic Communities; Italian Jews amount to around 24,000 (Pace, 2013b).

³ See Pace (2013c) for an overview on the places of worship of various religious minorities in Italy.

⁴ In the literature, they are sometimes also referred to as musallah (musallayat at the plural form).

There are several major cities in Lombardy where applications to construct a purpose-built mosque have been (repeatedly) presented to the local authorities, but rejected by them. This is for instance the case of Bergamo, Brescia, Lodi and Milano, to mention only some cities (Saint-Blancat and Schmidt di Friedberg, 2005; for similar cases in other Italian regions, see Allievi, 2010b and Galeotti, 2012). The president of the Lombardy Region, Roberto Maroni, has declared that mosques are “a virus whose spread we must prevent” (Montanari, 2014).

The case of Milan is particular striking. Although over 80,000 Muslims reside in Milan (Blangiardo, 2013), there is not a single purpose-built mosque. For around twenty years (from 1993 to 2011), the city was governed by right-wing governments which always opposed the construction of a purpose-built mosque in various ways. However, in the past five years, the city has been run by the left-wing administration of Giuliano Pisapia, which has declared on several occasions that it intends to remedy the lack of mosques in Milan. For instance, a couple of years ago Mayor Pisapia announced that a temporary purpose-built mosque would be constructed for the 2015 World Exhibition in Milan, and that it would become permanent after the Exhibition (Coppola & Santucci, 2014a, 2014b). However, the temporary mosque for Expo was not built. The only progress in this regard is the fact that, in September 2015, the Milan Municipality allocated through a public competition three public areas for the building of a place of worship for religious minorities. Two areas were assigned to Muslim associations for two purpose-built mosques (Dazzi, 2015a). However, the actual construction of these mosques will probably take time, and many bureaucratic hurdles may slow down the process (Dazzi, 2015b).

As will become clear in the following sections, this can happen also because the Italian framework of rules governing the construction of places of worship for minorities leaves ample decision-making power to the local public authorities: indeed, town councils have a *de facto*, and in some cases also *de jure*, faculty to block the building of a place of worship in their jurisdiction if they deem it undesirable.

2.3 THE NATIONAL LEGISLATIVE FRAMEWORK IN ITALY GOVERNING PLACES OF WORSHIP

The Italian Constitution recognises and defends the freedom of individuals and groups to profess the religion of their choice (e.g. articles 3, 7, 8, 19, and 20). Places of worship are deemed a functional part of exercising this constitutional right: in fact, the principle of religious freedom cannot be reduced to inward prayer, but must also be expressed through group worship (Bettetini, 2010). The availability of places of worship as intrinsic to the constitutional right of religious freedom is enshrined in several judgements passed by the Italian Constitutional Court (for instance, ruling no. 59/1958 and particularly no. 195/1993); similar judgements have been expressed by the European Court of Human Rights (see Manoussakis et al. vs Greece, 16 September 1996). Note that the national laws impose no special restrictions on the construction of new places of worship, whatever the religion (Tozzi, 2007): religious buildings are subject only to the standard set of building and planning regulations.

Despite this apparent latitude in terms of constitutional principles and national legislation, the reality at local level is very different. A constitutional law passed in 2001 (Legge costituzionale 3/2001, Modifiche al titolo V della parte seconda della Costituzione) ruled that town planning legislation was to be transferred to the regional authorities. The snag is that, in many cases, the regional laws on religious building lack the general and abstract character of the national law, with the result that forms of discrimination arise (Tozzi, 2010; D'Angelo, 2008), particularly as regards certain religious minorities such as Islam. As we shall argue in the following section, Lombardy in particular presents a blatant case of partiality in this respect (for an in-depth discussion on other regions of Italy, see Bettetini, 2010, Bolgiani, 2013, Rocella, 2008).

Note that this situation of discrimination at the local level is possible because Italy lacks a specific national law regulating the detailed and concrete aspects of the Constitutional right of religious freedom for all creeds, just as Italy also lacks a model of integration of (or relation with) migrants. In this regard, differently from several other countries, for instance France, Germany or the UK, in Italy “there has been no real reflection on the legislative process, even less in order to build a coherent model [of integration of (or relation with) migrants]. Conflicting approaches have prevailed in different moments, characterizing different laws. It is not by chance that practically all the more important laws on migration have been linked to a sanatoria (a regularization), discussed and approved often using the term ‘emergency’ and always bearing an emergency situation in mind” (Allievi, 2010a, pp. 91-92; see also Russo Spena, 2010). In the

absence of such a national law – and of a national strategy for the integration of migrants – the current situation is characterized by a high level of fragmentation and differential treatment. Besides the privileges granted to the Catholic Church (Casuscelli, 2007b), which are linked to its great influence on modern Italian history (Pollard, 2008), every creed can negotiate special arrangements with the State by signing a concordat (*intesa*). These arrangements refer to different aspects: for instance, the automatic access of ministers of religion to state hospitals or prisons; civil registry of religious marriages; the facilitation of special religious practices regarding funerals; access to public funds through a voluntary check-off on taxpayer returns (the so-called 8 per mille). In Italy, many creeds have signed a concordat with the State – Judaism, Buddhism, Hinduism, or the Waldensian, Lutheran, Apostolic, and Orthodox churches (Tozzi, 2009; Lariccia, 2007; Casuscelli, 2007a) – but for a variety of reasons, Islam is not among them (Allievi, 1996, Ferrari, 2000).

3 THE SPECIFIC CASE OF THE PLANNING LAW ON PLACES OF WORSHIP IN LOMBARDY, ITALY

Lombardy is Italy's most populous region and has some 10 million inhabitants. Not surprisingly, therefore, the region has the largest number of immigrant residents: at the start of 2015 records show that around 1,152,000 non-Italians lived in the region, equal to 11.5% of the total population. The immigrants registered in Lombardy amounted to 23% of the total of immigrants legally resident in the country (ISTAT, 2015), a significant proportion of whom were Muslims (39.6%) (Menonna & Mirabelli, 2013). Nevertheless, recent regional laws have imposed tight restrictions on the allocation of Muslim places of worship.

The regional law in Lombardy that regulates urban planning is law no. 12/2005 (*Legge per il governo del territorio*), which has been modified several times over the years, including its provisions on places of worship. In this regard, the most recent significant adjustment was made in February 2015: regional law no. 2/2015, *Modifiche alla legge regionale 11 marzo 2005, n. 12 - Principi per la pianificazione delle attrezzature per servizi religiosi* (for a detailed overview of the legislation regarding religious buildings in force in Lombardy, see Marchei, 2014, and Rocella, 2006, 2008).

In general terms, the law states that both the regional authorities and local councils must promote the construction and maintenance of places of worship. This happens in two ways: first, by specifying in the municipal planning document (the *Piano di governo del territorio*) areas where a given place of worship may be created; second, by determining how public funds are allocated for the creation and maintenance of places of worship. To be noted is that the public funds allotted for places of worship are considerable in their amount: for example, from 2006 to 2011 the municipality of Milan assigned around 19.6 million euros (UAAR, 2014). By law, the recipients of these measures include both the Catholic Church and religious minorities.

Despite its declared principles, this regional law includes certain clauses that raise severe obstacles to religious minorities (and particularly Islam) in terms of their access to the benefits envisaged by the law itself; but it also hampers the chances of constructing a house of prayer even without any public funding.

Before analysing three main restrictions which are particularly relevant in this regard, a point should be stressed. A fairly recent modification to the regional planning laws (regional by-law no. 3/2011) extended the definition 'facilities for religious purposes' to include any kind of place with some connection to religion (such as religious schools and cultural centres). As a result, the restrictions that apply to places of worship proper, which we shall analyse below, now also apply, for instance, to cultural centres and religious association headquarters. Consequently, it is no longer possible to set up an Islamic cultural centre, and appoint a room for occasional prayer, if it does not abide by all the rules referring to religious facilities proper. Note that this situation persists despite the fact that various court

rulings (e.g. Tribunale Amministrativo Regione Lombardia - Brescia, Sentenza no. 242/2013) have determined that gathering for prayers on the premises of a cultural or social association is insufficient to qualify the space in question as a religious facility as such (Fabbri, 2013).

3.1 RESTRICTIONS ON THE CONSTRUCTION OF A NEW RELIGIOUS BUILDING

The regional law in Lombardy regulating urban planning sets three main obstacles to the construction of a new religious building for certain religious minorities: a widespread, organised and stable presence in a certain municipality; the presence of a plan for religious facilities; respect for the local landscape.

First obstacle: the requisite of a widespread, organised and stable presence. According to the regional planning law, if a religious minority has not signed a special agreement with the State (as stressed, this is the case of Islam), it must have a “widespread, organised and stable presence within the council’s jurisdiction” (regional law no. 2/2015) in order to access the benefits of the law. However, this requisite sounds particularly vague: what does a widespread, organised and stable presence mean exactly? What are the precise criteria on which its assessment must be grounded? The law does not answer these questions. Hence, such fuzzy criteria create leeway for discretionary decision-making in each council area. In fact, a municipal administration may simply reject an application by a Muslim association if it deems that the number of followers of Islam in its jurisdiction does not reach a certain – and otherwise unstated – quota (Casuscelli, 2009). The predictable consequence of this high degree of discretionality is the fact that creating a new mosque will become even more difficult than in the past because the majority of local councils in Lombardy are run by political parties and coalitions which are hostile to the presence of (Muslim) immigrants on their territory.

Second obstacle: local plans for religious facilities, and the ‘mosque referendum’. The recent modification made to regional planning law (regional law no. 2/2015) made it obligatory for all local councils to draw up a ‘Plan of Religious Facilities [Piano delle attrezzature religiose]’. In this scheme each council must identify specific areas in which to address the needs of the various communities of worshippers on its territory. This document is self-contained and distinct from the other specific plans constituting a local master plan according to the regional planning law, namely the ‘Strategic Plan [Documento di Piano]’, the ‘Public Services and Facilities Plan [Piano dei Servizi]’, and the ‘Regulatory Plan [Piano delle Regole]’. If this plan of religious facilities is lacking (for instance, because it is in the drafting phase; note that in Italy the drafting and approval of a spatial plan can take years), no new places of worship can be built.

To be noted is that houses of prayer are the only collective places that are granted a specific, dedicated plan in the planning system, separately from the Public Services and Facilities Plan, which allocates the spaces for all other public amenities such as schools, hospitals, and parks. Before the aforementioned legal modification was enacted, religious facilities were included in the Public Services and Facilities Plan.

When a municipality draws up a Plan of Religious Facilities, it is required by law to consider the opinions of civic committees, the police force, and the prefecture in order to evaluate the related issues of public security. The underlying concern seems to be that places of worship can pose a threat to public security. This impression would appear confirmed by the fact that the law makes it mandatory for new religious facilities to install CCTV cameras connected to the local police department, from where the authorities can monitor comings and goings at the building’s entrance.

Furthermore, the law stresses that the local councils are entitled to conduct a public ballot on the contents of the Plan of Religious Facilities; a popular vote that the press promptly dubbed the ‘mosque referendum’. Note that the law refers to the possibility of a local referendum only with reference to places of worship, but not, for instance, with reference to dangerous facilities like factories handling volatile substances or involving other health-risk activities (such as landfill sites).

Third obstacle: respect for the local landscape. The new regional by-law places yet another obstacle in the way of completing new facilities for religious minorities. It states that the “aesthetics and architecture of the new buildings must be congruous with the particular characteristics of the Lombard landscape” (regional law no. 2/2015). But what is the ‘Lombard landscape’? What are its specific features? Note that Lombardy covers a huge area amounting to 24,000 square kilometres (falling just short of the entire state of Belgium, and around half of Switzerland or the Netherlands), and has several distinctly different types of ‘landscape’ (mountains, plains, swampland, riverside) characterised by a marked variety of historical, natural, and settlement characteristics. One consequently wonders to what exactly this regional law is referring. Without specifying precisely what the distinctive characteristics of the Lombardy landscape are, in this case, too, the rule gives free rein to interpretation – and hence to improvisation and random discrimination.

3.2 RESTRICTIONS ON THE USE OF AN EXISTING BUILDING AS A PLACE OF WORSHIP

As pointed out earlier, in Italy most Islamic places of worship consist of informal prayer-halls, which in many cases are located in buildings whose original function was (or still is) quite unrelated to prayer, or whose main function is not worship. This applies for instance to the many Islamic cultural centres dotted around the country, where prayer is just one of the many functions performed alongside a busy schedule of social, cultural, and recreational activities. But it applies also to the headquarters of some immigrant associations where prayer is sometimes performed, or to secular buildings converted to prayer rooms. Consider that, in several of these places, prayer is practised only occasionally, since it is usually limited to Friday prayers or holiday prayers. In many cases, Muslims in Italy (but this applies also to Jehovah's Witnesses, for instance) have made up for the lack of official places of worship by establishing such informal prayer rooms.

However, the regional law on urban planning introduced several obstacles to this practice. It not only, as said, extended the definition 'facilities for religious purposes' to include any form of recreational centre or association locale with some connection to religion, so that all the requisites analysed in the previous section applies to them. The law set another obstacle to the creation of prayer-halls as well.

The regional by-law no. 12/2005 (art. 52) relaxed the regulations limiting changes to a property's end-use that did not require building alterations. Since then, such changes in end-use no longer require permits from the council planning department¹. The snag is that another by-law issued the following year (Legge regionale 12/2006, Modifiche e integrazioni alla legge regionale 11 marzo 2005, n. 12 "Legge per il governo del territorio") ruled that this relaxation of regulations no longer included places of worship, meaning that anyone wishing to change the end-use of a property for religious purposes must now apply for a building permit. (Note that Lombardy is now the only region in Italy in which changes of end-use for religious purposes are given special treatment: Fabbri, 2013).

Normally, a building permit is a standard document certifying that a specific transformation conforms to the standards laid down in the planning and building codes; hence, on paper, the purpose of the permit is merely to ensure compliance with the regulations, with no room for discretionary decisions by the public authorities (Mengoli, 2014). That said, in Italy the issue of a permit may be subject to all sorts of bottlenecks and red tape – legitimate or otherwise – implemented by municipal planning departments and other public bodies, as has been documented in a number of cases (D'Angelo, 2008, Rocella, 2008). This is exemplified for instance by the case of the mosque in Maderna Street, Milan. In 2013 the Islamic Turkish association Milli Gorus bought a warehouse and started work in order to transform it into the first purpose-built mosque of Milan, with a (small) dome and a (low) minaret. The renovation work on the warehouse was done in compliance with all the planning and building regulations. However, according to the regional law, in order for the building to be used as a house of worship, it had to receive authorization from the Municipality for a change in end-use, which it never obtained (Liso and Vanni, 2013).

3.3 RULING 63/2016 BY THE CONSTITUTIONAL COURT

The Italian Constitutional Court has recently examined the constitutionality of the Lombard by-law no. 2/2015, following a request by the Italian government. The government asked the Court to review various parts of the law; among them, also some of the provisions analysed in the previous sections: for instance, the requisite of the 'widespread, organised and stable presence' and that of respect for the local landscape. The ruling of the Court (Italian Constitutional Court, ruling 63/2016) was complex: it accepted several of the government's objections to the regional law, while it rejected some others. In particular, it declared unconstitutional the requisite of the widespread, organised and stable presence of a religious minority as a condition for accessing the benefits of the law, because this determines a situation of discrimination against certain religious minorities, which is in contrast with several articles of the Italian Constitution. By contrast, some other provisions of the law were not condemned by the Court. This is the case of respect for the local landscape, which, for the Constitutional Court, is a legitimate criterion on which assessment of a building project can be grounded. Despite the Court's judgement, this criterion

¹ Only in the case of premises with a floor area exceeding 150 square metres must prior notice be given to the municipality.

remains very vague, and, in our opinion, leaves a degree of discretionality to the municipalities which is too broad, creating the possibility of discrimination.

4 DISCUSSION: A CRITICAL ASSESSMENT OF THE LOMBARDY LAW AND A NORMATIVE PROPOSAL

4.1 A POSSIBLE REFORM

“The fact of pluralism [...] emerges as self-evident. [...] By definition, therefore, ‘diversity’ is an inescapable feature of human societies” (Triandafyllidou et al., 2012: 2). This unavoidable demand for pluralism is strikingly urgent in many European cities, and the growing complexities of ethnic, cultural and religious diversity pose new challenges to planning the urban environment (Qadeer, 1997; Moroni and Weberman, 2016).

We maintain that a specific reform of the planning system (for instance, of the Italian planning system) could help guarantee pluralism – including religious pluralism, at least in terms of its physical presence in the urban space. In particular, this reform should comprise a radical revision of traditional systems of spatial regulation, so as to ensure an impartial application of rules of a specific type, that is, rules curbing the negative side-effects of urban functions, instead of rules regulating the functions themselves, as happens at present. To achieve this end, three simultaneous conditions must be fulfilled, which we will analyse in the following sub-sections. (When describing these conditions, we shall imagine that the reform is applied to the Italian legislative system, but, in some respects, one may consider its application in other countries as well).

First condition: ensuring a system of more ‘general and abstract’ rules. Essentially, the rules to be applied must be as general as possible (i.e. referring to standard situations or actions, not to specific ones), and also abstract (i.e. applying equally to all, not to particular individuals or groups). The goal is to achieve equal treatment, but in a version more radical than the one currently advocated (Somaini, 2012).

At present, the above-mentioned rules introduced by the Lombard regional authorities are neither abstract nor general. Quite the opposite: they are tailored expressly to deal with specific subjects (e.g. specific religious faiths), and hence give rise to forms of discrimination born upstream, as it were. As stated above, the Lombard by-law no. 2/2015 determines different requirements depending on whether the religion in question is (or is not) ‘widespread, organised and stable’. Furthermore, this Lombard by-law envisages certain special requirements that apply exclusively to religious facilities (such as drafting a specific Plan of Religious Facilities), and which do not pertain to any other kind of public facility or community amenity.

One might concede that these general and abstract rules are in truth only a question of degree. Nevertheless, once their status has been acknowledged (and formally enshrined in the legislation more strictly than happens at present), it is no longer difficult to distinguish between blatant violations of these principles and sincere attempts to address the situation as best as possible. In other words, it is not difficult to grasp whether a rule satisfies the ideal only to a certain extent simply because one is progressively trying to reach the ideal in the existing conditions; or whether this occurs for other unacceptable reasons in light of the ideal itself (in the second case, any actor can legitimately object, even through the courts).

Second condition: preferring negative rules. Although the introduction of more general and abstract rules would per se address several problems of discrimination regarding the creation of places of worship for religious minorities (for instance in Italy), this approach would not be enough on its own. In fact, the implementation of a particular type of (abstract and general) rules is necessary. In particular, in our opinion, regulations should be applied not to the uses of land and buildings as such, but to the consequences incurred (e.g. by referring to a checklist of predefined negative side-effects or externalities). For instance: irrespective of a building’s actual function, a regulation could limit the decibels of noise that it may produce; this rule would apply equally to a bar, a sports complex, a Catholic church or a mosque, and be implemented for all areas assigned for new construction or modification (without distinction).

This bypasses the traditional planning practice of drawing up in advance an exhaustive list of the permissible and inadmissible end-uses (of both land and buildings) within a given territory, and of

assigning these according to distinct areas. In short, our contention is that planning regulations should apply only as means to curb any negative external side-effects resulting from activities performed in a given building; they should not in any way regulate the activity itself (Corkindale, 1998; Moroni, 2012; Rogge, 1979). It is essential to stress that the negative side-effects under discussion here are not ones that would hinder the socio-economic efficiency of a given area (the customary interpretation supplied by neoclassical economics). This has nothing to do with the oft-cited market failures: at stake here are the rights of the individual, and the crucial issue is finding the institutional requirements to reduce interpersonal conflict between individuals endowed with basic rights, and thereby broaden their chances of addressing different goals in a constantly evolving social and cultural flux (Cordato, 1980,1994).

Note that with this system, the issue of changing a building's end-use no longer applies, and the need for authorisation likewise disappears: if the plan does not contain a priori indications of a building's or land plot's end-use, then every change in a building's or land plot's end-use is always possible, provided that it does not cause negative side-effects. This would also solve another problem made clear by the Lombardy case: preparing a traditional zoning plan regulating the functions of lands and buildings is today made no easier by the difficulty of defining precisely what a place of worship is in the case of religious minorities. Is it only a specific building that has distinct religious connotations both internally and externally, or also, more generally, any building adapted for religious purposes? Is it only where rites are performed on a regular basis, or also a locale that occasionally doubles up as a house of worship? A place where only religious services are held, or where other events take place? And not least, how many people must gather in prayer to classify a building as a place of worship?

Third condition: impartial application of the (abstract, general and negative) rules. In liberal democratic states, an unbiased and impartial application of statutory laws and rules is a standard requisite (Sartori, 1957); this should be an inalienable principle. As we know, however, in practice things go very differently in some countries. This is for instance the case of Italy: discrimination against religious minorities occurs also through the biased application of the law, such as sluggish administration, bureaucratic holdups, and extra red-tape reserved for 'special interest' groups. Which is why it is crucial to eliminate any risk of discretionary procedure regarding (also) the implementation of planning and building regulations. For instance, one way to do this is to make the issue of building permits automatic if and when the transformations proposed conform to the regulations: thereby removing discretionary power of whatever kind from public officers in the planning department. Actually, this could be expedited by placing the application system online, either partially or entirely (Meijer and Visscher, 1998 and 2006; National Institute of Building Sciences, 2002). Note that all this is possible once the legislation has been purged of ambiguities like those found in Lombard's planning framework, a fuzziness that leaves the door open to interpretation and discriminatory practices, even in the application of the rules.

4.2 A COMPARISON WITH OTHER PERSPECTIVES

As well-known, numerous authors have inquired how urban planning can contribute to the growth of diversity and pluralism in general, and to the growth of religious diversity in particular (Burayidi, 2000a and 2015; Binnie et al., 2006; Dwyer et al., 2016; McClymont, 2015; Murtagh and Ellis, 2010; Qadeer, 1997 and 2016)¹. Even in the diversity of viewpoints and proposals, many of them declare that some kind of 'positive action' (i.e. 'affirmative action') by the public authorities – and by the planners as well – is of paramount importance. A 'positive action' implies that members of disadvantaged groups (such as Muslims) would be the target of specific measures in order to ensure them access equal to that of the majority population, for instance in terms of having a voice in the planning process and seeing their needs satisfied by urban policies. Among the various positive actions in the planning domain there are: developing methods for promoting participation in the planning process

which reflect the cultural specificity of different minority groups (Sandercock, 2000; Main and Rojas, 2015); appointing an officer specifically to deal with the problems and specificities of different cultural and religious communities, and training local authorities and planners in conflict negotiation and cultural sensitivity (Thompson, 2003); designing specific planning documents to deal with the needs of a multicultural and multi-religious city (Uyesugi and Shipley, 2005).

¹ For an overview on planning and diversity, see also Fincher et al., (2014), and van der Horst and Ouwehand (2012).

The discretionary power of mayors has been of fundamental importance in allowing the construction of mosques in several Belgian cities, despite the opposition by local councils and population (Torrekens, 2013). And “flexibility in planning norms and practices” (Qadeer, 1997, p. 493) is considered to be an key element of the Canadian approach to ethnic, cultural and religious diversity. In this regard, it is considered essential that individual planners and local authorities are encouraged (and trained) to become culturally inclusive, and to develop sensitivity to diversity in all its guises (Thompson, 2003). “It hardly needs to be said that the success of this kind of planning work depends very much on the skills and wisdom of the practitioners involved” (Sandercock, 2000, p. 27; see also Vahed and Vahed, 2014). The importance of this sensitivity appeared clear in the case, for instance, of some municipalities in Australia (Thompson, 2003); and it is an important element in the planning departments of several US and Canadian cities dealing effectively with diversity (Qadeer, 2015).

In many cases, scholars stressing the need for positive actions highlight the limits of a ‘normative approach’ to problems of pluralism and diversity in the urban sphere. As Sandercock (2000, pp. 15-16) argues, planning systems and regulations express the norms and values of the culturally dominant majority – that is, in Italy as well and in many Western countries, a Judeo-Christian, male and white majority. Hence, these norms are insensitive to religious minorities, in particular minorities distant from the mentioned traditions such as Muslims (on this topic, see also Burayidi, 2000b; Keetch and Richards, 1999; Diver and Thompson, 2007; Dunn, 2001; Fincher et al., 2014; Qadeer, 1997; Watson, 2005; Villaroman, 2012).

While we recognize that certain forms of positive action can be helpful (in particular, promoting various forms of participation, training officials and planners to deal with multicultural contexts, appointing specific public officers to address the problems of minorities), we believe that the principal reform must concern the background legal framework. The fact that the current legal framework is in many countries (as in Italy, particularly at the regional level) biased does not mean that it is impossible to create a more impartial one. A more impartial legal framework, based on a radical idea of equality of treatment, entails a profound revision of local plans and regulations.

As we argued with reference to Lombardy, here local authorities are not only reluctant to promote actions in favour of religious minorities; they often take advantage of the opportunities offered by the planning law in order to discriminate against them. At the same time, while the criticisms of a ‘normative approach’ to problems of diversity are convincing on certain points, they sometimes fail to consider some opportunities offered by this perspective. In many cities, building and zoning laws and practices have been revisited in order to accommodate the different needs emerging from cultural diversity (Burayidi and Wiles, 2015).

5 CONCLUSIONS

Religious diversity is a basic characteristic of a great many European cities, and is now an everyday reality of Italy’s urban environment. This diversity affects also the city’s physical structure, for instance through the appearance of new places with a religious characterization. This is the case, for example, of houses of worship of religious minorities. The spread of such ‘new’ places has inevitable repercussions also in terms of planning (theory and practice).

From this viewpoint, the case of the Lombardy region in Italy is paradigmatic: even if Italy’s Constitution explicitly guarantees the right of all religious minorities to create and enjoy places of worship, in practice this basic right is thwarted by the mesh of regional planning law and local planning practices. This is because the regional planning laws are prone to discriminatory decision-making by bureaucrats and policy-makers which violates the Constitutional right to religious freedom.

Planning theorists have often asked what it would take to foster and ensure diversity and pluralism in today’s cities and societies. Numerous proposals have been put forward in this regard. Although with several differences, roughly speaking we can state that the majority of these approaches claim that some type of ‘positive action’ is required on the part of the public authorities; at the same time, they often claim that any intervention on planning regulations would be insufficient and ultimately unsuccessful.

As we argued in the previous sections, we believe that in certain situations – as in the case of Italy – these positive actions run the risk of being ineffective simply because, for many reasons (for instance, political

ones), they are not implemented by local authorities. In Italy, contrary for instance to many US and Canadian cities, planning practice is not already responsive to ethno-cultural diversity, and planning departments have not already adopted pluralistic standards for the development of places of worship (Qadeer, 2015).

On the contrary, the efforts of many Italian local authorities are devoted to discriminating against certain religious minorities, something made possible by the discretionary power assigned to them by regional laws. This is why, when basic rights are at stake (including religious freedoms), it is crucial to ensure that rights are protected against the random impositions of the public authorities. This crucially refers also to planning and building regulations, since, as we stressed, in Italy it is exactly here, at the local level, that infringements of these rights occur.

For this reason, all regulations regarding land-use must be 'airtight' in how they work, and under no circumstances must they clash with the basic rights of individuals: they must function 'correctly' (that is, respect constitutional rights) even when employed by 'incorrect' public authorities (that is, public authorities willing to violate those rights).

Regrettably, the current Italian planning system (but this applies to other Western countries as well) seems more eager to satisfy the (presumed) needs of the urban fabric before it addresses the basic rights of the citizens themselves. This discrepancy is glaringly obvious in the case of the failure by certain Italian municipalities to ensure that religious minorities have their rightful places of worship, as required by the Italian Constitution. What is sorely needed at present is an inversion of the ratio between the government powers over the territory and religious rights (Rocella, 2008): along with other constitutional rights, the right for appropriate places of worship should have priority over planning decisions; and the town plan itself must ensure that those constitutional rights are honoured to the full. Faced with communities and institutions that frequently display hostility to the presence of ethnic and religious minorities on 'their' soil, endowing local administrations with discriminatory powers puts the democratic process in jeopardy. For this reason, it is essential to eliminate a priori the faculty of local councils to exercise differentiation (i.e. discrimination) through land use planning, thus avoiding any backlash on the basic rights of the citizen.

To achieve this, we suggest that radical changes should be made to the way in which land-uses are planned, governed and regulated. In particular, it is important to evolve towards systems composed of more general and abstract rules that deal first with the possible harmful side-effects, rather than interfere with the end-uses (i.e. preference should be given to forms of 'nomocratic planning': Moroni, 2012; Holcombe, 2013)¹. This is obviously just an 'ideal', which may prove difficult to implement immediately and which would require several adjustments in order to be put into effect. However, we think it important to place it at the centre of the thoughts of planning theorists working on problems of (religious) diversity, who do not always consider the potential of a 'normative approach' to these questions.

¹ Note that this does not involve introducing any special (and controversial) new 'group rights' or 'collective rights' into the system – something that many advocate as a means to provide minorities with better chances of building and managing places of worship (Calder et al., 2014). Instead, our proposal lies comfortably within the sphere of the universal rights of the individual. Indeed, it is worth noting that certain proposals that concern group rights actually seem to stem – as in the present case – from the notion that planning bodies can freely differentiate and decide specific land-uses at will.

ID 1741 | IMMIGRANTS AS AGENTS OF URBAN TRANSFORMATION: TESTING NEW TYPOLOGIES AND NEW BRIDGES BETWEEN CONCEPTS AND EMPIRICISM

Marina Gaboleiro Carreiras¹

¹ULisboa - IGOT

marinacarreiras@campus.ul.pt

ABSTRACT: The paper reflects on migrations and discusses how the role of immigrants in cities can be assessed. In a complex context of migrations and urban transformations I explore the relationship between these two components. Is the role of immigrants in urban spaces analysed by policy makers? Is the diversity of migrants and foreigners considered on urban planning and housing policies? What categories of immigrants do government agencies and supranational institutions contemplate? Do the variables considered when categorizing immigrants express the complex reality of migration? These are some of the questions that guided the reflections presented here. Being an exploratory work I will not seek to answer these questions but rather to critically discuss their pertinence. In the Portuguese context this discussion is relevant due to territorial imbalances and inconsistencies, affordable housing shortages and enhancing discourses on the value of the contribution immigrants make. When studying immigrants and foreigners who enter and remain in Portugal, it is clear, that the new and overlapping situations do not fit the traditional categories of immigration and tourism. Thus I propose a set of categories more adjusted to these circumstances considering immigrants and foreigners in the cities, their housing needs and specificities. Methodologically, the research consisted of a literature review and was carried out employing analysis of several laws and documents focusing conditions for entry and to stay on Portugal and the right to housing. The paper is divided into four sections. Section one gives a brief overview of the migrations complexities and some problems and challenges arising from this situation. Particular attention is paid to the migration studies and to the impacts of migration flows in cities. Throughout the section two I discuss the concept of immigrant and the way this one is operationalized in legal and administrative categories. This analysis confirms that traditional categories of migrants weren't broadened by the inclusion of the effects of migrations in the urban spaces. Recognizing this gap, in section three I propose a new approach who consider the impacts of immigrants and foreigners in the city, especially in its housing component. For the drawing of this exploratory typology I considered the situation in the Portugal, namely in the city of Lisbon. Conclusions are outlined in the last section.

1 THE COMPLEXITIES OF MIGRATIONS IN CITIES

Migrations are embedded in a globalized system, urbanized and framed by the interdependence between mobility of people, information and objects (Sheller & Urry, 2006). In an increasingly vast relational network of places, cities are particularly important (Sassen, 1991) and countries lose prominence. Consequently, the issues of social cohesion, sustainable development and migrations are becoming increasingly relevant to local authorities and communities. The migrations are a phenomenon eminently urban and the spatial inclusion of migrants in the city is a topic of interest, in the current context of globalization, urban complexification (exponential urban growth, fragmentation, gentrification), increasing mobility, diversification of migratory flows (King, 2010) and transnational practices (Vertovec, 2010).

Although the large diversity of migratory experiences appears as a striking feature nowadays, this is not unprecedented. In Europe, before the 19th century, diverse migratory movements were reported, determined by labour, religious, political, study and leisure reasons (Fassmann, 2009). The currently mentioned complexity of migrations is due not only to the diversity but also to the intensity of movements, covering an extensive combination of reasons of migration, travelled distance, fragmentation of movements (King, 2010; Sheller & Urry, 2006). The ease of mobility and communication, the new systems of economic and social organization allows and encourages new migratory modalities disregarded in traditional visions of migration associated with simples and permanent movements from one place to another (King, 2010). Nowadays there are sharp new and flexible mobility patterns, including migrations led by temporary workers, international students, artists and retirees, as well as hybrid situations between tourism and migration, namely residential tourism, which is becoming more popular, being no longer an

exclusive of the elites. Within this scope there is a need for innovative approaches, who allows to operationalize new concepts. These intentions should, go hand in hand with strategies to capture and analyse data related with these realities. More details on this are given in the work of a remarkable number of international organizations and scholars (Fassmann, Reeger, & Sievers, 2009; GCIM, 2005; Lemaitre, Liebig, Thoreau, & Fron, 2007; Ruhs, 2005; OECD Secretariat, 2015).

The impacts of immigration in the production and appropriation of urban space are least discussed than in other areas (economic, political, demographic, cultural). Despite this it is recognized that changes in migratory dynamics have repercussions in the urban space. In this regard note the existence of a literature that highlights the role of immigrants from the global South in the process of development and reinvention of western cities (Davis, 2001; Ford, Klevisser, & Carli, 2008), examines the relation between migrants and urban landscape (Gésero, 2014) and their effects in the housing market (Malheiros, 2001; Teixeira, 2015).

2 WHO IS AN IMMIGRANT?

Human mobility is a fundamental component of the economy and international migration. As a result migration plays an important role at local, national, regional and global levels and the management of migratory flows is a key issue not only in national political agendas, but also for supranational institutions. Certainly a set of phenomena in the context of migration is not controlled by governments, such as the entry of undocumented migrants, asylum seekers and the formation of new ethnic communities (Bertossi, 2008; Castles, 2004) and there are disconnections between migration policies and their results, between political discourses and laws and regulations Castles (2004). But even so, policies should not be underestimated. The States have the formal political right to control their borders, to decide who may and may not cross its borders and under which circumstances. Furthermore, as Ley (2010:8) points, states can play an active role in globalization, in particular by strengthening some imbalances in migratory movements As will be seen migration policies tend to be selective, namely through programmes and legislation that attracts welcomed people, creating special entry and stay conditions. For some individuals borders may be insurmountable barriers and for other mere places of passage.

Countries and companies seek human resources to improve their competitiveness and this is done in multiple ways. Correspondingly border control tends to differentiate those interested in entering. Some immigrants work on tasks that nationals are reluctant to do. The group of economic migrants is often devalued unless they are highly educated and have relevant skills for the host country while others are valued and engaged in high-value activities, such as immigrants and foreigners recognized as potential investors and promoters of economic development in the host country (GCIM, 2005).

Countries categorize immigrants legally and administratively by differentiating groups of individuals that can remain in national territory, for a predetermined period of time, defining the conditions that they must fulfil in order to have the right to remain there. As will be seen, this type of categorization is mainly linked to the connection of the immigrant with the work and length of stay, and these two dimensions are related to each other (OECD Secretariat, 2015). At the same time it must be noted several efforts to standardize statistics on migration (Lemaitre et al., 2007) and more recently to explore data on temporary migration (OECD Secretariat, 2015; Vargas-Silva, 2016). Despite the attempts, no universal uniform definitions of the concept of immigrant, standards for the regulation of statistics and methods of gathering statistics on international migration have been achieved. The debates around the concept of immigrant and its operationalization are complex. Note the diversity of criteria considered, namely nationality, country of birth, length and motive of stay (ONU, 2002:10).

There are clear limitations associated with concepts and statistical data undermining a real picture of the migration and comparative analyses (Bose, 2012; Fassmann et al., 2009; Skeldon, 2012). The conceptualization of immigrant categories is supported by different sets of scales, distinct interests of nation-states, supra-national institutions and intergovernmental organizations.

The national statistics who describe international migration are closely related to the country's history and migrations in the country (Fassmann et al., 2009:17). Nevertheless there are evolutions taking place. In this dynamic reality the "classical" understanding of immigration associated to a movement in space with a minimum time of permanence in the destination has been successively rethought. It should be noted that the duration of the stay has changed rapidly and is now possible to recognize as a (temporary) immigrant

a person who stays in a host country for three months, something that would be unthinkable in the early twentieth century. The overlapping between migration, mobility and tourism makes it difficult to categorize groups present in the city even accepting that categories will always be a simplification of reality.

The complexity of mobility and migration is only partially considered within the legal and administrative. The categorization of immigrants is essentially delineated considering their positioning in relation to the labour market. Obtaining a residence permit/visa is essentially related to work, study or mixed situations (work and other reasons). Thus the type of visa granted and the entry and exit status of the country is closely related to the type of access to the labour market. Given this scenario, the level of education and skills is a distinguishing factor among migrants, something easily explained in a context of global competitiveness, in which countries and cities seek to raise resources (labour supply, capital).

If migration policies are to be framed in an integrated view, considering the economic and social perspectives of the phenomenon and the impact that migrations will have on the host society in multiple dimensions, the repercussions of the migrant presence in the urban space must also be considered. And finally these aspects should be considered in urban planning. Immigrants can make undeniable contributions to urban dynamics, particularly through an influx of young people, growing number of births and attenuation of aging, provision of new products and services, job creation, revitalization and animation of declining areas, production of new urban landscapes, cosmopolitanism and diversity of religions and cultural offerings.

The segmentation of migrations and the debates surrounding new categories of immigrants have diversified and become more and more widespread. There are an increasing number of studies who focuses international students, sun seekers, residential tourism, and lifestyle migrants. But while there is an impressive debate about the diverse migratory segments, becomes difficult to present a global view of the migrations, as already stated by Castles (2010) who argue the need for an interdisciplinary study of migrations, connecting migration processes to societal changes. Following the previous point, considering the desirable interdisciplinary and comprehensive vision of migration and the purposes of the present paper it is relevant to discuss the legal and administrative categories of migrants and the variables that characterize them, something not sufficiently critically discussed (Fassmann et al., 2009; Janoschka & Haas, 2014) but which reflects power relations and the drivers of migration policies. Despite all complexity in migration the variables to be considered in the categorization of immigrants have not changed significantly, being essentially based on the economic dimension.

It would be possible and useful to express the impacts of immigrants and foreign in the territory through the legal categories, towards a more comprehensive role of the immigrants as agents of urban transformations?

3 IMMIGRANTS AS AGENTS OF URBAN TRANSFORMATION

Migrants, foreigners and city users relate in multiple ways to the urban space. They contribute to modify the image of the neighbourhoods and of the cities, when they invest, live, or are present in the urban space. The following describes some of the most meaningful ways this groups impact the cities in its urban dimension. Next, I turn to the Portuguese context. To shed light on the research topic I confront the migration and urban situation, the positioning of immigrants in the housing market and the policies that can reinforce the role of immigrants as agents of transformation of the urban space. With this in mind, I present an exploratory framework how allows to confront migration and urban dimensions through typologies. In this frame it is listed a wide group agents and not only “traditional” immigrants, for the already mentioned overlapping between immigrants, foreigners, tourists.

3.1 INTRICATE INTERRELATIONS BETWEEN MIGRANTS AND URBAN SPACE

Among the new phenomena contributing to the study of the relationship between migration and city production are the new contexts of super diversity (Hall, 2015), the lifestyle migration, residential tourism, the foreign investment in the real estate market (Bernardos, Martínez-Rigol, Frago, & Carreras, 2014) and the increasing number of international students and skilled workers.

The term "lifestyle migration" (Benson & O'Reilly, 2009; Janoschka & Haas, 2014) is associated with privileged forms of mobility, which do not occur primarily due to economic reasons or safety issues, unlike migrant workers, refugees, asylum seekers. The lifestyle migration refers to leisure-oriented mobilities that are conceived as the spatial mobility of affluent people of all ages who move between places, that have the potential to provide a better quality of life, and it covers retirement migration, leisure migration, second home ownership and seasonal migration (Benson & O'Reilly, 2009). The migratory movements associated to these realities can modify urban spaces, promote the real estate business and eventually foster changes in the community life of the destination neighbourhoods (Janoschka, 2010). Foreign groups are encouraged by some states to enter and invest in the country, namely through the purchase of property (Ley, 2010; Sumption & Hooper, 2014). The investment in residential tourism, the development of second homes, the short-term use of housing for tourism purposes and the promotion of housing directed to foreigners induces questions about some consequences of these situations like socio-spatial changes, changes in the housing market, gentrification, empty buildings during a large part of the year, real estate speculation, etc.

Spatial distribution patterns, socio-spatial segregation, housing trajectories and housing preferences are classic themes of the social sciences being object of diverse approaches that allow to reflect on housing provision, social mechanisms and actions of agents. Ethnic issues are also addressed in these themes. The presence of immigrants in peripheral and devalued areas tend to question situations of social exclusion and even conflict and presence of violence through the ethnic dimension (Malheiros et al., 2007) and refer to the expulsion, relocation, involvement or empowerment of ethnic minorities living in those areas (Kempen & Dekker, 2006).

In the context of the central areas the dynamics occur under the watchful eye of political decision makers, scholars, and society in general. Here the immigrant presence is contextualized in a discourse of diversity and interculturality as a distinctive element and promoter of a neighbourhood or city, making it potentially more attractive (Loukaitou-Sideris & Soureli, 2012; Shaw & Bagwell, 2012). In these scenarios, the improvement of the urban space may even enhance gentrification and socio-ethnic transformation, resulting in a threat to ethnic diversity, intercultural practices and inclusive urban spaces, with detrimental effects on the most disadvantaged communities (Mendes, 2012). Moreover the increase in housing costs may affect the future installation of low-income immigrants and force the departure of those who live there. The right to the city, for the resident or for the present (Darling, 2016), is exposed in these situations, being discussed by academics and citizen groups. As will be seen, this is a problem that has been intensified in Portugal, for example in Lisbon, due to the intensification of tourism, the rise in the price of housing and the increasing supply of real estate for temporary inhabitants (Mendes, 2017).

Access to housing, conditions and location of immigrants' residence express the integration of these communities into the host countries. Housing is a human basic need, has a social dimension and additionally it has a territorial and economic content. Consequently, reflections on housing and immigration allows a multilevel understanding of immigrant integration, structural aspects (migration dynamics, urban policies, etc.), local contexts (socio-spatial structures, local level programs and measures, characteristics of the housing supply) as well as the characteristics of the families and individuals in question (economic situation, cultural preferences, relevance of contact networks, etc.). Housing is an economic and social asset and is a platform for accessing the city, living space, with an active role in building interactions and access to social rights. For all this, is justified a closer look at housing issues in the present study.

3.2 THE PORTUGUESE CASE

The study of immigration in Portugal is relatively recent. After the 1974 revolution and subsequent independence of the former colonies in Africa, the number of immigrants increased significantly but immigration only becomes a hot topic from the late eighties and nineties of the last century, due to the growth and diversification of immigration flows, associated to the entry of Portugal into the European Union, which gave rise to economic development. The strong social and economic impact of the presence of the new populations in the country and the lower visibility given to emigration in these decades it also acted in immigration valorisation (Baganha & Gois, 1999; Malheiros, 2011).

More recently, the noticeable decrease in immigration¹ coupled with the growing emigration volume has modified the picture. One could think that the new context has potentially made the analysis of the flows of foreigners arriving in Portugal and immigration potentially less relevant but the issue of immigration remains significant for Portuguese society. There is a maintenance of a stock of immigrants (including foreigners and recent naturalized), and new dynamics: significant reduction of inflows, consolidation of the immigrant presence associated with situations of family reunification, emergence of new Asian groups such as those from China, Bangladesh or Nepal, discourses and strategies for attracting international students, skilled worker, immigrant investor as those covered by the residence permit for investment activity (ARI) and by the tax regime of the non-habitual residents (NHR regime).

Additionally the benefits of the presence of immigrants to Portuguese society have been evidenced expressing contributions on the demography, diversity and cultural and economic dynamics of the country (Oliveira, 2014; Peixoto, Craveiro, Malheiros, & Oliveira, 2017; Rosa, Seabra, & Santos, 2003). The effects of migrations on population decline, even leads to discuss the relevance of the notion of "migration replacement", understanding that the aging of the population can be counteracted by a certain volume of immigrants.

By contrast repercussions of migrations in the urban space are less mentioned despite the contributions of immigrants in the configuration of the urban landscape (Gésero, 2014). The spatial expression of migrations within the Portuguese territory must take into account the evolution and characteristics of migratory flows, but also the process of urban growth, the characteristics of the housing stock, the principles of spatial planning, housing and urban policies.

The urban development in Portugal is characterized by a rapid urban growth at the end of the 20th century, not accompanied by desirable spatial planning measures. The inability to regulate urbanization which was replaced by an absence of action in the face of the complex urban patterns originated (combinations of urban sprawl, fragmentation) (Portas, 2011). In addition the housing in Portugal is also a problem. Notwithstanding the housing and urbanism rights enshrined in the Constitution of the Portuguese Republic (CRP) there was an absence of housing policies and the inability of the State to regulate Real Estate activity which significantly contributed to the persistence of housing lack (Ferreira, 1987; Nunes, 2011; Serra, 2002).

Recently affected by the economic crisis, the housing market undergoes transformations, confirming as perceived tendencies, the commodification and privatization of the housing sector. These processes were facilitated by a reinforcement of the discourses of valorisation of the urban rehabilitation and of the rental market framed by new legal acts which generates profits for property owners and investors, namely through "touristification" and gentrification² of the central and historical urban areas.

Another trend is the reduction of state intervention in housing. The social housing stock, despite little significant in quantitative terms, it was decisive for the improvement of the quality of life of many families living in precarious conditions in the last decades of the 20th century. There was an investment decrease in this sector namely in the maintenance and management of the existing neighbourhoods, and a shrinkage of the housing public promotion, starting from the from the early years of the new millennium, when the construction cycle associated with the Special Rehabilitation Program (PER) closed (IHUR, 2015).

In addition to the changes associated with the housing supply and the functioning of the market, the economic crisis had strong impacts on the access and maintenance of housing by many families, mainly the most vulnerable ones. Notwithstanding the prices for housing continue to be high, with a low number of affordable housing (in the private and public sector). The immigrant population, mainly non-EU immigrants shares these difficulties and adds to these, associated to their overrepresentation in unfavourable

¹ The Portuguese Immigration and borders service (SEF) accounts 445262 foreigners in 2010, 395195 in 2014 and 3388731 in 2015. According to the Ministry of Justice and the Portuguese National Statistical Institute (INE) a part of this decrease is explained by naturalizations.

² Gentrification is the process of social recomposition of the population in a given territory, as a result of the urban transformations that occurred in that territory, namely through renovation and urban regeneration operations. The improvements in the built environment and the social and economic revaluation of the area increase the economic value of housing and commercial spaces, making them inaccessible to the low-income population. As a result, there is a gradual replacement of the poorest residents by groups of higher socio-economic status. For a detailed review on this topic see Smith (1996) and Rodrigues (2008).

employment situations, situations of discrimination, difficulties and inequalities in access to credit, restrictions and constraints on access to public housing and other social supports and less access to information (Fonseca & Malheiros, 2013; Malheiros & Fonseca, 2011).

On the other hand, must not be forgotten, the financialization of the real estate sector in which the foreign investment is also present. The housing market, facing with the stagnation in construction and in the acquisition of own house, relied on new strategies based on urban regeneration and dynamization of the rental market, the luxury market, of the temporary and shortterm use of housing for tourism purposes. In this context, foreign investment seems to have had positive repercussions on market growth, not being negligible the advantages attributed to investors by the Portuguese government through ARI and NHR regime as well strategies to raise tourism and for attracting students and skilled workers.

Immigrants in Portugal have different profiles, as a result of the dates of entry into the country, nationality, socioeconomic characteristics and legal status. In turn, this diversity results in different positions in the Portuguese housing market. In a simplified way there is a duality in the access to housing by immigrants based on their economic capacity and investment interest in the housing sector. Some are in an advantageous position and can access higher levels of the real estate market, namely luxury segments. This group tends to appreciate spaces with qualified architecture and urbanism, in well-equipped areas and with socially prestigious status, and many times cultural and historical values associated. These areas, if only accessible to the classes with greater economic power, promote auto-segregation. This type of demand is especially profitable for the real estate sector by allowing a higher profit margin.

The others, the vast majority of immigrants are in less qualified segments of the labour market that places them at the level of the lower and middle-low social classes, and therefore in a vulnerable position to access housing. In this case they develop housing strategies towards the lower segments of the market, not only formal but also informal. This duality is confirmed through the situation of foreigners in the Lisbon housing stock (Malheiros & Fonseca, 2011; Ramos et al., 2015).

In the Portuguese context, there is no depth debate regarding the impacts of the Residence Visa for the investors and the implementation of favourable tax regimes for non-habitual residents. Although these are explored in individual projects (Loureiro, 2016; Mesquita, 2014; Quintela, 2014) the discussion has not been wide-ranging, especially with regard to the consequences of these at local and national level. This paper addresses the theme because the benefits deriving from these programs tend to be associated with investments in the real estate market. Other strategies for attracting foreigners should also be followed up, such as those targeted to international students and tourists, groups that have been growing as indicated by Alves (2015) and INE (2015).

Immigrant investor programs are strategies for attracting foreign investment. According to the political choice of the countries in which they are applied, it grants right of residence, citizenship or tax benefits to investors, professionals qualified (foreigners or even national citizens). The beneficiaries of these programmes choose to do it in countries with attractive social, economic, political and security conditions (Loureiro, 2016; Sumption & Hooper, 2014). Within a competitive context of demand for resources and capital the Portuguese government had implemented the residence permit for investment (ARI) in 2012, under the Law 29/2012 of 9 August. The program provides a valid residency permit in Portugal (Golden Visa) in exchange of capital investment made through: a) the purchase of real estate; b) investment in funds or c) creation of jobs. The acquisition of real estate is the most significant investment in this program (see Table 1) considering either the number of residence permits (94% of total residence permits were obtained through the acquisition of real estate) or the value of the investments (90% of the investment was made in real estate).

The tax regime of the non-habitual resident is implemented in Portugal in 2009 and is aimed at foreign or Portuguese citizens who have been abroad and wish to live in Portugal. The objective of the programme, according to information available, on the Portuguese finance website¹, is to attract non-resident professionals qualified in high value-added activities, intellectual property, industrial know-how and beneficiaries of pensions abroad.

¹http://info.portaldasfinancas.gov.pt/NR/rdonlyres/83762009-3DC2-47FC-ABBE-35EFE35E8865/0/IRS_RNH_PT.pdf

To understand the purposes, impact of these programmes and its target in the real estate sector it is important to remember that these supports are instituted in a time of economic crisis, which has had high impacts, especially in the real estate sector. According to Quintela (2014:76) the Real Estate Mediating Professionals and Companies Association (APEMIP) revealed that investments made under the scopes of ARI and NHR, including investments from national emigrants had increase real estate sales since June 2013.

Types of investment	Number of Resident Permit		Investment	
	Nº	%	Eur	%
Acquisition of property	4712	94,18	2.772.806.471,60	90,1
Transfer of funds	284	5,68	305.696.704,02	9,9
Job creation	7	0,14	---	0,0
Total	5003	100,00	3.078.503.175,62	100,0

Table 1 – Resident Permit for investment Activities (ARI) – 8/10/2012 to 30/11/2016

* Considering family unification the total number of resident permits is 13133.

Source: adapted from statistical map, available in http://www.sef.pt/documentos/56/Mapa_ARI_PT_abril17.pdf

These kinds of programmes are controversial in different ways. These policies are characterized as a way of “selling visas and citizenship” (Sumption & Hooper, 2014) and as a mechanism to transform a country in a tax haven for foreigners (Mesquita, 2014), illustrating distinct response by the State to immigrants, according with their resources. Moreover is hard to reach a consensus on whether these programmes are promoting migration or investments. Within the framework of the ARI it is required to the beneficiary a minimum time of physical/residential time stay in the territory but this period of time is limited to seven days in the first year of the benefit¹. The contradiction increases when some measures concern with procedures related with ARI are set out in the Strategic Plan for Migration (measure 76). Within the NHR Regime and according to the Portuguese tax law, the so-called NHR will have to stay in Portugal for more than 183 days, followed or interpolated or have a dwelling, under conditions, who proves the intention to maintain and occupy the dwelling as habitual residence (Mesquita, 2014:7). This condition occurs along with doubts related to how effectively control the length of the stay in the country.

Moreover the economic benefits of this kind of programme to the country aren't clear (Loureiro, 2016:18). As Sumption and Hoope (2014) have highlighted there may be some shortterm benefits such as job creation, rising house prices, and increased tax revenues, but in the long run these programs could lead to stagnation in the housing market.

3.3 A TYPOLOGICAL PROPOSAL

Considering what has been described, I propose a typology of immigrants and foreigners to explore their impacts and relations in the housing sector. In this exploratory framework I considered the housing dimension, although the ambition to present a wider framework who allows a more comprehensive perspective of the immigration and processes of urban transformation (spatial, demographic, economic, social and cultural). For now our main point is to warn about in the use of traditional categories of immigrants when studying both migration and cities. Taking into account the various urban uses, housing is one of the most significant allowing a set of analyses, as already mentioned. At this stage of the research is possible to easily explore, quantitative data from secondary source who considerer both nationality and housing, namely collected through census. For a broader analysis of the role of immigrants in urban space, would be required intensive fieldwork on immigrant entrepreneurship and urban experiences of diverse ethnic groups.

The typological proposal was performed considering two situations in confrontation: the most significant entries of foreigners and immigrants in the country and the known impacts they have on the housing market (see table 2). I started by categorizing immigrants and foreigners presents in the city having resorted to traditional variables linked to migration like the motive to entry, the duration of stay, the education level. Thought the various combinations of variables are specified some groups of immigrants and foreigners. The purpose to enter the country and the length of stay is seen as motivation factor to

¹ Dispatch no. 1661-A/2013 de 28 January 2013

invest more or less in the housing, If the the immigrant is coming alone or with family or if there is an expectation of family reunification can also be established as to deal with. For international students and tourists the choice of a place to stay probably is more related with the presence of amenities, historical and cultural status of the neighbourhood than for long-term workers. Finally the level of education and the immigrant status is indicative of the purchasing power that a given group has, a determining factor for the demand of housing.

To describe the impacts of foreigners and immigrants in the housing market has been incorporated their housing preferences. The short term labour market migrants as well as students will probable access an accommodation in the rental market. Situations of homeownership are more likely to happen for long term migrants and other beneficiaries of the aforementioned programs. Many of the beneficiaries of these programs have acquired a home, either on a permanent basis to remain in the territory or as a form of monetization of capital, namely through lease or subsequent sale of propriety.

By contrast social and institutional support is fundamental, for some of the people entering the country, namely asylum seekers, refugees, not only for the housing component but also for other needs. However the public support does not answer to the housing problems of many immigrants in disadvantaged situations. There are many restrictions and constraints on access to public housing and a very limited number of accommodations. For the groups of foreigners who declare a short stay in the country, like tourists and visitors their needs tend to be fulfil by the offer of short-term rental markets (like the one promoted by Airbnb) or tourist accommodations. I include this last group in this framework because a first visit to the city can be one first step in a migration experience and the presence of tourists and visitors can be a driver of change in the real estate (Gant, 2015).

Through this framework it is possible to identify clear relations between mobilities and the housing market as wells as pointing implicitly new settlements patterns and urban transformations. At a later stage this relations could be further developed considered the geography of the studied groups, the type of location area (holiday regions, historical centre, elite zones, renewed areas, etc) and also the preferential socio-spatial locations (whether groups want to be closer to similar groups in social and/or ethnic terms).

Categories of immigrants and foreigners				Impacts in housing market -				
Motive for entry	Duration of stay*	Migrants education and status	Categories (examples)	Home ownership		Rent Market	Social and institutional support (social housing)	Informal market
				Investment	Occupied dwelling			
Labour related	Short-term	Predominantly high	Intra-company transferees; Posted workers, Managers, Researchers, Professors and other key personnel professionals, Job seekers			XXX		
		Mixed or undefined	Accompanying family members of temporary workers			XXX		XXX
		Predominantly low	Seasonal workers (agricultural activities or others) or other workers			XXX		XXX
	Long-term	Predominantly high	Highly skilled workers		XXX	XXX		
		Mixed or undefined	Family reunification		XXX	XXX	XXX	XXX
		Predominantly low	Low skilled workers			XXX	XXX	XXX
Study related or Mixed labour and other purposes	Short-term	Predominantly high	Students, Trainees, Youth programme			XXX		
		Mixed or undefined	Working holiday makers			XXX		
		Predominantly low	Am-pair			XXX		
Investment/ retirement	Very short-term to long-term	Predominantly high	Residence permit for investment activities	XXX	XXX			
	Short-term to long-term	Predominantly high	Non Habitual Residents	XXX	XXX			
Humanitary categories	Uncertainty	---	Asylum seekers, medical treatment, refugees				XXX	
Others	Very short to short-term	---	Tourists, travellers, visitors			XXX		

* Long-term stays are last more than 1 year; Short-term more than 3 months; and less than 1 year and very short-term less than 3 months

Table 2 – Immigrants and foreigners and impacts on the housing market

4 FINAL CONSIDERATIONS

Immigrants and foreigners contribute to change in the urban dynamics to which it made an active contribution the impacts of these groups in the housing sector. In Portugal, despite the small number of immigrants, there is an increasingly diverse real estate market and rental market, especially targeted to foreign investors and lifestyle migrants, confirming a trend, already announced by Sumption and Hooper (2014). At the same time difficulties in accessing housing by the most disadvantaged groups, including labour immigrants, persist. It is argued that these aspects should be considered not only in the context of migration but also in the context of urban planning and spatial planning, under an interdisciplinary and comprehensive vision. So the implementation of measures for the management of migration flows, the impacts of the entry and stay of foreigners and immigrants in the territory must be considered and reflected in spatial planning strategies. However migration policies are still very much anchored to economical dimensions of migrations associated with labour, despite the discourses that praise interdisciplinary approaches of migration - a complex phenomenon of contemporary societies with social, economic and political implications. Thus we defend that should be given greater prominence to the diversity of migrants and foreigners and their role in urban spaces. This can be done through a confrontation between the management of the entry, presence, exit and status of foreigners and the territorial planning policies, in which we include the housing policies. There are several limitations in this paper, part of them related with the exploratory nature (preparatory and preliminary) of the approach intended to be developed in the future. The discussion has focused on housing sector, not being possible to explore data about impacts of immigrants in other dimensions. Further data collection is required to achieve that objective, namely through mixed methods. It should also be noted that the study and analysis of the situation in Portugal, with specificities, must be framed in the European and international context. Notwithstanding, the time and data restrictions, it was possible to confirm the need to develop approaches that deepen the role of immigrants as agents of urban space transformation, where it is considered that migration policies are not negligible. Broadly, this paper has underlined the importance of discussing and reflecting migrations in an unconventional way and in different fields of study. The Portuguese case has made possible to outline diverse situations that deserve further development, namely the strategies, disguised as immigrant recruitment programs to attract immigrants, which clearly support the real estate sector.

In view of the debate here sustained, it is evident the relevance of an interdisciplinary view. The categorization of immigrants and foreigners present in the country and about to enter, considering their relations with the urban space could be an interesting starting point to deepen these issues in an empirical study, and to influence public policies in the medium and long term.

innazhang@126.com ; 495113462@qq.com

ABSTRACT: There are many scenic, distinctive characteristic towns in Europe, such as Cordoba, Cuenca, Portofino, Kema and so on. They are famous tourist attractions, visitors often linger there. China's town plans and constructions often refer to European towns. Recently, China issued "The Notice of Fostering Characteristic Towns", which decided to carry out nationwide characteristic towns' cultivation work, it plans to cultivate about 1000 characteristic towns before 2020, China also identified 127 national characteristic towns for the first batch. This article takes the characteristic towns as the research object, and takes the field research, cases comparison and the policy analysis as the research methods, thinks the characteristic towns forms the link between Europe and China in 3 levels. It referred to Europe towns a lot in China's town plans and constructions, especially in the layout forms and architectural styles. For example, the Shannan town in Hangzhou city determines to build "China's Greenwich Town". These learning, imitation and reference form the first level of the link and dialogue between Europe and China. The Chinese governments support the development of characteristic towns by providing a number of favorable policies, which achieved remarkable results. Policy supporting comes from both local and national governments, such as local governments give Land use indicators and tax reliefs, the national government gives special funds and so on. This paper argues that this approach deserved to be promoted, European countries and local governments can also introduce similar incentive policies to promote the further development of the characteristic towns. This promotion of support policies will form the second level of the link and dialogue between Europe and China. This article prospects that Europe and China will achieve the third level of link and dialogue by promoting enterprise cooperation, such as European enterprises go to China to lead the construction of characteristic towns, Chinese enterprises go to Europe to lead the construction characteristic towns. This may create a win-win situation. These three levels of link and dialogue upgrade gradually and interact with the process, containing good social and economic benefits. They deserve attentions and active treatments.

1 INTRODUCTION

Europe has many scenic, distinctive characteristic towns, such as Spain's Cordoba, Cuenca; Italy's Portofino, Verona; France's Kema, Annecy; Switzerlandand's Davos, Interlaken, Vevey; Germany's Heidelberg, Meersburg and so on. These towns have beautiful scenery, deep cultural heritage and featured industry functions. They integrate into the surrounding landscape environment, become famous tourist attractions, visitors often linger there.

The rise of the construction of Chinese characteristic towns began in Zhejiang Province. In April 2015, the Zhejiang Provincial Government promulgated the "Guidance on Accelerating the Planning and Construction of Characteristic Towns". Then, the government introduced the list of the first batch of 37 characteristic towns. The following table is part of the list. In January 2016, the list of the second batch of 42 characteristic towns was introduced.

Town's Name	Featured Industry	City
Shangcheng Yuhuangshannan Town	Fund, Securities	Hangzhou
Jianggan Dinglan Town	IT	Hangzhou
Xihu Yunqi Town	Cloud Computing	Hangzhou
Xihu Longwu Town	Tea	Hangzhou
Yuhang Mengxiang Town	Information Industry	Hangzhou
Yuhang Yishang Town	Arts	Hangzhou
Fuyang Guigu Town	IT	Hangzhou
Tonglin Jiankang Town	Health Industry	Hangzhou
Lian Yunzhizao Town	Cloud Manufacturing	Hangzhou
Jiangbei Dongli Town	Equipment Manufacturing	Ningbo
Meishan Haiyangjingrong Town	Finance	Ningbo
Fenghua Binhaiyangsheng Town	Health Industry	Ningbo
Onhai Shishangzhizhao Town	Intelligent Manufacturing	Wenzhou
Cangnan Taishang Town	Trade	Wenzhou
Huzhou Sichou Town	Silk	Huzhou
Nanxun Sanlianhubi Town	Writing Brush	Huzhou
Deqing Dilixingzi Town	Geo Information	Huzhou
Yuecheng Huangjin Town	Wine	Shaoxing
Zhuji Wapi Town	Socks	Shaoxing
Wupu Wenquan Town	Spa Resort	Jinhua

2 THREE LEVELS OF LINK AND DIALOGUE

2.1 THE FIRST LEVEL OF LINK AND DIALOGUE

Some of the Chinese characteristic towns referred to European (also the American) towns in the planning and construction, mainly including the following two aspects. First, the reference and imitation are in the layout form, architectural style and so on. For example, the taiwushi town in Shanghai Songjiang District copied the British river town style and residential characteristics, reflecting the modern, international, ecological and tourism culture. This type of imitation and reference were common in the past years, It was blamed a lot. Opponents argue that China should build a town with Chinese characteristics rather than a European style. In recent years, this "direct copy" type of imitation became rare.

I believe that Chinese characteristic towns should not directly copy the European town's architectural style, which should be based on China's own style. Sometimes modern style is also suitable for same new characteristic towns.

Figure 2 - Taiwushi Town in Shanghai, Which has Both Supporters and Opponents

Figure 3 – Modern Style and Chinese Traditional Style are Generally Accepted

I believe that high quality of European rural environment is highly worth studying by China. It should learn from the European towns' overall environment of harmony, natural, beautiful, clean and tidy and other aspects, to enhance the overall quality and style of China's rural environment. In recent years, China are undertaking "the Beautiful Countryside Construction", which should be integrated with the construction of characteristic towns to improve the rural environment, to enhance the rural livability and ecology.

Figure 3 – High Quality of European Rural Environment is highly worth studying

Second, the reference and imitation are in the industry characteristics, for example, Jilin Province said: "Using the snow and ice advantages to build China's Davos town." Hangzhou Yuhuang Shannan town is committed to build China's Greenwich Town. Huangshan City has formed friendly cities with Interlaken, Taipinghu town in Huangshan City is committed to build China's Interlaken, a sports leisure town.

Chinese Characteristic Town's Name	Objectives
Shangcheng Yuhuangshannan Town, Zhejiang	China's Greenwich
Fuyang Guigu Town, Zhejiang	China's Silicon Valley
Jilin Province	China's Davos
Taipinghu Town, Anhui	China's Interlaken
Yuhang Yichuang Town, Zhejiang	China's Milan
Yuhang Mengxiang Town, Zhejiang	China's Silicon Valley

Table2 – Some Chinese Characteristic Towns' Objective Towns

China's characteristic towns imitate and learn from the European (American) towns from the architectural style, spatial layout, the overall environment and industry cultivation which formed the link of the first level.

2.2 THE SECOND LEVEL OF LINK AND DIALOGUE

Chinese governments had provided a number of favorable policies in the support for the characteristic towns, which had achieved remarkable results. Policy support came from both the local governments and the national government, such as the local governments giving land indicators and tax relief, the national government providing special fund support.

Specific preferential policies generally lie in the following aspects: tax policy, land policy, income policy, financial support policies, etc. These preferential policies are not only related to the main project development enterprises, settled enterprises can also be related. For example, in Sichuan Province, the provincial finance provided a special fund of 1.5 billion yuan in 3 years, integrated special funds nearly 500 million yuan, through the "Reward Instead of Subsidy" competition mechanism to support the characteristic towns' infrastructure construction. In Shandong Province, it put forward no less than 5000 acres of new construction land plan indicators each year for the 100 characteristic towns, which are separately and directly issued.

This paper argues that this practice is worthy of promotion, European national and local governments can introduce similar incentive policies to promote the further development of European towns, which will create the second-level link and dialogue.

2.3 THE THIRD LEVEL OF LINK AND DIALOGUE

China's local debt refers to the special infrastructure enterprises set up by the local government borrows debt to provide basic, public services. The local government provides security to the debt. Over the years, local debt is an important source of funds for urban development in China. Because of the risk that the local government can not pay, the Chinese central government has imposed strict restrictions on the local government's borrowing, and it is very difficult for the local governments to carry out the construction of the characteristic towns through bank loans. At present, many local governments introduce private capital and private enterprises, the use of Public-Private-Partnership model (hereinafter referred to as "PPP model") to build characteristic towns.

PPP model refers to based on the concession agreement the government and private organizations formed a partnership in order to cooperate in the construction of urban infrastructure projects, provide some kind of public goods and services. They clear the rights and obligations through signing a contract which ensure the smooth completion of cooperation. Finally, the both sides can achieve more favorable results than the individual action which means a win-win ending.

This model solves the funds bottleneck of the construction of the characteristic towns, which plays a positive role in the capital market. It revitalizes the asset resources and provides diversified financial support for the construction of characteristic towns.

It can be expected: through the construction of characteristic towns Europe and China can form the third level of the link and dialogue, which lies in the enterprise-level win-win possibility, such as the European enterprises go to China to lead the construction or operation of the characteristic towns, Chinese enterprises go to Europe to lead the construction or operation of the characteristic towns too.

3 TO DEVELOP CHINA'S CHARACTERISTIC TOWNS SHOULD AVOID THESE TWO PROBLEMS

3.1 AVOIDING EXCESSIVE AND BLINDNESS IN CHARACTERISTIC TOWNS' DEVELOPMENT

With the support of the national government for the characteristics towns, local governments at all levels are keen to launch the local characteristic towns, showing the phenomenon of the emergence of the characteristic towns everywhere in China. Emerging some problems such as "performance project" oriented development, creating things out of nothing, ugly copycat, misconfiguring the resources, etc. The construction of the characteristic towns has also become a new "nuggets" to a number of housing prices. Some characteristic towns's real estate percentage is far more than other industries, which formed new house reserve. It exacerbated the property excess and did not match the national government's requirements of property de-stocking.

Constructing characteristic towns are different from the construction of large quantities of real estate projects. In the construction process of the characteristic towns, it needs not only integrate the the needs and wisdom of governments, enterprises, financial institutions, social organizations, but also integrate local culture and the future residents' and visitors' needs in the beginning. While around the same time of encouraging the construction of characteristic towns, we must pay more attention to science, sustainable development. Excessive and blindness in characteristic towns' development should be strictly prohibited. It should also avoid constructing different towns with the same outlook.

Governments should introduce relevant policies to promote and standardize the healthy development of characteristic towns. It should be strictly prohibited of the whole town development once for all. Reserving land more than proper scale in the name of characteristic towns should also be prohibited. It should be forbidden to engage in large-scale commercial housing development by taking the opportunity of the construction Characteristic towns' industry is the key to its success, the industry should avoid vague and having no basis. The main industries should be chosen accurately and concentrated. Only in this way, it can stand and grow big. In addition to strengthening and improving their own "vertical" industrial chain, It should complete the "horizontal" gathering as well, such as the gathering of the fund, talent, technology, information and other elements. It should promote economic factors and cultural elements' highly integration and make the industrial chain and innovation chain in one, which finally will build a good, sustainable industrial ecosystem.

3.2 AVOIDING APPLYING EXCESSIVE EMPHASIS ON TOURISM

At present, most of the China's characteristics towns planned the development of tourism as the leading direction. They took the international well-known towns as development goals. But the vast majority do not have the conditions to become a world-class tourist town.

Accurate positioning is an important aspect of the development of the characteristic towns, through combine their own characteristics, identify the industry positioning, scientific planning, mining industry features, continuing humanities and protecting ecological, the formation of "production, town, people, culture" four integrated organics. It should find the most important, dominant, potential industry as the main direction, and make a difference positioning with other characteristics towns. Most of the China's characteristics towns should not put too much emphasis on tourism. The first job for them to do is to set up their own characteristics, make livable and workable, provide the good basic services.

4 PROSPECTS

The characteristic towns concerned about the livable, workable, travelable, which integrate "innovation, coordination, green, open, sharing" five main ideas, highlight the integration features of the industry, ecology, culture. It will become the model sample of China's new urbanization strategy and highlight the "people-oriented" development.

It can be expected that highly concentrated the population, industry, cultural, tourism and other resources the characteristic towns' construction is becoming a new model of China's urbanization development. China's characteristic towns' construction should focus on the following points: the characteristics of the industry development, the integrity of public services, good ecological environment, featured style and pattern, history and culture heritage protection, governance and institutional innovation, policy support and institutional mechanisms to explore.

At the same time, these three levels of link and dialogue upgrade gradually and interact with the process, containing good social and economic benefits. They deserves attention and active treatment. of the characteristic towns too.

T08 | REGIONAL ECONOMICS AND SCARCE RESOURCES PLANNING

CO-CHAIRS: MICHAEL GETZNER; PANTELIS SKAYANNIS; JOÃO MOURATO

In times of globalization, dominance of financial markets, European integration, and neo-liberal policy frameworks and approaches – to name just a few fashionable buzz-words of current economic and political development – the demand for material and immaterial resources grows and reveals the issue of their scarcity, that in turn raises the question of allocation. Some scholars think that a new focus on regional economies, networks and structures is necessary to overcome political and economic gridlocks. However, regional economies and regional economic policies are truly embedded in national and international environments; thus the leeway of regional policies seems to be limited. Regional planning and regional economic policies can, nevertheless, contribute to decisions on how scarce resources are used regionally.

The co-chairs welcome papers and case studies in this area. Track papers could specifically focus on the following issues:

- Is scarcity a real problem or is it created because of the way modern life is structured?
- Government and governance for the design and implementation of regional economic policies. Is there space for a regional governance of scarce resources?

Contribution of planning and regional economics to an efficient, effective, and equitable management of scarce resources.

Valuation of scarce regional resources (e.g. human capital, infrastructure, land, ecological resources) from different methodological perspectives (qualitative and quantitative). - Empirical, methodological or theoretical approaches to regional planning and/or regional economics with respect to scarce regional resources.

Presentation of empirical urban and regional development projects and/or policies in relation to facing problems related to the management of space in the current context of strategic dilemmas.

ID 1344 | OVERCOMING RESOURCE SCARCITY BY IMPLEMENTING STRATEGIC REGIONAL PLANS THROUGH URBAN-REGIONAL DEVELOPMENT PROJECTS: A EUROPEAN PERSPECTIVE

Eduardo Oliveira¹; Anna M. Hersperger¹

eduardo.oliveira@wsl.ch ; anna.hersperger@wsl.ch

1 INTRODUCTION

The objective of this paper is to highlight some preliminary findings of an ongoing research project (2016-2020) entitled “From Plans to Land Change: How Strategic Spatial Planning Contributes to the Development of Urban Regions” (CONCUR) in which the author, as a postdoc researcher, and the co-author, as the project coordinator, are involved. The project is financed by the Swiss National Science Foundation and is based at the Swiss Federal Research Institute WSL in Switzerland. A team of circa 7 researchers investigates different aspects concerning how strategic planning contributes to the development of urban regions. In this paper, we argue that urban regions in Europe and beyond are currently encountering a range of challenges, such as providing a varied and efficient transportation network, affordable housing, green infrastructure, public spaces, and attractive investment conditions (Albrechts et al., 2017). In addition, a number of urban regions have been experiencing dynamic changes in the scale and scope of metropolitan governance (Zimmermann and Getimis, 2017), and new forms of flexible territorial governance arrangements have emerged (Oliveira, 2017). These economic, social and governance driven challenges unfold in a context of limited financial, human, infrastructural, land and ecological resources.

The hypothesis of departure postulated in this paper is that urban regions, in a scenario of limited resources, have been implementing strategic spatial plans through area-specific and functionally-oriented urban-regional development projects (URDP). Examples of such projects include the repurposing of outdated harbour, industrial or railway facilities, the reconfiguration of green infrastructures, the reinforcement of the public transportation network and the development of new residential areas. This is a claim in line with that of Tiwari and Winters (2016), who argue that “strategic planning today is used to determine where a project will be in the future” (p. 2). These authors also argue that one of the reasons that public administrations adopt a more intensively project-based approach to spatial planning is that governments are cash-strapped and must therefore prioritize capital-intensive actions in a market-sensitive environment (Tiwari and Winters, 2016). Carmona et al. (2009) underline that strategic planning is seen as the best means for an urban region to take advantage of the opportunities of globalization; and urban projects are the chief mechanism for implementing a futuristic vision of a global-oriented strategy. Urban development projects exist in urban regions with very different histories and development levels (Cohen, 1966), from Europe (Meijsmans, 2007) to elsewhere in the world (Carmona et al. 2009). Fast-track plan implementation through projects has been criticized, however, because these projects are often linked to neo-liberal aspirations of the entrepreneurial city (Moulaert et al., 2001). Other scholars decry the poor integration of urban projects in wider spatial planning processes (Swyngedouw et al., 2002).

The theoretical investigation in this paper is developed further by drawing on the qualitative analysis of 43 in-depth interviews with regional planners and planning experts on the European urban regions of Barcelona, Cardiff, Copenhagen, Dublin, Edinburgh, Hamburg, Hannover, Helsinki-Uusimaa, Lyon, Milan, Oslo-Akershus, Stockholm, Stuttgart and Vienna. This qualitative method of research was considered the most appropriate method to provide answers to the following research questions (RQ): RQ 1: What are the reasons for the implementation of strategic spatial plans through urban-regional development projects? RQ 2: How are the territorial governance arrangements behind the implementation of strategic plans through urban-regional development projects characterized?

Following this introduction, the paper continues with an explanation of what we mean by URDP. The third section provides methodological details. The fourth section includes a discussion of the case-study findings, derived from the interviews. In the concluding remarks of the paper, we support the statements of the co-chairs of this conference track, who argue that regional planning could contribute to decision-

making on how scarce resources can be used efficiently at the regional scale. In this paper, we advance this argument by exploring the practical linkage between the implementation of strategic spatial plans through URDP and how spatial transformation can thrive in such a context of resource scarcity. Nevertheless, we acknowledge that additional research is needed to improve knowledge on how strategic spatial planning contributes to spatial transformation and development of urban regions in an uncertain world that is undergoing rapid economic, demographic and environmental changes.

2 A WORKING DEFINITION OF URDP

Strategic spatial planning is usually undertaken at the urban regional level (see Ziafati Bafarasat, 2016; Albrechts and Balducci, 2013). Strategic spatial planning involves the construction of new institutional arenas within structures of government that are constantly changing. Although it may be more or less clear what strategic spatial planning entails in supporting spatial transformation, Oosterlynck et al. (2011), in line with Albrechts (2006), argue that plan implementation, social innovation and political decision-making are “black boxes” for spatial planners. According to Oosterlynck et al. (2011), spatial projects support plan implementation and are prepared for the spatial transformation of a specific territory or territorial area, such as an industrial site, a harbour facility, a green space or an abandoned railway structure, rather than for the transformation of a whole urban region or any other territory in its totality; however, they generally also involve aims for a structural change and catalysing effect at the urban regional level. For Albrechts (2006), spatial projects ideally are coordinated by public institutions, such as regional entities and/or municipalities, in close cooperation or partnership with private interest groups (e.g., real estate agents, retail companies) and non-governmental organizations (NGOs; eg environmental NGOs) and “aim at transforming the spatial, economic and socio-cultural fabric of a larger area through a timely intervention” (Albrechts, 2006, p. 1492).

For Ziafati Bafarasat (2016), the idea of urban-regional development projects, strategic projects and area-specific projects as an approach to steer spatial transformation is entrenched in the urban project tradition in several European countries (Meijsmans, 2007). In Italy, for example, strategic spatial planning at the urban regional level tends to involve some strategic areas, articulated into several key strategic domains, each of which has some spatial projects (see Sartorio, 2005). In the UK, in the 2000s the first strategic (national) plans were prepared for Northern Ireland, Scotland and Wales, aimed at integrating social, economic and environmental objectives into spatial strategies. Strategic spatial planning in the UK is highly market led and development oriented and aims at enhancing economic growth through strategic projects (see Reimer et al., 2014). In Switzerland, strategic spatial planning at the cantonal level comprises laying down the main principles of spatial development and identifying key strategic projects (see Ringli, 2003). In the Netherlands, the shift in spatial planning towards a regional economic approach and territorial competitiveness has enhanced the involvement of public and private interest groups in collaboration or partnership, whilst foreign investors are encouraged to participate in major public infrastructure projects (see also Reimer et al., 2014).

Based on overlapping descriptions given by Abdelwahab and Serag (2017), Oosterlynck et al. (2011), Carmona et al., (2009), Van den Broeck (2008) and Albrechts (2006), we have summarized five types of projects: (i) Urban projects are mainly driven by strategies within the context of globalization and increasing international, intercity and interregional competition. They are aimed at regenerating urban areas for promoting economic development, housing availability, and cultural activities (Albrechts, 2006); (ii) Rural projects are aimed at transforming rural and suburban areas into a more sustainable and dynamic form of development, as well as providing public services such as mail delivery, electricity and sewer systems (Albrechts, 2006); (iii) Strategic projects are the result of a process aimed at developing shared terms for sustainability and spatial quality. Strategic projects can be a catalyst for effective structural and fundamental changes, as they intervene in a concrete way in a spatial and social context. They must generate synergies between social, cultural, economic and spatial dimensions (Van den Broeck, 2008); (iv) Large urban projects are aimed at revitalizing city centres and central business districts, given the change from a manufacturing to a service-oriented economy and the increase international competition. Large urban projects have also been used to position urban regions in a global context (Carmona et al., 2009); (v) Strategic planning projects set a proper future development vision for the city, and they define and limit urban expansion onto agricultural lands. This type of project ensures proper service provision in the different areas of the city and guarantees sufficient housing provision to meet future needs (Abdelwahab and Serag, 2017).

As the result of the combination of these descriptions, our working definition of urban-regional development projects postulated in this paper is that URDP are spatial projects derived directly from the content of the strategic regional plan in force or those projects prepared after the publication of local development plans which have been elaborated in line with a strategic regional plan. Development projects are often negotiated or prepared through collaboration or partnerships between multiple levels of government and private interest groups and are backed by specific funding schemes. URDP are considered here as projects targeting rural (e.g., through infrastructure provision) and urban areas (e.g., through city centre regeneration) but, despite the target area, they must be of regional importance. Urban-regional development projects are a fast-track plan implementation approach to ensure that spatial transformation happens at the ground level in key strategic domains, such as housing, transportation, green-infrastructures, retail, industry, financial services, tourism, culture and sports. Fourteen urban regions were selected as case studies for this investigation. Details about these regions are provided below.

3 SELECTION OF CASE STUDIES AND METHODOLOGY

The 14 above-mentioned European urban regions were chosen because: (i) they represent different European planning systems, which is essential for generalizing the findings and for ensuring the diversity of plans and spatial projects, and (ii) their strategic plans are in force, or are about to be approved. The specific designations of the plans under discussion can be found in Table 1.

Source: Authors' own. *Alphabetical order; **Organizations with which the respondents were affiliated**.

Table 1 - List of the organizations interviewed** and the discussed strategic plans.

Forty-three qualitative, semi-structured interviews were conducted with urban and regional planners responsible for processes of plan making and plan implementation and with other knowledgeable urban and regional planning experts, such as academics and members of planning institutes. The interviews were carried out in English at the interviewees' workplaces between May and November 2016 and

followed an interview guide. Regarding the analysis of data on plan implementation, the interview transcripts were first organized into alphabetical order by case study and a single PDF file was created. Second, by employing the method of process tracing (see Schmitt and Van Well, 2016), each page on which references to (i) plan implementation, (ii) projects, (iii) urban projects, (iv) rural projects, (v) strategic projects, (vi) large urban projects, (vii) strategic planning projects, (viii) development projects, or (ix) strategic development areas were identified was isolated for in-depth analysis of the context; concrete examples of projects were located whenever provided by the respondents. Finally, quotations from the interviewees were extracted to support the discussion of the research questions (RQ). The findings of the interviews are discussed below and summarized in Table 2.

4 DEBATING PLAN IMPLEMENTATION THROUGH PROJECTS

This section draws on the analysis of the interviews to detail the reasons for plan implementation through projects (RQ 1) and the governance arrangements behind this plan implementation approach (RQ 2).

4.1 BARCELONA

Plan implementation in the Àrea Metropolitana de Barcelona (AMB) is the result of the “combination of small interventions with large urban projects” aimed at improving the core city and surrounding municipalities as a whole (interview at AMB). The respondents at AMB and Mediaurban highlighted that while some of the small projects, such as the construction of “urban facilities and parks”, several city-making interventions are mostly aimed at boosting place attachment; large scale projects are mainly related to expansion of residential areas as well as improvement of the transportation network. According to the respondents, the reasons for the implementation of plans through urban-regional development projects are mainly related to the need for more effective management of the financial resources, which are limited at the municipal level. Municipalities need to cooperate with the AMB in order to see spatial transformation taking shape in their administrative territory. Numerous urban regeneration projects of regional interest are being promoted in multilevel collaborations arrangements involving AMB and the municipalities composing the urban region (interview at AMB). Examples of such projects are the urban improvement of La Rectoria in the municipality of Begues and the improvement of the Parc Fluvial de la riera de Rafamans in the municipality of La Palma de Cervelló.

4.2 CARDIFF

Discussing plan implementation in Cardiff as an urban region requires references to the recently approved Cardiff Capital Region City Deal (see <http://www.cardiffcapitalregioncitydeal.wales/>), as this deal “is a way to get support from London for specific projects” (interview at Cardiff City Council, CCC). This means that the Strategic Development Plan for the Cardiff City Region (forthcoming) and the more strategic visions of the Cardiff Local Development Plan 2006-2026 will be both implemented through development projects and subsidized by the city deal. This city deal sets out a transformative approach to determine how Cardiff Capital Region will deliver the scale and nature of investment needed to support the area’s growth plans (interview at CCC). The city deal is developed through cooperation between the UK Government, the municipalities of Blaenau Gwent, Bridgend, Caerphilly, Cardiff, Merthyr Tydfil, Monmouthshire, Newport, Rhondda Cynon Taff, Torfaen and Vale of Glamorgan, and the Welsh Government. Urban-regional development projects in the areas of infrastructure provision, transport planning (e.g., South Wales Metro project), digital network improvement, and support for enterprise and business growth and for new residential areas are the priority areas for project development (interview at CCC). The main objectives of the South Wales Metro project, “a Welsh Government lead scheme” (interview at CCC and Cardiff University), are: improving connectivity; linking communities with all major commercial, social and leisure attractors; enabling the region to function as a single coherent economic entity with comparable journey times for public and private transport modes; and offering realistic travel choices. South Wales Metro project has gained momentum with the city deal, as this funding scheme is the only funding source available for its implementation (interview with expert of practice in connectivity and transport).

4.3 COPENHAGEN

The Finger Plan 2015 has mainly been implemented through local development plans (interview at Danish Business Authority, DBA). However, due to scarce land resources available for the growing population, together with the relocation of industrial facilities from the harbour area to elsewhere, some urban development projects have been prepared. One of these projects is the Nordhavn project (interview at University of Copenhagen, UC). This project contemplates the transformation of an active industrial port into a modern residential and business area. When completed, Nordhavn will have room for 40,000 residents and an equal number of work places (interview at DBA and interview at UC). Limited financial resources, primarily at the local level, also mean that some municipalities in the Greater Copenhagen Area are becoming “even more entrepreneurs while engaging with getting private funding” to support plan implementation, often through a variety of small development projects in the urban functions of housing, transportation, environmental protection and water management (interview at UC). This more entrepreneurial style of spatial planning adopted by municipalities has paved the way for collaborations between municipalities and private interest groups, such as housing developers. Collectively, these groups have contributed to spatial transformation in the Greater Copenhagen Area. Development projects are the result of pair-wise partnerships between the Danish Business Authority, the city of Copenhagen and the municipalities located in the Greater Copenhagen Area (interview at DBA).

4.4 DUBLIN

The implementation of the Regional Planning Guidelines for Greater Dublin Area 2010-2022 (RPG GDA 2010-2022) mainly unfolds at the ground level through projects, which are prepared through pair-wise partnerships between municipalities, such as Dublin City Council, and private investors (interview at Eastern and Midland Regional Assembly, EMRA). Limited financial resources and reutilization of abandoned industrial and harbour facilities are the main reasons for the implementation of plans through projects. The Dublin City Development Plan 2016-2022, for example, contemplates a number of Strategic Development Zones (SDZs). These SDZs enable government authorities to “designate certain parcels of land for a fast-track planning process, where the development of those lands is considered to be of strategic national importance” (interview at Dublin City Council, DCC). A key purpose of SDZs is to enable the fast-track delivery of new residential and non-residential development in locations of strategic importance in the Greater Dublin Area. One of these SDZs is the “North Lotts and Grand Canal Dock” (<http://www.dublincity.ie/main-menu-services-planning-urban-development-plans-local-area-plans/north-lotts-grand-canal-dock>), which involves the repurposing of the docklands into a residential and business area. A number of collaborations, braced by various funding schemes, support the development of these SDZs.

4.5 EDINBURGH

The key role of the SESplan - Strategic Development Planning Authority for the Edinburgh and South East Scotland Region is to prepare and maintain an up-to-date Strategic Development Plan (SDP) for the area which takes a long-term view of how the area will change (interviews at SESplan and City of Edinburgh Council, CEC). As in Cardiff, the Edinburgh and South East Scotland City Region Deal (<http://www.acceleratinggrowth.org.uk/>) has recently been approved. This city deal is a mechanism for accelerating growth by obtaining significant government investment. The governance arrangements behind the formulation of projects funded by the city deal are the result of collaborations between the council areas of Edinburgh, East Lothian, Midlothian, West Lothian, the Scottish Borders, the southern half of Fife, the UK and Scottish Governments. Projects will be mainly directed at improving infrastructure, boosting economic performance through innovation hubs, expanding the regional housing programme and reinforcing tourism activity (interviews at SESplan and CEC). The financial capital derived from the city deal is crucial for overcoming the limited financial resources in Edinburgh and the South East Scotland urban region. Implementing the SESplan Strategic Development Plan through development projects is needed for spatial transformation to actually occur. At the time of the interviews, in Edinburgh it was not possible to identify specific projects but only the priority areas for intervention, such as housing and employment land.

4.6 HAMBURG

The Hamburg Metropolitan Region (HMR) works on “an informal basis” situation, which hinders its capability to engage in strategic regional planning (interviews at HMR). The HMR works on the basis of informal cooperation by bringing multiple interest groups together to “cooperate on projects” (interview at HMR). The HMR mainly reacts “to the initiatives that come from the region, from the municipalities, from the counties and from the members of the HMR” (interview at HMR). Plan implementation happens through area-specific development projects. In the HMR, the scarce land resources, the limited technical resources at the local level of government, and the need to effectively manage financial, human and natural resources are the reasons for the implementation of plans through projects. These projects are mainly developed through collaborations between HMR and municipalities located in Hamburg Region. Rural partnerships support projects aimed at contributing to the resolution of urban-rural inequalities. The HMR makes three development funding schemes available to support cross-border, settlement development, nature protection, biotope and transportation projects (interview at HMR): (i) Strengthening the Metropolitan Region’s “international competitiveness” through projects on topics such as economic development, tourism and culture; (ii) Providing public services, particularly inter-district solutions for technical infrastructure and for interlinking public transport; (iii) Managing spatial structure and land use, for example through settlement and zoning plans and ecosystems management and protection. These funding schemes are pivotal in supporting regional cooperation. Several projects spanning administrative municipal borders, from landscape protection to numerous park and ride and bike and ride facilities, have been subsidised.

4.7 HANNOVER

The interviewee at Leibniz University Hannover (LUH) convincingly highlighted that “Hannover is a benchmark for regional planning in Germany” and also that there is “a continuous tradition of spatial planning at the regional level” which greatly influences strategic regional plan making and plan implementation. According to the respondents at Region Hannover (RH), the Regional Spatial Planning Program 2016 (RROP 2016) is implemented through local development plans – “we can give some impulses, such as funding to support local infrastructures, but we don’t do it on our own”. The RH provides support “not only with money, but also with knowledge and technical expertise” so municipalities can develop new residential areas and propose reuse of former industrial sites, among other projects of regional interest (interviews at RH). The RROP 2016 works as a framework, which means that all development projects have to be implemented in line with the strategic regional plan. There is no margin of manoeuvre for additional projects which are not included in the plan unless they are catalytic projects for the Region Hannover. Scarce land resources, weak technical capability at the local level of government, and the need to effectively manage financial, human and natural resources are the reasons for the implementation of plans through development projects. These projects are mainly driven by collaborations between Region Hannover and municipalities.

4.8 HELSINKI-UUSIMAA

According to the respondents at Helsinki-Uusimaa Regional Council (HURC), the regional land use planning for Helsinki-Uusimaa Region 2016 is mainly implemented by means of local development plans. The HURC regional planners have been developing multiple methodologies to support plan implementation, such as the action plan. This “action plan is to support the implementation or the management of the Helsinki-Uusimaa regional plan.” (interview at HURC). The action plan is essentially focused on the expansion of the residential offer to meet the growing demand for housing in the urban region. Helsinki-Uusimaa Regional Council also sees the “regional plan as a tool for reinforcing the public transportation network”. The regional plan facilitates project-making, as it brings together municipalities to coordinate actions that help fulfil the content of the plan. There are several housing development projects underway, as well as projects of regional interest aimed at strengthening transportation links, including walking and cycling routes (interview at the City of Helsinki). Scarce land resources and limited financial resources at the local level of government are the reasons for the implementation of plans through urban-regional development projects. These projects are developed in coordinated collaborations or partnerships between Helsinki-Uusimaa Regional Council and municipalities, and they are in line with local land use plans.

4.9 LYON

SCOT 2030 - territorial coherence scheme for Greater Lyon – is mainly focused on economic and housing development. SCOT 2030 also devotes attention to environmental issues, nature protection and preservation of agriculture areas (interview at Le Sepal). It became clear after the interviews in Lyon that SCOT 2030 is an envisioned framework and that the local development plans in the urban region (Le Plan Local d'Urbanisme, PLU) have to be developed in line with SCOT 2030. In addition, it became clear that the implementation of SCOT 2030 will occur through revised PLUs. SCOT 2030 is also seen as an essential planning tool for boosting territorial cooperation and development projects (interview at Le Sepal). According to the interviewee at University Lumière Lyon, SCOT 2030 is essentially an “economic project...elaborated with the economical actors in the urban region”; is flexible enough to allow the development of urban-regional projects, such as project of Lyon's central business district and multimodal hub, Part-Dieu district (<http://www.lyon-partdieu.com>). Ongoing projects are aimed at fulfilling housing needs, preserving land for food and energy production, and safeguarding spaces for retail and industrial expansion (interview at Le Sepal). Scarce financial resources is the reason for the implementation of plans through projects. These projects are mainly developed through collaborations between Greater Lyon and private interest groups.

4.10 MILAN

The current regional planning efforts in the Milan urban region reflect a number of changes in the territorial governance system that have been taking place all over Italy, mainly since the publication of Law 56 on 7th April 2014 (interview at Città Metropolitana di Milano, CMM). Milan has always been a city governed by a variety of several actors; some of them represent economic interests, while others represent foundations, higher education institutions and chambers of commerce (interview at Politecnico di Milano). To a certain extent, these actors “have been crucial in...finding specific solutions to specific territorial problems through projects and have also contributed to the shaping of the urban agenda” (interview at Politecnico di Milano). Furthermore, “the role of the municipalities has not been so central as in other European cities, so there has always been a dynamic between the role of the municipality and the role of interest groups”; “there are a lot of projects that have a distinctive urban dimension that were independently promoted by interest groups” (interview at Politecnico di Milano). In Milan, “there has been a lot of civic involvement, grassroots involvement, projects, very transverse projects funded by a bank, a foundation, but involving social cooperatives, associations of inhabitants, also some local firms or schools...I think this is the richness of this region” (interview at Politecnico di Milano). The welfare project, numerous urban regeneration projects and habitability projects are examples of urban-regional development projects identified by the interviewees. These projects are established to overcome socio-economic imbalances, to contribute to social cohesion and to meet the rising housing demands due to an increase in population (interview at CMM). Limited financial resources and scarce land resources are the reasons for the implementation of plans through development projects. These projects are promoted both by public entities and by private interests groups.

4.11 OSLO-AKERSHUS

The case study Oslo-Akershus could be considered a great example of urban-regional collaboration and a truly functional urban area (interview at Oslo City Council, OCC). It brings together the City of Oslo and Akershus County Council to work in a coordinated manner on land use and transportation planning (interview at OCC). In March 2012, Oslo City Council and Akershus County Council adopted the Regional Plan for Land Use and Transport in Oslo and Akershus 2015. This plan will be in force until 2030, with potential extension until 2050. Plan implementation in Oslo-Akershus urban region unfolds at the ground level through the implementation of local development and master plans. To support plan implementation, an action program has been developed (interview at OCC). One of the 10 actions of the program is to “move different enterprises and especially logistics from the centre of Oslo to some clusters outside of the core city” (interview at OCC). In this regard, “a strong cooperation between Oslo City Council and Akershus County Council is pivotal” (interview at OCC). The interviews at Akershus County Council made clear that the Regional Plan for Land Use and Transport in Oslo and Akershus 2015 will be implemented in the coming years after each decision is negotiated and consensus among governments and interest groups is reached. Development projects can only be implemented after the elaboration of an area-specific

“master plan” (interview at OCC). The projects underway are related to the need to reinforce the housing offer and the transportation network. Environmental preoccupations, the need to give a new use to outdated industrial and brewery facilities, and scarce land resources for new residential areas are the reasons for the implementation of plans through development projects. These projects are developed only after consensus building is achieved among the County and City Councils and various private and non-for-profit interest groups..

4.12 STOCKHOLM

The Regional development plan RUFS is the chief regional plan for the Stockholm region (interview at Stockholm County Council, SCC). RUFS 2010 is now in force. Work is underway, however, to develop the next regional development plan – RUFS 2050 (to be officially released in June 2017). RUFS 2050 is a further development of RUFS 2010, and the vision is for Stockholm to be Europe’s most attractive metropolitan region. RUFS “performs an important function and expresses the collective desire of the Stockholm region” (interview at SCC). Plan implementation in the Stockholm urban region “has to be done through the municipalities by the means of the implementation of land use plans” (interview at Stockholm City Council, SCityC). According to the interviewee at SCityC, most of the municipalities in the Stockholm urban region “have a very common idea of how the region will develop”. In this regard, the municipalities, including Stockholm City, “are very involved in large urban projects” such as the Stockholm Royal Seaport, where 10,000 new homes mixed with work spaces will be built. The respondent at SCityC also underlined that Stockholm has to be more project oriented so it can better respond to the need to densify the city. However, any forthcoming project has to be developed strictly in line with both RUFS and local plans. Urban-regional development projects in the Stockholm region have been used as fast-track planning interventions, not because of financial restrictions, but as a way to respond quickly to increasing housing needs. There have also been major projects in water management as well as in reinforcement of the public transportation network. Environmental preoccupations, the need to transform an outdated harbour area and the scarcity of housing land are the reasons for the implementation of plans through development projects. These projects are developed in a cooperative manner involving Stockholm City Council and Stockholm County Council.

4.13 STUTTGART

The implementation of the Strategic Regional Plan 2009 for Region Stuttgart is done through local land use plans and landscape plans, such as those used to plan the Neckar Landscape Park (interview at Verband Region Stuttgart, VRS). Plan implementation is also done by projects, which are mainly focused on improving the green infrastructures (interview at VRS). Projects developed based on inter-municipal collaboration are more likely to be subsidized by specific funds made available by the VRS (interview at VRS). Despite the VRS’s request for intra-regional cross-border projects, all projects must comply with the landscape plans in force. The chief aim of the co-funding scheme for green projects (i.e., regeneration of green-infrastructures mainly for recreational purposes) is “to balance and to improve quality of life and quality of environment” (interview at VRS). The VRS monitors and evaluates the implementation of projects and considers whether municipalities still want to develop the proposed projects or not, so funding is effectively allocated in projects that will really be beneficial for the whole population. The VRS also supports the municipalities in the urban region in preparing applications seeking funding for transportation and urban regeneration projects. Limited financial resources at the municipal level, scarce land resources and environmental preoccupations, mainly the need to preserve the natural resources available, are the main reasons for the implementation of plans through development projects. These projects are developed through collaborations between VRS and the municipalities located in the region, with the participation of private investors depending on the type of project.

4.14 VIENNA

Strategic regional planning in the Vienna urban region is highly complex, the respondents at Vienna City Council (VCC), at Austrian Institute for Regional Studies and Spatial Planning (AISP) and at Vienna University of Technology (VUT) emphasized. Austria is a parliamentary representative democracy
